… On balance, the committee concluded that its policy of agreeing a total remuneration package for each executive director comprising an annual base salary, a short-term incentive in the form of an annual cash bonus, long-term incentives through participation in share incentive plans, pension contributions, other usual security and health benefits, and benefits in kind, continued to be appropriate.…

The committee's policy continues to be to ensure that executive directors and members of the executive committee are rewarded for their contribution to the group's operating and financial performance at levels which take account of industry, market and country benchmarks, and that their remuneration is appropriate to their scale of responsibility and performance, and will attract, motivate and retain individuals of the necessary calibre. The committee takes account of the need to be competitive in the different parts of the world in which the company operates.…

The committee considers that alignment with shareholders' interests and linkage to SABMiller's long-term strategic goals is best achieved through a twin focus on earnings per share and, from 2010 onwards, additional value created for shareholders, and a blend of absolute and relative performance.

Source: SABMiller plc, Annual Report 2010.

In the United States, similar disclosures are required in a company's proxy statement that is filed with the SEC. Exhibit 7 shows the disclosure of American Eagle Outfitters, Inc.'s executive compensation program, including a description of the key elements and objectives.

Exhibit 7 Excerpts from Executive Compensation Disclosures of American Eagle Outfitters, Inc.

Compensation Program Elements

Our executive compensation program is designed to place a sizeable amount of pay at risk for all executives and this philosophy is intended to cultivate a pay-for-performance environment. Our executive compensation plan design has six key elements:

- Base Salary
- Annual Incentive Bonus
- Long-term Incentive Cash Plan—in place for the Chief Executive Officer and Vice Chairman, Executive Creative Director only
- Restricted Stock ("RS")—issued as Units ("RSUs") and Awards ("RSAs")
- Performance Shares ("PS")
- Non-Qualified Stock Options ("NSOs")

(continued)

Exhibit 7 (Continued)

Two of the elements (Annual Incentive Bonus and LTICP) were entirely "at risk" based on the Company's performance in Fiscal 2009 and were subject to forfeiture if the Company did not achieve threshold performance goals. Performance Shares are entirely "at risk" and subject to forfeiture if the Company does not achieve threshold performance goals by the close of Fiscal 2011, as described below. At threshold performance, the CEO's total annual compensation declines by 46% relative to target performance. The NEO's total annual compensation declines by an average of 33% relative to target performance. Company performance below threshold levels results in forfeiture of all elements of direct compensation other than base salary, RSUs and NSOs. NSOs provide compensation only to the extent that vesting requirements are satisfied and our share price appreciates.

We strategically allocate compensation between short-term and long-term components and between cash and equity in order to maximize executive performance and retention. Long-term compensation and equity awards comprise an increasingly larger proportion of total compensation as position level increases. The portion of total pay attributable to long-term incentive cash and equity compensation increases at successively higher levels of management. This philosophy ensures that executive compensation closely aligns with changes in stockholder value and achievement of performance objectives while also ensuring that executives are held accountable for results relative to position level.

Source: American Eagle Outfitters, Inc. Proxy Statement (Form Def 14A) filed 26 April 2010.

Share-based compensation, in addition to theoretically aligning the interests of employees (management) with shareholders, has the advantage of potentially requiring no cash outlay.[13] Share-based compensation arrangements can take a variety of forms, including those that are equity-settled and those that are cash-settled. However, share-based compensation is treated as an expense and thus as a reduction of earnings even when no cash changes hands. In addition to decreasing earnings through compensation expense, stock options have the potential to dilute earnings per share.

Although share-based compensation is generally viewed as motivating employees and aligning managers' interests with those of the shareholders, there are several disadvantages of share-based compensation. One disadvantage is that the recipient of the share-based compensation may have limited influence over the company's market value (consider the scenario of overall market decline), so share-based compensation does not necessarily provide the desired incentives. Another disadvantage is that the increased ownership may lead managers to be risk averse. In other words, fearing a large market value decline (and loss in individual wealth), managers may seek less risky (and less profitable) projects. An opposite effect, excessive risk taking, can also occur with the awarding of options. Because options have skewed payouts that reward excessive risk taking, managers may seek more risky projects. Finally, when share-based compensation is granted to employees, existing shareholders' ownership is diluted.

For financial reporting, a company reports compensation expense during the period in which employees earn that compensation. Accounting for cash salary payments and cash bonuses is relatively straightforward. When the employee has earned the salary or bonus, an expense is recorded. Typically, compensation expense for managers is reported in sales, general, and administrative expenses on the income statement.

13 Although issuing employee stock options requires no initial cash outlay, the company implicitly forgoes issuing new shares of stock at the then-current market price (and receiving cash) when the options are exercised.

Share-based compensation is more varied and includes such items as stock, stock options, stock appreciation rights, and phantom shares. By granting shares or share options in addition to other compensation, companies are paying additional compensation for services rendered by employees. Under both IFRS and US GAAP, companies use the fair value of the share-based compensation granted to measure the value of the employees' services for purposes of reporting compensation expense. However, the specifics of the accounting depend on the type of share-based compensation given to the employee. Under both IFRS and US GAAP, the usual disclosures required for share-based compensation include (1) the nature and extent of share-based compensation arrangements during the period, (2) how the fair value of a share-based compensation arrangement was determined, and (3) the effect of share-based compensation on the company's income for the period and on its financial position.

Two common forms of equity-settled share-based compensation, stock grants and stock options, are discussed below.

STOCK GRANTS

13

h explain how accounting for stock grants and stock options affects financial statements, and the importance of companies' assumptions in valuing these grants and options.

A company can grant stock to employees outright, with restrictions, or contingent on performance. For an outright stock grant, compensation expense is reported on the basis of the fair value of the stock on the grant date—generally the market value at grant date. Compensation expense is allocated over the period benefited by the employee's service, referred to as the service period. The employee service period is presumed to be the current period unless there are some specific requirements, such as three years service in the future, before the employee is vested (has the right to receive the compensation).

Another type of stock award is a restricted stock, which requires the employee to return ownership of those shares to the company if certain conditions are not met. Common restrictions include the requirements that employees remain with the company for a specified period or that certain performance goals are met. Compensation expense for restricted stock grants is measured as the fair value (usually market value) of the shares issued at the grant date. This compensation expense is allocated over the employee service period.

Shares granted contingent on meeting performance goals are called performance shares. The amount of the grant is usually determined by performance measures other than the change in stock price, such as accounting earnings or return on assets. Basing the grant on accounting performance addresses employees' potential concerns that the stock price is beyond their control and thus should not form the basis for compensation. However, performance shares can potentially have the unintended impact of providing incentives to manipulate accounting numbers. Compensation expense is equal to the fair value (usually market value) of the shares issued at the grant date. This compensation expense is allocated over the employee service period.

14 STOCK OPTIONS

h explain how accounting for stock grants and stock options affects financial statements, and the importance of companies' assumptions in valuing these grants and options.

Like stock grants, compensation expense related to option grants is reported at fair value under both IFRS and US GAAP. Both require that fair value be estimated using an appropriate valuation model.

Whereas the fair value of stock grants is usually based on the market value at the date of the grant, the fair value of option grants must be estimated. Companies cannot rely on market prices of options to measure the fair value of employee stock options because features of employee stock options typically differ from traded options. To measure the fair value of employee stock options, therefore, companies must use a valuation model. The choice of valuation or option pricing model is one of the critical elements in estimating fair value. Several models are commonly used, such as the Black–Scholes option pricing model or a binomial model. Accounting standards do not prescribe a particular model. Generally, though, the valuation method should (1) be consistent with fair value measurement, (2) be based on established principles of financial economic theory, and (3) reflect all substantive characteristics of the award.

Once a valuation model is selected, a company must determine the inputs to the model, typically including exercise price, stock price volatility, estimated life of each award, estimated number of options that will be forfeited, dividend yield, and the risk-free rate of interest.[14] Some inputs, such as the exercise price, are known at the time of the grant. Other critical inputs are highly subjective—such as stock price volatility or the estimated life of stock options—and can greatly change the estimated fair value and thus compensation expense. Higher volatility, a longer estimated life, and a higher risk-free interest rate increase the estimated fair value, whereas a higher assumed dividend yield decreases the estimated fair value.

Combining different assumptions with alternative valuation models can significantly affect the fair value of employee stock options. Below is an excerpt from GlaxoSmithKline, plc explaining the assumptions and model used in valuing its stock options. (Although not discussed in the disclosure, from 2007 to 2009 the trends of decreasing interest rates, lower share price, and increasing dividend yield would decrease estimated fair values and thus lower option expense. In contrast, the trend of increasing volatility would increase the estimated fair values.)

Exhibit 8 Assumptions Used in Stock Option Pricing Models: Excerpts from Financial Statements of GlaxoSmithKline, plc

Note 42—Employee share schemes *[excerpt]*

Option pricing

For the purposes of valuing options and awards to arrive at the share based payment charge, the Black–Scholes option pricing model has been used. The assumptions used in the model for 2007, 2008 and 2009 are as follows:

14 The estimated life of an option award incorporates such assumptions as employee turnover and is usually shorter than the expiration period.

Exhibit 8 (Continued)

	2009	2008	2007
Risk-free interest rate	1.4% – 2.9%	1.3% – 4.8%	4.7% – 5.3%
Dividend yield	5.20%	4.80%	4.00%
Volatility	23% – 29%	19% – 24%	17% – 25%
Expected lives of options granted under:			
Share option schemes	5 years	5 years	5 years
Savings-related share option and share award schemes	3–4 years	3 years	3 years
Weighted average share price for grants in the year:			
Ordinary Shares	£11.72	£11.59	£14.41
ADS*	$33.73	$45.02	$57.59

* American Depositary Shares

Volatility is determined based on the three and five year share price history where appropriate. The fair value of performance share plan grants take into account market conditions. Expected lives of options were determined based on weighted average historic exercises of options.

Source: GlaxoSmithKline Annual Report 2009.

In accounting for stock options, there are several important dates, including the grant date, the vesting date, the exercise date, and the expiration date. The **grant date** is the day that options are granted to employees. The **service period** is usually the period between the grant date and the vesting date.

The **vesting date** is the date that employees can first exercise the stock options. The vesting can be immediate or over a future period. If the share-based payments vest immediately (i.e., no further period of service is required), then expense is recognised on the grant date. If the share-based awards do not vest until a specified service period is completed, compensation expense is recognised and allocated over the service period. If the share-based awards are conditional upon the achievement of a performance condition or a market condition (i.e., a target share price), then compensation expense is recognised over the estimated service period. The **exercise date** is the date when employees actually exercise the options and convert them to stock. If the options go unexercised, they may expire at some pre-determined future date, commonly 5 or 10 years from the grant date.

The grant date is also usually the date that compensation expense is measured if both the number of shares and the option price are known. If facts affecting the value of options granted depend on events after the grant date, then compensation expense is measured at the exercise date. In the example below, Coca Cola, Inc. reported, in the 2009 Form 10-K, $241 million of compensation expense from option grants.

EXAMPLE 7

Disclosure of Stock Options' Current Compensation Expense, Vesting, and Future Compensation Expense

Using information from Coca Cola, Inc.'s Note 9 to financial statements, given below, determine the following:

1 Total compensation expense relating to options already granted that will be recognised in future years as options vest.

2 Approximate compensation expense in 2010 and 2011 relating to options already granted.

Excerpts from Note 9: Stock Compensation Plans in the Notes to Financial Statements of Coca Cola, Inc.

NOTE 9: STOCK COMPENSATION PLANS

Our Company grants stock options and restricted stock awards to certain employees of the Company. Total stock-based compensation expense was approximately $241 million in 2009, $266 million in 2008 and $313 million in 2007 and was included as a component of selling, general and administrative expenses in our consolidated statements of income. The total income tax benefit recognized in our consolidated statements of income for share-based compensation arrangements was approximately $68 million, $72 million and $91 million for 2009, 2008 and 2007, respectively.

As of December 31, 2009, we had approximately $335 million of total unrecognised compensation cost related to nonvested share-based compensation arrangements granted under our plans. This cost is expected to be recognized over a weighted-average period of 1.7 years as stock-based compensation expense. This expected cost does not include the impact of any future stock-based compensation awards.

Source: Coca Cola, Inc. Form 10-K filed 26 February 2010.

Solution to 1:

Coca Cola, Inc. discloses that unrecognised compensation expense relating to stock options already granted but not yet vested totals $335 million.

Solution to 2:

The options already granted will vest over the next 1.7 years. Compensation expense related to stock options already granted will be $197 million ($335/1.7 years) in 2010 and $138 million in 2011 ($335 total less $197 expensed in 2010). New options granted in the future will likely raise the total reported compensation expense.

As the option expense is recognised over the relevant vesting period, the impact on the financial statements is to ultimately reduce retained earnings (as with any other expense). The offsetting entry is an increase in paid-in capital. Thus, the recognition of option expense has no net impact on total equity.

OTHER TYPES OF SHARE -BASED COMPENSATION

15

g explain issues associated with accounting for share-based compensation;

Both stock grants and stock options allow the employee to obtain direct ownership in the company. Other types of share-based compensation, such as stock appreciation rights (SARs) or phantom stock, compensate an employee on the basis of changes in the value of shares without requiring the employee to hold the shares. These are referred to as cash-settled share-based compensation. With SARs, an employee's compensation is based on increases in a company's share price. Like other forms of share-based compensation, SARs serve to motivate employees and align their interests with shareholders. The following are two additional advantages of SARs:

- The potential for risk aversion is limited because employees have limited downside risk and unlimited upside potential similar to employee stock options, and
- Shareholder ownership is not diluted.

Similar to other share-based compensation, SARs are valued at fair value and compensation expense is allocated over the service period of the employee. While phantom share plans are similar to other types of share-based compensation, they differ somewhat because compensation is based on the performance of hypothetical stock rather than the company's actual stock. Unlike SARs, phantom shares can be used by private companies or business units within a company that are not publicly traded or by highly illiquid companies.

SUMMARY

This reading discussed two different forms of employee compensation: post-employment benefits and share-based compensation. Although different, the two are similar in that they are forms of compensation outside of the standard salary arrangements. They also involve complex valuation, accounting, and reporting issues. Although IFRS and US GAAP are converging on accounting and reporting, it is important to note that differences in a country's social system, laws, and regulations can result in differences in a company's pension and share-based compensation plans that may be reflected in the company's earnings and financial reports.

Key points include the following:

- Defined contribution pension plans specify (define) only the amount of contribution to the plan; the eventual amount of the pension benefit to the employee will depend on the value of an employee's plan assets at the time of retirement.
- Balance sheet reporting is less analytically relevant for defined contribution plans because companies make contributions to defined contribution plans as the expense arises and thus no liabilities accrue for that type of plan.
- Defined benefit pension plans specify (define) the amount of the pension benefit, often determined by a plan formula, under which the eventual amount of the benefit to the employee is a function of length of service and final salary.
- Defined benefit pension plan obligations are funded by the sponsoring company contributing assets to a pension trust, a separate legal entity. Differences exist in countries' regulatory requirements for companies to fund defined benefit pension plan obligations.

- Both IFRS and US GAAP require companies to report on their balance sheet a pension liability or asset equal to the projected benefit obligation minus the fair value of plan assets. The amount of a pension asset that can be reported is subject to a ceiling.
- Under IFRS, the components of periodic pension cost are recognised as follows: Service cost is recognised in P&L, net interest income/expense is recognised in P&L, and remeasurements are recognised in OCI and are not amortised to future P&L.
- Under US GAAP, the components of periodic pension cost recognised in P&L include current service costs, interest expense on the pension obligation, and expected returns on plan assets (which reduces the cost). Other components of periodic pension cost—including past service costs, actuarial gains and losses, and differences between expected and actual returns on plan assets—are recognised in OCI and amortised to future P&L.
- Estimates of the future obligation under defined benefit pension plans and other post-employment benefits are sensitive to numerous assumptions, including discount rates, assumed annual compensation increases, expected return on plan assets, and assumed health care cost inflation.
- Employee compensation packages are structured to fulfill varied objectives, including satisfying employees' needs for liquidity, retaining employees, and providing incentives to employees.
- Common components of employee compensation packages are salary, bonuses, and share-based compensation.
- Share-based compensation serves to align employees' interests with those of the shareholders. It includes stocks and stock options.
- Share-based compensation has the advantage of requiring no current-period cash outlays.
- Share-based compensation expense is reported at fair value under IFRS and US GAAP.
- The valuation technique, or option pricing model, that a company uses is an important choice in determining fair value and is disclosed.
- Key assumptions and input into option pricing models include such items as exercise price, stock price volatility, estimated life of each award, estimated number of options that will be forfeited, dividend yield, and the risk-free rate of interest. Certain assumptions are highly subjective, such as stock price volatility or the expected life of stock options, and can greatly change the estimated fair value and thus compensation expense.

PRACTICE PROBLEMS

The following information relates to Questions 1–7

Kensington plc, a hypothetical company based in the United Kingdom, offers its employees a defined benefit pension plan. Kensington complies with IFRS. The assumed discount rate that the company used in estimating the present value of its pension obligations was 5.48 percent. Information on Kensington's retirement plans is presented in Exhibit 1.

Exhibit 1 Kensington plc Defined Benefit Pension Plan

(in millions)	**2010**
Components of periodic benefit cost	
Service cost	£228
Net interest (income) expense	273
Remeasurements	–18
Periodic pension cost	£483
Change in benefit obligation	
Benefit obligations at beginning of year	£28,416
Service cost	228
Interest cost	1,557
Benefits paid	–1,322
Actuarial gain or loss	0
Benefit obligations at end of year	£28,879
Change in plan assets	
Fair value of plan assets at beginning of year	£23,432
Actual return on plan assets	1,302
Employer contributions	693
Benefits paid	–1,322
Fair value of plan assets at end of year	£24,105
Funded status at beginning of year	–£4,984
Funded status at end of year	–£4,774

1 At year-end 2010, £28,879 million represents:

© 2019 CFA Institute. All rights reserved.

A the funded status of the plan.

B the defined benefit obligation.

C the fair value of the plan's assets.

2 For the year 2010, the net interest expense of £273 represents the interest cost on the:

A ending benefit obligation.

B beginning benefit obligation.

C beginning net pension obligation.

3 For the year 2010, the remeasurement component of Kensington's periodic pension cost represents:

A the change in the net pension obligation.

B actuarial gains and losses on the pension obligation.

C actual return on plan assets minus the amount of return on plan assets included in the net interest expense.

4 Which of the following is *closest* to the actual rate of return on beginning plan assets and the rate of return on beginning plan assets that is included in the interest income/expense calculation?

A The actual rate of return was 5.56 percent, and the rate included in interest income/expense was 5.48 percent.

B The actual rate of return was 1.17 percent, and the rate included in interest income/expense was 5.48 percent.

C Both the actual rate of return and the rate included in interest income/expense were 5.48 percent.

5 Which component of Kensington's periodic pension cost would be shown in OCI rather than P&L?

A Service cost

B Net interest (income) expense

C Remeasurements

6 The relationship between the periodic pension cost and the plan's funded status is *best* expressed in which of the following?

A Periodic pension cost of –£483 = Ending funded status of –£4,774 – Employer contributions of £693 – Beginning funded status of –£4,984.

B Periodic pension cost of £1,322 = Benefits paid of £1,322.

C Periodic pension cost of £210 = Ending funded status of –£4,774 – Beginning funded status of –£4,984.

7 An adjustment to Kensington's statement of cash flows to reclassify the company's excess contribution for 2010 would *most likely* entail reclassifying £210 million (excluding income tax effects) as an outflow related to:

A investing activities rather than operating activities.

B financing activities rather than operating activities.

C operating activities rather than financing activities.

The following information relates to Questions 8–12

XYZ SA, a hypothetical company, offers its employees a defined benefit pension plan. Information on XYZ's retirement plans is presented in Exhibit 1. It also grants stock options to executives. Exhibit 2 contains information on the volatility assumptions used to value stock options.

Exhibit 1 XYZ SA Retirement Plan Information 2009

Employer contributions	1,000
Current service costs	200
Past service costs	120
Discount rate used to estimate plan liabilities at beginning of year	7.00%
Benefit obligation at beginning of year	42,000
Benefit obligation at end of year	41,720
Actuarial loss due to increase in plan obligation	460
Plan assets at beginning of year	39,000
Plan assets at end of year	38,700
Actual return on plan assets	2,700
Expected rate of return on plan assets	8.00%

Exhibit 2 XYZ SA Volatility Assumptions Used to Value Stock Option Grants

Grant Year	Weighted Average Expected Volatility
2009 valuation assumptions	
2005–2009	21.50%
2008 valuation assumptions	
2004–2008	23.00%

8 The total periodic pension cost is *closest* to:

A 320.

B 1,020.

C 1,320.

9 The amount of periodic pension cost that would be reported in P&L under IFRS is *closest* to:

A 28.

B 538.

C 1,020.

10 Assuming the company chooses not to immediately recognise the actuarial loss and assuming there is no amortisation of past service costs or actuarial gains and losses, the amount of periodic pension cost that would be reported in P&L under US GAAP is *closest* to:

A 28.

B 59.

C 530.

11 Under IFRS, the amount of periodic pension cost that would be reported in OCI is *closest* to:

A 20.

B 490.

C 1,020.

12 Compared to 2009 net income as reported, if XYZ had used the same volatility assumption for its 2009 option grants that it had used in 2008, its 2009 net income would have been:

A lower.

B higher.

C the same.

The following information relates to Questions 13–18

Stereo Warehouse is a US retailer that offers employees a defined benefit pension plan and stock options as part of its compensation package. Stereo Warehouse prepares its financial statements in accordance with US GAAP.

Peter Friedland, CFA, is an equity analyst concerned with earnings quality. He is particularly interested in whether the discretionary assumptions the company is making regarding compensation plans are contributing to the recent earnings growth at Stereo Warehouse. He gathers information from the company's regulatory filings regarding the pension plan assumptions in Exhibit 1 and the assumptions related to option valuation in Exhibit 2.

Exhibit 1 Assumptions Used for Stereo Warehouse Defined Benefit Plan

	2009	2008	2007
Expected long-term rate of return on plan assets	6.06%	6.14%	6.79%
Discount rate used to estimate PBO at beginning of year	4.85	4.94	5.38
Estimated future salary increases	4.00	4.44	4.25
Inflation	3.00	2.72	2.45

Exhibit 2 Option Valuation Assumptions

	2009	2008	2007
Risk-free rate	4.6%	3.8%	2.4%
Expected life	5.0 yrs	4.5 yrs	5.0 yrs
Dividend yield	1.0%	0.0%	0.0%
Expected volatility	29%	31%	35%

13 Compared to the 2009 reported financial statements, if Stereo Warehouse had used the same expected long-term rate of return on plan assets assumption in 2009 as it used in 2007, its year-end 2009 pension obligation would *most likely* have been:

A lower.

B higher.

C the same.

14 Compared to the reported 2009 financial statements, if Stereo Warehouse had used the same discount rate as it used in 2007, it would have *most likely* reported lower:

A net income.

B total liabilities.

C cash flow from operating activities.

15 Compared to the assumptions Stereo Warehouse used to compute its periodic pension cost in 2008, earnings in 2009 were *most favorably* affected by the change in the:

A discount rate.

B estimated future salary increases.

C expected long-term rate of return on plan assets.

16 Compared to the pension assumptions Stereo Warehouse used in 2008, which of the following pairs of assumptions used in 2009 is *most likely* internally inconsistent?

A Estimated future salary increases, inflation

B Discount rate, estimated future salary increases

C Expected long-term rate of return on plan assets, discount rate

17 Compared to the reported 2009 financial statements, if Stereo Warehouse had used the 2007 volatility assumption to value its employee stock options, it would have *most likely* reported higher:

A net income.

B compensation expense.

C deferred compensation liability.

18 Compared to the assumptions Stereo Warehouse used to value stock options in 2008, earnings in 2009 were most favorably affected by the change in the:

A expected life.

B risk-free rate.

C dividend yield.

The following information relates to question 19–25

The board of directors at Sallie-Kwan Industrials (SKI), a publicly traded company, is meeting with various committees following the release of audited financial statements prepared in accordance with US GAAP. The finance committee (FC) is next on the agenda to review retirement benefits funding and make recommendations to the board.

SKI's three retirement benefit plans are described as follows:

Plan A

- Benefit: Annual payments for life equal to 1% of the employee's final salary for each year of service beyond the date of the plan's establishment
- The employer makes regular contributions to the plan in order to meet the future obligation
- Closed to new participants; benefits accrue for existing participants
- Fair value of assets: €5.98 billion
- Present value of obligation: €4.80 billion
- Present value of reductions in future contributions: €1.50 billion
- Ten-year vesting schedule; 70% of the participants are fully vested

Plan B

- Benefit: Discretionary retirement withdrawals; amounts depend on the plan's investment performance
- Employer makes its agreed-upon contribution to the plan on behalf of the employee in the same period during which the employee provides the service; SKI is current on this obligation
- The employee may also contribute to the plan during employment years
- Available to all employees after one year of service; 80% of the employees are fully vested

Plan C

- Benefit: Medical, prescription drug, and dental coverage for the retiree, spouse, and dependents under age 18
- 80% funded
- Available to all employees on day one of service

The FC chair reviews Plan A's funded status and the amount recorded on the balance sheet with the board, explaining that the current service cost change from last quarter has primarily resulted from a higher percentage of employees that are expected to leave before the full vesting period.

A board member inquires how Plan A's periodic pension costs affect SKI's operating performance. The FC chair reviews the adjustments needed to account for individual pension components that are considered operating costs and those considered non-operating costs, when calculating profit before taxation. Note 16 in the income statement lists the following: current service costs of €40 million, interest costs of €263 million, expected return on plan assets of €299 million, and actual return on plan assets of €205 million. Moreover, Note 16 indicates that SKI was required to use expected return on plan assets for the reporting year in question.

Next, the FC chairman presents the following case study data to illustrate SKI's current pension obligation for an average fully vested participant in Plan A with 10 years of prior service:

- Current annual salary: €100,000
- Years to retirement: 17
- Retirement life expectancy: 20 years
- Current plan assumptions:
  - Annual compensation increase: 6%
  - Discount rate: 4%
  - Compensation increases are awarded on the first day of the service year; no adjustments are made to reflect the possibility that the employee may leave the firm at an earlier date.

A discussion ensues regarding the effect on the pension obligation, for an average participant, of changing Plan A's annual compensation increase to 5%.

Lastly, the FC chair recommends that the board consider modifying some key assumptions affecting Plan A in response to recent market trends. The chair also reviews how these changes will alter SKI's plan obligation.

Recommendation 1: Change the assumed discount rate to 5%.

Recommendation 2: Increase the retirement life expectancy assumption by eight years.

Recommendation 3: Reduce investment risk by decreasing the expected return to 3%.

19 The participant bears the greatest amount of investment risk under which plan?

A Plan A

B Plan B

C Plan C

20 The plan for which the amount of SKI's financial obligation is defined in the current period with no obligation for future retirement benefits is:

A Plan A.

B Plan B.

C Plan C.

21 For Plan A, SKI should report a net pension:

A asset of €1.50 billion.

B asset of €1.18 billion.

C liability of €1.18 billion.

22 Based on the FC chair's explanation about the current service cost change, the present value of Plan A's obligation:

A decreased.

B stayed the same.

C increased.

23 Based on Note 16, after reclassifying pension components to reflect economic income or expense, the net adjustment to profit before taxation is:

A –€205 million.

B –€94 million.

C +€129 million.

24 Based on the case study illustration and the effect of changing the annual compensation rate, the annual unit credit for the average participant would decrease by an amount *closest* to:

A €4,349.

B €4,858.

C €5,446.

25 All else being equal, which of the following FC recommendations will increase the plan's obligation?

A Recommendation 1

B Recommendation 2

C Recommendation 3

The following information relates to question 26–31

Natalie Holmstead, a senior portfolio manager, works with Daniel Rickards, a junior analyst. Together they are evaluating the financial statements of Company XYZ (XYZ) with a focus on post-employment benefits. XYZ has a defined benefit pension plan and prepares financial statements according to IFRS requirements.

Rickards calculates the current service cost for a single employee's defined benefit pension obligation using the projected unit credit method. The employee is expected to work for 7 years before retiring and has 15 years of vested service. Rickards assumes a discount rate of 4.00% and a lump sum value of the employee's benefit at retirement of $393,949.

Next, Holmstead and Rickards discuss the present value of the defined benefit obligation (PVDBO). Rickards makes the following statements to clarify his understanding:

Statement 1 An actuarial loss is accompanied by an increase in the PVDBO.

Statement 2 The PVDBO measures the present value of future benefits earned by plan participants and includes plan assets.

Statement 3 The company should use the expected long-term rate of return on plan assets as the discount rate to calculate the PVDBO.

XYZ's pension plan offers benefits based on the employee's final year's salary. Rickards calculates the PVDBO as of the end of the current period, based on the information presented in Exhibit 1.

Exhibit 1 Select XYZ Defined Benefit Pension Plan Data

	Current Period	Prior Period
Assumed future compensation growth rate	2.5%	3.0%
Plan assets (in $ millions)	3,108	
Net pension liability (in $ millions)	525	
Present value of reductions of future contributions (in $ millions)	48	

Rickards adjusts the balance sheet and cash flow statement information presented in Exhibit 2 to better reflect the economic nature of certain items related to the pension plan.

Exhibit 2 Select XYZ Balance Sheet and Cash Flow Data (in $ millions)

Item	Current Period
Total assets	24,130
Total liabilities	17,560
Total equity	6,570
Total pension cost	96
Pension contribution	66
Financing cash flow	2,323
Operating cash flow	–1,087
Effective tax rate	30%

Finally, Rickards examines the data in Exhibit 3 and calculates the effect of a 100-basis-point increase in health care inflation on XYZ's debt-to-equity ratio.

Exhibit 3 Sensitivity of Accumulated Post-Employment Benefit Obligations to Changes in Assumed Health Care Inflation (in $ millions)

Item	100-bp Increase	100-bp Decrease
Benefit obligation change	$93	–$76
Benefit expense change	$12	–$10

26 The current service cost is *closest* to:

- **A** $14,152.
- **B** $15,758.
- **C** $17,907.

27 Which of Rickards's statements about the PVDBO is correct?

- **A** Statement 1
- **B** Statement 2
- **C** Statement 3

28 Based on Exhibit 1, the PVDBO is *closest* to:

- **A** $3,585 million.
- **B** $3,633 million.
- **C** $3,681 million.

29 Based on Exhibit 1 and the method XYZ uses to link pension benefits to salaries, the change in the compensation growth rate compared with the prior period will *most likely* result in:

- **A** lower periodic pension cost.

B no change in the periodic pension cost.

C higher periodic pension cost.

30 Based on Exhibit 2, Rickards should adjust the operating and financing cash flows by:

A \$21 million.

B \$30 million.

C \$96 million.

31 Based on Exhibits 2 and 3, as well as Holmstead's assumption about future health care inflation, the debt-to-equity ratio calculated by Rickards for XYZ should be *closest* to:

A 2.69.

B 2.71.

C 2.73.

SOLUTIONS

1 B is correct. The £28,879 million year-end benefit obligation represents the defined benefit obligation.

2 C is correct. The net interest expense of £273 million represents the interest cost on the beginning net pension obligation (beginning funded status) using the discount rate that the company uses in estimating the present value of its pension obligations. This is calculated as –£4,984 million times 5.48 percent = –£273 million; this represents an interest expense on the amount that the company essentially owes the pension plan.

3 C is correct. The remeasurement component of periodic pension cost includes both actuarial gains and losses on the pension obligation and net return on plan assets. Because Kensington does not have any actuarial gains and losses on the pension obligation, the remeasurement component includes only net return on plan assets. In practice, actuarial gains and losses are rarely equal to zero. The net return on plan assets is equal to actual returns minus beginning plan assets times the discount rate, or £1,302 million – (£23,432 million × 0.0548) = £18 million.

4 A is correct. The actual return on plan assets was 1,302/23,432 = 0.0556, or 5.56 percent. The rate of return included in the interest income/expense is the discount rate, which is given in this example as 5.48 percent.

   The rate of 1.17 percent, calculated as the net interest income divided by beginning plan assets, is not used in pension cost calculations.

5 C is correct. Under IFRS, the component of periodic pension cost that is shown in OCI rather than P&L is remeasurments.

6 A is correct. The relation between the periodic pension cost and the plan's funded status can be expressed as Periodic pension cost = Ending funded status – Employer contributions – Beginning funded status.

7 B is correct. Kensington's periodic pension cost was £483. The company's contributions to the plan were £693. The £210 difference between these two numbers can be viewed as a reduction of the overall pension obligation. To adjust the statement of cash flows to reflect this view, an analyst would reclassify the £210 million (excluding income tax effects) as an outflow related to financing activities rather than operating activities.

8 B is correct. The total periodic pension cost is the change in the net pension liability adjusted for the employer's contribution into the plan. The net pension liability increased from 3,000 to 3,020, and the employer's contribution was 1,000. The total periodic pension cost is 1,020. This will be allocated between P&L and OCI.

9 B is correct. Under IFRS, the components of periodic pension cost that would be reported in P&L are the service cost (composed of current service and past service costs) and the net interest expense or income, calculated by multiplying the net pension liability or net pension asset by the discount rate used to measure the pension liability. Here, the service costs are 320 (= 200 + 120) and the net interest expense is 210 [= (42,000 + 120 – 39,000) × 7%]. Thus, the total periodic pension cost is equal to 538.

10 A is correct. Under US GAAP—assuming the company chooses not to immediately recognise the actuarial loss and assuming there is no amortisation of past service costs or actuarial gains and losses—the components of periodic pension cost that would be reported in P&L include the current service cost of 200,

the interest expense on the pension obligation at the beginning of the period of 2,940 (= 7.0% × 42,000), and the expected return on plan assets, which is a reduction of the cost of 3,120 (= 8.0% × 39,000). Summing these three components gives 20.

11 B is correct. The component of periodic pension cost that would be reported in OCI is the remeasurements component. It consists of actuarial gains and losses on the pension obligation and net return on plan assets. Here, the actuarial loss was 460. In addition, the actual return on plan assets was 2,700, which was 30 lower than the return of 2,730 (= 39,000 × 0.07) incorporated in the net interest income/expense. Therefore, the total remeasurements are 490.

12 A is correct. In 2009, XYZ used a lower volatility assumption than it did in 2008. Lower volatility reduces the fair value of an option and thus the reported expense. Using the 2008 volatility estimate would have resulted in higher expense and thus lower net income.

13 C is correct. The assumed long-term rate of return on plan assets is not a component that is used in calculating the pension obligation, so there would be no change.

14 B is correct. A higher discount rate (5.38 percent instead of 4.85 percent) will reduce the present value of the pension obligation (liability). In most cases, a higher discount rate will decrease the interest cost component of the net periodic cost because the decrease in the obligation will more than offset the increase in the discount rate (except if the pension obligation is of short duration). Therefore, periodic pension cost would have been lower and reported net income higher. Cash flow from operating activities should not be affected by the change.

15 B is correct. In 2009, the three relevant assumptions were lower than in 2008. Lower expected salary increases reduce the service cost component of the periodic pension cost. A lower discount rate will increase the defined benefit obligation and increase the interest cost component of the periodic pension cost (the increase in the obligation will, in most cases, more than offset the decrease in the discount rate). Reducing the expected return on plan assets typically increases the periodic pension cost.

16 A is correct. The company's inflation estimate rose from 2008 to 2009. However, it lowered its estimate of future salary increases. Normally, salary increases will be positively related to inflation.

17 B is correct. A higher volatility assumption increases the value of the stock option and thus the compensation expense, which, in turn, reduces net income. There is no associated liability for stock options.

18 C is correct. A higher dividend yield reduces the value of the option and thus option expense. The lower expense results in higher earnings. Higher risk-free rates and expected lives result in higher call option values.

19 B is correct. Plan B is a defined contribution (DC) pension plan because the amount of future benefit is not defined and SKI has an obligation to make only agreed-upon contributions. The actual future benefits depend on the investment performance of the individual's plan assets, and the employee bears the investment risk.

A is incorrect because Plan A is a defined benefit (DB) pension plan. In a DB plan, the amount of future benefit is defined based on the plan's formula (i.e., 1% of the employee's final salary for each year of service). With a DB pension plan, SKI bears the investment risk.

C is incorrect because Plan C is a health care plan and is classified as a DB plan. Under IFRS and US GAAP, all plans for pensions and other post-employment benefits (OPB) other than those explicitly structured as DC plans are classified as DB plans. The amount of future benefit depends on plan specifications and type of benefit, and it represents a promise by the firm to pay benefits in the future. SKI, not the employee, is responsible for estimating future increases in costs, such as health care, over a long time horizon.

20 B is correct. Plan B is a DC pension plan. SKI's financial obligation is defined in each period, and the employer makes its agreed-upon contribution to the plan on behalf of the employee in the same period during which the employee provides the service. SKI is current on this obligation and has no additional financial obligation for the current period.

21 B is correct. SKI's DB pension plan is overfunded by €1.18 billion, the amount by which the fair value of the pension plan assets exceeds the defined benefit obligation (€5.98 billion – €4.80 billion). When a company has a surplus in a DB pension plan, the amount of assets that can be reported is the lower of the surplus or the asset ceiling (the present value of future economic benefits, such as refunds from the plan or reductions in future contributions). In this case, the asset ceiling is given as €1.50 billion, so the amount of SKI's reported net pension asset is the amount of the surplus, because this amount is lower than the asset ceiling.

22 A is correct. A higher percentage of employees is expected to leave before the full 10-year vesting period, which would decrease the present value of the DB obligation. If the employee leaves the company before meeting the 10-year vesting requirement, she may be entitled to none or a portion of the benefits earned up until that point. In measuring the DB obligation, the company considers the probability that some employees may not satisfy the vesting requirements (i.e., may leave before the vesting period) and use this probability to calculate the current service cost and the present value of the obligation.

23 B is correct. Operating income is adjusted to include only the current service costs, the interest cost component is reclassified as interest expense, and the actual return on plan assets is added as investment income. Profit before taxation adjusted for actual rather than expected return on plan assets will decrease by €94 million (205 – 299).

	Total (€ millions)
Current service costs	– €40
Interest costs	– €263
Expected return on plan assets	+ €299
Total of pension and OPB expenses	– €4 million
Actual return (loss) on plan assets	€205 million

Because the actual return on plan assets is less than the expected return on plan assets, operating income will be adjusted downward by 299 – 205 = 94. Alternatively, the adjustments to the individual pension cost components are as follows:

Line Items to Adjust	Adjustments (€ millions)
Revenue	—
Net operating expenses	+4 − 40 = −36
Operating profit	—
Interest expense	−263
Interest and investment income	+205
Share of post-tax results of associates	—
Adjustment to profit before taxation	−€94 million

24 B is correct. The final year's estimated earnings at the end of Year 1 for the average participant would decrease by approximately €35,747.71.

	Current Assumptions	Case Study Assumptions
Current salary	€100,000	€100,000
Years until retirement	17	17
Years of service (includes prior 10)	27	27
Retirement life expectancy	20	20
Annual compensation increases	6%	5%
Discount rate	4%	4%
Final year's estimated earnings	€254,035.17	€218,287.46
Estimated annual payment for each of the 20 years	€68,589.50	€58,937.61
Value at the end of year 17 (retirement date) of the estimated future payments	€932,153.69	€800,981.35
Annual unit credit	€34,524.21	€29,665.98

Because there are now 17 years until retirement, there are 16 years until retirement from the end of Year 1. The final year's estimated earnings, estimated at the end of Year 1, are as follows:

Current year's salary × [(1 + Annual compensation increase)$^{\text{Years until retirement}}$]

Annual compensation increase of 6%: €100,000 × [$(1.06)^{16}$] = €254,035.17

Annual compensation increase of 5%: €100,000 × [$(1.05)^{16}$] = €218,287.46

The estimated annual payment for each of the 20 years (retirement life expectancy) is

(Estimated final salary × Benefit formula) × Years of service

Annual compensation increase of 6%: (€254,035.17 × 0.01) × (10 + 17) = €68,589.50

Annual compensation increase of 5%: (€218,287.46 × 0.01) × (10 + 17) = €58,937.61

The value at the end of Year 17 (retirement date) of the estimated future payments is the PV of the estimated annual payment for each of the 20 years at the discount rate of 4%:

Annual compensation increase of 6%: PV of €68,589.50 for 20 years at 4% = €932,153.69

Annual compensation increase of 5%: PV of €58,937.61 for 20 years at 4% = €800,981.35

The annual unit credit = Value at retirement/Years of service:

Annual compensation increase of 6%: €932,153.69/27 = €34,524.21

Annual compensation increase of 5%: €800,981.35/27 = €29,665.98

The annual unit credit for the average participant would decrease by €34,524.21 − €29,665.98 = €4,858.23.

25 B is correct. An increase in the retirement life expectancy (from 20 to 28 years) will increase the DB pension obligation, because Plan A pays annual payments for life.

26 A is correct. Current service cost is the present value of annual unit credit earned in the current period.

Annual unit credit (benefit) per service year = Value at retirement / Years of service.

Years of service = 15 (vested years of past service) + 7 (expected years until retirement) = 22.

Annual unit credit = \$393,949 / 22 = \$17,906.77.

$$\begin{aligned}&\text{Current service cost (for 1 year)}\\&\quad= \text{Annual unit credit}\Big/\big[(1+\text{Discount rate})^{(\text{Years until retirement at the end of Year 1})}\\&\quad= \$17{,}906.77\Big/(1+0.04)^{6} = \$14{,}151.98.\end{aligned}$$

27 A is correct. To estimate the PVDBO, the company must make a number of assumptions, such as future compensation increases, discount rates, and expected vesting. If changes in assumptions increase the obligation, the increase is referred to as an actuarial loss.

B is incorrect because the PVDBO does not include the value of plan assets in the calculation.

C is incorrect because the expected long-term rate of return on plan assets is not used to calculate the PVDBO. The interest rate used to calculate the PVDBO is based on current rates of return on high-quality corporate bonds (or government bonds, in the absence of a deep market in corporate bonds) with currency and durations consistent with the currency and durations of the benefits.

28 B is correct. The funded status of a pension plan is calculated as follows:

Funded status = Fair value of the plan assets − PVDBO

Based on the information provided in Exhibit 1, the PVDBO is calculated as follows:

PVDBO = Funded status (Net pension liability) + Plan assets

\$525 + \$3,108 = \$3,633 million

29 A is correct. A decrease in the assumed future compensation growth rate will decrease a company's pension obligation when the pension formula is based on the final year's salary. Lowering the assumed future compensation growth rate decreases the service and interest components of periodic pension costs because of a decreased annual unit credit.

30 A is correct. Rickards' task is to adjust the balance sheet and cash flow statement information to better reflect the economic nature of certain items related to the pension plan. When a company's periodic contribution to a plan is lower than the total pension cost of the period, it can be viewed as a source of financing. To reflect this event, the deficit amount is adjusted by the effective tax rate and should be reclassified from an operating cash flow to a financing cash flow. The company's contribution to the pension plan was \$66 million, which is \$30 million less than the pension cost of \$96 million. The \$30 million difference is \$21 million on an after-tax basis, using the effective tax rate of 30%. Therefore, \$21 million should be classified as an operating cash outflow (negative value) and a financing cash inflow (positive value).

31 C is correct. To calculate the debt-to-equity ratio, both liabilities and total equity need to be adjusted for the estimated impact of a 100-bp increase in health care costs. The proposed increase in health care costs will increase total liabilities and decrease equity by the same amount. Consequently, the debt-to-equity ratio changes as follows:

Sensitivity of benefit obligation to 100-bp increase = \$93

Adjusted liabilities = \$17,560 + \$93 = \$17,653

Adjusted equity = \$6,570 − \$93 = \$6,477

Adjusted debt-to-equity ratio = \$17,653/\$6,477 = 2.7255 ≈ 2.73

Consequently, a 100-bp increase in health care costs increases the debt-to-equity ratio to approximately 2.73.

LEARNING OUTCOMES

Mastery	*The candidate should be able to:*
☐	**a.** compare and contrast presentation in (reporting) currency, functional currency, and local currency;
☐	**b.** describe foreign currency transaction exposure, including accounting for and disclosures about foreign currency transaction gains and losses;
☐	**c.** analyze how changes in exchange rates affect the translated sales of the subsidiary and parent company;
☐	**d.** compare the current rate method and the temporal method, evaluate how each affects the parent company's balance sheet and income statement, and determine which method is appropriate in various scenarios;
☐	**e.** calculate the translation effects and evaluate the translation of a subsidiary's balance sheet and income statement into the parent company's presentation currency;
☐	**f.** analyze how the current rate method and the temporal method affect financial statements and ratios;
☐	**g.** analyze how alternative translation methods for subsidiaries operating in hyperinflationary economies affect financial statements and ratios;
☐	**h.** describe how multinational operations affect a company's effective tax rate;
☐	**i.** explain how changes in the components of sales affect the sustainability of sales growth;
☐	**j.** analyze how currency fluctuations potentially affect financial results, given a company's countries of operation.

1 INTRODUCTION AND FOREIGN CURRENCY TRANSACTIONS: FOREIGN CURRENCY TRANSACTION EXPOSURE TO FOREIGN EXCHANGE RISK AND ANALYTICAL ISSUES

a compare and contrast presentation in (reporting) currency, functional currency, and local currency;

b describe foreign currency transaction exposure, including accounting for and disclosures about foreign currency transaction gains and losses;

According to the World Trade Organization, merchandise exports worldwide were nearly US$15 trillion in 2010.[1] The amount of worldwide merchandise exports in 2010 was more than twice the amount in 2003 (US$7.4 trillion) and more than four times the amount in 1993 (US$3.7 trillion). The top five exporting countries in 2010, in order, were China, the United States, Germany, Japan, and the Netherlands. In the United States alone, 293,131 companies were identified as exporters in 2010, but only 2.2% of those companies were large (more than 500 employees).[2] The vast majority of US companies with export activity were small or medium-sized entities.

The point illustrated by these statistics is that many companies engage in transactions that cross national borders. The parties to these transactions must agree on the currency in which to settle the transaction. Generally, this will be the currency of either the buyer or the seller. Exporters that receive payment in foreign currency and allow the purchaser time to pay must carry a foreign currency receivable on their books. Conversely, importers that agree to pay in foreign currency will have a foreign currency account payable. To be able to include them in the total amount of accounts receivable (payable) reported on the balance sheet, these foreign currency denominated accounts receivable (payable) must be translated into the currency in which the exporter (importer) keeps its books and presents financial statements.

The prices at which foreign currencies can be purchased or sold are called foreign exchange rates. Because foreign exchange rates fluctuate over time, the value of foreign currency payables and receivables also fluctuates. The major accounting issue related to foreign currency transactions is how to reflect the changes in value for foreign currency payables and receivables in the financial statements.

Many companies have operations located in foreign countries. For example, the Swiss food products company Nestlé SA reports that it has factories in 83 countries and a presence in almost every country in the world. US-based Procter & Gamble's annual filing discloses more than 400 subsidiaries located in more than 80 countries around the world. Foreign subsidiaries are generally required to keep accounting records in the currency of the country in which they are located. To prepare consolidated financial statements, the parent company must translate the foreign currency financial statements of its foreign subsidiaries into its own currency. Nestlé, for example, must translate the assets and liabilities its various foreign subsidiaries carry in foreign currency into Swiss francs to be able to consolidate those amounts with the Swiss franc assets and liabilities located in Switzerland.

A multinational company like Nestlé is likely to have two types of foreign currency activities that require special accounting treatment. Most multinationals (1) engage in transactions that are denominated in a foreign currency and (2) invest in foreign

1 World Trade Organization, *International Trade Statistics 2011*, Table I4, page 21.

2 US Census Bureau, Department of Commerce. *A Profile of US Importing and Exporting Companies, 2009–2010.* Released 12 April 2012.

subsidiaries that keep their books in a foreign currency. To prepare consolidated financial statements, a multinational company must translate the foreign currency amounts related to both types of international activities into the currency in which the company presents its financial statements.

This reading presents the accounting for foreign currency transactions and the translation of foreign currency financial statements. The conceptual issues related to these accounting topics are discussed, and the specific rules embodied in International Financial Reporting Standards (IFRS) and US GAAP are demonstrated through examples. Fortunately, differences between IFRS and US GAAP with respect to foreign currency translation issues are minimal.

Analysts need to understand the effects of foreign exchange rate fluctuations on the financial statements of a multinational company and how a company's financial statements reflect foreign currency gains and losses, whether realized or not.

1.1 Foreign Currency Transactions

When companies from different countries agree to conduct business with one another, they must decide which currency will be used. For example, if a Mexican electronic components manufacturer agrees to sell goods to a customer in Finland, the two parties must agree whether the Finnish company will pay for the goods in Mexican pesos, euro, or perhaps even a third currency such as the US dollar. If the transaction is denominated in Mexican pesos, the Finnish company has a foreign currency transaction but the Mexican company does not. To account for the inventory being purchased and the account payable in Mexican pesos, the Finnish company must translate the Mexican peso amounts into euro using appropriate exchange rates. Although the Mexican company also has entered into an international transaction (an export sale), it does not have a foreign currency transaction and no translation is necessary. It simply records the sales revenue and account receivable in Mexican pesos, which is the currency in which it keeps its books and prepares financial statements.

The currency in which financial statement amounts are presented is known as the **presentation currency**. In most cases, a company's presentation currency will be the currency of the country where the company is located. Finnish companies are required to keep accounting records and present financial results in euro, US companies in US dollars, Chinese companies in Chinese yuan, and so on.

Another important concept in accounting for foreign currency activities is the **functional currency**, which is the currency of the primary economic environment in which an entity operates. Normally, the functional currency is the currency in which an entity primarily generates and expends cash. In most cases, an organization's functional currency will be the same as its presentation currency. And, because most companies primarily generate and expend cash in the currency of the country where they are located, the functional and presentation currencies are most often the same as the **local currency** where the company operates.

Because the local currency generally is an entity's functional currency, a multinational corporation with subsidiaries in a variety of different countries is likely to have a variety of different functional currencies. The Thai subsidiary of a Japanese parent company, for example, is likely to have the Thai baht as its functional currency, whereas the Japanese parent's functional currency is the Japanese yen. But in some cases, the foreign subsidiary could have the parent's functional currency as its own. For example, prior to its 2011 acquisition of McAfee, Intel Corporation had determined that the US dollar was the functional currency for all of its significant foreign subsidiaries. However, subsequent to the acquisition of McAfee, as stated in Intel Corporation's 2011 Annual Report, Note 1: Basis of Presentation, "Certain of the operations acquired from McAfee have a functional currency other than the US dollar."

By definition, for accounting purposes, a foreign currency is any currency other than a company's functional currency, and **foreign currency transactions** are those denominated in a currency other than the company's functional currency. Foreign currency transactions occur when a company (1) makes an import purchase or an export sale that is denominated in a foreign currency or (2) borrows or lends funds where the amount to be repaid or received is denominated in a foreign currency. In each of these cases, the company has an asset or a liability denominated in a foreign currency.

1.1.1 *Foreign Currency Transaction Exposure to Foreign Exchange Risk*

Assume that FinnCo, a Finland-based company, imports goods from Mexico in January under 45-day credit terms, and the purchase is denominated in Mexican pesos. By deferring payment until April, FinnCo runs the risk that from the date the purchase is made until the date of payment, the value of the Mexican peso might increase relative to the euro. FinnCo would then need to spend more euro to settle its Mexican peso account payable. In this case, FinnCo is said to have an **exposure to foreign exchange risk**. Specifically, FinnCo has a foreign currency **transaction exposure**. Transaction exposure related to imports and exports can be summarized as follows:

- *Import purchase.* A transaction exposure arises when the importer is obligated to pay in foreign currency and is allowed to defer payment until sometime after the purchase date. The importer is exposed to the risk that from the purchase date until the payment date the foreign currency might increase in value, thereby increasing the amount of functional currency that must be spent to acquire enough foreign currency to settle the account payable.
- *Export sale.* A transaction exposure arises when the exporter agrees to be paid in foreign currency and allows payment to be made sometime after the purchase date. The exporter is exposed to the risk that from the purchase date until the payment date, the foreign currency might decrease in value, thereby decreasing the amount of functional currency into which the foreign currency can be converted when it is received.

The major issue in accounting for foreign currency transactions is how to account for the foreign currency risk—that is, how to reflect in the financial statements the change in value of the foreign currency asset or liability. Both IFRS and US GAAP require the change in the value of the foreign currency asset or liability resulting from a foreign currency transaction to be treated as a gain or loss reported on the income statement.[3]

1.1.1.1 Accounting for Foreign Currency Transactions with Settlement before Balance Sheet Date Example 1 demonstrates FinnCo's accounting, assuming that it purchased goods on account from a Mexican supplier that required payment in Mexican pesos, and that it made payment before the balance sheet date. The basic principle is that all transactions are recorded at the spot rate on the date of the transaction. The foreign currency risk on *transactions*, therefore, arises only when the transaction date and the payment date are different.

3 International standards are presented in International Accounting Standard (IAS) 21, "The Effects of Changes in Foreign Exchange Rates," and US GAAP standards are presented in FASB ASC Topic 830, "Foreign Currency Matters."

EXAMPLE 1

Accounting for Foreign Currency Transactions with Settlement before the Balance Sheet Date

FinnCo purchases goods from its Mexican supplier on 1 November 20X1; the purchase price is 100,000 Mexican pesos. Credit terms allow payment in 45 days, and FinnCo makes payment of 100,000 pesos on 15 December 20X1. FinnCo's functional and presentation currency is the euro. Spot exchange rates between the euro (EUR) and Mexican peso (MXN) are as follows:

1 November 20X1	MXN1 = EUR0.0684
15 December 20X1	MXN1 = EUR0.0703

FinnCo's fiscal year end is 31 December. How will FinnCo account for this foreign currency transaction, and what effect will it have on the 20X1 financial statements?

Solution:

The euro value of the Mexican peso account payable on 1 November 20X1 was EUR6,840 (MXN100,000 × EUR0.0684). FinnCo could have paid for its inventory on 1 November by converting 6,840 euro into 100,000 Mexican pesos. Instead, the company purchases 100,000 Mexican pesos on 15 December 20X1, when the value of the peso has increased to EUR0.0703. Thus, FinnCo pays 7,030 euro to purchase 100,000 Mexican pesos. The net result is a loss of 190 euro (EUR7,030 – EUR6,840).

Although the cash outflow to acquire the inventory is EUR7,030, the cost included in the inventory account is only EUR6,840. This cost represents the amount that FinnCo could have paid if it had not waited 45 days to settle its account. By deferring payment, and because the Mexican peso increased in value between the transaction date and settlement date, FinnCo has to pay an additional 190 euro. The company will report a foreign exchange loss of EUR190 in its net income in 20X1. This is a realized loss because FinnCo actually spent an additional 190 euro to purchase its inventory. The net effect on the financial statements, in EUR, can be seen as follows:

Balance Sheet					Income Statement		
Assets		= Liabilities +	Stockholders' Equity		Revenues and Gains	Expenses and Losses	
Cash	–7,030		Retained			Foreign	
Inventory	+6,840		earnings	–190		exchange loss	–190
	–190						

1.1.1.2 Accounting for Foreign Currency Transactions with Intervening Balance Sheet Dates

Another important issue related to the accounting for foreign currency transactions is what, if anything, should be done if a balance sheet date falls between the initial transaction date and the settlement date. For foreign currency transactions whose settlement dates fall in subsequent accounting periods, both IFRS and US GAAP require adjustments to reflect intervening changes in currency exchange rates. Foreign currency transaction gains and losses are reported on the income statement, creating one of the few situations in which accounting rules allow, indeed require, companies to include (recognize) a gain or loss in income before it has been realized.

Subsequent foreign currency transaction gains and losses are recognized from the balance sheet date through the date the transaction is settled. Adding together foreign currency transaction gains and losses for both accounting periods (transaction initiation to balance sheet date and balance sheet date to transaction settlement) produces an amount equal to the actual realized gain or loss on the foreign currency transaction.

EXAMPLE 2

Accounting for Foreign Currency Transaction with Intervening Balance Sheet Date

FinnCo sells goods to a customer in the United Kingdom for £10,000 on 15 November 20X1, with payment to be received in British pounds on 15 January 20X2. FinnCo's functional and presentation currency is the euro. Spot exchange rates between the euro (€) and British pound (£) are as follows:

15 November 20X1	£1 = €1.460
31 December 20X1	£1 = €1.480
15 January 20X2	£1 = €1.475

FinnCo's fiscal year end is 31 December. How will FinnCo account for this foreign currency transaction, and what effect will it have on the 20X1 and 20X2 financial statements?

Solution:

The euro value of the British pound account receivable at each of the three relevant dates is determined as follows:

		Account Receivable (£10,000)	
Date	**€/£ Exchange Rate**	**Euro Value**	**Change in Euro Value**
15 Nov 20X1	€1.460	14,600	N/A
31 Dec 20X1	€1.480	14,800	+ 200
15 Jan 20X2	€1.475	14,750	– 50

A change in the euro value of the British pound receivable from 15 November to 31 December would be recognized as a foreign currency transaction gain or loss on FinnCo's 20X1 income statement. In this case, the increase in the value of the British pound results in a transaction gain of €200 [£10,000 × (€1.48 – €1.46)]. Note that the gain recognized in 20X1 income is unrealized, and remember that this is one of few situations in which companies include an unrealized gain in income.

Any change in the exchange rate between the euro and British pound that occurs from the balance sheet date (31 December 20X1) to the transaction settlement date (15 January 20X2) will also result in a foreign currency transaction gain or loss. In our example, the British pound weakened slightly against the euro during this period, resulting in an exchange rate of €1.475/ £1 on 15 January 20X2. The £10,000 account receivable now has a value of €14,750, which is a decrease of €50 from 31 December 20X1. FinnCo will recognize a foreign currency transaction loss on 15 January 20X2 of €50 that will be included in the company's calculation of net income for the first quarter of 20X2.

From the transaction date to the settlement date, the British pound has increased in value by €0.015 (€1.475 – €1.460), which generates a realized foreign currency transaction gain of €150. A gain of €200 was recognized in 20X1 and a loss of €50 is recognized in 20X2. Over the two-month period, the net gain recognized in the financial statements is equal to the actual realized gain on the foreign currency transaction.

In Example 2, FinnCo's British pound account receivable resulted in a net foreign currency transaction gain because the British pound strengthened (increased) in value between the transaction date and the settlement date. In this case, FinnCo has an asset exposure to foreign exchange risk. This asset exposure benefited the company because the foreign currency strengthened. If FinnCo instead had a British pound account payable, a liability exposure would have existed. The euro value of the British pound account payable would have increased as the British pound strengthened, and FinnCo would have recognized a foreign currency transaction loss as a result.

Whether a change in exchange rate results in a foreign currency transaction gain or loss (measured in local currency) depends on (1) the nature of the exposure to foreign exchange risk (asset or liability) and (2) the direction of change in the value of the foreign currency (strengthens or weakens).

		Foreign Currency	
Transaction	**Type of Exposure**	**Strengthens**	**Weakens**
Export sale	Asset (account receivable)	Gain	Loss
Import purchase	Liability (account payable)	Loss	Gain

A foreign currency receivable arising from an export sale creates an asset exposure to foreign exchange risk. If the foreign currency strengthens, the receivable increases in value in terms of the company's functional currency and a foreign currency transaction gain arises. The company will be able to convert the foreign currency when received into more units of functional currency because the foreign currency has strengthened. Conversely, if the foreign currency weakens, the foreign currency receivable loses value in terms of the functional currency and a loss results.

A foreign currency payable resulting from an import purchase creates a liability exposure to foreign exchange risk. If the foreign currency strengthens, the payable increases in value in terms of the company's functional currency and a foreign currency transaction loss arises. The company must spend more units of functional currency to be able to settle the foreign currency liability because the foreign currency has strengthened. Conversely, if the foreign currency weakens, the foreign currency payable loses value in terms of the functional currency and a gain exists.

1.1.2 *Analytical Issues*

Both IFRS and US GAAP require foreign currency transaction gains and losses to be reported in net income (even if the gains and losses have not yet been realized), but neither standard indicates where on the income statement these gains and losses should be placed. The two most common treatments are either (1) as a component of other operating income/expense or (2) as a component of non-operating income/expense, in some cases as a part of net financing cost. The calculation of operating profit margin is affected by where foreign currency transaction gains or losses are placed on the income statement.

EXAMPLE 3

Placement of Foreign Currency Transaction Gains/Losses on the Income Statement—Effect on Operating Profit

Assume that FinnCo had the following income statement information in both 20X1 and 20X2, excluding a foreign currency transaction gain of €200 in 20X1 and a transaction loss of €50 in 20X2.

	20X1	20X2
Revenues	€20,000	€20,000
Cost of goods sold	12,000	12,000
Other operating expenses, net	5,000	5,000
Non-operating expenses, net	1,200	1,200

FinnCo is deciding between two alternatives for the treatment of foreign currency transaction gains and losses. Alternative 1 calls for the reporting of foreign currency transaction gains/losses as part of "Other operating expenses, net." Under Alternative 2, the company would report this information as part of "Non-operating expenses, net."

FinnCo's fiscal year end is 31 December. How will Alternatives 1 and 2 affect the company's gross profit margin, operating profit margin, and net profit margin for 20X1? For 20X2?

Solution:

Remember that a gain would serve to reduce expenses, whereas a loss would increase expenses.

20X1—Transaction Gain of €200				
	Alternative 1		Alternative 2	
Revenues	€20,000		€20,000	
Cost of goods sold	(12,000)		(12,000)	
Gross profit	8,000		8,000	
Other operating expenses, net	(4,800)	incl. gain	(5,000)	
Operating profit	3,200		3,000	
Non-operating expenses, net	(1,200)		(1,000)	incl. gain
Net profit	€2,000		€2,000	

Profit margins in 20X1 under the two alternatives can be calculated as follows:

	Alternative 1	Alternative 2
Gross profit margin	€8,000/€20,000 = 40.0%	€8,000/€20,000 = 40.0%
Operating profit margin	3,200/20,000 = 16.0%	3,000/20,000 = 15.0%
Net profit margin	2,000/20,000 = 10.0%	2,000/20,000 = 10.0%

20X2—Transaction Loss of €50		
	Alternative 1	Alternative 2
Revenues	€20,000	€20,000
Cost of goods sold	(12,000)	(12,000)

20X2—Transaction Loss of €50				
	Alternative 1		Alternative 2	
Gross profit	8,000		8,000	
Other operating expenses, net	(5,050)	incl. loss	(5,000)	
Operating profit	2,950		3,000	
Non-operating expenses, net	(1,200)		(1,250)	incl. loss
Net profit	€1,750		€1,750	

Profit margins in 20X2 under the two alternatives can be calculated as follows:

	Alternative 1	Alternative 2
Gross profit margin	€8,000/€20,000 = 40.0%	€8,000/€20,000 = 40.0%
Operating profit margin	2,950/20,000 = 14.75%	3,000/20,000 = 15.0%
Net profit margin	1,750/20,000 = 8.75%	1,750/20,000 = 8.75%

Gross profit and net profit are unaffected, but operating profit differs under the two alternatives. In 20X1, the operating profit margin is larger under Alternative 1, which includes the transaction gain as part of "Other operating expenses, net." In 20X2, Alternative 1 results in a smaller operating profit margin than Alternative 2. Alternative 2 has the same operating profit margin in both periods. Because exchange rates do not fluctuate by the same amount or in the same direction from one accounting period to the next, Alternative 1 will cause greater volatility in operating profit and operating profit margin over time.

Because accounting standards do not provide guidance on the placement of foreign currency transaction gains and losses on the income statement, companies are free to choose among the alternatives. Two companies in the same industry could choose different alternatives, which would distort the direct comparison of operating profit and operating profit margins between those companies.

A second issue that should be of interest to analysts relates to the fact that unrealized foreign currency transaction gains and losses are included in net income when the balance sheet date falls between the transaction and settlement dates. The implicit assumption underlying this accounting requirement is that the unrealized gain or loss as of the balance sheet date reflects the company's ultimate net gain or loss. In reality, though, the ultimate net gain or loss may vary dramatically because of the possibility for changes in trend and volatility of currency prices.

This effect was seen in the previous hypothetical Example 2 with FinnCo. Using given currency exchange rate data shows that the real-world effect can also be quite dramatic. Assume that a French company purchased goods from a Canadian supplier on 1 December 20X1, with payment of 100,000 Canadian dollars (C$) to be made on 15 May 20X2. Actual exchange rates between the Canadian dollar and euro (€) during the period 1 December 20X1 and 15 May 20X2, the euro value of the Canadian dollar account payable, and the foreign currency transaction gain or loss are shown below:

		Account Payable (C$100,000)	
	€/C$	€ Value	Change in € Value (Gain/Loss)
1 Dec X1	0.7285	72,850	N/A
31 Dec X1	0.7571	75,710	2,860 loss

(continued)

	€/C$	Account Payable (C$100,000)	
		€ Value	Change in € Value (Gain/Loss)
31 Mar X2	0.7517	75,170	540 gain
15 May X2	0.7753	77,530	2,360 loss

As the Canadian dollar strengthened against the euro in late 20X1, the French company would have recorded a foreign currency transaction loss of €2,860 in the fourth quarter of 20X1. The Canadian dollar reversed course by weakening over the first three months of 20X2, resulting in a transaction gain of €540 in the first quarter, and then strengthened against the euro in the second quarter of 20X2, resulting in a transaction loss of €2,360. At the time payment is made on 15 May 20X2, the French company realizes a net foreign currency transaction loss of €4,680 (€77,530 – €72,850).

2 DISCLOSURES RELATED TO FOREIGN CURRENCY TRANSACTION GAINS AND LOSSES

b describe foreign currency transaction exposure, including accounting for and disclosures about foreign currency transaction gains and losses;

Because accounting rules allow companies to choose where they present foreign currency transaction gains and losses on the income statement, it is useful for companies to disclose both the amount of transaction gain or loss that is included in income and the presentation alternative they have selected. IFRS require disclosure of "the amount of exchange differences recognized in profit or loss," and US GAAP require disclosure of "the aggregate transaction gain or loss included in determining net income for the period," but neither standard specifically requires disclosure of the line item in which these gains and losses are located.

Exhibit 1 provides disclosures from BASF AG's 2011 annual report that the German company made related to foreign currency transaction gains and losses. Exhibit 2 presents similar disclosures found in the Netherlands-based Heineken NV's 2011 Annual Report. Both companies use IFRS to prepare their consolidated financial statements.

BASF's income statement in Exhibit 1 does not include a separate line item for foreign currency gains and losses. From Note 6 in Exhibit 1, an analyst can determine that BASF has chosen to include "Income from foreign currency and hedging transactions" in "Other operating income." Of the total amount of €2,008 million reported as "Other operating income" in 2011, €170 million is attributable to foreign currency and hedging transaction income. It is not possible to determine from BASF's financial statements whether or not these gains were realized in 2011, and any unrealized gain reported in 2011 income might or might not be realized in 2012.

Note 7 in Exhibit 1 indicates that "Expenses from foreign currency and hedging transactions as well as market valuation" in 2011 were €399 million, making up 15% of Other operating expenses. Combining foreign currency transaction gains and losses results in a net loss of €229 million, which is equal to 2.55% of BASF's "Income before taxes and minority interests."

Exhibit 1 Excerpts from BASF AG's 2011 Annual Report Related to Foreign Currency Transactions

Consolidated Statements of Income Million €	Explanation in Notes	2011	2010
Sales	(4)	73,497	63,873
Cost of sales		(53,986)	(45,310)
Gross profit on sales		**19,511**	**18,563**
Selling expenses		(7,323)	(6,700)
General and administrative expenses		(1,315)	(1,138)
Research and development expenses		(1,605)	(1,492)
Other operating income	(6)	2,008	1,140
Other operating expenses	(7)	(2,690)	(2,612)
Income from operations	(4)	**8,586**	**7,761**
(detail omitted)			
Financial result	(8)	**384**	**(388)**
Income before taxes and minority interests		**8,970**	**7,373**
Income taxes	(9)	(2,367)	(2,299)
Income before minority interests		**6,603**	**5,074**
Minority interests	(10)	(415)	(517)
Net income		**6,188**	**4,557**

Notes:

1 Summary of Accounting Policies

Foreign currency transactions: The cost of assets acquired in foreign currencies and revenues from sales in foreign currencies are recorded at the exchange rate on the date of the transaction. Foreign currency receivables and liabilities are valued at the exchange rates on the balance sheet date.

6 Other Operating Income

Million €	2011	2010
Reversal and adjustment of provisions	170	244
Revenue from miscellaneous revenue-generating activities	207	142
Income from foreign currency and hedging transactions	170	136
Income from the translation of financial statements in foreign currencies	42	76
Gains on the disposal of property, plant and equipment and divestitures	666	101
Reversals of impairments of property, plant and equipment	—	40
Gains on the reversal of allowance for doubtful business-related receivables	77	36
Other	676	365
	2,008	1,140

Income from foreign currency and hedging transactions concerned foreign currency transactions, the measurement at fair value of receivables and payables in foreign currencies, as well as currency derivatives and other hedging transactions.

(continued)

Exhibit 1 (Continued)

7 Other Operating Expenses

Million €	**2011**	**2010**
Restructuring measures	233	276
Environmental protection and safety measures, costs of demolition and removal, and planning expenses related to capital expenditures that are not subject to mandatory capitalization	203	98
Valuation adjustments on tangible and intangible assets	366	247
Costs from miscellaneous revenue-generating activities	220	180
Expenses from foreign currency and hedging transactions as well as market valuation	399	601
Losses from the translation of the financial statements in foreign currencies	56	63
Losses from the disposal of property, plant and equipment and divestitures	40	24
Oil and gas exploration expenses	184	190
Expenses from additions to allowances for business-related receivables	124	107
Expenses from the use of inventories measured at market value and the derecognition of obsolete inventory	233	188
Other	632	638
	2,690	2,612

Expenses from foreign currency and hedging transactions as well as market valuation concern foreign currency translations of receivables and payables as well as changes in the fair value of currency derivatives and other hedging transactions.

In Exhibit 2, Heineken's Note 2, Basis of Preparation, part (c) explicitly states that the euro is the company's functional currency. Note 3(b)*(i)* indicates that monetary assets and liabilities denominated in foreign currencies at the balance sheet date are translated to the functional currency and that foreign currency differences arising on the translation (i.e., translation gains and losses) are recognized on the income statement. Note 3(r) discloses that foreign currency gains and losses are included on a net basis in the other net finance income and expenses. Note 12, "Net finance income and expense," shows that a net foreign exchange loss of €107 million existed in 2011 and a net gain of €61 million arose in 2010. The net foreign currency transaction gain in 2010 amounted to 3.1% of Heineken's profit before income tax that year, and the net translation loss in 2011 represented 5.3% of the company's profit before income tax in that year. Note 12 also shows gains and losses related to changes in the fair value of derivatives, some of which related to foreign currency derivatives.

Notes:

2 Basis of preparation

c Functional and presentation currency

These consolidated financial statements are presented in euro, which is the Company's functional currency. All financial information presented in euro has been rounded to the nearest million unless stated otherwise.

3 Significant accounting policies

b Foreign currency

i. Foreign currency transactions

Transactions in foreign currencies are translated to the respective functional currencies of Heineken entities at the exchange rates at the dates of the transactions. Monetary assets and liabilities denominated in foreign currencies at the reporting date are retranslated to the functional currency at the exchange rate at that date. . . . Foreign currency differences arising on retranslation are recognised in profit or loss, except for differences arising on the retranslation of available-for-sale (equity) investments and foreign currency differences arising on the retranslation of a financial liability designated as a hedge of a net investment, which are recognised in other comprehensive income.[4]

r Interest income, interest expenses and other net finance income and expenses

(continued)

4 Note that this excerpt uses "retranslation" in the same way that "translation" is used throughout the rest of this reading. The translation of currency for foreign subsidiaries will be covered in the next section.

Exhibit 2 (Continued)

…Foreign currency gains and losses are reported on a net basis in the other net finance income and expenses.

Net finance income/(expenses)	**(430)**	**(509)**

Disclosures related to foreign currency are commonly found both in the Management Discussion & Analysis (MD&A) and the Notes to Financial Statements sections of an annual report. In applying US GAAP to account for its foreign currency transactions, Yahoo! Inc. reported the following in the Quantitative and Qualitative Disclosures about Market Risk section of its 2011 annual report:

> Our exposure to foreign currency transaction gains and losses is the result of assets and liabilities, (including inter-company transactions) that are denominated in currencies other than the relevant entity's functional currency.... We may enter into derivative instruments, such as foreign currency forward contracts or other instruments to minimize the short-term foreign currency fluctuations on such assets and liabilities. The gains and losses on the forward contracts may not offset any or more than a portion of the transaction gains and losses on certain foreign currency receivables, investments and payables recognized in earnings. Transaction gains and losses on these foreign exchange contracts are recognized each period in other income, net included on the consolidated statements of income. During the years ended December 31, 2011, 2010, and 2009, we recorded net realized and unrealized foreign currency transaction gains of $9 million and $13 million, and a transaction loss of $1 million, respectively.

Yahoo!'s disclosure clearly explains that both realized and unrealized foreign currency transaction gains and losses are reflected in income, specifically as a part of non-operating activities. The net foreign currency transaction gain in 2011 of $9 million represented only 1.1% of the company's pretax income ($827.5 million) for the year.

Some companies may choose not to disclose either the location or the amount of their foreign currency transaction gains and losses, presumably because the amounts involved are immaterial. There are several reasons why the amount of transaction gains and losses can be immaterial for a company:

1 The company engages in a limited number of foreign currency transactions that involve relatively small amounts of foreign currency.

2 The exchange rates between the company's functional currency and the foreign currencies in which it has transactions tend to be relatively stable.

3 Gains on some foreign currency transactions are naturally offset by losses on other transactions, such that the net gain or loss is immaterial. For example, if a US company sells goods to a customer in Canada with payment in Canadian dollars to be received in 90 days and at the same time purchases goods from a supplier in Canada with payment to be made in Canadian dollars in 90 days, any loss that arises on the Canadian dollar receivable due to a weakening in the value of the Canadian dollar will be exactly offset by a gain of equal amount on the Canadian dollar payable.

4 The company engages in foreign currency hedging activities to offset the foreign exchange gains and losses that arise from foreign currency transactions. Hedging foreign exchange risk is a common practice for many companies engaged in foreign currency transactions.

The two most common types of hedging instruments used to minimize foreign exchange transaction risk are foreign currency forward contracts and foreign currency options. Nokia Corporation describes its foreign exchange risk management approach in its 2011 Form 20-F annual report in Note 34, Risk Management. An excerpt from that note follows:

> Nokia operates globally and is thus exposed to foreign exchange risk arising from various currencies. Foreign currency denominated assets and liabilities together with foreign currency denominated cash flows from highly probable or probable purchases and sales contribute to foreign exchange exposure. These transaction exposures are managed against various local currencies because of Nokia's substantial production and sales outside the Euro zone.
>
> According to the foreign exchange policy guidelines of the Group, which remains the same as in the previous year, material transaction foreign exchange exposures are hedged unless hedging would be uneconomical due to market liquidity and/or hedging cost. Exposures are defined using nominal values of the transactions. Exposures are mainly hedged with derivative financial instruments such as forward foreign exchange contracts and foreign exchange options. The majority of financial instruments hedging foreign exchange risk have duration of less than a year. The Group does not hedge forecasted foreign currency cash flows beyond two years.

Elsewhere in its annual report, Nokia provides additional disclosures about the currencies to which it has exposure and the accounting for different types of hedges. The company also summarizes the effect of material exchange rate movements. For example, the 4.2% appreciation of the US dollar in 2011 had a positive effect on net sales expressed in euro (40% of Nokia's net sales are in US dollars or currencies closely following the US dollar) and a negative effect on product cost (60% of Nokia's components are sourced in US dollars); this resulted in a slightly negative effect on operating profit.

3 TRANSLATION OF FOREIGN CURRENCY FINANCIAL STATEMENTS AND TRANSLATION CONCEPTUAL ISSUES

c analyze how changes in exchange rates affect the translated sales of the subsidiary and parent company;

Many companies have operations in foreign countries. Most operations located in foreign countries keep their accounting records and prepare financial statements in the local currency. For example, the US subsidiary of German automaker BMW AG keeps its books in US dollars. IFRS and US GAAP require parent companies to prepare consolidated financial statements in which the assets, liabilities, revenues, and expenses of both domestic and foreign subsidiaries are added to those of the parent company. To prepare worldwide consolidated statements, parent companies must translate the foreign currency financial statements of their foreign subsidiaries into the parent company's presentation currency. BMW AG, for example, must translate both the US dollar financial statements of its US subsidiary and the South African rand financial statements of its South African subsidiary into euro to consolidate these foreign operations. If, for example, the US dollar and South African rand appreciate against the euro over the course of a given year, the amount of sales translated into euro will be greater than if the subsidiary's currencies weaken against the euro.

IFRS and US GAAP have similar rules for the translation of foreign currency financial statements. To fully understand the results from applying these rules, however, several conceptual issues must first be examined.

3.1 Translation Conceptual Issues

In translating foreign currency financial statements into the parent company's presentation currency, two questions must be addressed:

1 What is the appropriate exchange rate to use in translating each financial statement item?

2 How should the translation adjustment that inherently arises from the translation process be reflected in the consolidated financial statements? In other words, how is the balance sheet brought back into balance?

These issues and the basic concepts underlying the translation of financial statements are demonstrated through the following example.

Spanco is a hypothetical Spain-based company that uses the euro as its presentation currency. Spanco establishes a wholly owned subsidiary, Amerco, in the United States on 31 December 20X1 by investing €10,000 when the exchange rate between the euro and the US dollar is €1 = US$1. The equity investment of €10,000 is physically converted into US$10,000 to begin operations. In addition, Amerco borrows US$5,000 from local banks on 31 December 20X1. Amerco purchases inventory that costs US$12,000 on 31 December 20X1 and retains US$3,000 in cash. Amerco's balance sheet at 31 December 20X1 thus appears as follows:

Amerco Balance Sheet, 31 December 20X1 (in US Dollars)

Cash	$3,000	Notes payable	$5,000
Inventory	12,000	Common stock	10,000
Total	$15,000	Total	$15,000

To prepare a consolidated balance sheet in euro as of 31 December 20X1, Spanco must translate all of the US dollar balances on Amerco's balance sheet at the €1 = US$1 exchange rate. The translation worksheet as of 31 December 20X1 is as follows:

Translation Worksheet for Amerco, 31 December 20X1

	USD	Exchange Rate (€)	EUR
Cash	$3,000	1.00	€3,000
Inventory	12,000	1.00	12,000
Total	$15,000		€15,000
Notes payable	5,000	1.00	5,000
Common stock	10,000	1.00	10,000
Total	$15,000		€15,000

By translating each US dollar balance at the same exchange rate (€1.00), Amerco's translated balance sheet in euro reflects an equal amount of total assets and total liabilities plus equity and remains in balance.

During the first quarter of 20X2, Amerco engages in no transactions. During that period, however, the US dollar weakens against the euro such that the exchange rate on 31 March 20X2 is €0.80 = US$1.

To prepare a consolidated balance sheet at the end of the first quarter of 20X2, Spanco now must choose between the current exchange rate of €0.80 and the historical exchange rate of €1.00 to translate Amerco's balance sheet amounts into euro. The original investment made by Spanco of €10,000 is a historical fact, so the company wants to translate Amerco's common stock in such a way that it continues to reflect this amount. This goal is achieved by translating common stock of US$10,000 into euro using the historical exchange rate of €1 = US$1.

Two approaches for translating the foreign subsidiary's assets and liabilities are as follows:

1 All assets and liabilities are translated at the **current exchange rate** (the spot exchange rate on the balance sheet date).

2 Only **monetary assets and liabilities** are translated at the current exchange rate; **non-monetary assets and liabilities** are translated at **historical exchange rates** (the exchange rates that existed when the assets and liabilities were acquired). Monetary items are cash and receivables (payables) that are to be received (paid) in a fixed number of currency units. Non-monetary assets include inventory, fixed assets, and intangibles, and non-monetary liabilities include deferred revenue.

These two different approaches are demonstrated and the results analyzed in turn.

3.1.1 *All Assets and Liabilities Are Translated at the Current Exchange Rate*

The translation worksheet on 31 March 20X2, in which all assets and liabilities are translated at the current exchange rate (€0.80), is as follows:

Translation Worksheet for Amerco, 31 March 20X2

	US Dollar	Exchange Rate (€)	Euro	Change in Euro Value since 31 Dec 20X1
Cash	$3,000	0.80 C	€2,400	−€600
Inventory	12,000	0.80 C	9,600	−2,400
Total	$15,000		€12,000	−€3,000

(continued)

Translation Worksheet for Amerco, 31 March 20X2

	US Dollar	Exchange Rate (€)	Euro	Change in Euro Value since 31 Dec 20X1
Notes payable	5,000	0.80 C	4,000	−1,000
Common stock	10,000	1.00 H	10,000	0
Subtotal	$15,000		14,000	−1,000
Translation adjustment			(2,000)	−2,000
Total			€12,000	−€3,000

Note: C = current exchange rate; H = historical exchange rate

By translating all assets at the lower current exchange rate, total assets are written down from 31 December 20X1 to 31 March 20X2 in terms of their euro value by €3,000. Liabilities are written down by €1,000. To keep the euro translated balance sheet in balance, a *negative* translation adjustment of €2,000 is created and included in stockholders' equity on the consolidated balance sheet.

Those foreign currency balance sheet accounts that are translated using the current exchange rate are revalued in terms of the parent's functional currency. This process is very similar to the revaluation of foreign currency receivables and payables related to foreign currency transactions. The net translation adjustment that results from translating individual assets and liabilities at the current exchange rate can be viewed as the *net* foreign currency translation gain or loss caused by a change in the exchange rate:

(€600)	loss on cash
(€2,400)	loss on inventory
€1,000	gain on notes payable
(€2,000)	net translation loss

The negative translation adjustment (net translation loss) does not result in a cash outflow of €2,000 for Spanco and thus is unrealized. The loss could be realized, however, if Spanco were to sell Amerco at its book value of US$10,000. The proceeds from the sale would be converted into euro at €0.80 per US$1, resulting in a cash inflow of €8,000. Because Spanco originally invested €10,000 in its US operation, a *realized* loss of €2,000 would result.

The second conceptual issue related to the translation of foreign currency financial statements is whether the unrealized net translation loss should be included in the determination of consolidated net income currently or deferred in the stockholders' equity section of the consolidated balance sheet until the loss is realized through sale of the foreign subsidiary. There is some debate as to which of these two treatments is most appropriate. This issue is discussed in more detail after considering the second approach for translating assets and liabilities.

3.1.2 *Only Monetary Assets and Monetary Liabilities Are Translated at the Current Exchange Rate*

Now assume only monetary assets and monetary liabilities are translated at the current exchange rate. The worksheet at 31 March 20X2, in which only monetary assets and liabilities are translated at the current exchange rate (€0.80), is as follows:

Translation Worksheet for Amerco, 31 March 20X2

	US Dollar	Exchange Rate (€)	Euro	Change in Euro Value since 31 Dec 20X1
Cash	$3,000	0.80 C	€2,400	−€600
Inventory	12,000	1.00 H	12,000	0
Total	$15,000		€14,400	−€600
Notes payable	5,000	0.80 C	4,000	−1,000
Common stock	10,000	1.00 H	10,000	0
Subtotal	$15,000		14,000	−1,000
Translation adjustment			400	400
Total			€14,400	−€600

Note: C = current exchange rate; H = historical exchange rate

Using this approach, cash is written down by €600 but inventory continues to be carried at its euro historical cost of €12,000. Notes payable is written down by €1,000. To keep the balance sheet in balance, a positive translation adjustment of €400 must be included in stockholders' equity. The translation adjustment reflects the *net* translation gain or loss related to monetary items only:

(€600)	loss on cash
€1,000	gain on notes payable
€400	net translation gain

The positive translation adjustment (net translation gain) also is *unrealized*. The gain could be *realized*, however, if:

1. The subsidiary uses its cash (US$3,000) to pay as much of its liabilities as possible, and
2. The parent sends enough euro to the subsidiary to pay its remaining liabilities (US$5,000 − US$3,000 = US$2,000). As of 31 December 20X1, at the €1.00 per US$1 exchange rate, Spanco will have sent €2,000 to Amerco to pay liabilities of US$2,000. On 31 March 20X2, given the €0.80 per US$1 exchange rate, the parent needs to send only €1,600 to pay US$2,000 of liabilities. As a result, Spanco would enjoy a foreign exchange gain of €400.

The second conceptual issue again arises under this approach. Should the unrealized foreign exchange gain be recognized in current period net income or deferred on the balance sheet as a separate component of stockholders' equity? The answer to this question, as provided by IFRS and US GAAP, is described in Section 4, Translation Methods.

3.1.3 *Balance Sheet Exposure*

Those assets and liabilities translated at the *current* exchange rate are revalued from balance sheet to balance sheet in terms of the parent company's presentation currency. These items are said to be *exposed* to translation adjustment. Balance sheet items translated at *historical* exchange rates do not change in parent currency value and therefore are not exposed to translation adjustment. Exposure to translation adjustment is referred to as balance sheet translation exposure, or accounting exposure.

A foreign operation will have a **net asset balance sheet exposure** when assets translated at the current exchange rate are greater than liabilities translated at the current exchange rate. A **net liability balance sheet exposure** exists when liabilities translated at the current exchange rate are greater than assets translated at the current exchange rate. Another way to think about the issue is to realize that there is a net asset balance sheet exposure when exposed assets are greater than exposed liabilities and a net liability balance sheet exposure when exposed liabilities are greater than exposed assets. The sign (positive or negative) of the current period's translation adjustment is a function of two factors: (1) the nature of the balance sheet exposure (asset or liability) and (2) the direction of change in the exchange rate (strengthens or weakens). The relationship between exchange rate fluctuations, balance sheet exposure, and the current period's translation adjustment can be summarized as follows:

Balance Sheet Exposure	Foreign Currency (FC)	
	Strengthens	**Weakens**
Net asset	Positive translation adjustment	Negative translation adjustment
Net liability	Negative translation adjustment	Positive translation adjustment

These relationships are the same as those summarized in Section 1 with respect to foreign currency transaction gains and losses. In reference to the example in Section 3, for instance, the amount of exposed assets (the US$3,000 cash) was less than the amount of exposed liabilities (US$5,000 of notes payable), implying a net liability exposure. Further, in the example the foreign currency (US$) weakened, resulting in a positive translation adjustment.

The combination of balance sheet exposure and direction of exchange rate change determines whether the current period's translation adjustment will be positive or negative. After the initial period of operations, a cumulative translation adjustment is required to keep the translated balance sheet in balance. The cumulative translation adjustment will be the sum of the translation adjustments that arise over successive accounting periods. For example, assume that Spanco translates all of Amerco's assets and liabilities using the current exchange rate (a net asset balance sheet exposure exists), which, because of a weakening US dollar in the first quarter of 20X2, resulted in a negative translation adjustment of €2,000 on 31 March 20X2 (as shown in Section 3). Assume further that in the second quarter of 20X2, the US dollar strengthens against the euro and there still is a net asset balance sheet exposure, which results in a *positive* translation adjustment of €500 for that quarter. Although the current period translation adjustment for the second quarter of 20X2 is positive, the cumulative translation adjustment as of 30 June 20X2 still will be negative, but the amount now will be only €1,500.

4 TRANSLATION METHODS

d compare the current rate method and the temporal method, evaluate how each affects the parent company's balance sheet and income statement, and determine which method is appropriate in various scenarios;

The two approaches to translating foreign currency financial statements described in the previous section are known as (1) the **current rate method** (all assets and liabilities are translated at the current exchange rate), and (2) the **monetary/non-monetary method** (only monetary assets and liabilities are translated at the current exchange rate). A variation of the monetary/non-monetary method requires not only monetary assets and liabilities but also non-monetary assets and liabilities that are measured at their current value on the balance sheet date to be translated at the current exchange rate. This variation of the monetary/non-monetary method sometimes is referred to as the **temporal method**.

The basic idea underlying the temporal method is that assets and liabilities should be translated in such a way that the measurement basis (either current value or historical cost) in the foreign currency is preserved after translating to the parent's presentation currency. To achieve this objective, assets and liabilities carried on the foreign currency balance sheet at a current value should be translated at the current exchange rate, and assets and liabilities carried on the foreign currency balance sheet at historical costs should be translated at historical exchange rates. Although neither the IASB nor the FASB specifically refer to translation methods by name, the procedures specified by IFRS and US GAAP for translating foreign currency financial statements essentially require the use of either the current rate or the temporal method.

Which method is appropriate for an individual foreign entity depends on that entity's functional currency. As noted earlier, the functional currency is the currency of the primary economic environment in which an entity operates. A foreign entity's functional currency can be either the parent's presentation currency or another currency, typically the currency of the country in which the foreign entity is located. Exhibit 3 lists the factors that IFRS indicate should be considered in determining a foreign entity's functional currency. Although not identical, US GAAP provide similar indicators for determining a foreign entity's functional currency.

When the functional currency indicators listed in Exhibit 3 are mixed and the functional currency is not obvious, IFRS indicate that management should use its best judgment in determining the functional currency. In this case, however, indicators 1 and 2 should be given priority over indicators 3 through 9.

Exhibit 3 Factors Considered in Determining the Functional Currency

In accordance with IFRS, the following factors should be considered in determining an entity's functional currency:

1 The currency that mainly influences sales prices for goods and services.
2 The currency of the country whose competitive forces and regulations mainly determine the sales price of its goods and services.
3 The currency that mainly influences labour, material, and other costs of providing goods and services.
4 The currency in which funds from financing activities are generated.
5 The currency in which receipts from operating activities are usually retained.

Additional factors to consider in determining whether the foreign entity's functional currency is the same as the parent's functional currency are

6 Whether the activities of the foreign operation are an extension of the parent's or are carried out with a significant amount of autonomy.
7 Whether transactions with the parent are a large or a small proportion of the foreign entity's activities.

(continued)

Exhibit 3 (Continued)

8 Whether cash flows generated by the foreign operation directly affect the cash flow of the parent and are available to be remitted to the parent.

9 Whether operating cash flows generated by the foreign operation are sufficient to service existing and normally expected debt or whether the foreign entity will need funds from the parent to service its debt.

The following three steps outline the functional currency approach required by accounting standards in translating foreign currency financial statements into the parent company's presentation currency:

1 Identify the functional currency of the foreign entity.

2 Translate foreign currency balances into the foreign entity's functional currency.

3 Use the current exchange rate to translate the foreign entity's functional currency balances into the parent's presentation currency, if they are different.

To illustrate how this approach is applied, consider a US parent company with a Mexican subsidiary that keeps its accounting records in Mexican pesos. Assume that the vast majority of the subsidiary's transactions are carried out in Mexican pesos, but it also has an account payable in Guatemalan quetzals. In applying the three steps, the US parent company first determines that the Mexican peso is the functional currency of the Mexican subsidiary. Second, the Mexican subsidiary translates its foreign currency balances (i.e., the Guatemalan quetzal account payable), into Mexican pesos using the current exchange rate. In step 3, the Mexican peso financial statements (including the translated account payable) are translated into US dollars using the current rate method.

Now assume, alternatively, that the primary operating currency of the Mexican subsidiary is the US dollar, which thus is identified as the Mexican subsidiary's functional currency. In that case, in addition to the Guatemalan quetzal account payable, all of the subsidiary's accounts that are denominated in Mexican pesos also are considered to be foreign currency balances (because they are not denominated in the subsidiary's functional currency, which is the US dollar). Along with the Guatemalan quetzal balance, each of the Mexican peso balances must be translated into US dollars as if the subsidiary kept its books in US dollars. Assets and liabilities carried at current value in Mexican pesos are translated into US dollars using the current exchange rate, and assets and liabilities carried at historical cost in Mexican pesos are translated into US dollars using historical exchange rates. After completing this step, the Mexican subsidiary's financial statements are stated in terms of US dollars, which is both the subsidiary's functional currency and the parent's presentation currency. As a result, there is no need to apply step 3.

The following two sections describe the procedures to be followed in applying the functional currency approach in more detail.

4.1 Foreign Currency Is the Functional Currency

In most cases, a foreign entity will operate primarily in the currency of the country where it is located, which will differ from the currency in which the parent company presents its financial statements. For example, the Japanese subsidiary of a French parent company is likely to have the Japanese yen as its functional currency, whereas the French parent company must prepare consolidated financial statements in euro.

When a foreign entity has a functional currency that differs from the parent's presentation currency, the foreign entity's foreign currency financial statements are translated into the parent's presentation currency using the following procedures:

1 All assets and liabilities are translated at the current exchange rate at the balance sheet date.
2 Stockholders' equity accounts are translated at historical exchange rates.
3 Revenues and expenses are translated at the exchange rate that existed when the transactions took place. For practical reasons, a rate that approximates the exchange rates at the dates of the transactions, such as an average exchange rate, may be used.

These procedures essentially describe the *current rate method*.

When the current rate method is used, the cumulative translation adjustment needed to keep the translated balance sheet in balance is reported as a separate component of stockholders' equity.

The basic concept underlying the current rate method is that the entire investment in a foreign entity is exposed to translation gain or loss. Therefore, all assets and all liabilities must be revalued at each successive balance sheet date. The net translation gain or loss that results from this procedure is unrealized, however, and will be realized only when the entity is sold. In the meantime, the unrealized translation gain or loss that accumulates over time is deferred on the balance sheet as a separate component of stockholders' equity. When a specific foreign entity is sold, the cumulative translation adjustment related to that entity is reported as a realized gain or loss in net income.

The current rate method results in a net asset balance sheet exposure (except in the rare case in which an entity has negative stockholders' equity):

Items Translated at Current Exchange Rate

Total assets > Total liabilities → Net asset balance sheet exposure

When the foreign currency increases in value (i.e., strengthens), application of the current rate method results in an increase in the positive cumulative translation adjustment (or a decrease in the negative cumulative translation adjustment) reflected in stockholders' equity. When the foreign currency decreases in value (i.e., weakens), the current rate method results in a decrease in the positive cumulative translation adjustment (or an increase in the negative cumulative translation adjustment) in stockholders' equity.

4.2 Parent's Presentation Currency Is the Functional Currency

In some cases, a foreign entity might have the parent's presentation currency as its functional currency. For example, a Germany-based manufacturer might have a 100%-owned distribution subsidiary in Switzerland that primarily uses the euro in its day-to-day operations and thus has the euro as its functional currency. As a Swiss company, however, the subsidiary is required to record its transactions and keep its books in Swiss francs. In that situation, the subsidiary's Swiss franc financial statements must be translated into euro as if the subsidiary's transactions had originally been recorded in euro. US GAAP refer to this process as *remeasurement*. IFRS do not refer to this process as remeasurement but instead describe this situation as "reporting foreign currency transactions in the functional currency." To achieve the objective of translating to the parent's presentation currency as if the subsidiary's transactions had been recorded in that currency, the following procedures are used:

1 a Monetary assets and liabilities are translated at the current exchange rate.
  b Non-monetary assets and liabilities measured at historical cost are translated at historical exchange rates.

c Non-monetary assets and liabilities measured at current value are translated at the exchange rate at the date when the current value was determined.

2 Stockholders' equity accounts are translated at historical exchange rates.

3 a Revenues and expenses, other than those expenses related to non-monetary assets (as explained in 3.b. below), are translated at the exchange rate that existed when the transactions took place (for practical reasons, average rates may be used).

b Expenses related to non-monetary assets, such as cost of goods sold (inventory), depreciation (fixed assets), and amortization (intangible assets), are translated at the exchange rates used to translate the related assets.

These procedures essentially describe the *temporal method*.

Under the temporal method, companies must keep record of the exchange rates that exist when non-monetary assets (inventory, prepaid expenses, fixed assets, and intangible assets) are acquired, because these assets (normally measured at historical cost) are translated at historical exchange rates. Keeping track of the historical exchange rates for these assets is not necessary under the current rate method. Translating these assets (and their related expenses) at historical exchange rates complicates application of the temporal method.

The historical exchange rates used to translate inventory (and cost of goods sold) under the temporal method will differ depending on the cost flow assumption—first in, first out (FIFO); last in, first out (LIFO); or average cost—used to account for inventory. Ending inventory reported on the balance sheet is translated at the exchange rate that existed when the inventory's acquisition is assumed to have occurred. If FIFO is used, ending inventory is assumed to be composed of the most recently acquired items and thus inventory will be translated at relatively recent exchange rates. If LIFO is used, ending inventory is assumed to consist of older items and thus inventory will be translated at older exchange rates. The weighted-average exchange rate for the year is used when inventory is carried at weighted-average cost. Similarly, cost of goods sold is translated using the exchange rates that existed when the inventory items assumed to have been sold during the year (using FIFO or LIFO) were acquired. If weighted-average cost is used to account for inventory, cost of goods sold will be translated at the weighted-average exchange rate for the year.

Under both international and US accounting standards, when the temporal method is used, the translation adjustment needed to keep the translated balance sheet in balance is reported as a gain or loss in net income. US GAAP refer to these as *remeasurement* gains and losses. The basic assumption underlying the recognition of a translation gain or loss in income relates to timing. Specifically, if the foreign entity primarily uses the parent company's currency in its day-to-day operations, then the foreign entity's monetary items that are denominated in a foreign currency generate translation gains and losses that will be realized in the near future and thus should be reflected in current net income.

The temporal method generates either a net asset or a net liability balance sheet exposure, depending on whether assets translated at the current exchange rate—that is, monetary assets and non-monetary assets measured on the balance sheet date at current value (exposed assets)—are greater than or less than liabilities translated at the current exchange rate—that is, monetary liabilities and non-monetary liabilities measured on the balance sheet date at current value (exposed liabilities):

Items Translated at Current Exchange Rate

Exposed assets > Exposed liabilities → Net asset balance sheet exposure

Exposed assets < Exposed liabilities → Net liability balance sheet exposure

Most liabilities are monetary liabilities. Only cash and receivables are monetary assets, and non-monetary assets generally are measured at their historical cost. As a result, liabilities translated at the current exchange rate (exposed liabilities) often exceed assets translated at the current exchange rate (exposed assets), which results in a net liability balance sheet exposure when the temporal method is applied.

4.3 Translation of Retained Earnings

Stockholders' equity accounts are translated at historical exchange rates under both the current rate and the temporal methods. This approach creates somewhat of a problem in translating retained earnings (R/E), which are the accumulation of previous years' income less dividends over the life of the company. At the end of the first year of operations, foreign currency (FC) retained earnings are translated into the parent's currency (PC) as follows:

Net income in FC		[Translated according to the method used to translate the income statement]	=	Net income in PC
– Dividends in FC	×	Exchange rate when dividends declared	=	– Dividends in PC
R/E in FC				R/E in PC

Retained earnings in parent currency at the end of the first year become the beginning retained earnings in parent currency for the second year, and the translated retained earnings in the second year (and subsequent years) are then calculated in the following manner:

Beginning R/E in FC		[From last year's translation]	→	Beginning R/E in PC
+ Net income in FC		[Translated according to method used to translate the income statement]	=	+ Net income in PC
– Dividends in FC	×	Exchange rate when dividends declared	=	– Dividends in PC
Ending R/E in FC				Ending R/E in PC

Exhibit 4 summarizes the translation rules as discussed in Section 4.

Exhibit 4 Rules for the Translation of a Foreign Subsidiary's Foreign Currency Financial Statements into the Parent's Presentation Currency under IFRS and US GAAP

	Foreign Subsidiary's Functional Currency	
	Foreign Currency	**Parent's Presentation Currency**
Translation method:	**Current Rate Method**	**Temporal Method**
Exchange rate at which financial statement items are translated from the foreign subsidiary's bookkeeping currency to the parent's presentation currency:		
Assets		

(continued)

Most expenses	Average rate	Average rate
Expenses related to assets translated at historical exchange rate, such as cost of goods sold, depreciation, and amortization	Average rate	Historical rates
Treatment of the translation adjustment in the parent's consolidated financial statements	Accumulated as a separate component of equity	Included as gain or loss in net income

4.4 Highly Inflationary Economies

When a foreign entity is located in a highly inflationary economy, the entity's functional currency is irrelevant in determining how to translate its foreign currency financial statements into the parent's presentation currency. IFRS require that the foreign entity's financial statements first be restated for local inflation using the procedures outlined in IAS 29, "Financial Reporting in Hyperinflationary Economies." Then, the inflation-restated foreign currency financial statements are translated into the parent's presentation currency using the current exchange rate.

US GAAP require a very different approach for translating the foreign currency financial statements of foreign entities located in highly inflationary economies. US GAAP do not allow restatement for inflation but instead require the foreign entity's financial statements to be remeasured as if the functional currency were the reporting currency (i.e., the temporal method).

US GAAP define a highly inflationary economy as one in which the cumulative three-year inflation rate exceeds 100% (but note that the definition should be applied with judgment, particularly because the trend of inflation can be as important as the absolute rate). A cumulative three-year inflation rate of 100% equates to an average of approximately 26% per year. IAS 21 does not provide a specific definition of high inflation, but IAS 29 indicates that a cumulative inflation rate approaching or exceeding 100% over three years would be an indicator of hyperinflation. If a country in which a foreign entity is located ceases to be classified as highly inflationary, the functional currency of that entity must be identified to determine the appropriate method for translating the entity's financial statements.

The FASB initially proposed that companies restate for inflation and then translate the financial statements, but this approach met with stiff resistance from US multinational corporations. Requiring the temporal method ensures that companies avoid a "disappearing plant problem" that exists when the current rate method is used in a country with high inflation. In a highly inflationary economy, as the local currency loses purchasing power within the country, it also tends to weaken in value in relation to other currencies. Translating the historical cost of assets such as land and buildings at progressively weaker exchange rates causes these assets to slowly disappear from the parent company's consolidated financial statements. Example 4 demonstrates the effect of three different translation approaches when books are kept in the currency of a highly inflationary economy. Example 4 pertains to Turkey in the period 2000 to 2002, when it was recognized as one of the few highly inflationary countries. Turkey is no longer viewed as having a highly inflationary economy. (In 2010, the International Practices Task Force of the Center for Audit Quality SEC Regulations Committee indicated that Venezuela had met the thresholds for being considered highly inflationary.)

EXAMPLE 4

Foreign Currency Translation in a Highly Inflationary Economy

Turkey was one of the few remaining highly inflationary countries at the beginning of the 21st century. Annual inflation rates and selected exchange rates between the Turkish lira (TL) and US dollar during the 2000–2002 period were as follows:

Date	Exchange Rates	Year	Inflation Rate (%)
01 Jan 2000	TL542,700 = US$1		
31 Dec 2000	TL670,800 = US$1	2000	38
31 Dec 2001	TL1,474,525 = US$1	2001	69
31 Dec 2002	TL1,669,000 = US$1	2002	45

Assume that a US-based company established a subsidiary in Turkey on 1 January 2000. The US parent sent the subsidiary US$1,000 on 1 January 2000 to purchase a piece of land at a cost of TL542,700,000 (TL542,700/US$ × US$1,000 = TL542,700,000). Assuming no other assets or liabilities, what are the annual and cumulative translation gains or losses that would be reported under each of three possible translation approaches?

Solution:

Approach 1: Translate Using the Current Rate Method

The historical cost of the land is translated at the current exchange rate, which results in a new translated amount at each balance sheet date.

Date	Carrying Value	Current Exchange Rate	Translated Amount in US$	Annual Translation Gain (Loss)	Cumulative Translation Gain (Loss)
01 Jan 2000	TL542,700,000	542,700	$1,000	N/A	N/A
31 Dec 2000	542,700,000	670,800	809	($191)	($191)
31 Dec 2001	542,700,000	1,474,525	368	(441)	(632)
31 Dec 2002	542,700,000	1,669,000	325	(43)	(675)

At the end of three years, land that was originally purchased with US$1,000 would be reflected on the parent's consolidated balance sheet at US$325 (and remember that land is not a depreciable asset). A cumulative translation loss of US$675 would be reported as a separate component of stockholders' equity on 31 December 2002. Because this method accounts for adjustments in exchange rates but does not account for likely changes in the local currency values of assets, it does a poor job of accurately reflecting the economic reality of situations such as the one in our example. That is the major reason this approach is not acceptable under either IFRS or US GAAP.

Approach 2: Translate Using the Temporal Method (US GAAP ASC 830)

The historical cost of land is translated using the historical exchange rate, which results in the same translated amount at each balance sheet date.

Date	Carrying Value	Historical Exchange Rate	Translated Amount in US$	Annual Translation Gain (Loss)	Cumulative Translation Gain (Loss)
01 Jan 2000	TL542,700,000	542,700	$1,000	N/A	N/A
31 Dec 2000	542,700,000	542,700	1,000	N/A	N/A
31 Dec 2001	542,700,000	542,700	1,000	N/A	N/A
31 Dec 2002	542,700,000	542,700	1,000	N/A	N/A

Under this approach, land continues to be reported on the parent's consolidated balance sheet at its original cost of US$1,000 each year. There is no translation gain or loss related to balance sheet items translated at historical exchange rates. This approach is required by US GAAP and ensures that non-monetary assets do not disappear from the translated balance sheet.

Approach 3: Restate for Inflation/Translate Using Current Exchange Rate (IAS 21)

The historical cost of the land is restated for inflation, and then the inflation-adjusted historical cost is translated using the current exchange rate.

Date	Inflation Rate (%)	Restated Carrying Value	Current Exchange Rate	Translated Amount in US$	Annual Translation Gain (Loss)	Cumulative Translation Gain (Loss)
01 Jan 00		TL542,700,000	542,700	$1,000	N/A	N/A
31 Dec 00	38	748,926,000	670,800	1,116	$116	$116
31 Dec 01	69	1,265,684,940	1,474,525	858	(258)	(142)
31 Dec 02	45	1,835,243,163	1,669,000	1,100	242	100

Under this approach, land is reported on the parent's 31 December 2002 consolidated balance sheet at US$1,100 with a cumulative, unrealized gain of US$100. Although the cumulative translation gain on 31 December 2002 is unrealized, it could have been realized if (1) the land had appreciated in TL value by the rate of local inflation, (2) the Turkish subsidiary sold the land for TL1,835,243,163, and (3) the sale proceeds were converted into US$1,100 at the current exchange rate on 31 December 2002.

This approach is required by IAS 21. It is the approach that, apart from doing an appraisal, perhaps best represents economic reality, in the sense that it reflects both the likely change in the local currency value of the land as well as the actual change in the exchange rate.

ILLUSTRATION OF TRANSLATION METHODS (EXCLUDING HYPERINFLATIONARY ECONOMIES) 5

d compare the current rate method and the temporal method, evaluate how each affects the parent company's balance sheet and income statement, and determine which method is appropriate in various scenarios;

e calculate the translation effects and evaluate the translation of a subsidiary's balance sheet and income statement into the parent company's presentation currency;

To demonstrate the procedures required in translating foreign currency financial statements (excluding hyperinflationary economies), assume that Interco is a Europe-based company that has the euro as its presentation currency. On 1 January 20X1, Interco establishes a wholly owned subsidiary in Canada, Canadaco. In addition to Interco making an equity investment in Canadaco, a long-term note payable to a Canadian bank was negotiated to purchase property and equipment. The subsidiary begins operations with the following balance sheet in Canadian dollars (C$):

Canadaco Balance Sheet, 1 January 20X1	
Assets	
Cash	C$1,500,000
Property and equipment	3,000,000
	C$4,500,000

(continued)

(Continued)	
Liabilities and Equity	
Long-term note payable	C$3,000,000
Capital stock	1,500,000
	C$4,500,000

Canadaco purchases and sells inventory in 20X1, generating net income of C$1,180,000, out of which C$350,000 in dividends are paid. The company's income statement and statement of retained earnings for 20X1 and balance sheet at 31 December 20X1 follow:

Canadaco Income Statement and Statement of Retained Earnings, 20X1	
Sales	C$12,000,000
Cost of sales	(9,000,000)
Selling expenses	(750,000)
Depreciation expense	(300,000)
Interest expense	(270,000)
Income tax	(500,000)
Net income	C$1,180,000
Less: Dividends, 1 Dec 20X1	(350,000)
Retained earnings, 31 Dec 20X1	C$830,000

Canadaco Balance Sheet, 31 December 20X1

Assets		Liabilities and Equity	
Cash	C$980,000	Accounts payable	C$450,000
Accounts receivable	900,000	Total current liabilities	450,000
Inventory	1,200,000	Long-term notes payable	3,000,000
Total current assets	C$3,080,000	Total liabilities	C$3,450,000
Property and equipment	3,000,000	Capital stock	1,500,000
Less: accumulated depreciation	(300,000)	Retained earnings	830,000
Total	C$5,780,000	Total	C$5,780,000

Inventory is measured at historical cost on a FIFO basis.

To translate Canadaco's Canadian dollar financial statements into euro for consolidation purposes, the following exchange rate information was gathered:

Date	€ per C$
1 January 20X1	0.70
Average, 20X1	0.75
Weighted-average rate when inventory was acquired	0.74
1 December 20X1 when dividends were declared	0.78
31 December 20X1	0.80

During 20X1, the Canadian dollar strengthened steadily against the euro from an exchange rate of €0.70 at the beginning of the year to €0.80 at year-end.

The translation worksheet that follows shows Canadaco's translated financial statements under each of the two translation methods. Assume first that Canadaco's functional currency is the Canadian dollar, and thus the current rate method must be used. The Canadian dollar income statement and statement of retained earnings are translated first. Income statement items for 20X1 are translated at the average exchange rate for 20X1 (€0.75), and dividends are translated at the exchange rate that existed when they were declared (€0.78). The ending balance in retained earnings as of 31 December 20X1 of €612,000 is transferred to the Canadian dollar balance sheet. The remaining balance sheet accounts are then translated. Assets and liabilities are translated at the current exchange rate on the balance sheet date of 31 December 20X1 (€0.80), and the capital stock account is translated at the historical exchange rate (€0.70) that existed on the date that Interco made the capital contribution. A positive translation adjustment of €202,000 is needed as a balancing amount, which is reported in the stockholders' equity section of the balance sheet.

If instead Interco determines that Canadaco's functional currency is the euro (the parent's presentation currency), the temporal method must be applied as shown in the far right columns of the table. The differences in procedure from the current rate method are that inventory, property, and equipment (and accumulated depreciation), as well as their related expenses (cost of goods sold and depreciation), are translated at the historical exchange rates that existed when the assets were acquired: €0.70 in the case of property and equipment, and €0.74 for inventory. The balance sheet is translated first, with €472,000 determined as the amount of retained earnings needed to keep the balance sheet in balance. This amount is transferred to the income statement and statement of retained earnings as the ending balance in retained earnings as of 31 December 20X1. Income statement items then are translated, with cost of goods sold and depreciation expense being translated at historical exchange rates. A negative translation adjustment of €245,000 is determined as the amount needed to arrive at the ending balance in retained earnings of €472,000, and this adjustment is reported as a translation loss on the income statement.

The positive translation adjustment under the current rate method can be explained by the facts that Canadaco has a net asset balance sheet exposure (total assets exceed total liabilities) during 20X1 and the Canadian dollar strengthened against the euro. The negative translation adjustment (translation loss) under the temporal method is explained by the fact that Canadaco has a net liability balance sheet exposure under this method (because the amount of exposed liabilities [accounts payable plus notes payable] exceeds the amount of exposed assets [cash plus receivables]) during 20X1 when the Canadian dollar strengthened against the euro.

Canadaco Income Statement and Statement of Retained Earnings, 20X1

Canadaco's Functional Currency Is:		*Local Currency (C$)*		*Parent's Currency (€)*	
		Current Rate		**Temporal**	
	C$	**Exch. Rate**	**€**	**Exch. Rate**	**€**

TRANSLATION ANALYTICAL ISSUES

6

f analyze how the current rate method and the temporal method affect financial statements and ratios;

The two different translation methods used to translate Canadaco's Canadian dollar financial statements into euro result in very different amounts to be included in Interco's consolidated financial statements. The chart below summarizes some of these differences:

Canadaco's Functional Currency Is:	*Local Currency (C$)*	*Parent's Currency (€)*	
	Translation Method		
Item	**Current Rate (€)**	**Temporal (€)**	**Difference (%)**
Sales	9,000,000	9,000,000	0.0
Net income	885,000	745,000	+18.8
Income before translation gain (loss)	885,000	990,000	−10.6
Total assets	4,624,000	4,282,000	+8.0
Total equity	1,864,000	1,522,000	+22.5

In this particular case, the current rate method results in a significantly larger net income than the temporal method. This result occurs because under the current rate method, the translation adjustment is not included in the calculation of income. If the translation loss were excluded from net income, the temporal method would result in a significantly larger amount of net income. The combination of smaller net income under the temporal method and a positive translation adjustment reported on the balance sheet under the current rate method results in a much larger amount of total equity under the current rate method. Total assets also are larger under the current rate method because all assets are translated at the current exchange rate, which is higher than the historical exchange rates at which inventory and fixed assets are translated under the temporal method.

To examine the effects of translation on the underlying relationships that exist in Canadaco's Canadian dollar financial statements, several significant ratios are calculated from the original Canadian dollar financial statements and the translated (euro) financial statements and presented in the table below.

Canadaco's Functional Currency Is:				***Local Currency (C$)***		***Parent's Currency (€)***
		C$		**Current Rate (€)**		**Temporal (€)**
Current ratio		6.84		6.84		6.64
Current assets		3,080,000		2,464,000		2,392,000
Current liabilities	=	450,000	=	360,000	=	360,000
Debt-to-assets ratio		0.52		0.52		0.56
Total debt		3,000,000		2,400,000		2,400,000
Total assets	=	5,780,000	=	4,624,000	=	4,282,000
Debt-to-equity ratio		1.29		1.29		1.58
Total debt		3,000,000		2,400,000		2,400,000
Total equity	=	2,330,000	=	1,864,000	=	1,522,000
Interest coverage		7.22		7.22		7.74
EBIT		1,950,000		1,462,500		1,567,500
Interest payments	=	270,000	=	202,500	=	202,500
Gross profit margin		0.25		0.25		0.26
Gross profit		3,000,000		2,250,000		2,340,000
Sales	=	12,000,000	=	9,000,000	=	9,000,000
Operating profit margin		0.16		0.16		0.17
Operating profit		1,950,000		1,462,500		1,567,500
Sales	=	12,000,000	=	9,000,000	=	9,000,000
Net profit margin		0.10		0.10		0.08
Net income		1,180,000		885,000		745,000
Sales	=	12,000,000	=	9,000,000	=	9,000,000
Receivables turnover		13.33		12.50		12.50
Sales		12,000,000		9,000,000		9,000,000
Accounts receivable	=	900,000	=	720,000	=	720,000
Inventory turnover		7.50		7.03		7.50
Cost of goods sold		9,000,000		6,750,000		6,660,000
Inventory	=	1,200,000	=	960,000	=	888,000
Fixed asset turnover		4.44		4.17		4.76
Sales		12,000,000		9,000,000		9,000,000
Property & equipment (net)	=	2,700,000	=	2,160,000	=	1,890,000
Return on assets		0.20		0.19		0.17
Net income		1,180,000		885,000		745,000
Total assets	=	5,780,000	=	4,624,000	=	4,282,000
Return on equity		0.51		0.47		0.49

Canadaco's Functional Currency Is:			*Local Currency (C$)*		*Parent's Currency (€)*
		C$	**Current Rate (€)**		**Temporal (€)**
Net income		1,180,000	885,000		745,000
Total equity	=	2,330,000	= 1,864,000	=	1,522,000

Comparing the current rate method (€) and temporal method (€) columns in the above table shows that financial ratios calculated from Canadaco's translated financial statements (in €) differ significantly depending on which method of translation is used. Of the ratios presented, only receivables turnover is the same under both translation methods. This is the only ratio presented in which there is no difference in the type of exchange rate used to translate the items that comprise the numerator and the denominator. Sales are translated at the average exchange rate and receivables are translated at the current exchange rate under both methods. For each of the other ratios, at least one of the items included in either the numerator or the denominator is translated at a different type of rate (current, average, or historical) under the temporal method than under the current rate method. For example, the current ratio has a different value under the two translation methods because inventory is translated at the current exchange rate under the current rate method and at the historical exchange rate under the temporal method. In this case, because the euro/Canadian dollar exchange rate on 31 December 20X1 (€0.80) is higher than the historical exchange rate when the inventory was acquired (€0.74), the current ratio is larger under the current rate method of translation.

Comparing the ratios in the Canadian dollar and current rate method (euro) columns of the above table shows that many of the underlying relationships that exist in Canadaco's Canadian dollar financial statements are preserved when the current rate method of translation is used (i.e., the ratio calculated from the Canadian dollar and euro translated amounts is the same). The current ratio, the leverage ratios (debt-to-assets and debt-to-equity ratios), the interest coverage ratio, and the profit margins (gross profit margin, operating profit margin, and net profit margin) are the same in the Canadian dollar and current rate method (euro) columns of the above table. This result occurs because each of the ratios is calculated using information from either the balance sheet or the income statement, but not both. Those ratios that compare amounts from the balance sheet with amounts from the income statement (e.g., turnover and return ratios) are different. In this particular case, each of the turnover and return ratios is larger when calculated from the Canadian dollar amounts than when calculated using the current rate (euro) amounts. The underlying Canadian dollar relationships are distorted when translated using the current rate method because the balance sheet amounts are translated using the current exchange rate while revenues and expenses are translated using the average exchange rate. (These distortions would not occur if revenues and expenses also were translated at the current exchange rate.)

Comparing the ratios in the Canadian dollar and temporal method (euro) columns of the table shows that translation using the temporal method distorts all of the underlying relationships that exist in the Canadian dollar financial statements, except inventory turnover. Moreover, it is not possible to generalize the direction of the distortion across ratios. In Canadaco's case, using the temporal method results in a larger gross profit margin and operating profit margin but a smaller net profit margin as compared with the values of these ratios calculated from the original Canadian dollar amounts. Similarly, receivables turnover is smaller, inventory turnover is the same, and fixed asset turnover is larger when calculated from the translated amounts.

In translating Canadaco's Canadian dollar financial statements into euro, the temporal method results in a smaller amount of net income than the current rate method only because IFRS and US GAAP require the resulting translation loss to be included in net income when the temporal method is used. The translation loss arises because the Canadian dollar strengthened against the euro and Canadaco has a larger amount of liabilities translated at the current exchange rate (monetary liabilities) than it has assets translated at the current exchange rate (monetary assets). If Canadaco had a net monetary asset exposure (i.e., if monetary assets exceeded monetary liabilities), a translation gain would arise and net income under the temporal method (including the translation gain) would be greater than under the current rate method. Example 5 demonstrates how different types of balance sheet exposure under the temporal method can affect translated net income.

EXAMPLE 5

Effects of Different Balance Sheet Exposures under the Temporal Method *(Canadaco's functional currency is the parent's functional currency)*

Canadaco begins operations on 1 January 20X1, with cash of C$1,500,000 and property and equipment of C$3,000,000. In Case A, Canadaco finances the acquisition of property and equipment with a long-term note payable and begins operations with net monetary liabilities of C$1,500,000 (C$3,000,000 long-term note payable less C$1,500,000 cash). In Case B, Canadaco finances the acquisition of property and equipment with capital stock and begins operations with net monetary assets of C$1,500,000. To isolate the effect that balance sheet exposure has on net income under the temporal method, assume that Canadaco continues to have C$270,000 in interest expense in Case B, even though there is no debt financing. This assumption is inconsistent with reality, but it allows us to more clearly see the effect of balance sheet exposure on net income. The only difference between Case A and Case B is the net monetary asset/liability position of the company, as shown in the following table:

Canadaco Balance Sheet, 1 January 20X1

	Case A	Case B
Assets		
Cash	C$1,500,000	C$1,500,000
Property and equipment	3,000,000	3,000,000
	C$4,500,000	C$4,500,000
Liabilities and Equity		
Long-term note payable	C$3,000,000	C$0
Capital stock	1,500,000	4,500,000
	C$4,500,000	C$4,500,000

Canadaco purchases and sells inventory in 20X1, generating net income of C$1,180,000, out of which dividends of C$350,000 are paid. The company has total assets of C$5,780,000 as of 31 December 20X1. Canadaco's functional currency is determined to be the euro (the parent's presentation currency), and the company's Canadian dollar financial statements are translated into euro using the temporal method. Relevant exchange rates are as follows:

Date	€ per C$
1 January 20X1	0.70
Average, 20X1	0.75
Weighted-average rate when inventory was acquired	0.74
1 December 20X1 when dividends were declared	0.78
31 December 20X1	0.80

What effect does the nature of Canadaco's net monetary asset or liability position have on the euro translated amounts?

Solution:

Translation of Canadaco's 31 December 20X1 balance sheet under the temporal method in Case A and Case B is shown in the following table:

Canadaco Balance Sheet on 31 December 20X1 under the Temporal Method

	Case A: Net Monetary Liabilities			Case B: Net Monetary Assets		
	C$	Exch. Rate	€	C$	Exch. Rate	€
Assets						
Cash	980,000	0.80 C	784,000	980,000	0.80 C	784,000
Accounts receivable	900,000	0.80 C	720,000	900,000	0.80 C	720,000
Inventory	1,200,000	0.74 H	888,000	1,200,000	0.74 H	888,000
Total current assets	3,080,000		2,392,000	3,080,000		2,392,000
Property and equipment	3,000,000	0.70 H	2,100,000	3,000,000	0.70 H	2,100,000
Less: accum. deprec.	(300,000)	0.70 H	(210,000)	(300,000)	0.70 H	(210,000)
Total assets	5,780,000		4,282,000	5,780,000		4,282,000
Liabilities and Equity						
Accounts payable	450,000	0.80 C	360,000	450,000	0.80 C	360,000
Total current liabilities	450,000		360,000	450,000		360,000
Long-term notes payable	3,000,000	0.80 C	2,400,000	0		0
Total liabilities	3,450,000		2,760,000	450,000		360,000
Capital stock	1,500,000	0.70 H	1,050,000	4,500,000	0.70 H	3,150,000
Retained earnings	830,000		472,000	830,000		772,000
Total	5,780,000		4,282,000	5,780,000		4,282,000

Note: C = current exchange rate; A = average-for-the-year exchange rate; H = historical exchange rate.

To keep the balance sheet in balance, retained earnings must be €472,000 in Case A (net monetary liability exposure) and €772,000 in Case B (net monetary asset exposure). The difference in retained earnings of €300,000 is equal to the translation loss that results from holding a Canadian dollar–denominated note payable during a period in which the Canadian dollar strengthens against the euro. This difference is determined by multiplying the amount of long-term note payable in Case A by the change in exchange rate during the year [C$3,000,000 × (€0.80 − €0.70) = €300,000]. Notes payable are exposed to foreign exchange risk under the temporal method, whereas capital stock is not. Canadaco could avoid the €300,000 translation loss related to long-term debt by financing the acquisition of property and equipment with equity rather than debt.

Translation of Canadaco's 20X1 income statement and statement of retained earnings under the temporal method for Case A and Case B is shown in the following table:

Canadaco Income Statement and Statement of Retained Earnings for 20X1 under the Temporal Method

	Case A: Net Monetary Liabilities			Case B: Net Monetary Assets		
	C$	Exch. Rate	€	C$	Exch. Rate	€
Sales	12,000,000	0.75 A	9,000,000	12,000,000	0.75 A	9,000,000
Cost of goods sold	(9,000,000)	0.74 H	(6,660,000)	(9,000,000)	0.74 H	(6,660,000)
Selling expenses	(750,000)	0.75 A	(562,500)	(750,000)	0.75 A	(562,500)
Depreciation expense	(300,000)	0.70 H	(210,000)	(300,000)	0.70 H	(210,000)
Interest expense	(270,000)	0.75 A	(202,500)	(270,000)	0.75 A	(202,500)
Income tax	(500,000)	0.75 A	(375,000)	(500,000)	0.75 A	(375,000)
Income before translation gain (loss)	1,180,000		990,000	1,180,000		990,000
Translation gain (loss)	N/A		(245,000)	N/A		55,000
Net income	1,180,000		745,000	1,180,000		1,045,000
Less: Dividends on 1 December 20X1	(350,000)	0.78 H	(273,000)	(350,000)	0.78 H	(273,000)
Retained earnings on 31 December 20X1	830,000		472,000	830,000		772,000

Note: C = current exchange rate; A = average-for-the-year exchange rate; H = historical exchange rate.

Income before translation gain (loss) is the same in both cases. To obtain the amount of retained earnings needed to keep the balance sheet in balance, a translation loss of €245,000 must be subtracted from net income in Case A (net monetary liabilities), whereas a translation gain of €55,000 must be added to net income in Case B (net monetary assets). The difference in net income between the two cases is €300,000, which equals the translation loss related to the long-term note payable.

When using the temporal method, companies can manage their exposure to translation gain (loss) more easily than when using the current rate method. If a company can manage the balance sheet of a foreign subsidiary such that monetary assets equal monetary liabilities, no balance sheet exposure exists. Elimination of balance sheet exposure under the current rate method occurs only when total assets equal total liabilities. This equality is difficult to achieve because it requires the foreign subsidiary to have no stockholders' equity.

For Canadaco, in 20X1, applying the current rate method results in larger euro amounts of total assets and total equity being reported in the consolidated financial statements than would result from applying the temporal method. The direction of these differences between the two translation methods is determined by the direction of change in the exchange rate between the Canadian dollar and the euro. For example, total exposed assets are greater under the current rate method because all assets are translated at the current exchange rate. The current exchange rate at 31 December 20X1 is greater than the exchange rates that existed when the non-monetary assets were acquired, which is the translation rate for these assets under the temporal method. Therefore, the current rate method results in a larger amount of total assets because the Canadian dollar strengthened against the euro. The current rate method would result in a smaller amount of total assets than the temporal method if the Canadian dollar had weakened against the euro.

Applying the current rate method also results in a much larger amount of stockholders' equity than the temporal method. A positive translation adjustment arises under the current rate method, which is included in equity, whereas a translation loss reduces total equity (through retained earnings) under the temporal method.

Example 6 shows the effect that the direction of change in the exchange rate has on the translated amounts. Canadaco's Canadian dollar financial statements are translated into euro, first assuming no change in the exchange rate during 20X1, and then assuming the Canadian dollar strengthens and weakens against the euro. Using the current rate method to translate the foreign currency financial statements into the parent's presentation currency, the foreign currency strengthening increases the revenues, income, assets, liabilities, and total equity reported on the parent company's consolidated financial statements. Likewise, smaller amounts of revenues, income, assets, liabilities, and total equity will be reported if the foreign currency weakens against the parent's presentation currency.

When the temporal method is used to translate foreign currency financial statements, foreign currency strengthening still increases revenues, assets, and liabilities reported in the parent's consolidated financial statements. Net income and stockholders' equity, however, translate into smaller amounts (assuming that the foreign subsidiary has a net monetary liability position) because of the translation loss. The opposite results are obtained when the foreign currency weakens against the parent's presentation currency.

EXAMPLE 6

Effect of Direction of Change in the Exchange Rate on Translated Amounts

Canadaco's Canadian dollar (C$) financial statements are translated into euro (€) under three scenarios: (1) the Canadian dollar remains stable against the euro, (2) the Canadian dollar strengthens against the euro, and (3) the Canadian dollar weakens against the euro. Relevant exchange rates are as follows:

	€ per C$		
Date	**Stable**	**Strengthens**	**Weakens**
1 January 20X1	0.70	0.70	0.70
Average, 20X1	0.70	0.75	0.65
Weighted-average rate when inventory was acquired	0.70	0.74	0.66
Rate when dividends were declared	0.70	0.78	0.62
31 December 20X1	0.70	0.80	0.60

What amounts will be reported on the parent's consolidated financial statements under the three different exchange rate assumptions if Canadaco's Canadian dollar financial statements are translated using the:

1 current rate method?

2 temporal method?

Solution to 1:

Current Rate Method: Using the current rate method, Canadaco's Canadian dollar financial statements would be translated into euro as follows under the three different exchange rate assumptions:

Canadaco Income Statement and Statement of Retained Earnings for 20X1 under the Current Rate Method

		C$ Stable		C$ Strengthens		C$ Weakens	
	C$	Exch. Rate	€	Exch. Rate	€	Exch. Rate	€
Sales	12,000,000	0.70	8,400,000	0.75 A	9,000,000	0.65 A	7,800,000
Cost of goods sold	(9,000,000)	0.70	(6,300,000)	0.75 A	(6,750,000)	0.65 A	(5,850,000)
Selling expenses	(750,000)	0.70	(525,000)	0.75 A	(562,500)	0.65 A	(487,500)
Deprec. expense	(300,000)	0.70	(210,000)	0.75 A	(225,000)	0.65 A	(195,000)
Interest expense	(270,000)	0.70	(189,000)	0.75 A	(202,500)	0.65 A	(175,500)
Income tax	(500,000)	0.70	(350,000)	0.75 A	(375,000)	0.65 A	(325,000)
Net income	1,180,000		826,000		885,000		767,000
Less: Dividends	(350,000)	0.70	(245,000)	0.78 H	(273,000)	0.62 H	(217,000)
Retained earnings	830,000		581,000		612,000		550,000

Note: C = current (period-end) exchange rate; A = average-for-the-year exchange rate; H = historical exchange rate.

Compared with the translated amount of sales and net income under a stable Canadian dollar, a stronger Canadian dollar results in a larger amount of sales and net income being reported in the consolidated income statement. A weaker Canadian dollar results in a smaller amount of sales and net income being reported in consolidated net income.

Canadaco Balance Sheet on 31 December 20X1 under the Current Rate Method

		C$ Stable		C$ Strengthens		C$ Weakens	
	C$	Exch. Rate	€	Exch. Rate	€	Exch. Rate	€
Assets							
Cash	980,000	0.70	686,000	0.80 C	784,000	0.60 C	588,000

(Continued)

	C$	C$ Stable		C$ Strengthens		C$ Weakens	
	C$	Exch. Rate	€	Exch. Rate	€	Exch. Rate	€
Accounts receivable	900,000	0.70	630,000	0.80 C	720,000	0.60 C	540,000
Inventory	1,200,000	0.70	840,000	0.80 C	960,000	0.60 C	720,000
Total current assets	3,080,000		2,156,000		2,464,000		1,848,000
Property and equipment	3,000,000	0.70	2,100,000	0.80 C	2,400,000	0.60 C	1,800,000
Less: accum. deprec.	(300,000)	0.70	(210,000)	0.80 C	(240,000)	0.60 C	(180,000)
Total assets	5,780,000		4,046,000		4,624,000		3,468,000
Liabilities and Equity							
Accounts payable	450,000	0.70	315,000	0.80 C	360,000	0.60 C	270,000
Total current liabilities	450,000		315,000		360,000		270,000
Long-term notes pay	3,000,000	0.70	2,100,000	0.80 C	2,400,000	0.60 C	1,800,000
Total liabilities	3,450,000		2,415,000		2,760,000		2,070,000
Capital stock	1,500,000	0.70	1,050,000	0.70 H	1,050,000	0.70 H	1,050,000
Retained earnings	830,000		581,000		612,000		550,000
Translation adjustment	N/A		0		202,000		(202,000)
Total equity	2,330,000		1,631,000		1,864,000		1,398,000
Total	5,780,000		4,046,000		4,624,000		3,468,000

Note: C = current (period-end) exchange rate; A = average-for-the-year exchange rate; H = historical exchange rate.

The translation adjustment is zero when the Canadian dollar remains stable for the year; it is positive when the Canadian dollar strengthens and negative when the Canadian dollar weakens. Compared with the amounts that would appear in the euro consolidated balance sheet under a stable Canadian dollar assumption, a stronger Canadian dollar results in a larger amount of assets, liabilities, and equity being reported on the consolidated balance sheet, and a weaker Canadian dollar results in a smaller amount of assets, liabilities, and equity being reported on the consolidated balance sheet.

Solution to 2:

Temporal Method: Using the temporal method, Canadaco's financial statements would be translated into euro as follows under the three different exchange rate scenarios:

Canadaco Balance Sheet on 31 December 20X1

		Temporal Method					
		C$ Stable		C$ Strengthens		C$ Weakens	
	C$	Exch. Rate	€	Exch. Rate	€	Exch. Rate	€
Assets							
Cash	980,000	0.70	686,000	0.80 C	784,000	0.60 C	588,000
Accounts receivable	900,000	0.70	630,000	0.80 C	720,000	0.60 C	540,000
Inventory	1,200,000	0.70	840,000	0.74 H	888,000	0.66 H	792,000
Total current assets	3,080,000		2,156,000		2,392,000		1,920,000
Property and equipment	3,000,000	0.70	2,100,000	0.70 H	2,100,000	0.70 H	2,100,000
Less: accum. deprec.	(300,000)	0.70	(210,000)	0.70 H	(210,000)	0.70 H	(210,000)
Total assets	5,780,000		4,046,000		4,282,000		3,810,000
Liabilities and Equity							
Accounts payable	450,000	0.70	315,000	0.80 C	360,000	0.60 C	270,000
Total current liabilities	450,000		315,000		360,000		270,000
Long-term notes pay	3,000,000	0.70	2,100,000	0.80 C	2,400,000	0.60 C	1,800,000
Total liabilities	3,450,000		2,415,000		2,760,000		2,070,000
Capital stock	1,500,000	0.70	1,050,000	0.70 H	1,050,000	0.70 H	1,050,000
Retained earnings	830,000		581,000		472,000		690,000
Total equity	2,330,000		1,631,000		1,522,000		1,740,000
Total	5,780,000		4,046,000		4,282,000		3,810,000

Note: C = current (period-end) exchange rate; A = average-for-the-year exchange rate; H = historical exchange rate.

Compared with the stable Canadian dollar scenario, a stronger Canadian dollar results in a larger amount of assets and liabilities but a smaller amount of equity reported on the consolidated balance sheet. A weaker Canadian dollar results in a smaller amount of assets and liabilities but a larger amount of equity reported on the consolidated balance sheet.

Canadaco Income Statement and Statement of Retained Earnings for 2008 under the Temporal Method

		C$ Stable		C$ Strengthens		C$ Weakens	
	C$	Exch. Rate	€	Exch. Rate	€	Exch. Rate	€
Sales	12,000,000	0.70	8,400,000	0.75 A	9,000,000	0.65 A	7,800,000
Cost of sales	(9,000,000)	0.70	(6,300,000)	0.74 H	(6,660,000)	0.66 H	(5,940,000)
Selling expenses	(750,000)	0.70	(525,000)	0.75 A	(562,500)	0.65 A	(487,500)
Depreciation expense	(300,000)	0.70	(210,000)	0.70 H	(210,000)	0.70 H	(210,000)
Interest expense	(270,000)	0.70	(189,000)	0.75 A	(202,500)	0.65 A	(175,500)
Income tax	(500,000)	0.70	(350,000)	0.75 A	(375,000)	0.65 A	(325,000)
Income before translation gain (loss)	1,180,000		826,000		990,000		662,000
Translation gain (loss)	N/A		0		(245,000)		245,000
Net income	1,180,000		826,000		745,000		907,000
Less: Dividends	(350,000)	0.70	(245,000)	0.78 H	(273,000)	0.62 H	(217,000)
Retained earnings	830,000		581,000		472,000		690,000

Note: C = current (period-end) exchange rate; A = average-for-the-year exchange rate; H = historical exchange rate.

No translation gain or loss exists when the Canadian dollar remains stable during the year. Because the subsidiary has a net monetary liability exposure to changes in the exchange rate, a stronger Canadian dollar results in a translation loss and a weaker Canadian dollar results in a translation gain. Compared with a stable Canadian dollar, a stronger Canadian dollar results in a larger amount of sales and a smaller amount of net income reported on the consolidated income statement. This difference in direction results from the translation loss that is included in net income. (As demonstrated in Example 5, a translation gain would have resulted if the subsidiary had a net monetary asset exposure.) A weaker Canadian dollar results in a smaller amount of sales but a larger amount of net income than if the Canadian dollar had remained stable.

Exhibit 5 summarizes the relationships illustrated in Examples 5 and 6, focusing on the typical effect that a strengthening or weakening of the foreign currency has on financial statement amounts compared with what the amounts would be if the foreign currency were to remain stable.

Exhibit 5 Effect of Currency Exchange Rate Movement on Financial Statements

	Temporal Method, Net Monetary Liability Exposure	Temporal Method, Net Monetary Asset Exposure	Current Rate Method
Foreign currency strengthens relative to parent's presentation currency	↑ Revenues ↑ Assets ↑ Liabilities ↓ Net income ↓ Shareholders' equity Translation loss	↑ Revenues ↑ Assets ↑ Liabilities ↑ Net income ↑ Shareholders' equity Translation gain	↑ Revenues ↑ Assets ↑ Liabilities ↑ Net income ↑ Shareholders' equity Positive translation adjustment
Foreign currency weakens relative to parent's presentation currency	↓ Revenues ↓ Assets ↓ Liabilities ↑ Net income ↑ Shareholders' equity Translation gain	↓ Revenues ↓ Assets ↓ Liabilities ↓ Net income ↓ Shareholders' equity Translation loss	↓ Revenues ↓ Assets ↓ Liabilities ↓ Net income ↓ Shareholders' equity Negative translation adjustment

7 TRANSLATION WHEN A FOREIGN SUBSIDIARY OPERATES IN AN HYPERINFLATIONARY ECONOMY

g analyze how alternative translation methods for subsidiaries operating in hyperinflationary economies affect financial statements and ratios;

As noted earlier, IFRS and US GAAP differ substantially in their approach to translating the foreign currency financial statements of foreign entities operating in the currency of a hyperinflationary economy. US GAAP simply require the foreign currency financial statements of such an entity to be translated as if the parent's currency is the functional currency (i.e., the temporal method must be used with the resulting translation gain or loss reported in net income). IFRS require the foreign currency financial statements first to be restated for inflation using the procedures of IAS 29, and then the inflation-adjusted financial statements are translated using the current exchange rate.

IAS 29 requires the following procedures in adjusting financial statements for inflation:

Balance Sheet

- Monetary assets and monetary liabilities are not restated because they are already expressed in terms of the monetary unit current at the balance sheet date. Monetary items consist of cash, receivables, and payables.
- Non-monetary assets and non-monetary liabilities are restated for changes in the general purchasing power of the monetary unit. Most non-monetary items are carried at historical cost. In these cases, the restated cost is determined by applying to the historical cost the change in the general price index from the

date of acquisition to the balance sheet date. Some non-monetary items are carried at revalued amounts; for example, property, plant, and equipment revalued according to the allowed alternative treatment in IAS 16, "Property, Plant and Equipment." These items are restated from the date of revaluation.

- All components of stockholders' equity are restated by applying the change in the general price level from the beginning of the period or, if later, from the date of contribution to the balance sheet date.

Income Statement

- All income statement items are restated by applying the change in the general price index from the dates when the items were originally recorded to the balance sheet date.
- The net gain or loss in purchasing power that arises from holding monetary assets and monetary liabilities during a period of inflation is included in net income.

The procedures for adjusting financial statements for inflation are similar in concept to the procedures followed when using the temporal method for translation. By restating non-monetary assets and liabilities along with stockholders' equity in terms of the general price level at the balance sheet date, these items are carried at their historical amount of purchasing power. Only the monetary items, which are not restated for inflation, are exposed to inflation risk. The effect of that exposure is reflected through the purchasing power gain or loss on the net monetary asset or liability position.

Holding cash and receivables during a period of inflation results in a **purchasing power loss**, whereas holding payables during inflation results in a **purchasing power gain**. This relationship can be demonstrated through the following examples.

Assume that the general price index (GPI) on 1 January 20X1 is 100; that is, a representative basket of goods and services can be purchased on that date for $100. At the end of 20X1, the same basket of goods and services costs $120; thus, the country has experienced an inflation rate of 20% [($120 – $100) ÷ $100]. Cash of $100 can be used to acquire one basket of goods on 1 January 20X1. One year later, however, when the GPI stands at 120, the same $100 in cash can now purchase only 83.3% of a basket of goods and services. At the end of 20X1, it now takes $120 to purchase the same amount as $100 could purchase at the beginning of the year. The difference between the amount of cash needed to purchase one market basket at year end ($120) and the amount actually held ($100) results in a purchasing power loss of $20 from holding cash of $100 during the year.

Borrowing money during a period of inflation increases purchasing power. Assume that a company expects to receive $120 in cash at the end of 20X1. If it waits until the cash is received, the company will be able to purchase exactly 1.0 basket of goods and services when the GPI stands at 120. If instead, the company borrows $120 on 1 January 20X1 when the GPI is 100, it can acquire 1.2 baskets of goods and services. This transaction results in a purchasing power gain of $20. Of course, there is an interest cost associated with the borrowing that offsets a portion of this gain.

A net purchasing power gain will arise when a company holds a greater amount of monetary liabilities than monetary assets, and a net purchasing power loss will result when the opposite situation exists. As such, purchasing power gains and losses are analogous to the translation gains and losses that arise when the currency is weakening in value and the temporal method of translation is applied.

Although the procedures required by IFRS and US GAAP for translating the foreign currency financial statements in high-inflation countries are fundamentally different, the results, in a rare occurrence, can be very similar. Indeed, if the exchange rate between two currencies changes by exactly the same percentage as the change in the general price index in the highly inflationary country, then the two methodologies produce the same results. Example 7 demonstrates this scenario.

EXAMPLE 7

Translation of Foreign Currency Financial Statements of a Foreign Entity Operating in a High Inflation Country

ABC Company formed a subsidiary in a foreign country on 1 January 20X1, through a combination of debt and equity financing. The foreign subsidiary acquired land on 1 January 20X1, which it rents to a local farmer. The foreign subsidiary's financial statements for its first year of operations, in foreign currency units (FC), are as follows:

Foreign Subsidiary Income Statement

(in FC)	20X1
Rent revenue	1,000
Interest expense	(250)
Net income	750

Foreign Subsidiary Balance Sheets

(in FC)	1 Jan 20X1	31 Dec 20X1
Cash	1,000	1,750
Land	9,000	9,000
Total	10,000	10,750
Note payable (5%)	5,000	5,000
Capital stock	5,000	5,000
Retained earnings	0	750
Total	10,000	10,750

The foreign country experienced significant inflation in 20X1, especially in the second half of the year. The general price index during the year was as follows:

1 January 20X1	100
Average, 20X1	125
31 December 20X1	200

The inflation rate in 20X1 was 100%, and the foreign country clearly meets the definition of a highly inflationary economy.

As a result of the high inflation rate in the foreign country, the FC weakened substantially during the year relative to other currencies. Relevant exchange rates between ABC's presentation currency (US dollars) and the FC during 20X1 were as follows:

	US$ per FC
1 January 20X1	1.00
Average, 20X1	0.80
31 December 20X1	0.50

What amounts will ABC Company include in its consolidated financial statements for the year ended 31 December 20X1 related to this foreign subsidiary?

Solution:

Assuming that ABC Company wishes to prepare its consolidated financial statements in accordance with IFRS, the foreign subsidiary's 20X1 financial statements will be restated for local inflation and then translated into ABC's presentation currency using the current exchange rate as follows:

	FC	Restatement Factor	Inflation-Adjusted FC	Exch. Rate	US$
Cash	1,750	200/200	1,750	0.50	875
Land	9,000	200/100	18,000	0.50	9,000
Total	10,750		19,750		9,875
Note payable	5,000	200/200	5,000	0.50	2,500
Capital stock	5,000	200/100	10,000	0.50	5,000
Retained earnings	750		4,750	0.50	2,375
Total	10,750		19,750		9,875
Revenues	1,000	200/125	1,600	0.50	800
Interest expense	(250)	200/125	(400)	0.50	(200)
Subtotal	750		1,200		600
Purchasing power gain/loss			3,550	0.50	1,775
Net income			4,750		2,375

All financial statement items are restated to the GPI at 31 December 20X1. The net purchasing power gain of FC3,550 can be explained as follows:

Gain from holding note payable	FC5,000 × (200 − 100)/100 =	FC5,000
Loss from holding beginning balance in cash	−1,000 × (200 − 100)/100 =	(1,000)
Loss from increase in cash during the year	−750 × (200 − 125)/125 =	(450)
Net purchasing power gain (loss)		FC3,550

Note that all inflation-adjusted FC amounts are translated at the current exchange rate, and thus no translation adjustment is needed.

Now assume alternatively that ABC Company wishes to comply with US GAAP in preparing its consolidated financial statements. In that case, the foreign subsidiary's FC financial statements are translated into US dollars using the temporal method, with the resulting translation gain/loss reported in net income, as follows:

	FC	Exch. Rate	US$
Cash	1,750	0.50 C	875
Land	9,000	1.00 H	9,000
Total	10,750		9,875
Note payable	5,000	0.50 C	2,500
Capital stock	5,000	1.00 H	5,000
Retained earnings	750		2,375
Total	10,750		9,875
Revenues	1,000	0.80 A	800
Interest expense	(250)	0.80 A	(200)
Subtotal	750		600
Translation gain*			1,775
Net income			2,375

* The dividend is US$0 and the increase in retained earnings is US$2,375 (from the balance sheet); so, net income is US$2,375, and thus the translation gain is US$1,775.
Note: C = current (period-end) exchange rate; A = average-for-the-year exchange rate; H = historical exchange rate

Application of the temporal method as required by US GAAP in this situation results in exactly the same US dollar amounts as were obtained under the restate/translate approach required by IFRS. The equivalence of results under the two approaches exists because of the exact one-to-one inverse relationship between the change in the foreign country's GPI and the change in the dollar value of the FC, as predicted by the theory of purchasing power parity. The GPI doubled and the FC lost half its purchasing power, which caused the FC to lose half its value in dollar terms. To the extent that this relationship does not hold, and it rarely ever does, the two different methodologies will generate different translated amounts. For example, if the 31 December 20X1 exchange rate had adjusted to only US$0.60 per FC1 (rather than US$0.50 per FC1), then translated net income would have been US$2,050 under US GAAP and US$2,850 under IFRS.

8 COMPANIES USE BOTH TRANSLATION METHODS AT THE SAME TIME AND DISCLOSURES RELATED TO TRANSLATION METHODS

f analyze how the current rate method and the temporal method affect financial statements and ratios;

Under both IFRS and US GAAP, a multinational corporation may need to use both the current rate and the temporal methods of translation at a single point in time. This situation will apply when some foreign subsidiaries have a foreign currency as their functional currency (and therefore are translated using the current rate method) and other foreign subsidiaries have the parent's currency as their functional currency (and therefore are translated using the temporal method). As a result, a multinational corporation's consolidated financial statements can reflect simultaneously both a net translation gain or loss that is included in the determination of net income (from foreign subsidiaries translated using the temporal method) and a separate cumulative translation adjustment reported on the balance sheet in stockholders' equity (from foreign subsidiaries translated using the current rate method).

Exxon Mobil Corporation is an example of a company that has a mixture of foreign currency and parent currency functional currency subsidiaries, as evidenced by the following excerpt from its 2011 annual report, Note 1 Summary of Accounting Policies:

> **Foreign Currency Translation.** The Corporation selects the functional reporting currency for its international subsidiaries based on the currency of the primary economic environment in which each subsidiary operates. Downstream and Chemical operations primarily use the local currency. However, the US dollar is used in countries with a history of high inflation (primarily in Latin America) and Singapore, which predominantly sells into the US dollar export market. Upstream operations which are relatively self-contained and integrated within a particular country, such as Canada, the United Kingdom, Norway and continental Europe, use the local currency. Some upstream operations, primarily in Asia and Africa, use the US dollar because they predominantly sell crude and natural gas production into US dollar–denominated markets. For all operations, gains or losses from remeasuring foreign currency transactions into the functional currency are included in income.

Because of the judgment involved in determining the functional currency of foreign operations, two companies operating in the same industry might apply this judgment differently. For example, although Exxon Mobil has identified the local currency as the functional currency for many of its international subsidiaries, Chevron Corporation has designated the US dollar as the functional currency for substantially all of its overseas operations, as indicated in its 2011 annual report, Note 1 Summary of Significant Accounting Policies:

> **Currency Translation**. The US dollar is the functional currency for substantially all of the company's consolidated operations and those of its equity affiliates. For those operations, all gains and losses from currency remeasurement are included in current period income. The cumulative translation effects for those few entities, both consolidated and affiliated, using functional currencies other than the US dollar are included in "Currency translation adjustment" on the Consolidated Statement of Equity.

Evaluating net income reported by Exxon Mobil against net income reported by Chevron presents a comparability problem. This problem can be partially resolved by adding the translation adjustments reported in stockholders' equity to net income for both companies. The feasibility of this solution depends on the level of detail disclosed by multinational corporations with respect to the translation of foreign currency financial statements.

8.1 Disclosures Related to Translation Methods

Both IFRS and US GAAP require two types of disclosures related to foreign currency translation:

1. the amount of exchange differences recognized in net income, and
2. the amount of cumulative translation adjustment classified in a separate component of equity, along with a reconciliation of the amount of cumulative translation adjustment at the beginning and end of the period.

US GAAP also specifically require disclosure of the amount of translation adjustment transferred from stockholders' equity and included in current net income as a result of the disposal of a foreign entity.

The amount of exchange differences recognized in net income consists of

- foreign currency *transaction* gains and losses, and
- *translation* gains and losses resulting from application of the temporal method.

Neither IFRS nor US GAAP require disclosure of the two separate amounts that constitute the total exchange difference recognized in net income, and most companies do not provide disclosure at that level of detail. However, BASF AG (shown earlier in Exhibit 1) is an exception. Note 6 in BASF's annual report separately discloses gains from foreign currency and hedging transactions and gains from translation of financial statements, both of which are included in the line item "Other Operating Income" on the income statement, as shown below:

6. Other Operating Income

Million €	2011	2010
Reversal and adjustment of provisions	170	244
Revenue from miscellaneous revenue-generating activities	207	142
Income from foreign currency and hedging transactions	170	136
Income from the translation of financial statements in foreign currencies	42	76
Gains on the disposal of property, plant and equipment and divestitures	666	101
Reversals of impairments of property, plant and equipment	—	40
Gains on the reversal of allowance for doubtful business-related receivables	77	36
Other	676	365
	2,008	1,140

The company provides a similar level of detail in Note 7 related to "Other Operating Expenses."

Disclosures related to foreign currency translation are commonly found in both the MD&A and the Notes to Financial Statements sections of an annual report. Example 8 uses the foreign currency translation–related disclosures made in 2011 by Yahoo! Inc.

EXAMPLE 8

Disclosures Related to Foreign Currency Translation: Yahoo! Inc. 2011 Annual Report

Yahoo! Inc. is a US-based digital media company that reports in US dollars and prepares financial statements in accordance with US GAAP.

The stockholders' equity section of Yahoo!'s consolidated balance sheets includes the following line items:

	31 December	
(in thousands)	**2010**	**2011**
Common stock	$1,306	$1,242
Additional paid-in capital	10,109,913	9,825,899
Treasury stock	—	(416,237)
Retained earnings	1,942,656	2,432,294
Accumulated other comprehensive income (loss)	504,254	697,869
Total Yahoo! Inc. stockholders' equity	12,558,129	12,541,067

The consolidated statement of stockholders' equity provides detail on the components comprising "Accumulated other comprehensive income." The relevant portion of that statement appears below:

	Years Ended 31 December		
	2009	**2010**	**2011**
Accumulated other comprehensive income			
Balance, beginning of year	120,276	369,236	504,254
Net change in unrealized gains/losses on available-for-sale securities, net of tax	(1,936)	3,813	(16,272)
Foreign currency translation adjustments, net of tax	250,896	131,205	209,887
Balance, end of year	369,236	504,254	697,869

Yahoo! reported the following net income in 2010 and 2011, as shown on the consolidated statement of income:

	2010	**2011**	**% Change**
Net income	$1,244,628	$1,062,699	−14.6%

Yahoo!'s disclosures for its three geographic segments are disclosed in a note to the financial statements. Revenue (excluding total acquisition costs) and direct segment operating costs are shown below:

	2009	**2010**	**2011**
Revenue ex-TAC by segment:			
Americas	3,656,752	3,467,850	3,142,879
EMEA	390,456	368,884	407,467
Asia Pacific	635,281	751,495	830,482
Total revenue ex-TAC	4,682,489	4,588,229	4,380,828

(continued)

	2009	2010	2011
Direct costs by segment:			
Americas	620,690	568,017	560,016
EMEA	115,778	118,954	135,266
Asia Pacific	138,739	146,657	194,394

In the MD&A section of the 2011 annual report, Yahoo! describes the source of its translation exposure:

> **Translation Exposure**
>
> We are also exposed to foreign exchange rate fluctuations as we convert the financial statements of our foreign subsidiaries and our investments in equity interests into US dollars in consolidation. If there is a change in foreign currency exchange rates, the conversion of the foreign subsidiaries' financial statements into US dollars results in a gain or loss which is recorded as a component of accumulated other comprehensive income which is part of stockholders' equity.
>
> Revenue ex-TAC (total acquisition costs) and related expenses generated from our international subsidiaries are generally denominated in the currencies of the local countries. The statements of income of our international operations are translated into US dollars at exchange rates indicative of market rates during each applicable period. To the extent the US dollar strengthens against foreign currencies, the translation of these foreign currency-denominated transactions results in reduced consolidated revenue and operating expenses. Conversely, our consolidated revenue and operating expenses will increase if the US dollar weakens against foreign currencies. Using the foreign currency exchange rates from the year ended December 31, 2010, revenue ex-TAC for the Americas segment for the year ended December 31, 2011 would have been lower than we reported by $6 million, revenue ex-TAC for the EMEA segment would have been lower than we reported by $16 million, and revenue ex-TAC for the Asia Pacific segment would have been lower than we reported by $59 million. Using the foreign currency exchange rates from the year ended December 31, 2010, direct costs for the Americas segment for the year ended December 31, 2011 would have been lower than we reported by $2 million, direct costs for the EMEA segment would have been lower than we reported by $5 million, and direct costs for the Asia Pacific segment would have been lower than we reported by $15 million.

Using the information above, address the following questions:

1. By how much did accumulated other comprehensive income change during the year ended 31 December 2011? Where can this information be found?
2. How much foreign currency translation adjustment was included in other comprehensive income for the year ended 31 December 2011? How does such an adjustment arise?
3. If foreign currency translation adjustment had been included in net income (rather than in other comprehensive income), how would the 2010/2011 change in income have been affected?

4 From what perspective does Yahoo! describe its foreign currency risk?

5 What percentage of total revenue ex-TAC was generated by the Asia-Pacific segment for the year ended 31 December 2011? What would this percentage have been if there had been no change in foreign currency exchange rates during the year?

Solutions:

1 Accumulated other comprehensive income increased by $193,615 thousand (from $504,254 thousand beginning balance to $697,869 thousand at the end of the year). This information can be found in two places: the stockholders' equity section of the balance sheet and the consolidated statement of stockholders' equity.

2 The amount of foreign currency translation adjustment included in other comprehensive income for 2011 was $209,887 thousand. The foreign currency translation adjustment arises from applying the current rate method to translate the foreign currency functional currency financial statements of foreign subsidiaries. Assuming that Yahoo!'s foreign subsidiaries have positive net assets, the positive translation adjustment in 2011 results from a strengthening in foreign currencies (weakening in the US dollar).

3 If foreign currency translation adjustment had been included in net income (rather than other comprehensive income), the percentage decrease in reported net income from 2010 to 2011 of 14.6% would have been smaller (7.5%).

	2010	2011	% Change
Net income	$1,244,628	$1,062,699	−14.6%
Foreign currency translation adjustment	131,205	209,887	
	$1,375,833	$1,272,586	−7.5%

4 Yahoo! describes its foreign currency risk from the perspective of how the US dollar fluctuates against foreign currencies because the dollar is the reporting currency. If the US dollar strengthens, then foreign currencies must weaken, which will result in reduced revenues, expenses, and income from foreign operations.

5 The Asia-Pacific segment represented 19.0% of total revenue ex-TAC. Information from the MD&A disclosure can be used to determine that if there had been no change in foreign currency exchange rates during the year, the segment would have represented a slightly lower percentage of total revenue (17.9%).

	2011, as reported			2011, if no change in exchange rates	
Revenue ex-TAC by segment:					
Americas	3,142,879	71.7%	6,000	3,136,879	73.0%
EMEA	407,467	9.3%	16,000	391,467	9.1%
Asia Pacific	830,482	19.0%	59,000	771,482	17.9%
Total revenue ex-TAC	4,380,828	100.0%		4,299,828	100.0%

As noted in the previous section, because of the judgment involved in determining the functional currency of foreign operations, two companies operating in the same industry might use different predominant translation methods. As a result, income reported by these companies may not be directly comparable. Exxon Mobil Corporation and Chevron Corporation, both operating in the petroleum industry, are an example of two companies for which this is the case. Whereas Chevron has identified the US dollar as the functional currency for substantially all of its foreign subsidiaries, Exxon Mobil indicates that its downstream and chemical operations, as well as some of its upstream operations, primarily use the local currency as the functional currency. As a result, Chevron primarily uses the temporal method with translation gains and losses included in income, while Exxon Mobil uses the current rate method to a much greater extent, with the resulting translation adjustments excluded from income. To make the income of these two companies more comparable, an analyst can use the disclosures related to translation adjustments to include these as gains and losses in determining an adjusted amount of income. Example 9 demonstrates this process for Exxon Mobil and Chevron.

EXAMPLE 9

Comparing Net Income for Exxon Mobil Corporation and Chevron Corporation

Exxon Mobil Corporation uses the current rate method to translate the foreign currency financial statements of a substantial number of its foreign subsidiaries and includes the resulting translation adjustments in the "Accumulated other non-owner changes in equity" line item in the stockholders' equity section of the consolidated balance sheet. Detail on the items composing "Accumulated other non-owner changes in equity," including "Foreign exchange translation adjustment," is provided in the consolidated statement of shareholders' equity.

Chevron Corporation uses the temporal method to translate the foreign currency financial statements of substantially all of its foreign subsidiaries. For those few entities using functional currencies other than the US dollar, however, the current rate method is used and the resulting translation adjustments are included in the "Accumulated other comprehensive loss" component of stockholders' equity. The consolidated statement of stockholders' equity provides detail on the changes in the component of stockholders' equity, including a "Currency translation adjustment."

Combining net income from the income statement and the change in the cumulative translation adjustment account from the statement of stockholders' equity, an adjusted net income in which translation adjustments are treated as gains and losses can be calculated for each company, as shown in the following table (amounts in millions of US dollars):

Exxon Mobil	2011	2010	2009
Reported net income	42,206	31,398	19,658
Translation adjustment	(867)	1,034	3,629
Adjusted net income	41,339	32,432	23,287

Chevron	2011	2010	2009
Reported net income	27,008	19,136	10,563
Translation adjustment	17	6	60
Adjusted net income	27,025	19,142	10,623

The direction, positive or negative, of the translation adjustment is the same for both companies in 2009 and 2010 but not in 2011. Overall, Exxon Mobil has significantly larger translation adjustments than Chevron because Exxon Mobil designates the local currency as functional currency for a substantially larger portion of its foreign operations.

A comparison of the relative amounts of net income generated by the two companies is different depending on whether reported net income or adjusted net income is used. Exxon Mobil's reported net income in 2009 is 1.90 times larger than Chevron's, whereas its adjusted net income is 2.2 times larger, as shown in the following table.

	2011	2010	2009
Exxon Mobil reported net income/ Chevron reported net income	1.6	1.6	1.9
Exxon Mobil adjusted net income/ Chevron adjusted net income	1.5	1.7	2.2

Including translation adjustments as gains and losses in the measurement of an adjusted net income provides a more comparable basis for evaluating the profitability of two companies that use different predominant translation methods. Bringing the translation adjustments into the calculation of adjusted net income still might not provide truly comparable measures, however, because of the varying effect that the different translation methods have on reported net income.

Some analysts believe that all non-owner changes in stockholders' equity, such as translation adjustments, should be included in the determination of net income. This approach is referred to as clean-surplus accounting, as opposed to dirty-surplus accounting, in which some income items are reported as part of stockholders' equity rather than as gains and losses on the income statement. One of the dirty-surplus items found in both IFRS and US GAAP financial statements is the translation adjustment that arises when a foreign currency is determined to be the functional currency of a foreign subsidiary. Disclosures made in accordance with IFRS and US GAAP provide analysts with the detail needed to calculate net income on a clean-surplus basis. In fact, both sets of standards now require companies to prepare a statement of comprehensive income in which unrealized gains and losses that have been deferred in stockholders' equity are included in a measure of comprehensive income.

MULTINATIONAL OPERATIONS AND A COMPANY'S EFFECTIVE TAX RATE 9

h describe how multinational operations affect a company's effective tax rate;

In general, multinational companies incur income taxes in the country in which the profit is earned. Transfer prices, the prices that related companies charge on intercompany transactions, affect the allocation of profit between the companies. An entity with operations in multiple countries with different tax rates could aim to set transfer prices such that a higher portion of its profit is allocated to lower tax rate jurisdictions. Countries have established various laws and practices to prevent aggressive transfer pricing practices. Transfer pricing has been defined as "the system of laws and practices used by countries to ensure that goods, services and intellectual property transferred between related companies are appropriately priced, based on market conditions, such that profits are correctly reflected in each jurisdiction."[5] Also, most countries are party to tax treaties that prevent double-taxation of corporate profits by granting a credit for taxes paid to another country.

Whether and when a company also pays income taxes in its home country depends on the specific tax regime. In the United States, for example, multinational companies are liable only for a residual tax on foreign income, after applying a credit for foreign taxes paid on that same income. The effect of the tax credit is that the multinational company owes taxes on the foreign income only to the extent that the US corporate tax rate exceeds the foreign rate of tax on that income. In addition, much of the foreign income earned by US multinationals is not taxed until it is repatriated.[6]

An analyst can obtain information about the effect of multinational operations from companies' disclosure on effective tax rates. Accounting standards require companies to provide an explanation of the relationship between tax expense and accounting profit. The explanation is presented as a reconciliation between the average effective tax rate (tax expense divided by pretax accounting profits) and the relevant statutory rate. The purpose of this disclosure is to enable users of financial statements to understand whether the relationship between tax expense and accounting profit in a particular fiscal period is unusual and to understand the significant factors—including the effect of foreign taxes—that could affect that relationship in the future.[7] Changes in the effective tax rate impact of foreign taxes could be caused by changes in the applicable tax rates and/or changes in the mix of profits earned in different jurisdictions.

EXAMPLE 10

Below are excerpts from the effective tax rate reconciliation disclosures by two companies: Heineken N.V., a Dutch brewer, and Colgate Palmolive, a US consumer products company. Use the disclosures to answer the following questions:

1 Which company's home country has a lower statutory tax rate?

2 What was the impact of multinational operations on each company's 2011 effective tax rate?

3 Changes in the tax rate impact of multinational operations can often be explained by changes of profit mix between countries with higher or lower marginal tax rates. What do Heineken's disclosures suggest about the geographic mix of its 2011 profit?

COLGATE-PALMOLIVE COMPANY Annual Report 2011
Notes to Consolidated Financial Statements
10. Income Taxes (excerpt)

The difference between the statutory US federal income tax rate and the Company's global effective tax rate as reflected in the Consolidated Statements of Income is as follows:

Percentage of Income before income taxes	2011	2010	2009
Tax at United States statutory rate	35.0%	35.0%	35.0%
State income taxes, net of federal benefit	0.4	1.1	0.5
Earnings taxed at other than United States statutory rate	(1.7)	(4.6)	(2.5)
Venezuela hyperinflationary transition charge	—	2.8	—

(continued)

(Continued)

Percentage of Income before income taxes	2011	2010	2009
Other, net	(1.1)	(1.7)	(0.8)
Effective tax rate	32.6%	32.6%	32.2%

Solution to 1:

Heineken's home country tax rate (25.0% in 2011) is lower than Colgate Palmolive's home country tax rate (35.0%).

Solution to 2:

The line item labeled "Effect of tax rates in foreign jurisdictions" indicates that multinational operations increased Heineken's effective tax rate by 3.5 percentage points. The line item labeled "Earnings taxed at other than United States statutory rate" indicates that multinational operations lowered Colgate Palmolive's effective tax rate by 1.7 percentage points in 2011.

Solution to 3:

Multinational operations increased Heineken's effective tax rate by 3.5 percentage points in 2011 but only 1.9 percentage points in 2010. This greater impact in 2011 could indicate that Heineken's profit mix in 2011 shifted to countries with higher marginal tax rates. (The change could also indicate that the marginal tax rates increased in the countries in which Heineken earns profits.)

10 ADDITIONAL DISCLOSURES ON THE EFFECTS OF FOREIGN CURRENCY

i. explain how changes in the components of sales affect the sustainability of sales growth;

j. analyze how currency fluctuations potentially affect financial results, given a company's countries of operation.

We turn now to the question of how an analyst can use multinational companies' disclosures to better understand the effects of foreign currency.

10.1 Disclosures Related to Sales Growth

Companies often make important disclosures about foreign currency effect on sales growth in the MD&A. Additional disclosures are also often made in financial presentations to the analyst community.

For a multinational company, sales growth is driven not only by changes in volume and price but also by changes in the exchange rates between the reporting currency and the currency in which sales are made. Arguably, growth in sales that comes from changes in volume or price is more sustainable than growth in sales that comes from changes in exchange rates. Further, management arguably has greater control over growth in sales resulting from greater volume or higher price than from changes in exchange rates. Thus, an analyst will consider the foreign currency effect on sales growth both for forecasting future performance and for evaluating a management team's historical performance.

Companies often include disclosures about the effect of exchange rates on sales growth in the MD&A. Such disclosures may also appear in other financial reports, such as company presentations to investors or earnings announcements. Exhibit 6 provides an example of disclosure from the MD&A, and Example 11 illustrates even more detailed disclosure from a company's report to analysts.

Exhibit 6

General Mills' 2011 annual report includes the following disclosures about the components of net sales growth in its international segment. The first excerpt is from the MD&A, and the second is from a supplementary schedule reconciling non-GAAP measures. Although the overall effect on international net sales growth was minimal "flat," the geographic detail provided in the supplementary schedule shows that the effects varied widely by region.

Excerpt from MD&A

Components of International Net Sales Growth

	Fiscal 2011 vs. 2010	Fiscal 2010 vs. 2009
Contributions from volume growth[a]	6 pts	Flat
Net price realization and mix	1 pt	3 pts
Foreign currency exchange	Flat	1 pt
Net sales growth	7 pts	4 pts

[a] Measured in tons based on the stated weight of our product shipments.

Excerpt from Supplementary Schedule on Non-GAAP Measures

International Segment and Region Sales Growth Rates Excluding Impact of Foreign Exchange

	Fiscal Year 2011		
	Percentage change in Net Sales as Reported	Impact of Foreign Currency Exchange	Percentage change in Net Sales on Constant Currency Basis
Europe	5%	−2%	7%
Canada	8	5	3
Asia/Pacific	14	5	9
Latin America	−5	−16	11
Total International segment	7%	Flat	7%

EXAMPLE 11

Use the information disclosed in Procter & Gamble Company's CAGNY [Consumer Analyst Group of New York] conference slides to answer the following questions:

1 Why does the company present "organic sales growth"?

2 On average, for the four quarters beginning October 2008 and ending September 2009, how did changes in foreign exchange rates affect P&G's reported sales growth?

The Procter & Gamble Company

2012 CAGNY CONFERENCE SLIDES

Reg G Reconciliation of Non-GAAP measures

In accordance with the SEC's Regulation G, the following provides definitions of the non-GAAP measures used in the earnings call and slides with the reconciliation to the most closely related GAAP measure.

1 *Organic Sales Growth:*

Organic sales growth is a non-GAAP measure of sales growth excluding the impacts of acquisitions, divestitures and foreign exchange from year-over-year comparisons. We believe this provides investors with a more complete understanding of underlying sales trends by providing sales growth on a consistent basis. "Organic sales" is also one of the measures used to evaluate senior management and is a factor in determining their at-risk compensation. The reconciliation of reported sales growth to organic sales is as follows:

Total P&G	Net Sales Growth	Foreign Exchange Impact	Acquisition/ Divestiture Impact	Organic Sales Growth
JAS 06	27%	−1%	−20%	6%
OND 06	8%	−3%	0%	5%
JFM07	8%	−2%	0%	6%
AMJ07	8%	−3%	0%	5%
JAS07	8%	−3%	0%	5%

JFM 12 (Estimate)	0% to 2%	3%	0%	3% to 5%
AMJ 12(Estimate)	–1% to 2%	5% to 4%	0%	4% to 6%

Solution to 1:

According to its disclosures, Procter & Gamble presents "organic sales growth" because the company believes it provides investors with a better understanding of underlying sales trends and because it is one of the measures used for management evaluation and compensation.

Solution to 2:

The average effect of foreign exchange changes during the period was negative: Although organic sales grew by 1%, the company reported net sales growth of –7% as a result of a negative 8% foreign exchange effect In other words, if no foreign exchange effect had occurred, reported sales growth and organic sales growth would have been equal, both at 1%.

10.2 Disclosures Related to Major Sources of Foreign Exchange Risk

Disclosures about the effects of currency fluctuations often include sensitivity analyses. For example, a company might describe the major sources of foreign exchange risk given its countries of operations and then disclose the profit impact of a given change in exchange rates.

Exhibit 7 includes two excerpts from the 2011 BMW AG annual report. The first excerpt, from the management report, describes the source of the company's currency risks and its approach to measuring and managing those risks. The second excerpt, from the additional disclosures section of the notes, presents the results of the company's sensitivity analysis.

Exhibit 7

Excerpts from 2011 BMW AG Annual Report

Excerpt from the management report describing the source of the company's currency risks and its approach to measuring and managing those risks:

"The sale of vehicles outside the euro zone gives rise to exchange risks. Three currencies (the Chinese renminbi, the US dollar and the British pound) accounted for approximately two-thirds of the BMW Group's foreign currency

(continued)

Exhibit 7 (Continued)

exposures in 2011. We employ cash-flow-at-risk models and scenario analyses to measure exchange rate risks. These tools provide information which serves as the basis for decision-making in the area of currency management.

"We manage currency risks both at a strategic (medium and long term) and at an operating level (short and medium term). In the medium and long term, foreign exchange risks are managed by "natural hedging", in other words by increasing the volume of purchases denominated in foreign currency or increasing the volume of local production. In this context, the expansion of the plant in Spartanburg, USA, and the new plant under construction in Tiexi* at the Shenyang site in China are helping to reduce foreign exchange risks in two major sales markets. For operating purposes (short and medium term), currency risks are hedged on the financial markets. Hedging transactions are entered into only with financial partners of good credit standing. Counterparty risk management procedures are carried out continuously to monitor the creditworthiness of those partners."

Excerpt, from the additional disclosures section of the notes, presenting the results of the company's sensitivity analysis risks:

"The BMW Group measures currency risk using a cash-flow-at-risk model. The starting point for analysing currency risk with this model is the identification of forecast foreign currency transactions or "exposures". At the end of the reporting period, the principal exposures for the coming year were as follows:

in € million	31.12.2011	31.12.2010
Euro/Chinese Renminbi	7,114	6,256
Euro/US Dollar	4,281	3,888
Euro/British Pound	3,266	3,056
Euro/Japanese Yen	1,334	1,086

"In the next stage, these exposures are compared to all hedges that are in place. The net cash flow surplus represents an uncovered risk position. The cash-flow-at-risk approach involves allocating the impact of potential exchange rate fluctuations to operating cash flows on the basis of probability distributions. Volatilities and correlations serve as input factors to assess the relevant probability distributions.

"The potential negative impact on earnings for the current period is computed on the basis of current market prices and exposures to a confidence level of 95% and a holding period of up to one year for each currency. Aggregation of these results creates a risk reduction effect due to correlations between the various portfolios.

"The following table shows the potential negative impact for the BMW Group—measured on the basis of the cash-flow-at-risk approach—attributable at the balance sheet date to unfavourable changes in exchange rates for the principal currencies."

in € million	31.12.2011	31.12.2010
Euro/Chinese Renminbi	180	265
Euro/US Dollar	121	103
Euro/British Pound	182	184
Euro/Japanese Yen	23	30

The level of detail varies in companies' disclosures about sensitivity of earnings to foreign currency fluctuations, with some companies providing information on the range of possible values of foreign exchange rates. An analyst can use sensitivity analysis disclosures in conjunction with his or her own forecast of exchange rates when developing forecasts of profit and cash flow. When detailed disclosures are provided, the analyst can explicitly incorporate foreign exchange impact. Alternatively, in the absence of detailed disclosures, the analyst can incorporate the sensitivity analysis when calibrating the downside risks to base-case profit and cash flow forecasts.

SUMMARY

The translation of foreign currency amounts is an important accounting issue for companies with multinational operations. Foreign exchange rate fluctuations cause the functional currency values of foreign currency assets and liabilities resulting from foreign currency transactions as well as from foreign subsidiaries to change over time. These changes in value give rise to foreign exchange differences that companies' financial statements must reflect. Determining how to measure these foreign exchange differences and whether to include them in the calculation of net income are the major issues in accounting for multinational operations.

- The local currency is the national currency of the country where an entity is located. The functional currency is the currency of the primary economic environment in which an entity operates. Normally, the local currency is an entity's functional currency. For accounting purposes, any currency other than an entity's functional currency is a foreign currency for that entity. The currency in which financial statement amounts are presented is known as the presentation currency. In most cases, the presentation currency will be the same as the local currency.
- When an export sale (import purchase) on an account is denominated in a foreign currency, the sales revenue (inventory) and foreign currency account receivable (account payable) are translated into the seller's (buyer's) functional currency using the exchange rate on the transaction date. Any change in the functional currency value of the foreign currency account receivable (account payable) that occurs between the transaction date and the settlement date is recognized as a foreign currency transaction gain or loss in net income.
- If a balance sheet date falls between the transaction date and the settlement date, the foreign currency account receivable (account payable) is translated at the exchange rate at the balance sheet date. The change in the functional currency value of the foreign currency account receivable (account payable) is recognized as a foreign currency transaction gain or loss in income. Analysts should understand that these gains and losses are unrealized at the time they are recognized and might or might not be realized when the transactions are settled.
- A foreign currency transaction gain arises when an entity has a foreign currency receivable and the foreign currency strengthens or it has a foreign currency payable and the foreign currency weakens. A foreign currency transaction loss arises when an entity has a foreign currency receivable and the foreign currency weakens or it has a foreign currency payable and the foreign currency strengthens.

- Companies must disclose the net foreign currency gain or loss included in income. They may choose to report foreign currency transaction gains and losses as a component of operating income or as a component of non-operating income. If two companies choose to report foreign currency transaction gains and losses differently, operating profit and operating profit margin might not be directly comparable between the two companies.
- To prepare consolidated financial statements, foreign currency financial statements of foreign operations must be translated into the parent company's presentation currency. The major conceptual issues related to this translation process are, What is the appropriate exchange rate for translating each financial statement item, and how should the resulting translation adjustment be reflected in the consolidated financial statements? Two different translation methods are used worldwide.
- Under the current rate method, assets and liabilities are translated at the current exchange rate, equity items are translated at historical exchange rates, and revenues and expenses are translated at the exchange rate that existed when the underlying transaction occurred. For practical reasons, an average exchange rate is often used to translate income items.
- Under the temporal method, monetary assets (and non-monetary assets measured at current value) and monetary liabilities (and non-monetary liabilities measured at current value) are translated at the current exchange rate. Non-monetary assets and liabilities not measured at current value and equity items are translated at historical exchange rates. Revenues and expenses, other than those expenses related to non-monetary assets, are translated at the exchange rate that existed when the underlying transaction occurred. Expenses related to non-monetary assets are translated at the exchange rates used for the related assets.
- Under both IFRS and US GAAP, the functional currency of a foreign operation determines the method to be used in translating its foreign currency financial statements into the parent's presentation currency and whether the resulting translation adjustment is recognized in income or as a separate component of equity.
- The foreign currency financial statements of a foreign operation that has a foreign currency as its functional currency are translated using the current rate method, and the translation adjustment is accumulated as a separate component of equity. The cumulative translation adjustment related to a specific foreign entity is transferred to net income when that entity is sold or otherwise disposed of. The balance sheet risk exposure associated with the current rate method is equal to the foreign subsidiary's net asset position.
- The foreign currency financial statements of a foreign operation that has the parent's presentation currency as its functional currency are translated using the temporal method, and the translation adjustment is included as a gain or loss in income. US GAAP refer to this process as remeasurement. The balance sheet exposure associated with the temporal method is equal to the foreign subsidiary's net monetary asset/liability position (adjusted for non-monetary items measured at current value).
- IFRS and US GAAP differ with respect to the translation of foreign currency financial statements of foreign operations located in a highly inflationary country. Under IFRS, the foreign currency statements are first restated for local inflation and then translated using the current exchange rate. Under US GAAP, the foreign currency financial statements are translated using the temporal method, with no restatement for inflation.

- Applying different translation methods for a given foreign operation can result in very different amounts reported in the parent's consolidated financial statements.
- Companies must disclose the total amount of translation gain or loss reported in income and the amount of translation adjustment included in a separate component of stockholders' equity. Companies are not required to separately disclose the component of translation gain or loss arising from foreign currency transactions and the component arising from application of the temporal method.
- Disclosures related to translation adjustments reported in equity can be used to include these as gains and losses in determining an adjusted amount of income following a clean-surplus approach to income measurement.
- Foreign currency translation rules are well established in both IFRS and US GAAP. Fortunately, except for the treatment of foreign operations located in highly inflationary countries, the two sets of standards have no major differences in this area. The ability to understand the impact of foreign currency translation on the financial results of a company using IFRS should apply equally well in the analysis of financial statements prepared in accordance with US GAAP.
- An analyst can obtain information about the tax impact of multinational operations from companies' disclosure on effective tax rates.
- For a multinational company, sales growth is driven not only by changes in volume and price but also by changes in the exchange rates between the reporting currency and the currency in which sales are made. Arguably, growth in sales that comes from changes in volume or price is more sustainable than growth in sales that comes from changes in exchange rates.

PRACTICE PROBLEMS

The following information relates to Questions 1–6

Pedro Ruiz is an analyst for a credit rating agency. One of the companies he follows, Eurexim SA, is based in France and complies with International Financial Reporting Standards (IFRS). Ruiz has learned that Eurexim used EUR220 million of its own cash and borrowed an equal amount to open a subsidiary in Ukraine. The funds were converted into hryvnia (UAH) on 31 December 20X1 at an exchange rate of EUR1.00 = UAH6.70 and used to purchase UAH1,500 million in fixed assets and UAH300 million of inventories.

Ruiz is concerned about the effect that the subsidiary's results might have on Eurexim's consolidated financial statements. He calls Eurexim's Chief Financial Officer, but learns little. Eurexim is not willing to share sales forecasts and has not even made a determination as to the subsidiary's functional currency.

Absent more useful information, Ruiz decides to explore various scenarios to determine the potential impact on Eurexim's consolidated financial statements. Ukraine is not currently in a hyperinflationary environment, but Ruiz is concerned that this situation could change. Ruiz also believes the euro will appreciate against the hryvnia for the foreseeable future.

1 If Ukraine's economy becomes highly inflationary, Eurexim will *most likely* translate inventory by:

A restating for inflation and using the temporal method.

B restating for inflation and using the current exchange rate.

C using the temporal method with no restatement for inflation.

2 Given Ruiz's belief about the direction of exchange rates, Eurexim's gross profit margin would be *highest* if it accounts for the Ukraine subsidiary's inventory using:

A FIFO and the temporal method.

B FIFO and the current rate method.

C weighted-average cost and the temporal method.

3 If the euro is chosen as the Ukraine subsidiary's functional currency, Eurexim will translate its fixed assets using the:

A average rate for the reporting period.

B rate in effect when the assets were purchased.

C rate in effect at the end of the reporting period.

4 If the euro is chosen as the Ukraine subsidiary's functional currency, Eurexim will translate its accounts receivable using the:

A rate in effect at the transaction date.

B average rate for the reporting period.

C rate in effect at the end of the reporting period.

5 If the hryvnia is chosen as the Ukraine subsidiary's functional currency, Eurexim will translate its inventory using the:

© 2018 CFA Institute. All rights reserved.

A average rate for the reporting period.

B rate in effect at the end of the reporting period.

C rate in effect at the time the inventory was purchased.

6 Based on the information available and Ruiz's expectations regarding exchange rates, if the hryvnia is chosen as the Ukraine subsidiary's functional currency, Eurexim will *most likely* report:

A an addition to the cumulative translation adjustment.

B a translation gain or loss as a component of net income.

C a subtraction from the cumulative translation adjustment.

The following information relates to Questions 7–12

Consolidated Motors is a US-based corporation that sells mechanical engines and components used by electric utilities. Its Canadian subsidiary, Consol-Can, operates solely in Canada. It was created on 31 December 20X1, and Consolidated Motors determined at that time that it should use the US dollar as its functional currency.

Chief Financial Officer Monica Templeton was asked to explain to the board of directors how exchange rates affect the financial statements of both Consol-Can and the consolidated financial statements of Consolidated Motors. For the presentation, Templeton collects Consol-Can's balance sheets for the years ended 20X1 and 20X2 (Exhibit 1), as well as relevant exchange rate information (Exhibit 2).

Exhibit 1 Consol-Can Condensed Balance Sheet for Fiscal Years Ending 31 December (C$ millions)

Account	20X2	20X1
Cash	135	167
Accounts receivable	98	—
Inventory	77	30
Fixed assets	100	100
Accumulated depreciation	(10)	—
Total assets	400	297
Accounts payable	77	22
Long-term debt	175	175
Common stock	100	100
Retained earnings	48	—
Total liabilities and shareholders' equity	400	297

Exhibit 2 Exchange Rate Information

	US$/C$
Rate on 31 December 20X1	0.86
Average rate in 20X2	0.92
Weighted-average rate for inventory purchases	0.92
Rate on 31 December 20X2	0.95

Templeton explains that Consol-Can uses the FIFO inventory accounting method and that purchases of C$300 million and the sell-through of that inventory occurred evenly throughout 20X2. Her presentation includes reporting the translated amounts in US dollars for each item, as well as associated translation-related gains and losses. The board responds with several questions.

- Would there be a reason to change the functional currency to the Canadian dollar?
- Would there be any translation effects for Consolidated Motors if the functional currency for Consol-Can were changed to the Canadian dollar?
- Would a change in the functional currency have any impact on financial statement ratios for the parent company?
- What would be the balance sheet exposure to translation effects if the functional currency were changed?

7 After translating Consol-Can's inventory and long-term debt into the parent company's currency (US$), the amounts reported on Consolidated Motor's financial statements on 31 December 20X2 would be *closest* to (in millions):

A $71 for inventory and $161 for long-term debt.

B $71 for inventory and $166 for long-term debt.

C $73 for inventory and $166 for long-term debt.

8 After translating Consol-Can's 31 December 20X2 balance sheet into the parent company's currency (US$), the translated value of retained earnings will be *closest* to:

A $41 million.

B $44 million.

C $46 million.

9 In response to the board's first question, Templeton would *most likely* reply that such a change would be justified if:

A the inflation rate in the United States became hyperinflationary.

B management wanted to flow more of the gains through net income.

C Consol-Can were making autonomous decisions about operations, investing, and financing.

10 In response to the board's second question, Templeton should reply that if the change is made, the consolidated financial statements for Consolidated Motors would begin to recognize:

A realized gains and losses on monetary assets and liabilities.

B realized gains and losses on non-monetary assets and liabilities.

C unrealized gains and losses on non-monetary assets and liabilities.

11 In response to the board's third question, Templeton should note that the change will *most likely* affect:

A the cash ratio.

B fixed asset turnover.

C receivables turnover.

12 In response to the board's fourth question, the balance sheet exposure (in C$ millions) would be *closest* to:

A –19.

B 148.

C 400.

The following information relates to Questions 13–18

Romulus Corp. is a US-based company that prepares its financial statements in accordance with US GAAP. Romulus Corp. has two European subsidiaries: Julius and Augustus. Anthony Marks, CFA, is an analyst trying to forecast Romulus's 20X2 results. Marks has prepared separate forecasts for both Julius and Augustus, as well as for Romulus's other operations (prior to consolidating the results.) He is now considering the impact of currency translation on the results of both the subsidiaries and the parent company's consolidated financials. His research has provided the following insights:

- The results for Julius will be translated into US dollars using the current rate method.
- The results for Augustus will be translated into US dollars using the temporal method.
- Both Julius and Augustus use the FIFO method to account for inventory.
- Julius had year-end 20X1 inventory of €340 million. Marks believes Julius will report €2,300 in sales and €1,400 in cost of sales in 20X2.

Marks also forecasts the 20X2 year-end balance sheet for Julius (Exhibit 1). Data and forecasts related to euro/dollar exchange rates are presented in Exhibit 2.

Exhibit 1 Forecasted Balance Sheet Data for Julius, 31 December 20X2 (€ millions)

Cash	50
Accounts receivable	100
Inventory	700
Fixed assets	1,450
Total assets	2,300
Liabilities	700
Common stock	1,500
Retained earnings	100
Total liabilities and shareholder equity	2,300

Exhibit 2 Exchange Rates ($/€)	
31 December 20X1	1.47
31 December 20X2	1.61
20X2 average	1.54
Rate when fixed assets were acquired	1.25
Rate when 20X1 inventory was acquired	1.39
Rate when 20X2 inventory was acquired	1.49

13 Based on the translation method being used for Julius, the subsidiary is *most likely:*

A a sales outlet for Romulus's products.

B a self-contained, independent operating entity.

C using the US dollar as its functional currency.

14 To account for its foreign operations, Romulus has *most likely* designated the euro as the functional currency for:

A Julius only.

B Augustus only.

C both Julius and Augustus.

15 When Romulus consolidates the results of Julius, any unrealized exchange rate holding gains on monetary assets should be:

A reported as part of operating income.

B reported as a non-operating item on the income statement.

C reported directly to equity as part of the cumulative translation adjustment.

16 When Marks translates his forecasted balance sheet for Julius into US dollars, total assets as of 31 December 20X2 (dollars in millions) will be *closest* to:

A $1,429.

B $2,392.

C $3,703.

17 When Marks converts his forecasted income statement data for Julius into US dollars, the 20X2 gross profit margin will be *closest* to:

A 39.1%.

B 40.9%.

C 44.6%.

18 Relative to the gross margins the subsidiaries report in local currency, Romulus's consolidated gross margin *most likely*:

A will not be distorted by currency translations.

B would be distorted if Augustus were using the same translation method as Julius.

C will be distorted because of the translation and inventory accounting methods Augustus is using.

The following information relates to Questions 19–24

Redline Products, Inc. is a US-based multinational with subsidiaries around the world. One such subsidiary, Acceletron, operates in Singapore, which has seen mild but not excessive rates of inflation. Acceletron was acquired in 2000 and has never paid a dividend. It records inventory using the FIFO method.

Chief Financial Officer Margot Villiers was asked by Redline's board of directors to explain how the functional currency selection and other accounting choices affect Redline's consolidated financial statements. Villiers gathers Acceletron's financial statements denominated in Singapore dollars (SGD) in Exhibit 1 and the US dollar/Singapore dollar exchange rates in Exhibit 2. She does not intend to identify the functional currency actually in use but rather to use Acceletron as an example of how the choice of functional currency affects the consolidated statements.

Exhibit 1 Selected Financial Data for Acceletron, 31 December 2007 (SGD millions)

Cash	SGD125
Accounts receivable	230
Inventory	500
Fixed assets	1,640
Accumulated depreciation	(205)
Total assets	SGD2,290
Accounts payable	185
Long-term debt	200
Common stock	620
Retained earnings	1,285
Total liabilities and equity	2,290
Total revenues	SGD4,800
Net income	SGD450

Exhibit 2 Exchange Rates Applicable to Acceletron

Exchange Rate in Effect at Specific Times	USD per SGD
Rate when first SGD1 billion of fixed assets were acquired	0.568
Rate when remaining SGD640 million of fixed assets were acquired	0.606
Rate when long-term debt was issued	0.588
31 December 2006	0.649
Weighted-average rate when inventory was acquired	0.654

(continued)

Exhibit 2 (Continued)

Exchange Rate in Effect at Specific Times	USD per SGD
Average rate in 2007	0.662
31 December 2007	0.671

19 Compared with using the Singapore dollar as Acceletron's functional currency for 2007, if the US dollar were the functional currency, it is *most likely* that Redline's consolidated:

A inventories will be higher.

B receivable turnover will be lower.

C fixed asset turnover will be higher.

20 If the US dollar were chosen as the functional currency for Acceletron in 2007, Redline could reduce its balance sheet exposure to exchange rates by:

A selling SGD30 million of fixed assets for cash.

B issuing SGD30 million of long-term debt to buy fixed assets.

C issuing SGD30 million in short-term debt to purchase marketable securities.

21 Redline's consolidated gross profit margin for 2007 would be *highest* if Acceletron accounted for inventory using:

A FIFO, and its functional currency were the US dollar.

B LIFO, and its functional currency were the US dollar.

C FIFO, and its functional currency were the Singapore dollar.

22 If the current rate method is used to translate Acceletron's financial statements into US dollars, Redline's consolidated financial statements will *most likely* include Acceletron's:

A USD3,178 million in revenues.

B USD118 million in long-term debt.

C negative translation adjustment to shareholder equity.

23 If Acceletron's financial statements are translated into US dollars using the temporal method, Redline's consolidated financial statements will *most likely* include Acceletron's:

A USD336 million in inventory.

B USD956 million in fixed assets.

C USD152 million in accounts receivable.

24 When translating Acceletron's financial statements into US dollars, Redline is *least likely* to use an exchange rate of USD per SGD:

A 0.671.

B 0.588.

C 0.654.

The following information relates to questions 25–33

Adrienne Yu is an analyst with an international bank. She analyzes Ambleu S.A. ("Ambleu"), a multinational corporation, for a client presentation. Ambleu complies with IFRS, and its presentation currency is the Norvoltian krone (NVK). Ambleu's two subsidiaries, Ngcorp and Cendaró, have different functional currencies: Ngcorp uses the Bindiar franc (₣B) and Cendaró uses the Crenland guinea (CRG).

Yu first analyzes the following three transactions to assess foreign currency transaction exposure:

Transaction 1:	Cendaró sells goods to a non-domestic customer that pays in dollars on the purchase date.
Transaction 2:	Ngcorp obtains a loan in Bindiar francs on 1 June 2016 from a European bank with the Norvoltian krone as its presentation currency.
Transaction 3:	Ambleu imports inventory from Bindiar under 45-day credit terms, and the payment is to be denominated in Bindiar francs.

Yu then reviews Transactions 2 and 3. She determines the method that Ambleu would use to translate Transaction 2 into its 31 December 2016 consolidated financial statements. While analyzing Transaction 3, Yu notes that Ambleu purchased inventory on 1 June 2016 for ₣B27,000/ton. Ambleu pays for the inventory on 15 July 2016. Exhibit 1 presents selected economic data for Bindiar and Crenland.

Exhibit 1 Selected Economic Data for Bindiar and Crenland

Date	Spot FB/NVK Exchange Rate	Bindiar Inflation Rate (%)	Spot CRG/NVK Exchange Rate	Crenland Inflation Rate (%)	Crenland GPI
31 Dec 2015	—	—	5.6780	—	100.0
1 Jun 2016	4.1779	—	—	—	—
15 Jul 2016	4.1790	—	—	—	—
31 Dec 2016	4.2374	3.1	8.6702	40.6	140.6
Average 2016	4.3450	—	—	—	—
31 Dec 2017	4.3729	2.1	14.4810	62.3	228.2
Average 2017	4.3618	—	11.5823	—	186.2

Prior to reviewing the 2016 and 2017 consolidated financial statements of Ambleu, Yu meets with her supervisor, who asks Yu the following two questions:

Question 1	Would a foreign currency translation loss reduce Ambleu's net sales growth?
Question 2	According to IFRS, what disclosures should be included relating to Ambleu's treatment of foreign currency translation for Ngcorp?

To complete her assignment, Yu analyzes selected information and notes from Ambleu's 2016 and 2017 consolidated financial statements, presented in Exhibit 2.

Exhibit 2 Selected Information and Notes from Consolidated Financial Statements of Ambleu S.A. (in NVK millions)

Income Statement	2017	2016	Balance Sheet	2017	2016
Revenue (1)	1,069	1,034	Cash (3)	467	425
Profit before tax	294	269	Intangibles (4)	575	570
Income tax expense (2)	–96	–94	—	—	—
Net profit	198	175	—	—	—

Note 1: Cendaro's revenue for 2017 is CRG125.23 million.
Note 2:

Reconciliation of Income Tax Expense	2017 (in NVK millions)	2016 (in NVK millions)
Income tax at Ambleu's domestic tax rate	102	92
Effect of tax rates on non-domestic jurisdictions	–14	–9
Unrecognized current year tax losses	8	11
Income tax expense	96	94

Note 3: The parent company transferred NVK15 million to Cendaró on 1 January 2016 to purchase a patent from a competitor for CRG85.17 million.
Note 4: The 2016 consolidated balance sheet includes Ngcorp's total intangible assets of NVK3 million, which were added to Ngcorp's balance sheet on 15 July 2016.

25 Which transaction would generate foreign currency transaction exposure for Ambleu?

A Transaction 1

B Transaction 2

C Transaction 3

26 Yu's determination regarding Transaction 2 should be based on the currency of the:

A loan.

B bank.

C borrower.

27 Based on Exhibit 1, what is the foreign exchange gain resulting from Transaction 3 on the 31 December 2016 financial statements?

A NVK1.70 per ton

B NVK90.75 per ton

C NVK248.54 per ton

28 What is the *best* response to Question 1?

A Yes

B No, because it would reduce organic sales growth

C No, because it would reduce net price realization and mix

29 Based on Exhibit 1, the *best* response to Question 2 is that Ambleu should disclose:

A a restatement for local inflation.

B that assets carried at historical cost are translated at historical rates.

C the amount of foreign exchange differences included in net income.

30 Based on Exhibit 1 and Note 1 in Exhibit 2, the amount that Ambleu should include in its 31 December 2017 revenue from Cendaró is *closest* to:

A NVK10.60 million.

B NVK13.25 million.

C NVK19.73 million.

31 Based on Exhibit 2 and Note 2, the change in Ambleu's consolidated income tax rate from 2016 to 2017 *most likely* resulted from a:

A decrease in Ambleu's domestic tax rate.

B more profitable business mix in its subsidiaries.

C stronger Norvoltian krone relative to the currencies of its subsidiaries.

32 Based on Exhibit 1 and Note 3 in Exhibit 2, the cumulative translation loss recognized by Ambleu related to the patent purchase on the 31 December 2017 financial statements is *closest* to:

A NVK0.39 million.

B NVK1.58 million

C NVK9.12 million.

33 Based on Exhibit 1 and Note 4 in Exhibit 2, the total intangible assets on Ngcorp's balance sheet as of 31 December 2016 are *closest* to:

A FB12.54 million.

B FB12.71 million.

C FB13.04 million.

The following information relates to questions 34–40

Triofind, Inc. (Triofind), based in the country of Norvolt, provides wireless services to various countries, including Norvolt, Borliand, Abuelio, and Certait. The company's presentation currency is the Norvolt euro (NER), and Triofind complies with IFRS. Triofind has two wholly owned subsidiaries, located in Borliand and Abuelio. The Borliand subsidiary (Triofind-B) was established on 30 June 2016, by Triofind both investing NER1,000,000, which was converted into Borliand dollars (BRD), and borrowing an additional BRD500,000.

Marie Janssen, a financial analyst in Triofind's Norvolt headquarters office, translates Triofind-B's financial statements using the temporal method. Non-monetary assets are measured at cost under the lower of cost or market rule. Spot BRD/NER exchange rates are presented in Exhibit 1, and the balance sheet for Triofind-B is presented in Exhibit 2.

Exhibit 1 Spot BRD/NER Exchange Rates

Date	BRD per NER
30 June 2016	1.15
Weighted-average rate when inventory was acquired (2016)	1.19
31 December 2016	1.20

(continued)

Exhibit 1 (Continued)

Date	BRD per NER
Weighted-average rate when inventory was acquired (2017)	1.18
30 June 2017	1.17

Exhibit 2 Triofind-B Balance Sheet for 2016 and 2017 (BRD)

Assets	31 December 2016	30 June 2017	Liabilities and Stockholders' Equity	31 December 2016	30 June 2017
Cash	900,000	1,350,000	Notes payable	500,000	500,000
Inventory	750,000	500,000	Common stock	1,150,000	1,150,000
			Retained earnings		200,000
Total	1,650,000	1,850,000	Total	1,650,000	1,850,000

Janssen next analyzes Triofind's Abuelio subsidiary (Triofind-A), which uses the current rate method to translate its results into Norvolt euros. Triofind-A, which prices its goods in Abuelio pesos (ABP), sells mobile phones to a customer in Certait on 31 May 2017 and receives payment of 1 million Certait rand (CRD) on 31 July 2017.

On 31 May 2017, Triofind-A also received NER50,000 from Triofind and used the funds to purchase a new warehouse in Abuelio. Janssen translates the financial statements of Triofind-A as of 31 July 2017 and must determine the appropriate value for the warehouse in Triofind's presentation currency. She observes that the cumulative Abuelio inflation rate exceeded 100% from 2015 to 2017. Spot exchange rates and inflation data are presented in Exhibit 3.

Exhibit 3 Spot Exchange Rates and Inflation Data for Triofind-A

Date	NER per CRD	NER per ABP	Abuelio Monthly Inflation Rate (%)
31 May 2017	0.2667	0.0496	—
30 June 2017	0.2703	0.0388	25
31 July 2017	0.2632	0.0312	22

Janssen gathers corporate tax rate data and company disclosure information to include in Triofind's annual report. She determines that the corporate tax rates for Abuelio, Norvolt, and Borliand are 35%, 34%, and 0%, respectively, and that Norvolt exempts the non-domestic income of multinationals from taxation. Triofind-B constitutes 25% of Triofind's net income, and Triofind-A constitutes 15%. Janssen also gathers data on components of net sales growth in different countries, presented in Exhibit 4.

Exhibit 4 Components of Net Sales Growth (%) Fiscal Year 2017

Country	Contribution from Volume Growth	Contribution from Price Growth	Foreign Currency Exchange	Net Sales Growth
Abuelio	7	6	–2	11
Borliand	4	5	4	13
Norvolt	7	3	—	10

34 Based on Exhibits 1 and 2 and Janssen's translation method, total assets for Triofind-B translated into Triofind's presentation currency as of 31 December 2016 are *closest* to:

A NER1,375,000.

B NER1,380,252.

C NER1,434,783.

35 Based on Exhibits 1 and 2, the translation adjustment for Triofind-B's liabilities into Triofind's presentation currency for the six months ended 31 December 2016 is:

A negative.

B zero.

C positive.

36 Based on Exhibits 1 and 2 and Janssen's translation method, retained earnings for Triofind-B translated into Triofind's presentation currency as of 30 June 2017 are *closest* to:

A NER150,225.

B NER170,940.

C NER172,414.

37 The functional currency for Triofind-A's sale of mobile phones to a customer in Certait is the:

A Certait real.

B Norvolt euro.

C Abuelio peso.

38 Based on Exhibit 3, the value of the new warehouse in Abuelio on Triofind's balance sheet as of 31 July 2017 is *closest* to:

A NER31,452.

B NER47,964.

C NER50,000.

39 Relative to its domestic tax rate, Triofind's effective tax rate is *most likely*:

A lower.

B the same.

C higher.

40 Based on Exhibit 4, the country with the highest sustainable sales growth is:

A Norvolt.

B Abuelio.

C Borliand.

SOLUTIONS

1 B is correct. IAS 21 requires that the financial statements of the foreign entity first be restated for local inflation using the procedures outlined in IAS 29, "Financial Reporting in Hyperinflationary Economies." Then, the inflation-restated foreign currency financial statements are translated into the parent's presentation currency using the current exchange rate. Under US GAAP, the temporal method would be used with no restatement.

2 B is correct. Ruiz expects the EUR to appreciate against the UAH and expects some inflation in the Ukraine. In an inflationary environment, FIFO will generate a higher gross profit than weighted-average cost. For either inventory choice, the current rate method will give higher gross profit to the parent company if the subsidiary's currency is depreciating. Thus, using FIFO and translating using the current rate method will generate a higher gross profit for the parent company, Eurexim SA, than any other combination of choices.

3 B is correct. If the parent's currency is chosen as the functional currency, the temporal method must be used. Under the temporal method, fixed assets are translated using the rate in effect at the time the assets were acquired.

4 C is correct. Monetary assets and liabilities such as accounts receivable are translated at current (end-of-period) rates regardless of whether the temporal or current rate method is used.

5 B is correct. When the foreign currency is chosen as the functional currency, the current rate method is used. All assets and liabilities are translated at the current (end-of-period) rate.

6 C is correct. When the foreign currency is chosen as the functional currency, the current rate method must be used and all gains or losses from translation are reported as a cumulative translation adjustment to shareholder equity. When the foreign currency decreases in value (weakens), the current rate method results in a negative translation adjustment in stockholders' equity.

7 B is correct. When the parent company's currency is used as the functional currency, the temporal method must be used to translate the subsidiary's accounts. Under the temporal method, monetary assets and liabilities (e.g., debt) are translated at the current (year-end) rate, non-monetary assets and liabilities measured at historical cost (e.g., inventory) are translated at historical exchange rates, and non-monetary assets and liabilities measured at current value are translated at the exchange rate at the date when the current value was determined. Because beginning inventory was sold first and sales and purchases were evenly acquired, the average rate is most appropriate for translating inventory and C$77 million × 0.92 = $71 million. Long-term debt is translated at the year-end rate of 0.95. C$175 million × 0.95 = $166 million.

8 B is correct. Translating the 20X2 balance sheet using the temporal method, as is required in this instance, results in assets of US$369 million. The translated liabilities and common stock are equal to US$325 million, meaning that the value for 20X2 retained earnings is US$369 million – US$325 million = US$44 million.

Temporal Method (20X2)

Account	C$	Rate	US$
Cash	135	0.95	128
Accounts receivable	98	0.95	93

Temporal Method (20X2)			
Account	**C$**	**Rate**	**US$**
Inventory	77	0.92	71
Fixed assets	100	0.86	86
Accumulated depreciation	(10)	0.86	(9)
Total assets	400		369
Accounts payable	77	0.95	73
Long-term debt	175	0.95	166
Common stock	100	0.86	86
Retained earnings	48	to balance	44
Total liabilities and shareholders' equity	400		369

9 C is correct. The Canadian dollar would be the appropriate reporting currency when substantially all operating, financing, and investing decisions are based on the local currency. The parent country's inflation rate is never relevant. Earnings manipulation is not justified, and at any rate changing the functional currency would take the gains off of the income statement.

10 C is correct. If the functional currency were changed from the parent currency (US dollar) to the local currency (Canadian dollar), the current rate method would replace the temporal method. The temporal method ignores unrealized gains and losses on non-monetary assets and liabilities, but the current rate method does not.

11 B is correct. If the Canadian dollar is chosen as the functional currency, the current rate method will be used and the current exchange rate will be the rate used to translate all assets and liabilities. Currently, only monetary assets and liabilities are translated at the current rate. Sales are translated at the average rate during the year under either method. Fixed assets are translated using the historical rate under the temporal method but would switch to current rates under the current rate method. Therefore, there will most likely be an effect on sales/fixed assets. Because the cash ratio involves only monetary assets and liabilities, it is unaffected by the translation method. Receivables turnover pairs a monetary asset with sales and is thus also unaffected.

12 B is correct. If the functional currency were changed, then Consol-Can would use the current rate method and the balance sheet exposure would be equal to net assets (total assets – total liabilities). In this case, 400 – 77 – 175 = 148.

13 B is correct. Julius is using the current rate method, which is most appropriate when it is operating with a high degree of autonomy.

14 A is correct. If the current rate method is being used (as it is for Julius), the local currency (euro) is the functional currency. When the temporal method is being used (as it is for Augustus), the parent company's currency (US dollar) is the functional currency.

15 C is correct. When the current rate method is being used, all currency gains and losses are recorded as a cumulative translation adjustment to shareholder equity.

16 C is correct. Under the current rate method, all assets are translated using the year-end 20X2 (current) rate of $1.61/€1.00. €2,300 × 1.61 = $3,703.

17 A is correct. Under the current rate method, both sales and cost of goods sold would be translated at the 20X2 average exchange rate. The ratio would be the same as reported under the euro. €2,300 – €1,400 = €900, €900/€2,300 = 39.1%. Or, $3,542 – $2,156 = $1,386, $1,386/$3,542 = 39.1%.

18 C is correct. Augustus is using the temporal method in conjunction with FIFO inventory accounting. If FIFO is used, ending inventory is assumed to be composed of the most recently acquired items, and thus inventory will be translated at relatively recent exchange rates. To the extent that the average weight used to translate sales differs from the historical rate used to translate inventories, the gross margin will be distorted when translated into US dollars.

19 C is correct. If the US dollar is the functional currency, the temporal method must be used. Revenues and receivables (monetary asset) would be the same under either accounting method. Inventory and fixed assets were purchased when the US dollar was stronger, so at historical rates (temporal method), translated they would be lower. Identical revenues/lower fixed assets would result in higher fixed-asset turnover.

20 A is correct. If the US dollar is the functional currency, the temporal method must be used, and the balance sheet exposure will be the net monetary assets of 125 + 230 − 185 − 200 = −30, or a net monetary liability of SGD30 million. This net monetary liability would be eliminated if fixed assets (non-monetary) were sold to increase cash. Issuing debt, either short-term or long-term, would increase the net monetary liability.

21 A is correct. Because the US dollar has been consistently weakening against the Singapore dollar, cost of sales will be lower and gross profit higher when an earlier exchange rate is used to translate inventory, compared with using current exchange rates. If the Singapore dollar is the functional currency, current rates would be used. Therefore, the combination of the US dollar (temporal method) and FIFO will result in the highest gross profit margin.

22 A is correct. Under the current rate method, revenue is translated at the average rate for the year, SGD4,800 × 0.662 = USD3,178 million. Debt should be translated at the current rate, SGD200 × 0.671 = USD134 million. Under the current rate method, Acceletron would have a net asset balance sheet exposure. Because the Singapore dollar has been strengthening against the US dollar, the translation adjustment would be positive rather than negative.

23 B is correct. Under the temporal method, inventory and fixed assets would be translated using historical rates. Accounts receivable is a monetary asset and would be translated at year-end (current) rates. Fixed assets are found as (1,000 × 0.568) + (640 × 0.606) = USD 956 million.

24 B is correct. USD0.671/SGD is the current exchange rate. That rate would be used regardless of whether Acceletron uses the current rate or temporal method. USD0.654 was the weighted-average rate when inventory was acquired. That rate would be used if the company translated its statements under the temporal method but not the current rate method. USD0.588/SGD was the exchange rate in effect when long-term debt was issued. As a monetary liability, long-term debt is always translated using current exchange rates. Consequently, that rate is not applicable regardless of how Acceletron translates its financial statements.

25 C is correct. In Transaction 3, the payment for the inventory is due in Bindiar francs, a different currency from the Norvoltian krone, which is Ambleu's presentation currency. Because the import purchase (account payable) is under 45-day credit terms, Ambleu has foreign currency transaction exposure. The payment is subject to fluctuations in the ₣B/NVK exchange rate during the 45-day period between the sale and payment dates. Thus, Ambleu is exposed to potential foreign currency gains if the Bindiar franc weakens against the Norvoltian krone or foreign currency losses if the Bindiar franc strengthens against the Norvoltian krone.

26 C is correct. The currency of Ngcorp as the borrowing foreign subsidiary, relative to that of Ambleu, determines Ambleu's choice of translation method for Transaction 2. Because Ngcorp's functional currency is the Bindiar franc and Ambleu's presentation currency is the Norvoltian krone, the current rate method rather than the temporal method should be used. Regardless of the currency in which the loan is denominated, the loan is first recorded in Ngcorp's financial statements. Then, Ngcorp's financial statements, which include the bank loan, are translated into Ambleu's consolidated financial statements.

27 A is correct. On Ambleu's balance sheet, the cost included in the inventory account is the translation of ₣B27,000/ton into Norvoltian krone on the purchase date. Ambleu could have paid this amount on the purchase date but chose to wait 45 days to settle the account. The inventory cost is determined using the ₣B/NVK exchange rate of 4.1779 on the purchase date of 1 June 2016. ₣B27,000/₣B4.1779/NVK = NVK6,462.58/ton

The cash outflow is the amount exchanged from the Norvoltian krone to the Bindiar franc to pay the ₣B27,000/ton owed for the inventory 45 days after the transaction date. This payment uses the ₣B/NVK exchange rate of 4.1790 on the settlement date of 15 July 2016.

₣B 27,000/₣B4.1790 per NVK = NVK6,460.88/ton

Foreign exchange gain = Inventory cost − Cash payment
= NVK6,462.58 − NVK6,460.88
= NVK1.70/ton

Thus, Ambleu's cash outflow is less than the cost included in the inventory account, and NVK1.70/ton is the realized foreign exchange gain relating to this transaction. By deferring payment for 45 days, and because the Bindiar franc decreased in value during this period, Ambleu pays NVK1.70/ton less than the inventory cost on the purchase date of 1 June 2016. Thus, Ambleu will report a foreign exchange gain in its 2016 net income.

28 A is correct. Net sales growth equals organic sales growth plus or minus the effects of acquisitions, divestitures, and foreign exchange. A foreign currency translation loss would reduce net sales growth. Thus the answer to Question 1 is yes.

29 C is correct. IFRS requires that Ambleu disclose "the amount of exchange differences recognized in profit or loss" when determining net income for the period. Because companies may present foreign currency transaction gains and losses in various places on the income statement, it is useful for companies to disclose both the amount of transaction gain or loss that is included in income as well as the presentation alternative used.

30 A is correct. Crenland experienced hyperinflation from 31 December 2015 to 31 December 2017, as shown by the General Price Index, with cumulative inflation of 128.2% during this period. According to IFRS, Cendaró's financial statements must be restated for local inflation, then translated into Norvoltian kroner using the current exchange rate. The 2017 revenue from Cendaró that should be included in Ambleu's income statement is calculated as follows:

Revenue in CRG × (GPI 31 December 2017/GPI average 2017) = Inflation-adjusted revenue in CRG

CRG125.23 million × (228.2/186.2) = CRG153.48 million

Inflation-adjusted revenue in CRG/31 December 2017 exchange rate (CRG/NVK) = Revenue in Norvoltian kroner

CRG153.48 million/14.4810 = NVK10.60 million

31 B is correct. The consolidated income tax rate is calculated as income tax expense divided by profit before tax. Note 2 shows that Ambleu's consolidated income tax rate decreases by 2.29%, from 34.94% (=94/269) in 2016 to 32.65% (=96/294) in 2017. The largest component of the decrease stems from the 1.42% change in the effect of tax rates in non-domestic jurisdictions, which lowers Ambleu's consolidated income tax rate in 2016 by 3.34% (=9/269) and in 2017 by 4.76% (=14/294). The decrease in 2017 could indicate that Ambleu's business mix shifted to countries with lower marginal tax rates, resulting in a lower consolidated income tax rate and more profit. (The change could also indicate that the marginal tax rates decreased in the countries in which Ambleu earns profits.)

32 B is correct. IAS 29 indicates that a cumulative inflation rate approaching or exceeding 100% over three years would be an indicator of hyperinflation. Because the cumulative inflation rate for 2016 and 2017 in Crenland was 128.2%, Cendaró's accounts must first be restated for local inflation. Then, the inflation-restated Crenland guinea financial statements can be translated into Ambleu's presentation currency, the Norvoltian krone, using the current exchange rate.

Using this approach, the cumulative translation loss on 31 December 2017 for the CRG85.17 million patent purchase is –NVK1.58 million, as shown in the following table.

Date	Inflation Rate (%)	Restated Carrying Value (CRG/MM)	Current Exchange Rate (CRG/NVK)	Translated Amount (NVK MM)	Annual Translation Gain/Loss (NVK MM)	Cumulative Translation Gain/Loss (NVK MM)
1 Jan 2016	—	85.17	5.6780	15.00	N/A	N/A
31 Dec 2016	40.6	119.75	8.6702	13.81	–1.19	–1.19
31 Dec 2017	62.3	194.35	14.4810	13.42	–0.39	–1.58

33 B is correct. Because Ngcorp has a functional currency that is different from Ambleu's presentation currency, the intangible assets are translated into Norvoltian kroner using the current rate method. The current ₣B/NVK exchange rate is 4.2374 as of 31 December 2016. Thus, the intangible assets on Ngcorp's 2016 balance sheet are NVK3 million × ₣B4.2374/NVK = ₣B12.71 million.

34 B is correct. Using the temporal method, monetary assets (i.e., cash) are translated using the current exchange rate (as of 31 December 2016) of BRD1.20/NER (or NER0.8333/BRD), and non-monetary assets are translated using the historical exchange rate when acquired. Inventory is translated at its 2016 weighted-average rate of BRD1.19/NER (or NER0.8403/BRD). Therefore, the total assets for Triofind-B translated into Norvolt euros (Triofind's presentation currency) as of 31 December 2016 are calculated as follows:

Assets	31 December 2016 (BRD)	Applicable Exchange Rate (NER/BRD)	Rate Used	NER
Cash	900,000	0.8333	Current	750,000
Inventory	750,000	0.8403	Average	630,252
Total	1,650,000			1,380,252

35 A is correct. The monetary balance sheet items for Triofind-B are translated at the current exchange rate, which reflects that the Borliand dollar weakened during the period relative to the Norvolt euro. The rate as of 30 June 2016 was BRD1.15/NER (or NER/BRD0.8696) and as of 31 December 2016 was BRD1.20/NER (or NER/BRD0.8333). Therefore, notes payable translates to NER416,667 (BRD500,000 × NER/BRD0.8333) as of 31 December 2016, compared with NER434,783 (BRD500,000 × NER/BRD0.8696) as of 30 June 2016. Thus, the translation adjustment for liabilities is negative.

36 A is correct. Triofind uses the temporal method to translate the financial statements of Triofind-B. The temporal method uses the current exchange rate for translating monetary assets and liabilities and the historical exchange rate (based on the date when the assets were acquired) for non-monetary assets and liabilities. Monetary assets and liabilities are translated using the current exchange rate (as of 30 June 2017) of NER1 = BRD1.17 (or NER0.8547/BRD), and non-monetary assets and liabilities are translated using the historical exchange rate (as of 30 June 2016) of NER1 = BRD1.15 (or NER0.8696/BRD). Inventory is translated at the 2017 weighted average rate of NER1 = BRD1.18 (or NER0.8475/BRD). The difference required to maintain equality between (a) total assets and (b) total liabilities and shareholder's equity is then recorded as retained earnings. The retained earnings for Triofind-B translated into Norvolt euros (Triofind's presentation currency) as of 30 June 2017 is calculated as follows:

Assets	30 June 2017 (BRD)	Exchange Rate (NER/BRD)	Rate Used	30 June 2017 (NER)	Liabilities and Stockholders' Equity	30 June 2017 (BRD)	Exchange Rate (NER/BRD)	Rate Used	30 June 2017 (NER)
Cash	1,350,000	0.8547	C	1,153,846	Notes Payable	500,000	0.8547	C	427,350
Inventory	500,000	0.8475	H	423,729	Common Stock	1,150,000	0.8696	H	1,000,000
					Retained Earnings	200,000			**150,225**
	1,850,000			1,577,575	Total	1,850,000			1,577,575

37 C is correct. The functional currency is the currency of the primary economic environment in which an entity operates. Abuelio is Triofind-A's primary economic environment, and its currency is the Abuelio peso (ABP). Another important factor used to determine the functional currency is the currency that mainly influences sales prices for goods and services. The fact that Triofind-A prices its goods in Abuelio pesos supports the case for the ABP to be the functional currency.

38 B is correct. Triofind complies with IFRS, and Abuelio can be considered a highly inflationary economy because its cumulative inflation rate exceeded 100% from 2015 to 2017. Thus, Triofind-A's financials must be restated to include local inflation rates and then translated using the current exchange rate into Norvolt euros, which is Triofind's presentation currency. This approach reflects both the likely change in the local currency value of the warehouse as well as the actual change in the exchange rate. The original purchase price is ABP1,008,065 (NER50,000/ABP0.0496). The value of the new warehouse in Abuelio as of 31 July 2017 is NER47,964, calculated as follows:

Date	Abuelio Monthly Inflation Rate (%)	Restated Warehouse Value (ABP)	NER/ABP	Warehouse Value (NER)
31 May 2017		1,008,065	0.0496	50,000
30 June 2017	25	1,260,081	0.0388	48,891
31 July 2017	22	1,537,298	0.0312	47,964

39 A is correct. Norvolt exempts the non-domestic income of multinationals from taxation. Because Norvolt has a corporate tax rate of 34%, the 0% tax rate in Borliand and the fact that 25% of Triofind's net income comes from Borliand should result in a lower effective tax rate on Triofind's consolidated financial statements compared with Triofind's domestic tax rate. Abuelio's tax rate of 35% is very close to that of Norvolt, and it constitutes only 15% of Triofind's net income, so its effect is unlikely to be significant.

40 B is correct. Although Borliand shows the highest growth in Norvolt euro terms, this result is partially because of currency fluctuations, which cannot be controlled. Abuelio had the highest change in sales resulting from price and volume at 13% (excluding foreign currency exchange). This growth is more sustainable than net sales growth, which includes currency fluctuations, because Triofind's management has more control over growth in sales resulting from greater volume or higher prices.

Analysis of Financial Institutions

by Jack T. Ciesielski, CPA, CFA, and Elaine Henry, PhD, CFA

Jack T. Ciesielski, CPA, CFA, is at R.G. Associates, Inc., former publisher of The Analyst's Accounting Observer (USA). Elaine Henry, PhD, CFA, is at Stevens Institute of Technology (USA).

LEARNING OUTCOMES

Mastery	The candidate should be able to:
☐	**a.** describe how financial institutions differ from other companies;
☐	**b.** describe key aspects of financial regulations of financial institutions;
☐	**c.** explain the CAMELS (capital adequacy, asset quality, management, earnings, liquidity, and sensitivity) approach to analyzing a bank, including key ratios and its limitations;
☐	**d.** describe other factors to consider in analyzing a bank;
☐	**e.** analyze a bank based on financial statements and other factors;
☐	**f.** describe key ratios and other factors to consider in analyzing an insurance company.

INTRODUCTION TO FINANCIAL INSTITUTIONS

1

a describe how financial institutions differ from other companies;

b describe key aspects of financial regulations of financial institutions;

Financial institutions provide a wide range of financial products and services. They serve as intermediaries between providers and recipients of capital, facilitate asset and risk management, and execute transactions involving cash, securities, and other financial assets.

Given the diversity of financial services, it is unsurprising that numerous types of financial institutions exist. Types of financial institutions include deposit-taking, loan-making institutions (referred to as *banks* in this reading), investment banks, credit card companies, brokers, dealers, exchanges, clearing houses, depositories, investment managers, financial advisers, and insurance companies. In many situations, overlap of services exists across types of institutions. For example, banks not only

© 2018 CFA Institute. All rights reserved.

take deposits and make loans but also may undertake investment management and other securities-related activities and may offer such products as derivatives, which are effectively insurance against adverse effects of movements in the interest rate, equity, and foreign currency markets. As another example of overlap, life insurance companies not only provide mortality-related insurance products but also offer savings vehicles. This reading focuses primarily on two types of financial institutions: banks (broadly defined as deposit-taking, loan-making institutions) and insurance companies.

Section 1 explains what makes financial institutions different from other types of companies, such as manufacturers or merchandisers. Sections 2–4 discuss how to analyze a bank. Sections 5 and 6 focus on analyzing insurance companies. A summary of key points concludes the reading.

1.1 What Makes Financial Institutions Different?

A distinctive feature of financial institutions—in particular, banks—is their systemic importance, which means that their smooth functioning is essential to the overall health of an economy. The most fundamental role of banks is to serve as intermediaries, accepting deposits from capital providers and providing capital via loans to borrowers. Their role as intermediaries between and among providers and recipients of capital creates financial inter-linkages across all types of entities, including households, banks, corporations, and governments. The network of inter-linkages across entities means that the failure of one bank will negatively affect other financial and non-financial entities. The larger the bank and the more widespread its inter-linkages, the greater its potential impact on the entire financial system. If an extremely large bank were to fail, the negative impact of its failure could spread and potentially result in the failure of the entire financial system.

Systemic risk has been defined as "a risk of disruption to financial services that is (i) caused by an impairment of all or parts of the financial system and (ii) has the potential to have serious negative consequences for the economy as a whole. Fundamental to the definition is the notion of contagion across the economy from a disruption or failure in a financial institution, market or instrument. All types of financial intermediaries, markets and infrastructure can potentially be systemically important to some degree."[1] The problem of systemic risk (the risk of failure of the financial system as a result of the failure of a major financial institution) has emerged as an issue in many countries around the world in the aftermath of the 2008 global financial crisis. *Financial contagion* is a situation in which financial shocks spread from their place or sector of origin to other locales or sectors. Globally, a faltering economy may infect other, healthier economies.

Because of their systemic importance, financial institutions' activities are heavily regulated. Regulations attempt to constrain excessive risk taking that could cause an entity to fail. Regulations address various aspects of a financial institution's operations, including the amount of capital that must be maintained, the minimum liquidity, and the riskiness of assets.

The liabilities of most banks are made up primarily of deposits. For example, as of December 2016, deposits constituted over 80% of the total liabilities of domestically chartered commercial banks in the United States.[2] The failure of a bank to honor its deposits could have negative consequences across the economy. Even the expectation

1 "Guidance to Assess the Systemic Importance of Financial Institutions, Markets and Instruments: Initial Considerations," report to the G–20 finance ministers and central bank governors, prepared by the staff of the International Monetary Fund and the Bank for International Settlements and the secretariat of the Financial Stability Board (October 2009): https://www.imf.org/external/np/g20/pdf/100109.pdf.

2 "Assets and Liabilities of Commercial Banks in the United States - H.8," Federal Reserve statistical release (https://www.federalreserve.gov).

that a bank might not be able to honor its deposits could cause depositors to withdraw their money from the bank, and a large sudden withdrawal of deposits (a bank run) could cause an actual failure and financial contagion across the economy. Therefore, deposits are often insured (up to a stated limit) by the government of the country in which the bank operates.

Another distinctive feature of financial institutions is that their assets are predominantly financial assets, such as loans and securities. In contrast, the assets of most non-financial companies are predominantly tangible assets. Financial assets create direct exposure to a different variety of risks, including credit risks, liquidity risks, market risks, and interest rate risks. Unlike many tangible assets, financial assets are often measured at fair market value for financial reporting.

This reading focuses on the financial analysis of banks and insurers (property and casualty insurers and life and health insurers). There are many other types of financial institutions, including different types of depository institutions. Some of these other financial institutions are described briefly in Exhibit 1. Note that the list in Exhibit 1 includes types of entities that an analyst may evaluate for potential investment and, therefore, excludes supra-national organizations. Typically, supra-national entities are formed by member countries to focus on lending activities in support of specific missions. For example, the World Bank—whose mission is to reduce poverty and support development globally—comprises 189 member countries and provides loans and grants through the International Bank for Reconstruction and Development and the International Development Association.[3] Other prominent examples of supra-national entities are the Asian Development and Asian Infrastructure Investment Bank.

Exhibit 1 A Sampling of Financial Institutions

The list that follows is illustrative only and should not be viewed as comprehensive. The list is organized by primary activity, but many service overlaps exist. Additionally, the structure of financial service providers differs across countries, and state ownership of financial institutions is more common in some countries.

Institutions That Provide Basic Banking Services

- **Commercial banks.** This term generally refers to institutions whose business focuses on classic banking services, such as taking deposits, making loans, and facilitating payment transactions. Historically, regulation in some countries, such as the United States and France, created distinctions between commercial banking activities (e.g., deposit taking and loan making), insurance activities, and investment banking activities, such as securities underwriting, trading, and investing. In general, this distinction has been declining. For example, in France, regulations beginning in the mid-1980s eliminated many restrictions on banks' allowable types of activities, and in the United States, a 1999 law granted commercial banks the ability to undertake broad-based securities and insurance activities.[4] Germany's universal banks provide commercial banking, investment banking, insurance, and other financial and non-financial services, and Spain's leading commercial banks are "dominant in cross-selling mutual funds to their retail clients."[5] Japanese banks are permitted to engage in a

Exhibit 1 (Continued)

range of activities including equity ownership in non-financial corporations (within limits) that strengthens their role in corporate governance beyond that typical of a creditor.[6]

- **Credit unions, cooperative and mutual banks.** These are depository institutions that function like banks and offer many of the same services as banks. They are owned by their members, rather than being publicly traded like many banks. Another difference from commercial banks is that these institutions are organized as non-profits and, therefore, do not pay income taxes.
- **Specialized financial service providers.**
  - **Building societies** and **savings and loan associations** are depository institutions that specialize in financing long-term residential mortgages.
  - **Mortgage banks** originate, sell, and service mortgages and are usually active participants in the securitization markets.
  - **Trust banks (Japan)** are commercial banks, and because their deposits are in the form of "money trusts" (typically with three- to five-year terms and one-year minimums), they can make long-term commercial loans and securities investments. Japan also has city banks (universal banks), regional banks, second regional banks, and Shinkin banks and credit cooperatives (which provide commercial banking services to their members—smaller enterprises and individuals).[7]
  - **Online payment companies**, such as Paypal (United States), Alipay (China), and other non-bank online payment companies, have expanded rapidly and continue to broaden service offerings.

Intermediaries within the Investment Industry

Within this category, services offered by different entities are particularly varied. A few of these are described briefly below.

- *Managers of pooled investment vehicles, such as open-end mutual funds, closed-end funds, and exchange-traded funds.* These financial institutions pool money from investors and buy and sell securities and other assets. The investors share ownership in the investment vehicle. Pooled investment vehicles, as required by regulation, disclose their investment policies, deposit and redemption procedures, fees and expenses, past performance statistics, and other information.
- *Hedge funds.* These funds also pool investors' money and invest it. They tend to follow more complex strategies; be less transparent, less liquid, and less regulated; and have higher fees and higher minimum investment amounts than open-end mutual funds, closed-end funds, and exchange-traded funds.
- *Brokers and dealers.* These firms facilitate trade in securities, earning a commission or spread on the trades.

6 Berger et al., *The Oxford Handbook of Banking.*
7 Berger et al., *The Oxford Handbook of Banking.*

Exhibit 1 (Continued)

Insurers

- **Property and casualty (P&C) insurance companies** provide protection against adverse events related to autos, homes, or commercial activities.
- **Life and health (L&H) insurers** provide mortality- and health-related insurance products. Life insurance companies also provide savings products.
- **Reinsurance companies** sell insurance to insurers. Rather than paying policyholder claims directly, they reimburse insurance companies for claims paid.[8]

1.2 Global Organizations

With respect to global systemic risk, important differences exist between the banking and insurance sectors.[9] Unlike banks, the overall insurance market has a smaller proportion of cross-border business, although the reinsurance business is largely international. The international aspect of the reinsurance business increases the importance of the insurance sector to the global financial system: Reinsurers may be an international link to financial institutions domiciled in different parts of the world, thereby increasing systemic vulnerability. Another important difference is that insurance companies' foreign branches are generally required to hold assets in a jurisdiction that are adequate to cover the related policy liabilities in that jurisdiction.

Aside from minimizing systemic risk, other reasons for the establishment of global and regional regulatory bodies include the harmonization and globalization of regulatory rules, standards, and oversight. Consistency of standards and regulations helps minimize regulatory arbitrage (whereby multinational companies capitalize on differences in jurisdictions' regulatory systems in order to avoid unfavorable regulation) around the world.

One of the most important global organizations focused on financial stability is the Basel Committee on Banking Supervision, which was established in 1974 and is a standing committee hosted and supported by the Bank for International Settlements. Members of the Basel Committee include central banks and entities responsible for supervising banks. The list of members of the Basel Committee in Exhibit 2 illustrates the range of entities involved with supervising banking activity in different countries and jurisdictions.

The Basel Committee developed the international regulatory framework for banks known as Basel III, which is the enhanced framework succeeding Basel I and Basel II. The purposes of the measures contained in Basel III are the following: "to improve the banking sector's ability to absorb shocks arising from financial and economic stress, whatever the source, improve risk management and governance, and strengthen banks' transparency and disclosures."[10]

Three important highlights of Basel III are the minimum capital requirement, minimum liquidity, and stable funding. First, Basel III specifies the minimum percentage of its risk-weighted assets that a bank must fund with equity capital. This minimum capital requirement prevents a bank from assuming so much financial leverage that it is unable to withstand loan losses (asset write-downs). Second, Basel III specifies that a bank must hold enough high-quality liquid assets to cover its liquidity needs in a 30-day liquidity stress scenario. This minimum liquidity requirement ensures that a bank would have enough cash to cover a partial loss of funding sources (e.g., customers' deposits, other borrowings) or a cash outflow resulting from off-balance-sheet funding commitments. Third, Basel III requires a bank to have a minimum amount of stable funding relative to the bank's liquidity needs over a one-year horizon. Stability of funding is based on the tenor of deposits (e.g., longer-term deposits are more stable than shorter-term deposits) and the type of depositor (e.g., funds from consumers' deposits are considered more stable than funds raised in the interbank markets).

As a result of preventing banks from assuming excessive financial leverage, Basel III has prompted banks to focus on asset quality, hold capital against other types of risk (such as operational risk), and develop improved risk assessment processes. Basel III also presents fundamental changes regarding the quality and composition of the capital base of financial institutions. It has improved the ability of their capital base to sustain losses, so these are confined to the financial institutions' capital investors and are not transmitted to depositors, taxpayers, or other institutions in the financial system, thereby reducing risk of contagion.

Having developed the regulatory framework, the Basel Committee monitors the adoption and implementation of Basel III by member jurisdictions.

A number of other important organizations are involved in international cooperation in the area of financial stability. Some of these international organizations are described briefly below.

- The Financial Stability Board includes representatives from supervisory and regulatory authorities for the G–20 members plus Hong Kong SAR, Singapore, Spain, and Switzerland. Its overall goal is to strengthen financial stability. It aims to identify systemic risk in the financial sector and coordinate actions that jurisdictional authorities can take to address the risks.

10 www.bis.org.

- The International Association of Deposit Insurers' objective is to "enhance the effectiveness of deposit insurance systems."
- The International Association of Insurance Supervisors (IAIS) includes representatives from insurance regulators and supervisors from most countries around the world. Its overall goal is to promote effective supervision of the insurance industry globally.
- The International Organization of Securities Commissions (IOSCO) includes representatives from the regulators of the securities markets of various countries and jurisdictions. Its overall goals include maintaining fair and efficient securities markets.

The latter two organizations are part of a Joint Forum with the Basel Committee. The Joint Forum comprises representatives from the Basel Committee, IAIS, and IOSCO and works on issues common to the banking, insurance, and securities sectors.

1.3 Individual Jurisdictions' Regulatory Authorities

The global organizations described in the previous section aim to foster financial stability by working with individual jurisdictions' regulatory authorities. It is the individual jurisdictions' regulatory bodies that have authority over specific aspects of a financial institution's operations.

Globally, there are many regulators with overlapping and differing responsibilities over financial institutions; the global network of regulators and the resulting regulations are complex. Although there is some overlap between member institutions in the Basel Committee and other global organizations mentioned in the previous section, specific membership varies. For example, the 83 member organizations of the International Association of Deposit Insurers include some institutions that are Basel Committee members, such as the US Federal Deposit Insurance Corporation (FDIC), and some that are not Basel Committee members, such as the Singapore Deposit Insurance Corporation Ltd. and Germany's Bundesverband deutscher Banken (Deposit Protection Fund). In some countries, the same regulatory body oversees both banking and insurance—for example, Japan's Financial Services Agency. And in other countries, there is a separate regulatory body for insurance companies—for example, the US National Association of Insurance Commissioners (NAIC) and the China Insurance Regulatory Commission.

As a financial institution's operations expand globally, compliance requirements increase. One of the most global financial institutions, HSBC Holdings, discloses that their operations are "regulated and supervised by approximately 400 different central banks and other regulatory authorities in those jurisdictions in which we have offices, branches or subsidiaries. These authorities impose a variety of requirements and controls."[11]

2 ANALYZING A BANK: THE CAMELS APPROACH

c explain the CAMELS (capital adequacy, asset quality, management, earnings, liquidity, and sensitivity) approach to analyzing a bank, including key ratios and its limitations;

e analyze a bank based on financial statements and other factors;

11 HSBC Holdings Form 20-F (31 December 2016).

In this section, the term "bank" is used in its general sense and applies to entities whose primary business activities are taking deposits and making loans. This section first describes an approach widely used as a starting point to analyze a bank, known as CAMELS, and follows with a description of additional factors to consider when analyzing a bank. The section concludes with a case study analysis of a real bank.

2.1 The CAMELS Approach

"CAMELS" is an acronym for the six components of a widely used bank rating approach originally developed in the United States.[12] The six components are **C**apital adequacy, **A**sset quality, **M**anagement capabilities, **E**arnings sufficiency, **L**iquidity position, and **S**ensitivity to market risk.

A bank examiner using the CAMELS approach to evaluate a bank conducts an analysis and assigns a numerical rating of 1 through 5 to each component. A rating of 1 represents the best rating, showing the best practices in risk management and performance and generating the least concern for regulators. A rating of 5 is the worst rating, showing the poorest performance and risk management practices and generating the highest degree of regulatory concern.[13] After the components are rated, a composite rating for the entire bank is constructed from the component ratings. This is not a simple arithmetic mean of the six component ratings: Each component is weighted by the examiner performing the study. The examiner's judgment will affect the weighting accorded to each component's rating. Two examiners could evaluate the same bank on a CAMELS basis and even assign the same ratings to each component and yet arrive at different composite ratings for the entire bank.

Although the CAMELS system was developed as a tool for bank examiners, it provides a useful framework for other purposes, such as equity or debt investment analysis of banks. The following sections discuss each component of the rating system.

2.1.1 *Capital Adequacy*

It is important for a bank (as with any company) to have adequate capital so that potential losses can be absorbed without causing the bank to become financially weak or even insolvent. Losses reduce the amount of a bank's retained earnings, which is one component of capital. Large enough losses could even result in insolvency. A strong capital position lowers the probability of insolvency and bolsters public confidence in the bank.

Capital adequacy for banks is described in terms of the proportion of the bank's assets funded with capital. For purposes of determining capital adequacy, a bank's assets are adjusted based on their risk, with riskier assets requiring a higher weighting. The risk weightings are specified by individual countries' regulators, and these regulators typically take Basel III into consideration. The risk adjustment results in an amount for risk-weighted assets to use when determining the amount of capital required to fund those assets. For example, cash has a risk weighting of zero, so cash is not included in the risk-weighted assets. As a result, no capital is required to fund cash. Corporate loans have a risk weighting of 100%, and certain risky assets, such as loans on high-volatility commercial real estate and loans that are more than 90 days past due, have a weighting greater than 100%. As a simple example, consider a hypothetical bank with three assets: $10 in cash, $1,000 in performing loans, and $10

12 Information on the evolution of risk assessment can be found in "Supervisory Risk Assessment and Early Warning Systems," Ranjana Sahajwala and Paul Van den Bergh, Basel Committee on Banking Supervision Working Paper No. 4 (December 2000). Further information about the CAMELS rating system can be found in the FDIC's description of the Uniform Financial Institutions Rating System at www.fdic.gov.
13 Sahajwala and Van den Bergh, "Supervisory Risk Assessment and Early Warning Systems."

in non-performing loans. The bank's risk-weighted assets (RWAs) would equal ($10 × 0%) + ($1,000 × 100%) + ($10 × 150%) = $1,015. Also, off-balance-sheet exposures are assigned risk weights and included in the risk-weighted assets.

For purposes of determining a bank's capital and its capital adequacy, a bank's capital is classified into hierarchical tiers. The most important of these tiers is Common Equity Tier 1 Capital. According to the FDIC:

> Basel III capital standards emphasize common equity tier 1 capital as the predominant form of bank capital. Common equity tier 1 capital is widely recognized as the most loss-absorbing form of capital, as it is permanent and places shareholders' funds at risk of loss in the event of insolvency. Moreover, Basel III strengthens minimum capital ratio requirements and risk-weighting definitions, increases Prompt Corrective Action (PCA) thresholds, establishes a capital conservation buffer, and provides a mechanism to mandate counter-cyclical capital buffers.[14]

Common Equity Tier 1 Capital includes common stock, issuance surplus related to common stock, retained earnings, accumulated other comprehensive income, and certain adjustments including the deduction of intangible assets and deferred tax assets. Other Tier 1 Capital includes other types of instruments issued by the bank that meet certain criteria. The criteria require, for example, that the instruments be subordinate to such obligations as deposits and other debt obligations, not have a fixed maturity, and not have any type of payment of dividends or interest that is not totally at the discretion of the bank. Tier 2 Capital includes instruments that are subordinate to depositors and to general creditors of the bank, have an original minimum maturity of five years, and meet certain other requirements.

The minimum capital requirements set forth in Basel III are described here because they are global. However, it is the individual countries' regulators who have authority to establish the minimum capital requirements for institutions within their jurisdiction.

- Common Equity Tier 1 Capital must be at least 4.5% of risk-weighted assets.
- Total Tier 1 Capital must be at least 6.0% of risk-weighted assets.
- Total Capital (Tier 1 Capital plus Tier 2 Capital) must be at least 8.0% of risk-weighted assets.[15]

EXAMPLE 1

Capital Position

Exhibit 3 presents an excerpt from an annual report disclosure by HSBC Holdings plc about its capital position. The excerpt shows the group's capital ratios, amount of capital by tier, and risk-weighted assets by type.

* "Capital required" represents the Pillar 1 capital charge at 8% of RWAs.
Source: HSBC Holdings plc Annual Report and Accounts 2016 (p. 127).

1. Based on Exhibit 3, did HSBC's capital ratios strengthen or weaken in 2016?
2. Based on Exhibit 3, what was the primary reason for the change in HSBC's capital ratios in 2016?

Solution to 1:

HSBC's capital ratios strengthened in 2016. Its Common Equity Tier 1 ratio increased from 11.9% of RWAs to 13.6% of RWAs. Its Tier 1 ratio also increased from 13.9% to 16.1%, and its Total Capital Ratio increased from 17.2% to 20.1%.

Solution to 2:

The primary reason for the change in HSBC's capital ratios in 2016 was a reduction in the amount of risk-weighted assets. Total risk-weighted assets declined from $1,102,995 million to $857,181 million.

2.1.2 *Asset Quality*

Asset quality pertains to the amount of existing and potential credit risk associated with a bank's assets, focusing primarily on financial assets. The concept of asset quality extends beyond the composition of a bank's assets and encompasses the strength of the overall risk management processes by which the assets are generated and managed.

Loans typically constitute the largest portion of a bank's assets. Asset quality for loans reported on the balance sheet depends on the creditworthiness of the borrowers and the corresponding adequacy of adjustments for expected loan losses. Loans are measured at amortized cost and are shown on the balance sheet net of allowances for loan losses.

Investments in securities issued by other entities, often another significant portion of a bank's assets, are measured differently, depending on how the security is categorized. Specifically, under International Financial Reporting Standards (IFRS),[16] financial assets are classified in one of three categories, depending on the company's business model for managing the asset and on the contractual cash flows of the asset. The financial asset's category specifies how it is subsequently measured (either amortized cost or fair value) and, for those measured based on fair value, how any changes in value are reported–either through other comprehensive income (OCI) or through profit and loss (PL). The three categories for financial assets are (1) measured at amortized cost, (2) measured at fair value through other comprehensive income (FVOCI), and (3) measured at fair value through profit and loss (FVTPL).

In contrast to IFRS, US GAAP require all equity investments "(except those accounted for under the equity method of accounting or those that result in consolidation of the investee) to be measured at fair value with changes in fair value recognized in net income."[17] Another exception to fair value measurement is that an equity investment without a readily determinable fair value can be measured at cost minus impairment. Thus, under US GAAP, the three categories used to classify and measure investments apply *only to debt securities*: held to maturity (measured at amortized cost), trading (measured at fair value through net income), and available for sale (measured at fair value through other comprehensive income).

The following example addresses asset quality from the perspective of overall asset composition. The example includes the asset portion of a bank's balance sheet. In practice, terminology used by different entities can vary, and an analyst should refer to the footnotes for further detail on a line item. Here, two comments can be helpful in interpreting the line items in the example. First, when determining the total amount of bank loans, two line items are clearly relevant: "Loans and advances to banks" and "Loans and advances to customers." In addition, note that "Reverse repurchase agreements" are a form of collateralized loan made by a bank to a client. In a repurchase agreement, a borrower (i.e., a bank client) sells a financial asset to a lender (i.e., a bank) and commits to repurchase the financial asset for a fixed price at a future date. The difference between the selling price and the higher repurchase price effectively constitutes interest on the borrowing. The borrower describes the transaction as a "repurchase agreement," and the lender describes the transaction as a "reverse repurchase agreement."[18] Second, the term "assets held for sale" is related to discontinued operations and specifically refers to long-term assets whose value is

16 IFRS 9 *Financial Instruments*, issued July 2014 and effective beginning January 2018.

17 Accounting Standards Update 2016-01 *Financial Instruments—Overall* (Subtopic 825-10) *Recognition and Measurement of Financial Assets and Financial Liabilities*. This Accounting Standards Update was issued in January 2016 and is effective for public business entities for fiscal years beginning after 15 December 2017.

18 The Office of Financial Research (part of the US Department of the Treasury) estimates that the size of the repurchase ("repo") market is $3.5 trillion.

driven mainly by their intended disposition rather than their continued use.[19] This term should not be confused with the securities-related term "available for sale" (described above).

EXAMPLE 2

Asset Quality: Composition of Assets

Exhibit 4 presents the asset portion of the balance sheet of HSBC Holdings, which is prepared according to IFRS.

Exhibit 4 Excerpt from Consolidated Balance Sheet

HSBC Holdings plc
Consolidated Balance Sheet [Excerpt]
at 31 December

Assets	2016 $m	2015 $m
Cash and balances at central banks	**128,009**	98,934

Source: HSBC Holdings plc Annual Report and Accounts 2016.

1 The following items are the most liquid: Cash and balances at central banks, Items in the course of collection from other banks, and Hong Kong Government certificates of indebtedness. What proportion of HSBC's total assets was invested in these liquid assets in 2015? In 2016? Did HSBC's balance sheet liquidity decrease or increase in 2016?

19 IFRS 5 *Non-Current Assets Held for Sale and Discontinued Operations.*

2 How did the percentage of investments to total assets change from 2015 to 2016? (Include trading assets, financial assets designated at fair value, and financial investments as investments.)

3 What proportion of HSBC's assets are loans? (As noted, the banks' loans include "Loans and advances to banks" and "Loans and advances to customers." In addition, "Reverse repurchase agreements" are a form of collateralized loan.)

Solution to 1:

HSBC's balance sheet liquidity increased in 2016.

In 2015, the proportion of HSBC's balance sheet invested in highly liquid assets was 5.5%

[($98,934 + $5,768 + $28,410)/$2,409,656 = 5.5%].

In 2016, the proportion of HSBC's balance sheet invested in highly liquid assets was 6.9%

[($128,009 + $5,003 + $31,228)/$2,374,986 = 6.9%].

Solution to 2:

The percentage of investments on HSBC's balance sheet increased in 2016.

In 2015, the percentage of investments to total assets was 28.1%

[($224,837 + $23,852 + $428,955)/$2,409,656 = 28.1%].

In 2016, the percentage of investments to total assets was 29.3%

[($235,125 + $24,756 + $436,797)/$2,374,986 = 29.3%].

Solution to 3:

In 2015, loans represented 48.2% [($90,401 + $924,454 + $146,255)/$2,409,656 = 48.2%] of HSBC's total assets, and in 2016, loans represented 46.8% [($88,126 + $861,504 + $160,974)/$2,374,986 = 46.8%] of HSBC's total assets.

The next example addresses asset quality from the perspective of credit quality. Assessment of credit risk is of course fundamental to banks' decisions about loans—the largest category of a banks' assets. As noted, investments in securities often constitute a significant portion of a bank's assets, and those activities also involve credit risk. Further, a bank's trading activities—including off-balance-sheet trading activities—create exposure to counterparty credit risk. Off-balance-sheet obligations such as guarantees, unused committed credit lines, and letters of credit represent potential assets (as well as potential liabilities) to the bank and thus involve credit risk. In addition to credit risk, other factors, such as liquidity, can also affect the value and marketability of a bank's assets. Diversification of credit risk exposure (and avoiding credit concentration) across the entire asset base—loans and investments—and among counterparties is an important aspect of asset quality.

EXAMPLE 3

Credit Quality of Assets

Exhibit 5 presents an excerpt from an annual report disclosure by HSBC Holdings plc about the credit quality of its financial instruments. The exhibit shows the distribution of financial instruments by credit quality.

Financial instruments included in the exhibit correspond to total amounts for some line items of assets listed on the balance sheet and to partial amounts for line items on the balance sheet where only a portion of the asset involves exposure to credit risk. Total amounts are included for the following balance sheet items: Cash and balances at central banks; Items in the course of collection from other banks; Hong Kong Government certificates of indebtedness; Derivatives; Loans and advances to banks; Loans and advances to customers; and Reverse repurchase agreements, non-trading. Partial amounts are included for the following balance sheet items: Trading assets; Financial assets designated at fair value; Financial investments; Assets held for sale; and Prepayments, accrued income and other assets.

Exhibit 5 Excerpt from Annual Report Disclosure of HSBC Holdings plc

		At 31 Dec. 2016 ($m)	At 31 Dec. 2015 ($m)
Neither past due nor impaired	Strong credit quality	$1,579,517	$1,553,830
	Good credit quality	$313,707	$331,141
	Satisfactory credit quality	$263,995	$293,178
	Sub-standard credit quality	$26,094	$26,199
	Past due but not impaired	$9,028	$13,030
	Impaired	$20,510	$28,058
	Total gross amount	$2,212,851	$2,245,436
	Impairment allowances	$(8,100)	$(11,027)
	Total	$2,204,751	$2,234,409

Source: HSBC Holdings plc Annual Report and Accounts 2016 (pp. 88–89).

1 Based on Exhibit 5, did the credit quality of HSBC's financial instruments improve or deteriorate in 2016? Specifically, how did the proportion of assets invested in strong credit quality instruments change from year to year?

2 Based on Exhibit 5, does the change in HSBC's impairment allowances in 2016 reflect the change in the credit quality of financial instruments (specifically the amount of impaired assets)?

Solutions Exhibit

		At 31 Dec. 2016 Percentage of total gross amount	At 31 Dec. 2015 Percentage of total gross amount	Percentage change in dollar amount
Neither past due nor impaired	Strong credit quality	71.4%	69.2%	1.7%
	Good credit quality	14.2%	14.7%	**–5.3%**
	Satisfactory credit quality	11.9%	13.1%	**–10.0%**
	Sub-standard credit quality	1.2%	1.2%	**–0.4%**
	Past due but not impaired	0.4%	0.6%	**–30.7%**
	Impaired	0.9%	1.2%	**–26.9%**
	Total gross amount	100.0%	100.0%	**–1.5%**
	Impairment allowances	**–0.4%**	**–0.5%**	**–26.5%**

Solution to 1:

Based on Exhibit 5, the credit quality of HSBC's financial instruments improved in 2016. As shown in the Solutions Exhibit, the percentage of total investment assets invested in strong credit quality instruments rose from 69.2% in 2015 to 71.4% in 2016 [$1,553,830/$2,245,436 = 69.2%; $1,579,517/$2,212,851 = 71.4%].

Solution to 2:

Yes. Based on Exhibit 5, the change in HSBC's impairment allowances in 2016 reflects the change in the credit quality of financial instruments. In general, it is expected that the amount of impairment allowances will be related to the amount of impaired assets. The 26.5% decrease in the amount of HSBC's impairment allowances in 2016 corresponds to the 26.9% decrease in impaired assets. As a corollary, the amount of impairment allowances as a percentage of impaired assets remained roughly constant in both years ($11,027/$28,058 = 39.3% for 2015 and $8,100/$20,510 = 39.5% for 2016).

2.1.3 *Management Capabilities*

Many of the attributes of effective management of financial institutions are the same as those for other types of entities. Effective management involves successfully identifying and exploiting appropriate profit opportunities while simultaneously managing risk. For all types of entities, compliance with laws and regulations is essential. A strong governance structure—with an independent board that avoids excessive compensation or self-dealing—is also critically important. Sound internal controls, transparent management communication, and financial reporting quality are indicators of management effectiveness. Across all entities, overall performance is ultimately the most reliable indicator of management effectiveness.

For financial institutions, a particularly important aspect of management capability is the ability to identify and control risk, including credit risk, market risk, operating risk, legal risk, and other risks. Directors of banks set overall guidance on risk exposure levels and appropriate implementation policies and provide oversight of bank management. Banks' senior managers must develop and implement effective procedures for measuring and monitoring risks consistent with that guidance.

2.1.4 *Earnings*

As with any entity, financial institutions should ideally generate an amount of earnings to provide an adequate return on capital to their capital providers and specifically to reward their stockholders through capital appreciation and/or distribution of the earnings. Further, all companies' earnings should ideally be high quality and trending upward. In general, high-quality earnings mean that accounting estimates are unbiased and the earnings are derived from sustainable rather than non-recurring items.

For banks, one important area involving significant estimates is loan impairment allowances. In estimating losses on the loan portfolio collectively, statistical analysis of historical loan losses can provide a basis for an estimation, but statistical analysis based on past data must be supplemented with management judgement about the potential for deviation in future. In estimating losses on individual loans, assessments are required concerning the likelihood of the borrower's default or bankruptcy and the value of any collateral. HSBC describes the complexity of estimating loan impairment allowances as follows: "The exercise of judgement requires the use of assumptions which are highly subjective and very sensitive to the risk factors, in particular to changes in economic and credit conditions across a large number of geographical areas. Many of the factors have a high degree of interdependency and there is no single factor to which our loan impairment allowances as a whole are sensitive."[20]

Banks also must use estimates in valuing some financial assets and liabilities that must be measured at fair value. When fair value of an investment is based on observable market prices, valuation requires little judgment. However, when fair values cannot be based on observable market prices, judgment is required.

Under both IFRS and US GAAP, fair value measurements of financial assets and liabilities are categorized on the basis of the type of inputs used to establish the fair value. Both sets of standards use the concept of a *fair value hierarchy*.[21] The three "levels" of the fair value hierarchy pertain to the observability of the inputs used to establish the fair value.

- Level 1 inputs are quoted prices for identical financial assets or liabilities in active markets.
- Level 2 inputs are observable but are not the quoted prices for identical financial instruments in active markets. Level 2 inputs include quoted prices for similar financial instruments in active markets, quoted prices for identical financial instruments in markets that are not active, and observable data such as interest rates, yield curves, credit spreads, and implied volatility. The inputs are used in a model to determine the fair value of the financial instrument.
- Level 3 inputs are unobservable. The fair value of a financial instrument is based on a model (or models) and unobservable inputs. Financial modeling, by its very nature, contains subjective estimates that are unobservable and will differ from one modeler to another. For example, a financial instrument's value might be based on an option-pricing model employing an unobservable and subjective estimate of the instrument's market volatility. Another example is that a financial instrument's value might be based on estimated future cash flows,

20 HSBC Holdings plc Annual Report and Accounts 2016, page 199: www.hsbc.com/investor-relations/group-results-and-reporting/annual-report

21 Refer to IFRS 13 *Fair Value Measurement* and Financial Accounting Standards Board ASC 820 *Fair Value Measurement*.

discounted to a present value. Neither the estimated future cash flows nor the discount rate can be observed objectively, because they depend on the determinations made by the modeler.

In practice, the "Level 1, 2, 3" fair value terminology can also refer to the valuation approach used. A Level 3 valuation technique is one that relies on one or more significant inputs that are unobservable. For example, as noted, a company might value a private equity investment using a model of estimated future cash flows.

Also, in practice, the "Level 1, 2, 3" terminology can refer to the assets or liabilities being valued using a given level of input. For example, investments can be referred to as "Level 1," "Level 2," or "Level 3" investments depending on whether their fair value is determined based on observable market prices for the exact instrument, observable market inputs for similar investments, or unobservable inputs, respectively.

Other areas involving significant estimates are common to non-financial and financial companies. Judging whether goodwill impairment exists requires estimating future cash flows of a business unit. Deciding to recognize a deferred tax asset relies on making assumptions about the probability of future taxes. Determining whether and how much of a liability to recognize in connection with contingencies (e.g., litigation) typically depends on professional expert advice but nonetheless requires some management judgment.

Regarding sustainability of a bank's earnings, it is important to examine the composition of earnings. Banks' earnings typically comprise (a) net interest income (the difference between interest earned on loans minus interest paid on the deposits supporting those loans), (b) service income, and (c) trading income. Of these three general sources, trading income is typically the most volatile. Thus, a greater proportion of net interest income and service income is typically more sustainable than trading income. In addition, lower volatility within net interest income is desirable: Highly volatile net interest income could indicate excessive interest rate risk exposure.

EXAMPLE 4

Composition of Earnings

An analyst has gathered the information in Exhibit 6 to evaluate how important each source of income is to HSBC.

Exhibit 6 Five-Year Summary of HSBC's Total Operating Income

	2016 ($m)	2015 ($m)	2014 ($m)	2013 ($m)	2012 ($m)
Net interest income	**$29,813**	$32,531	$34,705	$35,539	$37,672
Net fee income	**$12,777**	$14,705	$15,957	$16,434	$16,430
Net trading income	**$9,452**	$8,723	$6,760	$8,690	$7,091
Net income/(expense) from financial instruments designated at fair value	**($2,666)**	$1,532	$2,473	$768	($2,226)
Gains less losses from financial investments	**$1,385**	$2,068	$1,335	$2,012	$1,189

Source: HSBC Holdings plc Annual Report and Accounts 2016 (p. 31).

1 Based on Exhibit 6, what is HSBC's primary source of operating income, and what proportion of total operating income was earned from this source in 2016?

2 Based on Exhibit 6, what proportion of total operating income did HSBC earn from trading income in 2016?

3 Based on Exhibit 6, describe the trend in HSBC's operating income.

Solution to 1:

HSBC's primary source of operating income is net interest income. In 2016, 49.8% ($29,813/$59,836 = 49.8%) of total operating income was earned from net interest income in 2016.

Solution to 2:

In 2016, HSBC earned 15.8% ($9,452/$59,836 = 15.8%) of total operating income from trading activities.

Solution to 3:

From 2012 to 2016, HSBC's operating income declined each year. The composition of operating income was fairly constant from 2012 to 2015, with around 46% from net interest income and 21% from fee income.

Exhibit 7 Five-Year Summary of HSBC's Total Operating Income: Common-Size Statement

	2016	2015	2014	2013	2012
	As a Percentage of Total Operating Income				
Net interest income	49.8%	45.8%	46.5%	45.4%	45.6%
Net fee income	21.4%	20.7%	21.4%	21.0%	19.9%
Net trading income	15.8%	12.3%	9.1%	11.1%	8.6%
Net income/(expense) from financial instruments designated at fair value	−4.5%	2.2%	3.3%	1.0%	−2.7%
Gains less losses from financial investments	2.3%	2.9%	1.8%	2.6%	1.4%
Dividend income	0.2%	0.2%	0.4%	0.4%	0.3%
Net insurance premium income	16.6%	14.6%	16.0%	15.2%	15.8%

Total operating income	100.0%	100.0%	100.0%	100.0%	100.0%

2.1.5 *Liquidity Position*

Adequate liquidity is essential for any type of entity. Banks' systemic importance increases the importance of adequate liquidity. If a non-bank entity's insufficient liquidity prevents it from paying a current liability, the impact would primarily affect the entity's own supply chain. In contrast, because deposits constitute the primary component of a bank's current liabilities, the impact of a bank's failure to honor a current liability could affect an entire economy. Deposits in most banks are insured up to some specified amount by government insurers; thus, liquidity is a key focus of regulators.

The Basel III Regulatory Framework[22] cites the sudden illiquidity accompanying the financial crisis of 2008 as a main motivation for the introduction of a global liquidity standard. Because of the sudden pressures on liquidity at the inception of the financial crisis, some banks experienced difficulties, despite having an adequate capital base. Basel III thus introduced two minimum liquidity standards, both to be phased in over subsequent years.

- The Liquidity Coverage Ratio (LCR) is expressed as the minimum percentage of a bank's expected cash outflows that must be held in highly liquid assets. For this ratio, the expected cash outflows (the denominator) are the bank's anticipated one-month liquidity needs in a stress scenario, and the highly liquid assets (the numerator) include only those that are easily convertible into cash. The standards set a target minimum of 100%.
- The Net Stable Funding Ratio (NSFR) is expressed as the minimum percentage of a bank's *required* stable funding that must be sourced from *available* stable funding. For this ratio, required stable funding (the denominator) is a function of the composition and maturity of a bank's asset base, whereas available stable funding (the numerator) is a function of the composition and maturity of a bank's funding sources (i.e., capital and deposits and other liabilities). Under Basel III, the available stable funding is determined by assigning a bank's capital and liabilities to one of five categories presented in Exhibit 8, shown below. The amount assigned to each category is then multiplied by an available stable funding (ASF) factor, and the total available stable funding is the sum of the weighted amounts.[23]

22 Basel Committee on Banking Supervision, "Basel III: A Global Regulatory Framework For More Resilient Banks and Banking System": www.bis.org/publ/bcbs189.pdf.

23 Basel Committee on Banking Supervision, "Basel III: The Net Stable Funding Ratio" (October 2014, p. 3): www.bis.org/bcbs/publ/d295.pdf. Exhibit 8 is adapted from page 6 of this document.

Exhibit 8 Categories of Available Stable Funding

ASF Factor	Components of ASF Category
100%	■ Total regulatory capital (excluding Tier 2 instruments with residual maturity of less than one year) ■ Other capital instruments and liabilities with effective residual maturity of one year or more
95%	■ Stable non-maturity (demand) deposits and term deposits with residual maturity of less than one year provided by retail and small business customers
90%	■ Less stable non-maturity deposits and term deposits with residual maturity of less than one year provided by retail and small business customers
50%	■ Funding with residual maturity of less than one year provided by non-financial corporate customers ■ Operational deposits ■ Funding with residual maturity of less than one year from sovereigns, public sector entities, and multilateral and national development banks ■ Other funding with residual maturity between six months and less than one year not included in the above categories, including funding provided by central banks and financial institutions
0%	■ All other liabilities and equity not included in the above categories, including liabilities without a stated maturity (with a specific treatment for deferred tax liabilities and minority interests) ■ Net Stable Funding Ratio derivative liabilities net of Net Stable Funding Ratio derivative assets if Net Stable Funding Ratio derivative liabilities are greater than Net Stable Funding Ratio derivative assets ■ "Trade date" payables arising from purchases of financial instruments, foreign currencies, and commodities

The rationale for the Net Stable Funding Ratio is that it relates the liquidity needs of the financial institution's assets to the liquidity provided by the funding sources. With assets, for example, loans with long-dated maturities require stable funding whereas highly liquid assets do not. With funding sources, long-dated deposits and other liabilities are considered more stable than short-dated liabilities, and deposits from retail customers are considered more stable than deposits with the same maturity from other counterparties. The standards set a target minimum of greater than 100%.

Among the several liquidity-monitoring metrics described in Basel III,[24] two are discussed here: concentration of funding and contractual maturity mismatch. Concentration of funding refers to the proportion of funding that is obtained from a single source. Excessive concentration of funding exposes a bank to the risk that a single funding source could be withdrawn.

Contractual maturity mismatch refers to the maturity dates of a bank's assets compared to the maturity dates of a bank's funding sources. In a normal yield curve environment, where long-term interest rates are higher than short-term rates, a bank can maximize its net interest income—all else equal—by borrowing short term and lending long term. In doing so, the bank would minimize the interest paid to its

24 Basel Committee on Banking Supervision, "Basel III: A Global Regulatory Framework For More Resilient Banks and Banking System": www.bis.org/publ/bcbs189.pdf.

depositors and maximize interest earned on its loan assets. In excess, however, such maturity mismatches expose the bank to liquidity risk if the bank needs to return cash on its maturing deposits prior to the time that it receives cash repayment of loans from its borrowers. Monitoring maturity mismatch is thus an important tool in liquidity risk management.

EXAMPLE 5

The following excerpts from HSBC's annual report explain the bank's approach to management of its liquidity and funding risk. The disclosures state that the group's principal operating entities were within the risk tolerance levels established by the board for the Liquidity Coverage Ratio, the Net Stable Funding Ratio, depositor concentration, and term funding maturity concentration.

Exhibit 9 Liquidity Disclosure—Excerpts from HSBC's Annual Report

The management of liquidity and funding is primarily undertaken locally (by country) in our operating entities in compliance with the Group's LFRF [liquidity and funding risk management framework], and with practices and limits set by the GMB [Group Management Board] through the RMM [Risk Management Meeting of the Group Management Board] and approved by the Board. Our general policy is that each defined operating entity should be self-sufficient in funding its own activities. Where transactions exist between operating entities, they are reflected symmetrically in both entities.

As part of our asset, liability and capital management structure, we have established asset and liability committees ("ALCO") at Group level, in the regions and in operating entities. . . . The primary responsibility for managing liquidity and funding within the Group's framework and risk appetite resides with the local operating entities' ALCOs, Holdings ALCO and the RMM. . . .

The Liquidity Coverage Ratio ("LCR") aims to ensure that a bank has sufficient unencumbered high-quality liquid assets ("HQLA") to meet its liquidity needs in a 30-calendar-day liquidity stress scenario. HQLA consist of cash or assets that can be converted into cash at little or no loss of value in markets. We reported a Group European Commission ("EC") LCR at 31 December 2016 of 136% (31 December 2015: 116%) to the PRA [UK Prudential Regulation Authority]. . . . At 31 December 2016, all the Group's principal operating entities were within the LCR risk tolerance level established by the Board. . . . The liquidity position of the Group can also be represented by the stand-alone ratios of each of our principal operating entities. . . .

The Net Stable Funding Ratio ("NSFR") requires institutions to maintain sufficient stable funding relative to required stable funding, and reflects a bank's long-term funding profile (funding with a term of more than a year). It is designed to complement the LCR. At 31 December 2016, the Group's principal operating entities were within the NSFR risk tolerance level established by the Board and applicable under the LFRF.

The LCR and NSFR metrics assume a stressed outflow based on a portfolio of depositors within each deposit segment. The validity of these assumptions is challenged if the portfolio of depositors is not large enough to avoid depositor concentration. Operating entities are exposed to term re-financing concentration risk if the current maturity profile results in future maturities being overly concentrated in any defined period. At 31

Exhibit 9 (Continued)

December 2016, all principal operating entities were within the risk tolerance levels set for depositor concentration and term funding maturity concentration. These risk tolerances were established by the Board. . . .

[The table below displays the following liquidity metrics for HSBC's principal operating entities: individual LCR on an EC LCR basis and NSFR.]

Operating Entities' Liquidity Measures

	LCR		NSFR
	Dec-16 (%)	Dec-15 (%)	Dec-16 (%)
HSBC UK liquidity group	123	107	116
The Hongkong and Shanghai Banking Corporation, Hong Kong Branch	185	150	157
The Hongkong and Shanghai Banking Corporation, Singapore Branch	154	189	112
HSBC Bank USA	130	116	120
HSBC France	122	127	120
Hang Seng Bank	218	199	162

HSBC Bank China	253	183	49
HSBC Middle East, UAE Branch	241		141
HSBC Mexico	177		128
HSBC Private Bank	178		155

Source: HSBC Holdings plc Annual Report and Accounts 2016 (pp. 108, 143, and 144).

1 Based on the exhibit, in 2016, which of HSBC's operating entities had the highest level of liquid assets relative to its liquidity needs in a stress scenario?

2 Based on the exhibit, which of HSBC's operating entities had the most stable funding relative to its required need for stable funding?

3 Based on the exhibit, which of HSBC's operating entities is the furthest away from achieving the Basel III target for NSFR?

Solution to 1:

Based on the exhibit, HSBC Bank China had the highest level of liquid assets relative to its liquidity needs in a stress scenario. Its 2016 LCR of 253% is higher than that of any of the other HSBC entities.

Solution to 2:

Based on the exhibit, Hang Seng Bank had the most stable funding relative to its required need for stable funding. Its 2016 NSFR of 162% is higher than that of any of the other HSBC entities.

Solution to 3:

Based on the exhibit, HSBC Bank China is the furthest away from achieving the Basel III standard of NSFR greater than 100%. Its NSFR of 49% is lower than that of any of the other HSBC entities. (It is possible that these metrics result from RMB capital controls in China or jurisdictional issues; however, the example does not provide sufficient information to confirm the reason.)

2.1.6 *Sensitivity to Market Risk*

Almost every entity has some exposure to changes in interest rates, exchange rates, equity prices, or commodity prices. Every company in the United States, for example, is required to provide quantitative and qualitative disclosures in annual filings about exposure to market risk. The nature of banks' operations generally makes sensitivity of earnings to market risks a particularly important consideration for analysts. Mismatches in the maturity, repricing frequency, reference rates, or currency of banks' loans and deposits create exposure to market movements. Further, exposure to risk arises not only from loans and deposits on a bank's balance sheet but also from off-balance-sheet exposures, including, for example, guarantees or derivatives positions linked to interest rates, exchange rates, equities, or commodities. It is important to understand how an adverse change in any of these markets would affect a bank's earnings. It is also important to evaluate the strength of a bank's ability to manage market risks.

Banks disclose information about the sensitivity of earnings to different market conditions—namely, the earnings impact of a shift up or down in some market. Consider a bank's sensitivity to interest rate risk. Even in a purely hypothetical situation of a bank with assets and liabilities that are identical in terms of interest rates, maturity, and frequency of repricing, an increase in interest rates would cause the bank's net interest income to increase. This would occur simply because banks have more assets than liabilities. In reality, of course, the terms of a bank's assets and liabilities differ. Generally, the yield on a bank's loan assets is presumed to be higher than the rate it must pay its depositors, particularly consumer deposits. With respect to term structure, in a typical yield curve environment, longer-dated assets would have a higher yield *ceteris paribus* than shorter-dated funding sources, but another aspect of interest rate sensitivity is repricing frequency. For example, having assets with greater repricing frequency than liabilities would benefit earnings in a rising interest rate scenario. In sum, many structural factors affect interest rate sensitivity.

The following example includes an interest rate sensitivity disclosure showing the earnings impact of an upward and downward shift in interest rates. Disclosures such as these reflect the existing structure of a bank's assets and liabilities.

EXAMPLE 6

Market Risk

The following excerpts from HSBC's annual report explain the bank's approach to monitoring its market risk and illustrates one of the tools used by the bank: sensitivity analysis.

Exhibit 10 Excerpt from HSBC's Annual Report

Our objective is to manage and control market risk exposures while maintaining a market profile consistent with our risk appetite. We use a range of tools to monitor and limit market risk exposures including sensitivity analysis, value at risk and stress testing.

Exhibit 10 (Continued)

The following table sets out the assessed impact on our base case projected net interest income ("NII") for 2016 (excluding insurance) of a series of four quarterly parallel shocks of 25 basis points to the current market-implied path of interest rates worldwide at the beginning of each quarter from 1 January 2017. . . .

The sensitivities shown represent our assessment as to the change in expected base case net interest income under the two rate scenarios, assuming that all other non-interest rate risk variables remain constant, and there are no management actions. . . .

We expect NII to rise in the rising rate scenario and fall in the falling rate scenario. This is due to a structural mismatch between our assets and liabilities (on balance we would expect our assets to reprice more quickly, and to a greater extent, than our liabilities).

Net Interest Income Sensitivity (Audited)

	US dollar bloc ($m)	Rest of Americas bloc ($m)	Hong Kong dollar bloc ($m)	Rest of Asia bloc ($m)	Sterling bloc ($m)	Euro bloc ($m)	Total ($m)
Change in 2016 net interest income arising from a shift in yield curves of:							
+25 basis points at the beginning of each quarter	**605**	**47**	**504**	**280**	**61**	**212**	**1,709**
−25 basis points at the beginning of each quarter	**−1,024**	**−41**	**−797**	**−292**	**−261**	**9**	**−2,406**

Source: HSBC Holdings plc Annual Report and Accounts 2016 (pp. 78 and 117).

1 Based on the exhibit, by how much would HSBC's planned net interest income decrease if the yield curves shifted downward by 25 basis points at the beginning of each quarter for four quarters?

2 If a decrease in interest rates would hurt the earnings of banks such as HSBC, why would central banks lower interest rates so significantly following the financial crisis in order to prop up the financial sector?

Solution to 1.

HSBC's planned net interest income would decrease by $2,406 million if the yield curves shifted downward by 25 basis points at the beginning of each quarter.

Solution to 2.

An interest rate sensitivity table such as the one presented by HSBC is a static presentation and thus assumes that the relation between the structure of assets and liabilities in place at the time would remain stationary. Following the financial crisis, the central banks' actions reduced interest rates at which banks could borrow (effectively, to near zero), while the rates that banks were able to charge their loan customers were—while still low—far higher than their borrowing costs. Further, the central banks' actions were not intended solely to prop up banks' earnings but also to provide liquidity and stimulus to the overall economy.

As described in the example, another tool that HSBC uses to measure and monitor market risk is value at risk (VaR). Recall that VaR is a way to estimate the amount of potential loss based on simulations that incorporate historical pricing information. HSBC estimates its VaR using a 99% confidence level, a one-day holding period, and two prior years of pricing data on foreign exchange rates, interest rates, equity prices, commodity prices, and associated volatilities.

3 ANALYZING A BANK: NON-CAMELS FACTORS

d describe other factors to consider in analyzing a bank;

e analyze a bank based on financial statements and other factors;

While the CAMELS approach to assessing bank soundness is fairly comprehensive, there are important bank-specific attributes that it does not completely address. There are also important attributes not addressed by the CAMELS approach that apply to both banks and other types of companies.

3.1 Banking-Specific Analytical Considerations Not Addressed by CAMELS

The CAMELS acronym is useful as a composite of major factors, but it is neither comprehensive nor comprehensively integrated. Also, the ordering of the factors does not signify importance. For example, strong capital (the "C") and strong liquidity (the "L") are equally important in the Basel III standards.[25]

The following bank attributes are either unaddressed or not fully addressed by a CAMELS analysis:

- **Government support.** Governments do not normally strive to save a company or even an entire industry that may be facing failure. In capitalist societies, failure is the unfortunate occasional by-product of risk taking with capital, and bankruptcy laws and courts serve to administer the results of failed capital allocation. The banking industry is different from other industries, however, regarding government support. It is in a government's interest to have a healthy banking system because a nation's economy is affected by banks' lending activity, and a nation's central bank needs a healthy banking system for the effective transmission of monetary policy. A healthy banking system also facilitates commerce by providing adequate payment processing and instilling depositor confidence in the safekeeping of their deposits.

  Government agencies monitor the health of banks in the entire system and will close banks that might fail or will arrange mergers with healthy ones able to absorb them. This pruning activity addresses issues with banks that might otherwise weaken the banking system if left unattended. Alternatively, governments may directly assist banks to keep them afloat rather than closing them or

25 Basel Committee on Banking Supervision, "Basel III: A Global Regulatory Framework For More Resilient Banks and Banking System" (December 2010, p. 8, item B.34): www.bis.org/publ/bcbs189.pdf.

arranging for mergers with healthier banks. Visible examples of both assisting and pruning activities occurred during the financial crisis of 2008. For example, the US Treasury created the Troubled Asset Relief Program (TARP) to purchase loans held by banks and to provide equity injections to the banks. During the same period, the Treasury also arranged numerous mergers among banking giants, leading to even bigger banking giants.

CAMELS analysis will not provide an assessment of government support, but an investor can qualitatively assess whether a bank will enjoy the support of the government in times of economic distress. The following are factors to consider:

- *Size of the bank.* Is the bank large enough to bring damage to a significant part of the economy in the event of its failure? Is it "too big to fail"?
- *Status of the country's banking system.* Is the nation's banking system healthy enough to handle a particular bank's failure? Rather than force the banking system to cope with the failure of a particular bank, would it be a better solution for the government to intervene with taxpayer funds to support it? The global financial crisis of 2008–2009 led the US Federal Reserve to develop the concept of SIFIs: systemically important financial institutions, ones that would pose a significant risk to the economy in the event of a failure. Such institutions have been the target of an increased degree of regulation in the post-crisis era.

- **Government ownership.** Public ownership of banks may include a strong ownership representation by the government of their home country. Government ownership may exist for several reasons. A "development" view of government ownership incorporates a belief that government ownership aids financial development of the banks, leading to broad economic growth. A more pessimistic view is that a nation's banking system is not strong enough to stand on its own and attract large amounts of capital, because of low ethical standards within the industry or a lack of confidence in the banking system among the nation's public at large—an important source of funds for any bank.[26]

  Whatever the reason may be for a government's ownership stake in a bank, its presence adds another dimension of security for a bank investor. A government that owns a stake in a bank is likely to intervene on the bank's behalf in the event of economic distress. Conversely, a government that plans to reduce its ownership stake in a bank may directly reduce that dimension of security; however, that may not always be the case. During the global financial crisis of 2008–2009, some governments became reluctant owners of banks, which were ultimately supported by taxpayer funding. When government ownership of such banks was reduced after the crisis ended, markets viewed the reduction as a signal of renewed strength.

- **Mission of banking entity.** Not all banks share the same mission. For example, community banks primarily serve the needs of the immediate community in which they operate. That community's welfare could be driven by an economy based on farming, mining, or oil or could depend on a single large manufacturing entity. The fortunes of the banks and their borrowers and depositors would depend on economic factors that affect the primary industry or employer. Contrast that situation with a global banking entity absorbing deposits from all around the world while investing globally as well. The global bank is more diversified against a single risk than any community bank.

26 Rafael La Porta, Florencio Lopez-de-Silanes, and Andrei Shleifer, "Government Ownership of Banks," NBER Working Paper No. 7620 (March 2000).

The mission of the bank and the economics of its constituents will affect the way the bank manages its assets and liabilities. That is a qualitative assessment that the bank investor needs to make, and it is not addressed by a CAMELS analysis.

- **Corporate culture.** A bank's culture may be very risk averse and cautious and make only loans perceived to be low risk, or alternatively, it may be risk seeking and willing to take risk in pursuit of high returns on investment. Or a bank's culture may be somewhere in the middle of those two extremes. An overly cautious culture may be too risk averse to provide adequate returns to shareholders for taking on the risk of ownership. A highly risk-hungry culture may lead to boom and bust results and volatility. Differences in the cultural environment are particularly important for banks operating in multiple countries, where there may be a disconnect between corporate culture and national culture.

  A bank investor can qualitatively assess a bank's cultural environment by considering factors such as these:

  - Has the bank generated recent losses resulting from a narrowly focused investment strategy, such as a large, outsized exposure to a particularly risky country or area of the economy?
  - Has the bank restated its financial statements owing to financial reporting internal control failures?
  - Does the bank award above-average equity-based compensation to its top managers, possibly incentivizing risk-taking behavior and short-termism?
  - What does the bank's experience with loss reserves say about its culture? Has it frequently been slow to provide for losses, only to record large asset write-downs later?

3.2 Analytical Considerations Not Addressed by CAMELS That Are Also Relevant for Any Company

There are other factors relevant to the analysis of a bank—and to any kind of company—that are not covered by the CAMELS approach. The following factors merit consideration by debt and equity investors in banks as well as investors in non-banking entities:

- **Competitive environment.** A bank's competitive position, relative to its peers, may affect how it allocates capital and assesses risks; it may also affect the aforementioned cultural mindset. A regional bank may have a near-monopolistic hold on a particular region and not take very many risks beyond maintaining its grip. A global bank may be affected by the actions of other global banks. Managers of a global bank may not be satisfied with following the lead of other banks and may pursue ambitious goals of growing market share at all costs and with little regard for risks, or they may be content with more profitable but slower growth. It depends on how the bank's managers perceive their competitive position and how they will react to the perception.
- **Off-balance-sheet items.** Off-balance-sheet assets and liabilities pose a risk to entities and their investors if they should unexpectedly drain resources. The global financial crisis of 2008–2009 was hastened by the Lehman Brothers bankruptcy, and the opacity of their involvement with such financial instruments as credit derivatives prevented concise pre-crisis analysis of the risks they shouldered. However difficult to examine, off-balance-sheet exposures need consideration whenever one analyzes a bank or financial institution.

Not all off-balance-sheet items involve exotic or highly engineered financial instruments. Operating leases are a low-risk example of off-balance-sheet liabilities: They are not a recognized liability of a company, yet they provide a creditor with a claim on a company's future cash flows. Fortunately, visibility into such future obligations is easily accessed by investors in the lease footnotes.

A financial institution analyst should be alert to the existence in the financial statements of an accounting construct known as variable interest entities, or VIEs. Variable interest entities are a form of "special-purpose entity" usually formed solely for one purpose: perhaps to hold only certain assets or assets that may be financed with specific debt instruments. Before the accounting for variable interest entities was developed, companies sometimes used outside parties to take a majority ownership stake in the special-purpose entity, ensuring that they would not have to consolidate the special-purpose entity's assets and liabilities. The accounting standard setters developed the VIE model to capture the consolidation of such special-purpose entities. By meeting generalized criteria for consolidation apart from clearly defined equity ownership tests, a company that is the primary beneficiary of a VIE's existence may be required to consolidate the VIE's financial statements with its own, even if it has no equity ownership in it. Yet a variable interest entity may also result in off-balance-sheet assets and liabilities for a bank if the bank has an interest in the VIE but is not required to consolidate it. If the VIE is not consolidated with the bank, its existence and certain financial information must be disclosed. Those non-consolidated VIEs should be of interest to investors: The reasons given for non-consolidation should be examined for reasonableness, and the implications to the bank of various scenarios affecting the VIE should be considered.

Benefit plans are another "off-balance-sheet" item for investors to examine. Although these are not completely off-balance-sheet items because the net benefit plan assets or obligations appear on the balance sheet, the economics that drive them are different from the bank's business. Shortfalls in assets due to market performance can cause rapid increases in required contributions to plans. Interest rate decreases, which drive plan obligations higher, can also cause rapid cash drains for required contributions to plans. Bank investors should examine benefits plan footnotes to determine the degree of risk posed by such plans.

One particular off-balance-sheet item that is found in financial companies only—sometimes in banks—is assets under management (AUM). Banks may have trust departments that generate management fees based on the assets under management. Those assets belong to the clients and are not consolidated with a bank's balance sheet accounts, yet they drive the returns of the bank. If such returns are material to a bank's results, the bank investor should be concerned with the size and growth or decline in assets under management.

- **Segment information.** Banks may be organized in different lines of business. They can be organized according to domestic and foreign markets; they can be organized along consumer or industrial lines of business; they may offer financial services, such as leasing or market making in securities; and they may have related businesses that are not strictly banking driven, such as trust operations. Regardless of the lines of business a bank (or any other company) may pursue, segment information should illustrate the information used by the chief operating decision maker in the entity. That information can help the investor decide whether capital is being allocated well within the bank's internally competing operations.

- **Currency exposure.** Although it may not be a problem for smaller, regional banks that operate in a single currency, floating currency exchange rates can create problems for global banks. Banks may finance and lend in a variety of currencies, resulting in foreign currency transaction exposure. Large banks may actively trade in foreign currencies and actively hedge using foreign exchange derivatives, leading to unforeseen gains or losses when world events affect currencies unexpectedly; not all banks may be successful currency traders. Global banks face the same balance sheet translation issues that affect other multinational corporations. When a bank's home currency strengthens against the functional currencies of its foreign subsidiaries, the translation of balance sheet accounts at the end of an accounting period may lead to currency translation adjustments that can reduce capital.
- **Risk factors.** Investors should review the risk factors presented in a company's annual filing. Sometimes derided as a mere list of worst-case scenarios created by a company's legal counsel, the risk factors section of a company's filing can also fill gaps in an investor's knowledge about legal and regulatory issues that might not otherwise be uncovered.
- **Basel III disclosures.** The Basel III requirements include extensive disclosures that complement the minimum risk-based capital requirements and other quantitative requirements with the goal of promoting market discipline by providing useful regulatory information to investors and other interested parties on a consistent, comparable basis.[27]

4 ANALYZING A BANK: EXAMPLE OF CAMELS APPROACH

c explain the CAMELS (capital adequacy, asset quality, management, earnings, liquidity, and sensitivity) approach to analyzing a bank, including key ratios and its limitations;

e analyze a bank based on financial statements and other factors;

This section illustrates the CAMELS approach using Citigroup's financial statements as an example. The CAMELS approach is based on the evidence gathered by the analyst in assessing each CAMELS component, and this evidence will vary from investor to investor. Some aspects of the CAMELS approach will matter more to certain investors than others: An equity investor may be far more concerned with earnings and earnings quality than with capital adequacy. A fixed-income investor might be far more concerned with capital adequacy and liquidity than earnings. The interests of each type of investor will determine what kind of analysis they perform to assess each CAMELS component. The following example of Citigroup is not intended to show all possible analyses.

It should also be understood that although the CAMELS approach entails quantitative aspects, it is not a wholly formulaic approach to analyzing a bank. An analyst's judgment and discretion also matter greatly in the application of the CAMELS approach. Judgment and discretion figure into the kind of testing done by an investor

27 Basel Committee on Banking Supervision, "Standards: Revised Pillar 3 Disclosure Requirements" (January 2015, p. 3): https://www.bis.org/bcbs/publ/d309.pdf.

to gather evidence for the various CAMELS components, and judgment and discretion also figure into the rating of the various CAMELS components once the evidence has been reviewed.

The following sections present examples of the relevant information for each component and conclude with a summary assessment. In each case, the summary assessment includes a rating, where a rating of 1 is the highest and a rating of 5 is the lowest.

4.1 Capital Adequacy

As noted above, capital adequacy relates to the proportion of a bank's assets funded by capital, with the assets accorded varying risk weightings. Not only are assets stratified into risk classes, but the bank capital funding those assets is also stratified into tiers: Common Equity Tier 1 Capital, Total Tier 1 Capital, and Tier 2 Capital.

Common Equity Tier 1 Capital includes common stock, issuance surplus related to common stock, retained earnings, accumulated other comprehensive income, and certain adjustments, including the deduction of intangible assets and deferred tax assets.

Exhibit 11 shows the calculation of Citigroup's Common Equity Tier 1 Capital, Risk-Weighted Assets, and Common Equity Tier 1 Capital Ratio at the end of 2016 and 2015. Citigroup's ratio is well within the required limits in both years. The ratio declined slightly in 2016, from 14.60% to 14.35%. The decline in the ratio is mostly attributable to the increase in deferred tax assets disallowed in the computation of Common Equity Tier 1 Capital.

Exhibit 11 Components of Citigroup Common Equity Tier 1 Capital under Current Regulatory Standards (Basel III Advanced Approaches with Transition Arrangements)

(In millions of dollars)	31 Dec. 2016	31 Dec. 2015
Citigroup common stockholders' equity	$206,051	$205,286
Add: Qualifying non-controlling interests	259	369
Regulatory capital adjustments and deductions:		
Less: Net unrealized gains (losses) on securities available for sale (AFS), net of tax	(320)	(544)
Less: Defined benefit plan liability adjustment, net of tax	(2,066)	(3,070)
Less: Accumulated net unrealized losses on cash flow hedges, net of tax (4)	(560)	(617)
Less: Cumulative unrealized net gain (loss) related to changes in fair value of financial liabilities attributable to own creditworthiness, net of tax	(37)	176
Less: Intangible assets:		
Goodwill, net of related deferred tax liabilities	20,858	21,980
Identifiable intangible assets other than mortgage servicing rights (MSRs), net of related deferred tax liabilities	2,926	1,434
Less: Defined benefit pension plan net assets	514	318
Less: Deferred tax assets (DTAs) arising from net operating loss, foreign tax credit, and general business credit carry-forwards	12,802	9,464
Less: Excess over 10%/15% limitations for other DTAs,certain common stock investments, and mortgage servicing rights	4,815	2,652
Total Common Equity Tier 1 Capital	$167,378	$173,862
Risk-Weighted Assets under Current Regulatory Standards:		
Credit risk	$773,483	$791,036
Market risk	64,006	74,817

(continued)

Exhibit 11 (Continued)

(In millions of dollars)	31 Dec. 2016	31 Dec. 2015
Operational risk	329,275	325,000
Total risk-weighted assets	$1,166,764	$1,190,853
Common Equity Tier 1 Capital Ratio (Tier 1 Capital/Total risk-weighted assets)	**14.35%**	**14.60%**
Stated minimum Common Equity Tier 1 Capital Ratio	4.50%	4.50%

Total Tier 1 Capital includes other instruments issued by the bank that meet certain criteria based on their subordination to deposit and other debt obligations, bear no fixed maturity, and carry no requirement to pay dividends or interest without full discretion of the bank. Preferred stocks can be constructed to meet these criteria.

Exhibit 12 shows the calculation of Citigroup's Total Tier 1 Capital and Total Tier 1 Capital Ratio at the end of 2016 and 2015. Again, Citigroup's ratio is well within the required limits in both years. The ratio improved in 2016, from 14.81% to 15.29%. The increase in this ratio is mostly attributable to additional perpetual preferred stock qualifying for inclusion in 2016 and the decrease in the amount of deferred tax assets disallowed in the computation of Total Tier 1 Capital.

Exhibit 12 Components of Citigroup Total Tier 1 Capital under Current Regulatory Standards (Basel III Advanced Approaches with Transition Arrangements)

(In millions of dollars)	31 Dec. 2016	31 Dec. 2015
Common Equity Tier 1 Capital (from Exhibit 11)	$167,378	$173,862
Additional Tier 1 Capital:		
Qualifying perpetual preferred stock	19,069	16,571
Qualifying trust preferred securities	1,371	1,707
Qualifying non-controlling interests	17	12
Regulatory capital adjustments and deductions:		
Less: Cumulative unrealized net gain (loss) related to changes in fair value of financial liabilities attributable to own creditworthiness, net of tax	(24)	265
Less: Defined benefit pension plan net assets	343	476
Less: DTAs arising from net operating loss, foreign tax credit and general business credit carry-forwards	8,535	14,195
Less: Permitted ownership interests in covered funds	533	567
Less: Minimum regulatory capital requirements of insurance underwriting subsidiaries	61	229
Total additional Tier 1 Capital	$11,009	$2,558
Total Tier 1 Capital (Common Equity Tier 1 Capital + Additional Tier 1 Capital)	$178,387	$176,420
Total risk-weighted assets (from Exhibit 11)	$1,166,764	$1,190,853
Tier 1 Capital Ratio	**15.29%**	**14.81%**
Minimum Tier 1 Capital Ratio	6.00%	6.00%

Tier 2 Capital includes, on a limited basis, portions of the allowance for loan and lease losses and other instruments that are subordinate to depositors and general creditors. Exhibit 13 shows the calculation of Citigroup's Tier 2 Capital and Total Capital Ratio at the end of 2016 and 2015. Consistent with the Common Equity Tier 1 Capital Ratio and the Total Tier 1 Capital Ratio, the 2016 Total Capital Ratio far exceeds the minimum requirement. The Total Capital Ratio improved from the 2015 level, from 16.69% to 17.33%. The improvement was mostly due to the increase in Total Tier 1 Capital and the amount of qualifying subordinated debt.

Exhibit 13 Components of Citigroup Tier 2 Capital under Current Regulatory Standards (Basel III Advanced Approaches with Transition Arrangements)

(In millions of dollars)	31 Dec. 2016	31 Dec. 2015
Total Tier 1 Capital (Common Equity Tier 1 Capital + Additional Tier 1 Capital)	$178,387	$176,420
Qualifying subordinated debt	22,818	21,370
Qualifying trust preferred securities	317	0
Qualifying non-controlling interests	22	17
Excess of eligible credit reserves over expected credit losses	660	1,163
Regulatory capital adjustments and deductions:		
Add: Unrealized gains on AFS equity exposures includable in Tier 2 Capital	3	5
Less: Minimum regulatory capital requirements of insurance underwriting subsidiaries	61	229
Total Tier 2 Capital	$23,759	$22,326
Total Capital (Tier 1 Capital + Tier 2 Capital)	$202,146	$198,746
Total risk-weighted assets	$1,166,764	$1,190,853
Total Capital Ratio	**17.33%**	**16.69%**
Minimum Capital Ratio	**8.00%**	**8.00%**

In summary, Citigroup's capital adequacy at the end of 2016 appears to be solidly positive. For each of the three chief capital ratios, the company has exceeded the minimum levels required for being considered to be a well-capitalized bank. A rating of 1 could be justified by their ratios, which far exceeded the minimum levels.

4.2 Asset Quality

Asset quality matters greatly to a bank. As financial intermediaries in an economy, banks owe their existence to the creation of loans. If a bank's credit policies are unsound, its capital base can be quickly eroded during economic downturns, creating strains on the bank's liquidity and its ability to generate earnings. Creating new loans becomes problematic.

A portion of bank assets are held in highly liquid financial instruments, such as cash, deposits held at other banks, and instruments that may convert into cash in a very short time frame, such as repurchase agreements and some receivables. These are not highly risky assets.

Increasing in riskiness are the investments made by the bank in financial instruments with cash deemed to be in excess of operating needs. Under US GAAP and IFRS, these investments may be classified as available-for-sale investments, which are reported at fair value, or held-to-maturity investments, which are reported at their amortized cost unless an impairment occurs. While these investments are riskier than the liquid securities and reflect an investment decision made by management, their value is quite transparent and their reported value reflects their realizability in cash—although it takes more analytical effort to make that assertion for held-to-maturity securities.

The riskiest, and often the largest, asset classes are the loans underwritten by the bank. Loans embody credit risk and the judgment of management in extending credit to customers. The underwriting risks and the management judgments in assessing them are reflected in the allowance for loan losses. It is here that the analyst faces some of the most difficult assessments in understanding the quality of banking assets and is at a disadvantage, because some information simply is unavailable to an analyst (or investor). Conversely, an examiner for a supervisory regulator has the ability to see the bank from the inside and assess the soundness of loan (and investment) policies and procedures. An examiner may also review the construction and workings of internal control procedures and may be able to examine how exceptions to credit policies are being handled.[28]

Although the analyst is interested in all of those inner workings, he/she can be concerned only with circumstantial evidence that the credit policies are sound and are being maintained. That circumstantial evidence can be found in the financial statements, but it is not completely obvious from merely looking at a balance sheet. There are ways to find evidence of asset quality, as will be shown with Citigroup. Exhibit 14 shows the asset side of Citigroup's balance sheet on a condensed basis at the end of 2016 and 2015.

Exhibit 14 Citigroup Asset Composition, 31 December 2016 and 2015

	31 December 2016		31 December 2015	
(In millions of dollars)	$	% Total Assets	$	% Total Assets
Liquid assets:

28 See Section 3.1 of the FDIC's "RMS Manual of Examination Policies," available at https://www.fdic.gov/regulations/safety/manual/section3-1.pdf.

Exhibit 14 (Continued)

	31 December 2016		31 December 2015	
(In millions of dollars)	$	% Total Assets	$	% Total Assets
Allowance for loan losses	(12,060)	*−0.7%*	(12,626)	*−0.7%*
Total loans, net	612,309	*34.2%*	604,991	*35.0%*
Goodwill	21,659	*1.2%*	22,349	*1.3%*
Intangible assets (other than MSRs)	5,114	*0.3%*	3,721	*0.2%*
Mortgage servicing rights (MSRs)	1,564	*0.1%*	1,781	*0.1%*
Other assets	128,008	*7.1%*	133,743	*7.7%*
Total assets	$1,792,077	*100.0%*	$1,731,210	*100.0%*

Observations from the composition of the assets:

- Citigroup's liquid assets are the largest single group of all, at 37.4% in 2016, and slightly greater than the year before, indicating greater liquidity.
- The proportion of investments to total assets of 19.7% is practically unchanged from 2015; the majority of the investments are available-for-sale securities reported at fair value.
- Consumer and corporate loans are the highest-risk assets and in both years amount to more than one-third of all assets. They are the second largest class of assets after the liquid assets.

In assessing asset quality, an analyst would want to focus on the riskiest assets in the mix: the investments and the loans. He or she would want to determine that the investments, while transparent in value, represent sound investment decisions and that the loans result from similarly reasoned underwriting policies. The analyst would want assurance that the stated amount of loans is collectible and that the allowance for loan losses is reasonably stated.

First, take a look at the investments. Exhibit 15 shows Citigroup's available-for-sale securities by class at the end of 2016. Exhibit 15 was extracted from Note 13 of the 2016 10-K, which showed the amortized cost by investment instrument, gross unrealized gains, gross unrealized losses, and fair value as stated in the balance sheet. Added to the table were the gross unrealized gains and losses expressed as a percentage of amortized cost, which is the amount invested.

Asset-backed securities	6,810	6	22	6,794	*0.1%*	*0.3%*
Other debt securities	503	—	—	503	*0.0%*	*0.0%*
Total debt securities AFS	$299,892	$1,701	$2,560	$299,033	*0.6%*	*0.9%*
Marketable equity securities AFS	$377	$20	$6	$391	*5.3%*	*1.6%*
Total securities AFS	$300,269	$1,721	$2,566	$299,424	*0.6%*	*0.9%*

The fair value ($299,424 million) is less than the amortized cost ($300,269 million) in the aggregate, and the net difference is $845 million; the largest contributor to that loss is the state and municipal obligations, with a $757 million loss. At a 7% loss in value, those were the only securities to generate losses greater than 2%.

Observations from the AFS securities valuation table:

- Although Citigroup has not generated a net winning strategy with its available-for-sale investments, its losses do not suggest reckless abandon.
- In future years, new US GAAP standards will eliminate the AFS classification for marketable equity securities. They will still be measured at fair value, just as they were measured at year end 2016. Starting in 2018, however, the gains and losses resulting from remeasurement will be shown directly in the income statement instead of being recorded in other comprehensive income. As of 31 December 2016, Citigroup's unrealized gains on its AFS equity investments exceeded its unrealized losses. Based on market values at that point in time, the reclassification would benefit the group's income.

A closer look at the gross unrealized losses is possible, because Note 13 also contains a simple aging of the losses: It shows how much of the $2.566 billion of unrealized losses are less than 12 months old and how much of the losses are 12 months old or older, by category. The longer a loss position exists, the greater the possibility that a security is impaired on an "other-than-temporary" basis. It would be unusual for losses to exist for long periods of time and then suddenly reverse.

The aging for the losses in Citigroup's available-for-sale securities is shown in Exhibit 16. Observations from the aging of AFS unrealized losses table:

- A slight majority (54%) of the losses are less than 12 months old, making them of less concern than the rest.
- Of the $1.172 billion of gross unrealized losses 12 months old or older, 60% ($702 million) are related to state and municipal securities, which raises a concern that the largest class of losses may in fact become realized.

Exhibit 16 Citigroup Aging of Unrealized Losses on Available-for-Sale Securities at 31 December 2016

	Less than 12 months		12 months or longer		Total	
(In millions of dollars)	Fair value	Gross unrealized losses	Fair value	Gross unrealized losses	Fair value	Gross unrealized losses
Mortgage-backed securities

Total securities AFS	$122,278	$1,394	$22,358	$1,172	$144,636	$2,566

A similar analysis can be done for the held-to-maturity (HTM) securities. Even though they represent a much smaller proportion of total assets, they still provide evidence of the manager's investment acumen. The result of the HTM securities review of the losses and aging of the losses is consistent with the results of the available-for-sale securities review. Though not presented in exhibits because of space limitations, Citigroup's unrealized losses on its HTM securities totaled $457 million, which is 1.3% of the amount invested. Of that $457 million loss in value, 82% ($373 million) stemmed from held-to-maturity securities that were showing losses older than 12 months, of which $180 million related to state and municipal securities.

Observations on the HTM securities:

- The losses on the HTM securities are much less in dollar amount than the losses on the AFS securities, and although they are minor in percentage terms of a loss, they are troubling because of their age. Problem assets do not usually improve with age, and the fact that the bulk of the losses on the HTM securities are older than 12 months may indicate management reluctance to report economic reality.

- Because HTM securities are reported at amortized cost on the balance sheet, the classification obscures the fair value of the securities. The age of the securities generating the losses indicates that there may be more severe impairment than already recognized. The analysis of the HTM securities reinforces the observations noted in the analysis of the available-for-sale securities review.

Investment assets are not as significant in amount or as risky as the loans. The analyst wants to determine that the loans are the result of a sound credit policy and will be realized over their term. This cannot be determined without analyzing the allowance for loan losses. As was seen in Exhibit 14, **allowance for loan losses** is a balance sheet account; it is a contra asset account to loans. (It is analogous to an account common for non-financial institutions, allowance for bad debts, which is a contra asset account to accounts receivable.) **Provision for loan losses** is an income statement expense account that increases the amount of the allowance for loan losses. Actual loan losses (i.e., charge-offs—net of recoveries) reduce the amount of the allowance for loan losses.

The allowance for loan losses matters greatly to understanding loan quality, because total loans minus the allowance for loan losses represents the expected value of the loans. A bank's balance sheet will typically show the total amount of loans, the amount of allowance for loan losses, and the net amount. Importantly, the allowance for loan losses is discretionary by its very nature. Underestimating the allowance for loan losses would overstate the amounts reported for assets and net income. Almost every bank will disclose allowances for loan losses among its most critical accounting estimates.

To effectively assess the adequacy of the allowance for loan losses, an analyst can examine measures that involve less management discretion. Net charge-offs of loans are less discretionary indicators of loan quality than the allowance for loan losses but have the disadvantage of being a confirming event: The loan has already turned out to be a non-performing asset. Another disadvantage is that net charge-offs can be used in good times to pack away earnings to be brought into earnings later through recoveries of charge-offs. Non-performing loans are another measure that can help in assessing adequacy of the allowance for loan losses. Non-performing (i.e., non-accrual) loans are loans that are not currently paying their contractual amounts due, making them a more objective measure of the quality of loans in the portfolio.

Three ratios are helpful in assessing the quality of the allowance for loan losses:

- The ratio of the allowance for loan losses to non-performing loans
- The ratio of the allowance for loan losses to net loan charge-offs
- The ratio of the provision for loan losses to net loan charge-offs

In each ratio, a discretionary measure (such as the allowance for loan losses or provision for loan losses) is compared to a more objective measure.[29] In the case of Citigroup, the loans and the allowance for loan losses are stratified between consumer loans and corporate loans. Because the types of loan customers differ greatly, the analysis of each should be performed separately. Exhibit17 shows the variables required to compute the ratios for the last five years, selected from the management discussion and analysis of the relevant 10-Ks, and the resulting ratios.

29 For more discussion on the analysis of the allowance of loan loss reserves, see Stephen G. Ryan, *Financial Instruments and Institutions: Accounting and Disclosure Rules* (Hoboken, NJ: Wiley, 2002): 100–105.

Exhibit 17 Citigroup's Loan Loss Analysis Data at 31 December

(In millions of dollars)	2016	2015	2014	2013	2012
Data for Calculating Allowance for Loan Loss Ratios					
Allowance for loan losses:					
Consumer	$9,358	$9,835	$13,547	$16,974	$22,585
Corporate	$2,702	$2,791	$2,447	$2,674	$2,870
Provision for loan losses:					
Consumer	$6,323	$6,228	$6,695	$7,587	$10,312
Corporate	$426	$880	$133	$17	$146
Charge-offs:					
Consumer	$7,644	$8,692	$10,650	$12,400	$16,365
Corporate	$578	$349	$458	$369	$640
Recoveries:					
Consumer	$1,594	$1,634	$1,975	$2,138	$2,357
Corporate	$67	$105	$160	$168	$417
Net charge-offs:					
Consumer	$6,050	$7,058	$8,675	$10,262	$14,008
Corporate	$511	$244	$298	$201	$223
Non-accrual loans:					
Consumer	$3,158	$3,658	$5,905	$7,045	$9,136
Corporate	$2,421	$1,596	$1,202	$1,958	$2,394
Allowance for Loan Loss Ratios					
Allowance for loan losses to non-accrual loans:					
Consumer	2.96	2.69	2.29	2.41	2.47
Corporate	1.12	1.75	2.04	1.37	1.20
Allowance for loan losses to net loan charge-offs:					
Consumer	1.55	1.39	1.56	1.65	1.61
Corporate	5.29	11.44	8.21	13.30	12.87
Provision for loan losses to net loan charge-offs:					
Consumer	1.05	0.88	0.77	0.74	0.74
Corporate	0.83	3.61	0.45	0.08	0.65

Observations on the allowance for loan losses to non-accrual loans, which are loans that have experienced some non-payment from borrowers:

- For the consumer loans, the 2016 ratio of 2.96 is the highest level in the last five years, and this ratio has been increasing in the last two years. It indicates that the allowance (a discretionary amount) is increasing faster than the actual non-accrual loans, lending confidence to analysts that the allowance is being built in advance of loans turning out poorly.
- For the corporate loans, the 2016 ratio of 1.12 is less definitive. It might be expected that the ratio would be more volatile than for the consumer business because the corporate lending business is not homogeneous, and specific credits and their failures could cause spikes in the ratio. Still, the allowance has

declined in each of the last three years, and in 2016, it is at its lowest point in five years. This arouses concern that the allowance for loan losses may be a thin layer of protection against future losses.

Observations on the allowance for loan losses to net loan charge-offs:

- For the consumer loans, the 2016 ratio of 1.55 shows improvement from 2015 and indicates that there is a cushion between the allowance and the net loan charge-offs that has remained fairly constant over the last five years.
- For the corporate loans, the 2016 ratio of 5.29 shows an ample cushion between the allowance and the net loan charge-offs, although it declined greatly from 2015 and is much lower than at any time in the last five years.

Observations on the provision for loan losses to net loan charge-offs:

- The provision for loan losses is the amount added to the allowance each year, and one should expect that the provision correlates to the amount of net loan charge-offs.
- For the consumer loans, the 2016 ratio is the first ratio in five years where the provision exceeded the net loan charge-offs, and although it had been lower in the previous four years, the proportion of the provision to charge-offs had been increasing in the last three years. This indicates that the bank had become more conservative in its provisioning.
- For the corporate loans, the 2016 ratio significantly decreased from the previous year, and the ratio has been less than 1.0 in four of the last five years. This indicates that the provision for corporate loans has trailed the actual net charge-off experience. The large addition in 2015 gives the appearance of an urgent "catch-up" adjustment.

In summary, Citigroup's asset quality at the end of 2016 was mixed. The policies for investments appear to be fairly conservative, but the age of some of the investments with unrealized losses indicates a possible denial of impairment. With regard to loan quality, the ratio analysis of the allowance for loan losses suggests that the consumer loans appear to be well reserved, but the same ratio analysis for the corporate loans does not generate the same degree of comfort. A rating of 2.5—near the midpoint of the rating scale—could be assigned to the asset quality based on the mixed signals from the evidence.

4.3 Management Capabilities

External investors can observe only circumstantial evidence of management's quality. Some circumstantial evidence can be found through a review of the proxy statement.

Observations based on a review of Citigroup's 2016 proxy:

- Citigroup aims for two-thirds board representation of independent members, whereas the New York Stock Exchange requires only a majority of independent members.
- Citigroup has a separate CEO and chairman, often viewed as a good governance practice that avoids conflicts of interest. The positions have been separate since 2009.
- Citigroup's Risk Management Committee met frequently in 2016—14 times—providing evidence of attention to one of the most critical parts of a banking operation. Furthermore, the Risk Management Committee created a subcommittee in 2016 to provide oversight of data governance, data quality, and data integrity, and the subcommittee met seven times in 2016.

Although these are good practices, they do not constitute evidence of strong management capabilities. Rather, they provide evidence that an environment exists where strong management quality is permitted to flourish.

With a company as large as Citigroup, it is difficult to avoid related-party transactions. For example, BlackRock and Vanguard beneficially owned 5% or more of the outstanding shares of Citigroup's common stock as of 31 December 2016; during 2016, the company's subsidiaries provided ordinary course lending, trading, and other financial services to BlackRock and Vanguard. The proxy states that the transactions were on an arm's-length basis and contain customary terms that are substantially the terms of comparable transactions with unrelated third parties. Other related-party transactions exist and are discussed in the 10-K, but they are routine for a company of this size.

In terms of operational risk, evidence of the board's influence on management can be found in the unqualified opinion of Citigroup's auditor on the effectiveness of the system of internal controls. This is evidence of a minimally satisfactory environment in which a management should operate and not a clear signal of management competence. A qualified (or negative) opinion on the effectiveness of internal controls would be especially concerning for an investor.

In summary, although the board may be solidly constructed and appears to exert adequate control over the managers, the net performance of the company also speaks to the quality of management and directors. The asset quality, discussed above, was not overwhelmingly positive and detracts from the overall view of management quality. A rating of 2 could be assigned to management capabilities.

4.4 Earnings

Earnings ideally should be of high quality, and an indication of high-quality earnings is sustainability. Earnings are more sustainable if they are not dependent on the possibly opportunistic fine-tuning of discretionary estimates and not reliant on either non-recurring items or volatile sources of revenues.

As discussed above, allowance for loan losses and provisions for loan losses are estimated amounts that allow for management discretion. The provision for loan losses can have profound effects on the profitability of a bank in any single year and over long periods of time. Exhibit 18 shows the five-year change in Citigroup's pretax income through 2016 and the corresponding change in the consolidated total provisions for credit (i.e., loan loss reserves plus provisions for policyholder benefits and claims and unfunded lending commitments) drawn from the five-year selected financial data from the 2016 and 2015 10-Ks.

Exhibit 18 Historical Pretax Income and Total Provisions for Credit Losses

(In millions of dollars)	5- Year Net Change:	2016	2015	2014	2013	2012	2011
Pretax income		$21,477	$24,826	$14,701	$19,802	$8,165	$15,096
Change in pretax income	$6,381	($3,349)	$10,125	($5,101)	$11,637	($6,931)	—
Total provisions for credit losses		$6,982	$7,913	$7,467	$8,514	$11,329	$12,359

(continued)

Exhibit 18 (Continued)

(In millions of dollars)	5- Year Net Change:	2016	2015	2014	2013	2012	2011
Change in total provisions for credit losses	($5,377)	($931)	$446	($1,047)	($2,815)	($1,030)	—
Net difference	$1,004						

Observations on the provisions for credit losses:

- 2013 was the only year in which pretax income increased from the previous year while the total provisions for credit losses decreased. The $2.815 billion decrease in the credit loss provisions drove 24% of the increase.
- In 2016, 2014, and 2012, the pretax income declined from the previous year. The declines would have been more severe if they had not been buffered by decreases in the total provisions for credit losses in each year.
- Over the five-year span, the change in the total credit loss provisions contributed to improving the pretax earnings in four of the years. The only exception was 2015, when the total provisions increased only negligibly compared to the size of the decreases in the other years.
- On a longer-term basis, the five-year net change in the total provisions accounted for 84% of the net change in pretax income—an indication that not much profit growth happened elsewhere.

Another indicator of sustainability is the degree to which trading income is part of a bank's revenue stream. Trading income tends to be volatile and not necessarily sustainable. Higher-quality income would be net interest income and fee-based income: These provide sustainable, returning streams of income. An analyst should examine the composition of a bank's revenue stream to determine whether it is growing and to identify the drivers of growth or decline. The five-year summary of Citigroup's revenue stream, drawn from the five-year selected financial data from the 2016 and 2015 10-Ks, is shown in Exhibit 19.

Exhibit 19 Five-Year Summary of Composition of Citigroup's Revenue

(In millions of dollars)	2016	2015	2014	2013	2012
Net interest revenue	$45,104	$46,630	$47,993	$46,793	$46,686
Principal transactions (trading income)	7,585	6,008	6,698	7,302	4,980
All other non-interest revenue	17,186	23,716	22,528	22,629	17,864
Revenues, net of interest expense	$69,875	$76,354	$77,219	$76,724	$69,530
Percent attributable to trading income	10.9%	7.9%	8.7%	9.5%	7.2%
Percent of total:					
Net interest revenue	64.5%	61.1%	62.2%	61.0%	67.1%
All other non-interest revenue	24.6%	31.1%	29.2%	29.5%	25.7%

Observations on revenue composition:

- 2016 total revenues are almost unchanged from 2012 levels.
- At 10.9% of total revenues in 2016, trading income has been trending upward as a proportion of revenues in the last five years. Instead of increasing its sustainable, non-volatile revenues, Citigroup's principal transactions/trading income is moving in the opposite direction—increasing in absolute dollars and in relative importance.
- In 2016, all other non-interest revenue is at its lowest representative level since 2012.
- The net interest revenue proportion improved in 2016 but is still lower than it was in 2012.

A bank's net interest revenue results from the management of interest earned on loans and other interest-bearing assets and the management of interest paid on deposits and other interest-bearing liabilities. Thus, net interest revenue earned on average interest-bearing assets minus interest expense paid on average interest-bearing liabilities. Banks may create value through maturity transformation: They can borrow money on shorter terms than the terms for lending to customers. Although this can create value by lending for long terms at a higher rate than their short-term funding costs, it can also destroy value if the markets for short-term funding experience a dislocation or the yield curve unexpectedly inverts. Therefore, a bank's risk management practices, including its diversification practices, are integral to the maturity transformation process.

Analyzing the net interest revenue can provide an investor with a view of a bank management's activity and effectiveness in this area. To continue the example with Citigroup, the next two exhibits show the average balances (average volume column) for Citigroup's balance sheet accounts. Exhibit 20 shows Citigroup's average assets, as well as interest revenue and average interest rate earned on those assets. Exhibit 21 shows the company's average liabilities, the interest expense and average interest cost of those liabilities, and its equity accounts. It also includes the company's net interest revenue and net interest margin at the bottom.

Loans (net of unearned income)									
In US offices	**$360,957**	$354,434	$361,773	**$24,240**	$25,082	$26,076	**6.72%**	7.08%	7.21%
In offices outside the United States	**262,715**	273,064	296,666	**15,578**	15,465	18,723	**5.93**	5.66	6.31
Total	**$623,672**	$627,498	$658,439	**$39,818**	$40,547	$44,799	**6.38%**	6.46%	6.80%
Other interest-earning assets	**$56,398**	$63,209	$48,954	**$1,029**	$1,839	$507	**1.82%**	2.91%	1.04%
Total interest-earning assets	**$1,594,086**	$1,605,812	$1,673,774	**$58,077**	$59,040	$62,180	**3.64%**	3.68%	3.71%
Non-interest-earning assets	**$214,642**	$218,025	$223,141						
Total assets	**$1,808,728**	$1,823,837	$1,896,915						

Observations from Citigroup's average assets table:

- The overall average interest rate earned declined slightly in 2016, from 3.68% to 3.64%. One reason is due to changes occurring within the loans, which are the single largest category of assets. Citigroup sold its OneMain Financial subsidiary at the end of 2015, which was engaged in US consumer installment lending and is a high-yielding loan business. That disposal pressured the interest income earned from US offices, decreasing the earned interest rate from 7.08% in 2015 to 6.72% in 2016.
- Average loans in US offices increased to $360,957 million in 2016 from $354,434 million in 2015, despite the OneMain disposal, because of the mid-2016 acquisition of Costco's credit card portfolio, which was insufficient to offset the OneMain interest income.
- Average loans in offices outside the United States decreased to $262,715 million in 2016 from $273,064 million in 2015, partly because Citigroup disposed of its retail banking and credit cards businesses in Japan in the fourth quarter of 2015.
- Although Citigroup realized better interest income from its trading account assets in 2016, earning 2.97% compared to 2.90% in 2015, it allocated less capital to trading and earned less absolute interest income from the trading account assets.
- Despite lower capital committed to deposits with banks ($131,925 million in 2016 compared to $133,853 million in 2015), the higher realized average interest rate increased Citigroup's overall interest income. The same is true for its tax-exempt investments in US offices.

Exhibit 21 Citigroup's Average Balances and Interest Rates—Liabilities, Equity, and Net Interest Revenue

In millions of dollars, except rates	Average Volume			Interest Expense			% Average Rate		
	2016	**2015**	**2014**	**2016**	**2015**	**2014**	**2016**	**2015**	**2014**
Liabilities

(continued)

Exhibit 21 (Continued)

In millions of dollars, except rates	Average Volume			Interest Expense			% Average Rate		
	2016	**2015**	**2014**	**2016**	**2015**	**2014**	**2016**	**2015**	**2014**
Net interest revenue as a percentage of average interest-earning assets	**Total Average Interest-Earning Assets**			**Net Interest Revenue**			**Net Interest Margin**		
In US offices	**$859,311**	$923,309	$953,394	**$27,929**	$28,495	$27,496	**3.25%**	3.09%	2.88%
In offices outside the United States	**734,775**	682,503	720,380	**17,637**	18,624	20,994	**2.40**	2.73	2.91
Total	**$1,594,086**	$1,605,812	$1,673,774	**$45,566**	$47,119	$48,490	**2.86%**	2.93%	2.90%

Observations from Exhibit 21:

- Citigroup's cost of funding its assets increased in every category of liability in 2016. That attribute was even more pronounced in offices outside the United States, with the exception of deposit liabilities.
- This difference between US and non-US asset and liability performance extends to the net interest margin, net interest revenue as a percentage of average interest-earning assets, shown at the bottom of the table. Although the net interest margin improved to 3.25% in 2016 from 3.09% in 2015 for assets in US offices, it declined significantly for assets in offices outside the United States, from 2.73% in 2015 to 2.40% in 2016. The net interest margin in offices outside the United States has been declining consistently since 2014, when the US dollar began strengthening. Citigroup has been experiencing negative foreign currency translation impacts since then.
- An investor might exercise increased caution when observing management's future actions in making foreign investments. These results do not provide assurance that all capital is well allocated overseas or that currency risk is adequately managed. The lower returns might also be due to macroeconomic factors, such as lower yield curves (and even negative rates) overseas, creating fewer profitable opportunities. An investor should factor those possibilities into his consideration.

Analyzing the net interest revenue resulting from average interest-bearing asset and liability balances can be useful for analyzing what happened within a bank for a given period but not necessarily useful for projecting future earnings. The interest earned or paid on an average balance for a given period may have no bearing on what a bank may actually earn or pay in the next period. End-of-period balances of balance sheet components and their associated interest rates may make a better starting point for projecting future earnings than the average balance information.

In summary, the quality of Citigroup's earnings is not exceedingly high. The fact that the decreases in the provision for loan losses has driven 84% of the pretax earnings increases over the last five years does nothing to relieve quality concerns, nor does the increase in trading income over the last five years instill more confidence in the earnings quality. The analysis of the net interest revenue shows declining net interest margin over the last three years, largely attributable to the non-US offices. A rating of 3 could be justified for earnings quality.

A Brief Overview of Accounting for Derivatives

Accounting rules for derivatives are extensive. The following points are a very brief summary of this complex topic and are generally applicable to both IFRS and US GAAP.

- At inception, many derivatives contracts do not give rise to an asset or liability on the balance sheet or to a gain or loss on the income statement. For example, an interest rate swap contract can involve the exchange of future cash flows with equivalent present value. Thus, at inception, the only accounting record required for every derivatives contract is a disclosure of the notional amount of the contract. This disclosure appears in the notes to the financial statements.
- Measurement of the mark-to-market value of a derivatives contract creates an asset or liability and subsequently increases or decreases the value of the asset or liability.
- Changes in the value of the asset or liability are recorded either as part of profit and loss on the income statement or as part of comprehensive income, depending on the classification.
- Derivative instruments can be classified as a hedge of a cash flow or a hedge of a net investment in a foreign subsidiary. Classification of a derivatives contract as a hedge requires substantiating its correlation with the risk being hedged. If a derivatives contract is classified as one of these two types of hedges, changes in its value are recorded as part of other comprehensive income and will be recognized in net income over the life of the hedged transaction.
- If such a derivatives contract fails classification as a hedge and is instead a free-standing derivative instrument or if the hedge is classified as a third type, a hedge of a fair value, then changes in its fair value are reported as income or expense in the income statement at each reporting period. The immediate recognition of a gain or loss in earnings, instead of reporting it in other comprehensive income, can lead to unexpected volatility of earnings and missed earnings targets. Depending on the nature of the derivative transaction, a secondary effect of a contract's failure to qualify as a hedge may also require additional posting of collateral or cash.

4.5 Liquidity Position

A bank's liquidity is an extremely important matter for its own well-being in times of financial stress. Given the interdependence of banks, through such transactions as interbank deposits and acting as counterparties in derivative transactions, a bank's liquidity also matters for the well-being of other banks—and possibly an entire economy.

Capital alone is not sufficient to assure liquidity; there must be enough capital available in cash or near-cash for the meeting of obligations. The Basel III Regulatory Framework introduced two liquidity standards to provide assurance that capital would be adequately liquid for meeting obligations under stressful conditions.

The first is the Liquidity Coverage Ratio, which is the minimum percentage of a bank's expected cash outflows to be held in highly liquid assets. Expected net cash outflows are the bank's anticipated 30-day liquidity needs in a stress scenario, and the highly liquid assets include only those of high quality and immediately convertible into cash. Expected net cash outflows are calculated by applying prescribed outflow factors to various liability categories, with any available offsets by inflows from assets maturing within the 30-day stress period. Additionally, banks must include an add-on amount to account for possible maturity mismatches between contractual cash outflows and inflows during the 30-day period to arrive at total net outflows. The minimum

LCR threshold is 100%; anything less would indicate an inability to meet the liquidity needs. Exhibit 22 shows the components of Citigroup's LCR at 31 December 2016, 30 September 2016, and 31 December 2015.

Exhibit 22 Citigroup's Liquidity Coverage Ratio

(In billions of dollars)	31 Dec. 2016	30 Sep. 2016	31 Dec. 2015
High-quality liquid assets	$403.7	$403.8	$389.2
Net outflows	332.5	335.3	344.4
HQLA in excess of net outflows	$71.2	$68.5	$44.8
Liquidity Coverage Ratio	121%	120%	113%

Observations from the Liquidity Coverage Ratio:

- Citigroup's Liquidity Coverage Ratio has improved in the last two years.
- Citigroup's 2016 LCR indicates it can withstand cash outflows that are 21% higher than its 30-day liquidity needs in a stress scenario or, equivalently, it can withstand a stress level volume of cash outflows for 36.3 days (121% times 30 days). Either way, the LCR indicates adequate liquidity even in the absence of any (likely) remedial management steps in an actual stress event.

The second Basel III liquidity standard is the Net Stable Funding Ratio: a minimum percentage of required stable funding that must be sourced from available stable funding. Required stable funding depends on the composition and maturity of a bank's asset base; available stable funding is a function of the composition and maturity of a bank's funding sources (capital and liabilities). The Net Stable Funding Ratio is a kind of inverted Liquidity Coverage Ratio. Where the Liquidity Coverage Ratio evaluates short-term liquidity, the Net Stable Funding Ratio is a measure of the available stable funding to cover funding of longer-term, less liquid assets, such as loans. Highly liquid assets do not enter the calculation of the Net Stable Funding Ratio. As with the Liquidity Coverage Ratio, a ratio of 100% is the minimum acceptable threshold.

The Net Stable Funding Ratio is not yet a required Basel III standard as of the end of 2016; final rules are expected in 2017. Still, a rough calculation may be made, without the various weightings for components of both available and required stable funding that will be part of the final rules. Exhibit 23 shows one possible calculation of a Net Stable Funding Ratio, based on Citigroup's consolidated balance sheet amounts at 31 December 2016, 30 September 2016, and 31 December 2015. The calculation divides the estimated, unweighted amount of available stable funding by the estimated required amount of stable funding.

Exhibit 23 Citigroup's Net Stable Funding Ratio

(In billions of dollars)	31 Dec. 2016	30 Sep. 2016	31 Dec. 2015
Available stable funding:			
Total deposits	$929.4	$940.3	$907.9
Long-term debt	206.2	209.1	201.3
Common equity	205.9	212.3	205.1
Total available stable funding	$1,341.5	$1,361.6	$1,314.3
Required stable funding:			

Exhibit 23 (Continued)

(In billions of dollars)	31 Dec. 2016	30 Sep. 2016	31 Dec. 2015
Total investments	$353.3	$354.9	$343.0
Total loans, net	612.3	626.0	605.0
Goodwill	21.7	22.5	22.3
Intangible assets (other than MSRs)	5.1	5.4	3.7
Mortgage servicing rights (MSRs)	1.6	1.3	1.8
Other assets	128.0	116.5	133.7
Total required stable funding	$1,122.0	$1,126.6	$1,109.5
Net Stable Funding Ratio	120%	121%	118%

Observations on the approximated Net Stable Funding Ratio:

- Citigroup's Net Stable Funding Ratio, as calculated, has stayed relatively stable since the end of 2015, and the available stable funding is well above the minimum required funding needed.

In summary, Citigroup's liquidity position is very good, based on its Liquidity Coverage and Net Stable Funding Ratios. A rating of 1 is justifiable based on the results of the two ratios.

4.6 Sensitivity to Market Risk

Bank assets and liabilities are constantly subject to market risk, which impacts their earnings performance and liquidity. Analysts need to understand how adverse changes in interest rates, exchange rates, and other market factors can affect a bank's earnings and balance sheet.

Required disclosures in banks' financial statements make it possible to assess various sensitivities. The value at risk disclosure is helpful for assessing a bank's exposure to market factors. VaR statistics can be effective indicators of trends in intra-company risk taking; because of differences in calculation assumptions across companies, VaR is not as useful for assessing risk-taking activities between different companies.

Using a 99% confidence level, Citigroup estimates the value at risk of a potential decline in the value of a position or a portfolio under normal market conditions for an assumed single-day holding period. Citigroup uses a Monte Carlo simulation VaR model to capture material risk sensitivities of various asset classes/risk types. Citigroup's VaR includes positions that are measured at fair value but excludes investment securities classified as AFS or HTM. Exhibit 24 is an excerpt from Citigroup's 2016 VaR disclosure.

Exhibit 24 Citigroup Year-End and Average Trading VaR and Trading and Credit Portfolio VaR

(In millions of dollars)	12/31/16	2016 Average	12/31/15	2015 Average
Interest rate	$37	$35	$37	$44
Credit spread	63	62	56	69
Covariance adjustment [(1)]	(17)	(28)	(25)	(26)

(continued)

Exhibit 24 (Continued)

(In millions of dollars)	12/31/16	2016 Average	12/31/15	2015 Average
Fully diversified interest rate and credit spread	$83	$69	$68	$87
Foreign exchange	32	24	27	34
Equity	13	14	17	17
Commodity	27	21	17	19
Covariance adjustment (1)	(70)	(58)	(53)	(65)
Total trading VaR—all market risk factors, including general and specific risk (excluding credit portfolios) (2)	$85	$70	$76	$92
Specific risk-only component (3)	$3	$7	$11	$6
Total trading VaR—general market risk factors only (excluding credit portfolios) (2)	$82	$63	$65	$86
Incremental impact of the credit portfolio (4)	$20	$22	$22	$25
Total trading and credit portfolio VaR	$105	$92	$98	$117
VaR Effects on Earnings & Capital:				
Total trading and credit portfolio VAR	$105	$92	$98	$117
Net income from continuing operations	$15,033		$17,386	
Common equity	$205,867		$205,139	
Total VaR as % of:				
Net income from continuing operations	0.7%	0.6%	0.6%	0.7%
Common equity	0.1%	0.0%	0.0%	0.1%

Notes:

1 Covariance adjustment reflects the fact that the risks within each and across risk types are not perfectly correlated and, consequently, the total VaR on a given day will be lower than the sum of the VARs relating to each individual risk type.

2 The total trading VaR includes mark-to-market and certain fair value option trading positions except for certain hedges. Available-for-sale and accrual exposures are not included.

3 The specific risk-only component represents the level of equity and fixed income issuer-specific risk embedded in VAR.

4 The credit portfolio is composed of mark-to-market positions associated with non-trading business units.

Observations from the VaR table:

- Citigroup's average trading VaR declined in 2016 to $70 million from $92 million in the previous year, mainly owing to changes in interest rate exposures from mark-to-market hedging activity.
- Average trading and credit portfolio VaR also declined in 2016 to $92 million from $117 million in the previous year.
- Although total trading and credit portfolio VaR increased at year end 2016 to $105 million, compared to $98 million at year end 2015, the magnitude of this worst-case single-day VaR is still less than 1% of net income from continuing operations in both years, on either an end-of-period basis (0.7%) or an average basis (0.6%). The magnitude is even more minor compared to equity, representing 0.1% on the end-of-period basis and less than 0.1% on average.
- Importantly, Citigroup's VaR is a single-day measure of market shocks that can affect a company. Market dislocations can linger for days, weeks, and even longer. Although VaR is useful for measuring the effects of very short-term shocks, it does not address the effects of longer-term market impacts.

Another useful disclosure in Citigroup's 10-K focuses on the estimated sensitivity of Citigroup's capital ratios to numerator changes of $100 million in Common Equity Tier 1 Capital, Tier 1 Capital, and Total Capital and changes of $1 billion in risk-weighted assets at the end of 2016. These sensitivities consider only a single change to either a component of capital or risk-weighted assets; an event affecting more than one factor at a time may have a far greater impact than Citigroup's estimate. Exhibit 25 shows an excerpt of the sensitivity table, along with the actual ratios calculated at the end of 2016.

Exhibit 25 Citigroup Capital Ratio Estimated Sensitivities at 31 December 2016

	Common Equity Tier 1 Capital Ratio		Tier 1 Capital Ratio		Total Capital Ratio	
(In basis points)	Impact of $100 Million Change in Common Equity Tier 1 Capital	Impact of $1 Billion Change in Risk-Weighted Assets	Impact of $100 Million Change in Tier 1 Capital	Impact of $1 Billion Change in Risk-Weighted Assets	Impact of $100 Million Change in Total Capital	Impact of $1 Billion Change in Risk-Weighted Assets
Citigroup						
Advanced Approach	0.90	1.20	0.90	1.30	0.90	1.50
Standardized Approach	0.90	1.30	0.90	1.40	0.90	1.70
Actual capital ratio	14.35%	14.35%	15.29%	15.29%	17.33%	17.33%
Minimum capital ratio	4.50%	4.50%	6.00%	6.00%	8.00%	8.00%

From Citigroup's description of its risk-based capital ratios, p. 33 of 2016 10-K: "Total risk-weighted assets under the Advanced Approaches, which are primarily models based, include credit, market, and operational risk-weighted assets. Conversely, the Standardized Approach excludes operational risk-weighted assets and generally applies prescribed supervisory risk weights to broad categories of credit risk exposures. As a result, credit risk-weighted assets calculated under the Advanced Approaches are more risk sensitive than those calculated under the Standardized Approach. Market risk-weighted assets are derived on a generally consistent basis under both approaches."

Observations from the capital ratio sensitivity table:

- Regardless of the calculation (advanced or standardized approach), the effect of a $100 million change in capital or a $1 billion change in risk-weighted assets is practically nil compared to the actual capital ratios calculated at year end.
- At the same time, these are static measures of sensitivity and adjust for only one impact at a time.

In summary, Citigroup's sensitivity to market impacts appears to be controlled and provides circumstantial evidence of effective risk management. Based on the evidence, Citigroup could be justifiably rated at 1 for its management of sensitivities.

4.7 Overall CAMELS Assessment

After each CAMELS component has been analyzed and rated, the overall CAMELS assessment can be completed. One approach to consolidating CAMELS components on an entity basis would be to simply add all the components' ratings. A bank earning the best CAMELS rating, a rating of 1, for each component would have a total score of 6, and a bank that received the worst ratings would have a composite CAMELS score of 30. To translate the score into the corresponding composite CAMELS rating, the score could be divided by 6. This approach arrives at an arithmetic mean rating as the composite rating for the bank. Note that if each component receives the same rating, the weighting of the components is irrelevant. The arithmetic mean approach, however, fails to take into account the fact that some components of the CAMELS approach are more important to some analysts than others, as discussed in Section 4. Depending on the focus of the analysis, the analyst-weighted composite CAMELS score and rating could be quite different from the unweighted score and arithmetic mean of the ratings.

Exhibit 26 presents the calculation of Citigroup's overall CAMELS score from the point of view of an equity analyst who places twice as much value on asset quality and earnings than on the other CAMELS components.

Exhibit 26 Citigroup Overall CAMELS Score

	Rating	Weighting	Weighted Rating
Capital adequacy	1.0	1	1.00
Asset quality	2.5	2	5.00
Management	2.0	1	2.00
Earnings	3.0	2	6.00
Liquidity	1.0	1	1.00
Sensitivity	1.0	1	1.00
Total score	**10.5**	**8**	**16.00**
Converted to CAMELS rating (score divided by 6)	**1.75**		**2.00**

Note that without the weighting, which helps the analyst quantify his or her priorities, Citigroup has an overall CAMELS rating of 1.75—not perfect, but indicating a bank that is generally showing strong performance and risk management. Once the ratings are weighted, however, the composite score is 2.00 (16/8 = 2.00). The weighted score indicates a slightly higher degree of flaws that management may need to address.

ANALYZING PROPERTY AND CASUALTY INSURANCE COMPANIES

5

f describe key ratios and other factors to consider in analyzing an insurance company.

Insurance companies provide protection against adverse events. Insurance companies earn revenues from **premiums** (amounts paid by the purchaser of insurance products) and from investment income earned on the **float** (amounts collected as premium and not yet paid out as benefits). Insurance companies are typically categorized as property and casualty (P&C) or life and health (L&H). The products of the two types of insurance companies differ in contract duration and variability of claims.[30] P&C insurers' policies are usually short term, and the final cost will usually be known within a year of occurrence of an insured event, whereas L&H insurers' policies are usually longer term. P&C insurers' claims are more variable and "lumpier" because they arise from accidents and other unpredictable events, whereas L&H insurers' claims are more predictable because they correlate closely with relatively stable actuarially based mortality rates when applied to large populations.

For both types of insurance companies, important areas for analysis include business profile, earnings characteristics, investment returns, liquidity, and capitalization. In addition, for P&C companies, analysis of reserves and the combined ratio, an indicator of overall underwriting profitability, are important.

Some countries, including, for example, the United States, require insurance companies to prepare financial reports according to statutory accounting rules, which differ from US GAAP and IFRS, and have a greater focus on solvency.[31] This section discusses analysis based on US GAAP and IFRS financial reports. A discussion of P&C insurers is followed by a discussion of L&H insurers.

5.1 Property and Casualty Insurance Companies

Property and casualty (P&C) insurers provide risk management services to their insured parties. For the price of an insurance premium, they protect the insured parties against losses many times greater than the premiums paid. Premiums are collected at the outset of the insurance contract, creating a float period between their receipt and the time of any payout to the insured party for losses. During the float period, the insurance company will invest the premiums, providing another income stream apart from the underwriting results. In addition to being risk managers, insurance companies also act as investment companies.

Exhibit 27 displays the revenue composition for Travelers Companies, Inc. The net investment income is the second-highest revenue source, after premiums earned, and is significant relative to total revenues.

30 Refer to the Insurance Information Institute's website: www.iii.org.

31 In the United States, the National Association of Insurance Commissioners (NAIC) has developed a system of analytical tools (i.e., ratios and guideline values) for solvency monitoring, known as the NAIC Insurance Regulatory Information System (IRIS). Ratios in IRIS are based on statutory accounting reports.

Exhibit 27 Travelers Companies, Inc., Revenues Composition

(For the year ended 31 December, in millions)	2016		2015		2014	
Premiums	**$24,534**	*88.8%*	$23,874	*89.0%*	$23,713	*87.3%*
Net investment income	**2,302**	*8.3%*	2,379	*8.9%*	2,787	*10.3%*
Fee income	**458**	*1.7%*	460	*1.7%*	450	*1.7%*
Net realized investment gains	**68**	*0.2%*	3	*0.0%*	79	*0.3%*
Other revenues	**263**	*1.0%*	99	*0.4%*	145	*0.5%*
Total revenues	**$27,625**	*100.0%*	$26,815	*100.0%*	$27,174	*100.0%*

Property and casualty insurers try to minimize their payouts to insured parties by exercising care in the underwriting process and charging an adequate price for the risk that they will bear. They may try to diversify the risks they accept by not concentrating excessively on one kind of policy, market, or customer type. They may also diversify their risk by transferring policies, in whole or in part, to reinsurers. Reinsurers deal only with risks insured by other insurers; they do not originate primary policies.

Property and casualty insurance companies differ from life insurance companies in that the length of their duty to perform is comparatively short. Policies are often offered on an annual basis, and the event being covered is often known with certainty during the policy period—fire or weather events, for example. Insured events can also take much longer to emerge: For instance, environmental harm occurring during the policy period may not be obvious until well after the expiration of the policy period.

5.1.1 *Operations: Products and Distribution*

Property insurance policies protect against loss or damage to property—buildings, automobiles, environmental damage, and other tangible objects of value. The events causing loss or damage vary and determine the kind of policy in force. Events may be attributed to accidents, fire, theft, or catastrophe. Casualty insurance, sometimes called *liability insurance*, protects against a legal liability related to an insured event. Casualty insurance covers the liability to a third party, such as passengers, employees, or bystanders. A single insured event may contain both property and casualty losses: For instance, an automobile accident may result in both the loss of the automobile and injury to passengers. Such policies may be referred to as *multiple peril policies*.

Property and casualty insurance may be considered as personal lines or commercial lines, depending on the customer; some products may be sold in both lines. Types of property and casualty insurance include automobile property and liability policies (an example of both personal and commercial lines selling the same product), homeowners' insurance, workers' compensation, marine insurance, and reinsurance.

There are two methods of distributing insurance: direct writing and agency writing. Direct writers of insurance have their own sales and marketing staff. Direct writers also may sell insurance policies via the internet; through direct response channels, such as mail; and through groups with a shared interest or bond, such as membership in a profession. Agency writers use independent agents, exclusive agents, and insurance brokers to sell policies.

5.1.2 *Earnings Characteristics*

In the macro view, the property and casualty insurance business is cyclical. It is a price-sensitive business, with many competitors unafraid to cut prices to obtain market share. According to A.M. Best, a US insurance rating agency, there are approximately

1,200 property and casualty groups in the United States, comprising approximately 2,650 property and casualty companies. Of those groups, the top 150 accounted for approximately 92% of the consolidated industry's total net written premiums in 2015. Once the price cutting drives out profitability, creating a "soft" pricing market for insurance premiums, the insurers reach an uncomfortably depleted level of capital. Competition lessens and underwriting standards tighten, creating a "hard" pricing market. Consequently, premiums rise and the insurers return to more reasonable levels of profitability. The increase in profitability once again attracts more entrants into the market, and the cycle repeats.

In the micro view, there are operating cost considerations that affect insurer profitability apart from the "softness" or "hardness" of the insurance market, depending on the method of distribution. Direct writers have higher fixed costs because of the in-house nature of their distribution method: The sales and marketing staff are salaried employees. Agency writers do not have this fixed cost; instead, the commissions paid to agents and brokers are a variable cost.

The underwriting cycle is driven largely by the expenses of the participants. When the industry's combined ratio—the total insurance expenses divided by the net premiums earned—is low, it indicates a hard insurance market, attracting new entrants who cut prices and push the cycle downward. The effect can be seen in the denominator of the combined ratio: The lower prices for premiums decreases the total net premiums earned, and the combined ratio increases, indicating a soft market. Competitors leave the market, either because they want to forgo unprofitable underwriting or because of their own failure.

For a single insurance company, a combined ratio higher than 100% indicates an underwriting loss. In the United States, Statutory Accounting Practices define the combined ratio as the sum of two ratios, using statutory financial statements: an underwriting loss ratio and an expense ratio. The underwriting loss ratio—losses [= claims paid plus (ending loss reserves minus beginning loss reserves)] divided by net premiums earned—is an indicator of the quality of a company's underwriting activities. Underwriting activities include decisions on whether to accept an application for insurance coverage and decisions on the premiums charged for any coverage extended. The expense ratio (underwriting expenses, including sales commissions and related employee expenses, divided by net premiums written) is an indicator of the efficiency of a company's operations in acquiring and managing underwriting business. For financial disclosures, companies sometimes report modified versions of the combined ratio. For example, the combined ratio reported by Travelers calculates the expense ratio with net earned premiums in the denominator, which is consistent with US GAAP.[32] Other companies may make different presentations.

P&C insurers' investment income is not as volatile as their operating income, because the investments are relatively low-return, low-risk holdings, as we will discuss in the next section.

One critical expense for property and casualty insurers results from the management of their loss reserves. Proper estimation of liabilities is essential to the pricing of policies. Underestimation of loss reserves may lead to undercharging for risks assumed. Development of the loss reserves is based on historical information, yet the process also incorporates estimates about future losses. It is a material account that is subject to management discretion, and its improper estimation can have consequences for the property and casualty insurer. If the loss reserves and the annual adjustments to them are too optimistic, the pricing of the insurance policies may be insufficient for the risk being borne by the insurer and insolvency may ensue. Another problematic attribute of the loss reserves is the fact that the longer the insurer's obligation runs, the

32 The Travelers Companies, Inc., Form 10-K for the year ended 31 December 2016 (p. 36).

more difficult it can be to estimate the loss reserve properly. For example, insurance policies covering asbestos liabilities written long before courts began awarding more generous payouts have been problematic for insurers. Their current experience is far different from what they expected when they issued the policies, and the rapid growth in the award sizes made it difficult to properly estimate the associated loss reserves.

Exhibit 28 shows the roll-forward schedule of activity in Travelers Companies' loss reserve balances, drawn from the insurance claims footnote in its 2016 financial statements. It provides a high-level view of the way the components affect the balance sheet and the income statement and offers insights into the way a property and casualty insurance company manages its assumed risks. The roll-forward activity is denominated in terms of the reserves, net of reinsurance recoverables expected to reduce Travelers' ultimate liability. The beginning and ending balances are shown at their gross amounts, reduced by the reinsurance recoverables to arrive at the net reserves.

Exhibit 28 Travelers Companies, Inc., Loss Reserve Balances and Activity

(At and for the year ended 31 December, in millions)	2016	2015	2014
Gross claims and claim adjustment expense reserves at beginning of year	$48,272	$49,824	$50,865
Less reinsurance recoverables on unpaid losses	(8,449)	(8,788)	(9,280)
Net reserves at beginning of year	39,823	41,036	41,585
Estimated claims and claim adjustment expenses for claims arising in the current year	15,675	14,471	14,688
Estimated decrease in claims and claim adjustment expenses for claims arising in prior years	(680)	(817)	(885)
Total increases	14,995	13,654	13,803
Claims and claim adjustment expense payments for claims arising in:			
Current year	(6,220)	(5,725)	(5,895)
Prior years	(8,576)	(8,749)	(8,171)
Total payments	(14,796)	(14,474)	(14,066)
Acquisition	—	2	—
Unrealized foreign exchange gain	(74)	(395)	(286)
Net reserves at end of year	39,948	39,823	41,036
Plus reinsurance recoverables on unpaid losses	7,981	8,449	8,788
Gross claims and claim adjustment expense reserves at end of year	$47,929	$48,272	$49,824
Reinsurance at end of year:			
Reinsurance recoverables on unpaid losses	$7,981	$8,449	$8,788
Gross claims and claim adjustment expense reserves at end of year	$47,929	$48,272	$49,824
Percentage of claims and claim adjustment expense reserves covered by reinsurance	16.7%	17.5%	17.6%
Revisions' effect on income before income taxes:			
Downward revisions of claims and claim adjustment expenses for claims arising in prior years	$680	$817	$885

Exhibit 28 (Continued)

(At and for the year ended 31 December, in millions)	2016	2015	2014
Income before income taxes	$4,053	$4,740	$5,089
Percentage of contributions of downward revisions to income before income taxes	16.8%	17.2%	17.4%

Observations from Exhibit 28:

- The 2016 claims paid of $6,220 million is 39.7% of the estimated claims and claim adjustments of $15,675 million, indicating that a major part of Travelers Companies' liability exposure is fairly short term. The two prior years show a similar exposure term.
- The company employs significant levels of reinsurance to control its risk exposure. In reinsurance, one insurance company transfers, or cedes, a portion of its risk to another insurer (the "reinsurer") for a premium. The ceding company expects to recover its losses from the reinsurer. As the table shows, Travelers has been ceding between 16.7% and 17.6% of its gross loss reserves to reinsurers.
- The total increases in loss reserves, net of decreases in claims and claim adjustment expenses for prior years' claims, affect the income statement more than any other expense. In 2016, the $14,995 million of total increases in loss reserves represented 63.6% of the $23,572 million of total claims and expenses in the income statement (which is not presented here because of space limitations).
- The company decreased its prior years' estimates of claims by $680 million in 2016, $817 million in 2015, and $885 million in 2014. Downward revisions indicate that a company is estimating its initial recognized reserves conservatively, but aggressive revisions may also be a tool for manipulating earnings. Travelers Companies' downward revisions may appear minor in comparison to the total increases, but they have a profound effect on income before taxes. This effect is shown in the bottom of the exhibit: Downward revisions of prior years' estimates contributed 16.8% to income before income taxes in 2016, 17.2% in 2015, and 17.4% in 2014.

Depending on the ratios used, the ratios of insurers' profitability may distinguish between net premiums written and net premiums earned. Net premiums written are an insurer's direct premiums written, net of any such premiums ceded to other insurers. Premiums are usually billed in advance—for example, twice per year—and they are earned over the period of coverage provided by the insurance policy. Only the net premiums written that are earned over a relevant accounting period—for example, quarterly—are considered to be the net premiums earned.

Useful ratios in analyzing property and casualty insurance companies' profitability include the following:

- *Loss and loss adjustment expense ratio = (Loss expense + Loss adjustment expense)/Net premiums earned.* This ratio indicates the degree of success an underwriter has achieved in estimating the risks insured. The lower the ratio, the greater the success.
- *Underwriting expense ratio = Underwriting expense/Net premiums written.* This ratio measures the efficiency of money spent in obtaining new premiums. A lower ratio indicates higher success.

- *Combined ratio = Loss and loss adjustment expense ratio + Underwriting expense ratio.* This ratio indicates the overall efficiency of an underwriting operation. A combined ratio of less than 100 is considered efficient.
- *Dividends to policyholders (shareholders) ratio = Dividends to policyholders (shareholders)/Net premiums earned.* This ratio is a measure of liquidity, in that it relates the cash outflow of dividends to the premiums earned in the same period.
- *Combined ratio after dividends = Combined ratio + Dividends to policyholders (shareholders) ratio.* This ratio is a stricter measure of efficiency than the ordinary combined ratio, in that it takes into account the cash satisfaction of policyholders or shareholders after consideration of the total underwriting efforts. Dividends are discretionary cash outlays, and factoring them into the combined ratio presents a fuller description of total cash requirements.[33]

Exhibit 29 displays the calculation of these ratios for a group of property and casualty insurers based on their 2016 financial reports. Notice the wide variation in the results. Markel Corp. performed the best (combined ratio of 89%), and Hartford Financial Services Group performed relatively poorly (combined ratio of 131%). The high loss and loss adjustment expense ratio (82.2%) and underwriting expense ratio (48.8%) suggest its underwriting business requires additional management attention. A review of the three ratios related to operations shows that Travelers ranks as the median with respect to loss and loss adjustment expense ratio and below median for underwriting expense and combined ratios. This finding indicates that Travelers' operations are in the better-performing half of this group. After taking into account the dividend distribution policy in the combined ratio after dividends to policyholders (shareholders), Travelers' overall performance remains in the better-performing half of the group.

Exhibit 29 2016 Ratios Calculated for Selected Property and Casualty Insurers

($ millions)	Travelers Companies	Hartford Financial Services Group	W. R. Berkley Corp.	CNA Financial Corp.	Markel Corp.
Loss and loss adjustment expense ratio:					
Loss expense and loss adjustment expense	$15,070	$11,351	$3,846	$5,270	$2,051
Net premiums earned	$24,534	$13,811	$6,293	$6,924	$3,866
Loss and loss adjustment expense ratio	**61.4%**	**82.2%**	**61.1%**	**76.1%**	**53.1%**
Underwriting expense ratio:					
Underwriting expense	$8,139	$5,156	$2,396	$2,787	$1,437
Net premiums written	$24,958	$10,568	$6,424	$6,988	$4,001
Underwriting expense ratio	**32.6%**	**48.8%**	**37.3%**	**39.9%**	**35.9%**
Combined ratio:					
Loss and loss adjustment expense ratio	61.4%	82.2%	61.1%	76.1%	53.0%
Underwriting expense ratio	32.6%	48.8%	37.3%	39.9%	35.9%
Combined ratio	**94.0%**	**131.0%**	**98.4%**	**116.0%**	**89.0%**
Dividends to policyholders (shareholders) ratio:					

33 "Annual Report on the Insurance Industry," Federal Insurance Office, US Department of the Treasury (September 2015), available at www.treasury.gov.

Exhibit 29 (Continued)

($ millions)	Travelers Companies	Hartford Financial Services Group	W. R. Berkley Corp.	CNA Financial Corp.	Markel Corp.

5.1.3 *Investment Returns*

Property and casualty insurance companies face much uncertainty in the risks they insure, and their business is enormously competitive when insurance pricing moves into its "hard" stage. To counteract the environment of uncertainty, property and casualty insurers conservatively invest the collected premiums. They typically favor steady-return, low-risk assets, while shunning low-liquidity investments.

An illustration is found in Exhibit 30, which is the investment portion of the assets shown in the Travelers Companies' 2016 balance sheet. Investments represent 70% of total assets in 2016 and 2015. In both years, approximately 86% of the total investment portfolio is composed of fixed-maturity investments, and nearly another 7% of investments are short-term securities, which can be considered proxies for cash. Equity securities are only 1% of investments in both years, and real estate is also a very minor component of investments in both years.

Exhibit 30 The Travelers Companies, Inc., Portfolio Composition, 2016 and 2015

At 31 December *($ millions)*	2016		2015	
Fixed maturities, available for sale, at fair value (amortized cost $59,650 and $58,878)	$60,515	*85.9%*	$60,658	*86.1%*
Equity securities, available for sale, at fair value (cost $504 and $528)	732	*1.0%*	705	*1.0%*
Real estate investments	928	*1.3%*	989	*1.4%*
Short-term securities	4,865	*6.9%*	4,671	*6.6%*
Other investments	3,448	*4.9%*	3,447	*4.9%*
Total investments	$70,488	*100.0%*	$70,470	*100.0%*

As with any kind of company, the concentrations of assets merit attention. When considering the investments of a property and casualty insurer, the concentration of investments by type, maturity, credit quality, industry, or geographic location or within single issuers should be evaluated.

Investment performance can be estimated by dividing total investment income by invested assets (cash and investments). This metric can also be calculated on two different bases, by using investment income with and without unrealized capital gains, thus showing the relative importance of unrealized capital gains to the total investment income.

Given that property and casualty insurance companies stand ready to meet obligations for policy payouts, liquidity is a priority in the selection of assets. It will be addressed further in the following section.

5.1.4 *Liquidity*

The uncertainty of the payouts involved in the property and casualty business requires a high degree of liquidity so loss obligations can be met. Because the investments are typically low-risk, steady-return types of financial instruments, their nature is typically liquid. An analysis of the portfolio investments should take into account overall quality of the investments and the ease with which the investments can be converted into cash without affecting their value.

Evidence of the investment liquidity can be found by examining their status in the hierarchy of fair value reporting. Level 1 reported values are based on readily available prices for securities traded in liquid markets and thus indicate the most liquid of securities. Level 2 reported values are based on less liquid conditions: Prices for such securities are not available from a liquid market and may be inferred from similar securities trading in an active market. Thus, these securities are likely to be less liquid than those reported as Level 1 securities. Finally, Level 3 reported values are based on models and assumptions because there is no active market for the securities, implying illiquidity.

Exhibit 31 shows the fair value hierarchy for investment securities held by the Travelers Companies at 31 December 2016.

Exhibit 31 The Travelers Companies, Inc., Portfolio Composition by Fair Value Hierarchy

(at 31 December 2016, in millions)	Total	Level 1	Level 2	Level 3
Fixed maturities:				
US Treasury securities and obligations of US government and government agencies and authorities	$2,035	$2,035	$0	$0
Obligations of states, municipalities, and political subdivisions	31,910	—	31,898	12
Debt securities issued by foreign governments	1,662	—	1,662	—
Mortgage-backed securities, collateralized mortgage obligations, and pass-through securities obligations	1,708	—	1,704	4
All other corporate bonds	23,107	—	22,939	168
Redeemable preferred stock	93	3	90	—
Total fixed maturities	$60,515	$2,038	$58,293	$184
% of security class	*100.0%*	*3.4%*	*96.3%*	*0.3%*
Equity securities:				
Public common stock	$603	$603	$0	$0
Non-redeemable preferred stock	129	51	78	—
Total equity securities	$732	$654	$78	$0
% of security class	*100.0%*	*89.3%*	*10.7%*	*0.0%*

Travelers has very little of its portfolio invested in Level 1 assets—only 4.4% [($2,038 + $654)/($60,515 + $732) = 4.4%] on a combined fixed-income securities and equity securities basis. The majority is classified as Level 2 assets, implying less liquidity than Level 1, yet not implying illiquidity. The fair value footnote from the 10-K provides some assurance that the Level 2 assets are not illiquid (underline added by authors):

> The Company utilized a pricing service to estimate fair value measurements for approximately 98% of its fixed maturities at both December 31, 2016 and 2015. The pricing service utilizes market quotations for fixed maturity securities that have quoted prices in active markets. Since fixed maturities other than US Treasury securities generally do not trade on a daily basis, the pricing service prepares estimates of fair value measurements for these securities using its proprietary pricing applications, which include available relevant market information, benchmark curves, benchmarking of like securities, sector groupings and matrix pricing.
>
> Additionally, the pricing service uses an Option Adjusted Spread model to develop prepayment and interest rate scenarios. The pricing service evaluates each asset class based on relevant market information, relevant credit information, perceived market movements and sector news. The market inputs utilized in the pricing evaluation, listed in the approximate order of priority, include: benchmark yields, reported trades, broker/dealer quotes, issuer spreads, two-sided markets, benchmark securities, bids, offers, reference data, and industry and economic events. The extent of the use of each market input depends on the asset class and the market conditions. Depending on the security, the priority of the use of inputs may change or some market inputs may not be relevant. For some securities, additional inputs may be necessary.

The information does not provide an investor with absolute assurance of constant liquidity for the investments; instead, it provides persuasive evidence that the reported values are fair. The fact that the pricing service considers market information relating to liquidity (reported trades, broker/dealer quotes, issuer spreads, two-sided markets) in developing its price estimates increases an investor's confidence that the recognized values would reflect the prices Travelers might achieve if it liquidated the securities at year end 2016.

5.1.5 *Capitalization*

Unlike the banking sector, where international risk-based capital standards have existed since 1988, as of mid-2016, no such global standard exists for the insurance sector (although the IAIS is in the process of developing a risk-based global insurance capital standard).[34] The standard is expected to include a target minimum capital adequacy ratio. The ratio will be calculated as the amount of qualifying capital divided by the amount of risk-based capital required.

Although no risk-based global insurance capital standard exists, capital standards do exist in various jurisdictions. For example, in Europe, the EU adopted the "Solvency II regime" in 2014, which (among other provisions) establishes minimum capital requirements such that if an insurer falls below the requirements, the supervisory entity in the relevant country will be required to intervene.[35] In the United States, the NAIC risk-based capital requirements, begun in the 1990s, establish a minimum

34 See https://www.iaisweb.org/page/supervisory-material/insurance-capital-standard.

35 See http://europa.eu/rapid/press-release_MEMO-15-3120_en.htm.

amount of capital an insurer must have, based on its size and risk profile.[36] Under the NAIC regime, the formula for minimum risk-based capital for P&C insurers takes into account asset risk, credit risk, underwriting risk, and other relevant risks.

6 ANALYZING LIFE AND HEALTH INSURANCE COMPANIES

f describe key ratios and other factors to consider in analyzing an insurance company.

Insurance companies provide protection against adverse events. Insurance companies earn revenues from **premiums** (amounts paid by the purchaser of insurance products) and from investment income earned on the **float** (amounts collected as premium and not yet paid out as benefits). Insurance companies are typically categorized as property and casualty (P&C) or life and health (L&H). The products of the two types of insurance companies differ in contract duration and variability of claims. P&C insurers' policies are usually short term, and the final cost will usually be known within a year of occurrence of an insured event, whereas L&H insurers' policies are usually longer term. P&C insurers' claims are more variable and "lumpier" because they arise from accidents and other unpredictable events, whereas L&H insurers' claims are more predictable because they correlate closely with relatively stable actuarially based mortality rates when applied to large populations.

For both types of insurance companies, important areas for analysis include business profile, earnings characteristics, investment returns, liquidity, and capitalization. In addition, for P&C companies, analysis of reserves and the combined ratio, an indicator of overall underwriting profitability, are important.

Some countries, including, for example, the United States, require insurance companies to prepare financial reports according to statutory accounting rules, which differ from US GAAP and IFRS, and have a greater focus on solvency. This section discusses analysis based on US GAAP and IFRS financial reports. A discussion of P&C insurers is followed by a discussion of L&H insurers.

6.1 Life and Health Insurance Companies

Life and health insurance companies generate revenue from collecting premiums by selling life and health insurance policies—and for many firms, by providing investment products and services. Investment income is the other primary source of revenues.

6.1.1 *Operations: Products and Distribution*

The types of life insurance products vary widely, with some solely providing a benefit upon the death of the insured and others providing a savings vehicle. In the simplest types of life insurance, a premium is paid for coverage and when the insured dies, the beneficiary receives payment. For example, a term life policy provides a benefit if the insured dies within the fixed term of the contract but expires without value if the insured is still living at the end of the term. In other types of life insurance, the policy both provides a benefit upon the death of the insured and serves as a savings vehicle. Life insurance companies may also offer such investment products as annuities, with fixed payments or variable payments linked to market returns.

36 See www.naic.org/cipr_topics/topic_risk_based_capital.htm.

Health-related insurance products vary primarily by the type of coverage. Some products cover specific medical expenses and treatments, and others provide income payments if the policyholder is injured or becomes ill.

L&H companies sell their products either directly to consumers via electronic media or through agents. The agents may be either employees of the company, exclusive agents, or independent agents. Distribution via independent agents is more expensive for the insurance company but offers the benefits of minimizing fixed costs and increasing flexibility to pursue growth opportunities.[37]

It is helpful to understand the source of a company's revenue and any changes over time. Diversification reduces risks. L&H companies can be diversified across revenue sources, product offerings, geographic coverage, distribution channels, and investment assets.

EXAMPLE 7

Revenue Diversification

Exhibits 32 and 33 present selected income statement information for Aegon N.V. and MetLife, Inc., respectively.

Exhibit 32 Selected Consolidated Income Statement Information: Aegon N.V.

As percentage of total revenues	2016	2015	2014	2013	2012
Premiums	61.7%	55.1%	53.3%	55.2%	55.7%
Investment income, including derivatives gains	21.0%	28.5%	30.4%	28.1%	28.9%
Universal life and investment-type product policy fees, and other	17.3%	16.4%	16.3%	16.7%	15.4%
YOY percent change					
Premiums	1.6%	–1.3%	3.7%	–0.8%	

(Continued)

As percentage of total revenues	2016	2015	2014	2013	2012
Investment income, including derivatives gains	−32.9%	−10.6%	16.3%	−2.8%	
Universal life and investment-type product policy fees, and other	−4.6%	−4.1%	5.3%	8.7%	

Solution to 1:

MetLife appears to have greater diversification across revenue sources because it generates only about 62% of total revenues from premiums, compared to nearly 70% for Aegon. It should be noted that premium income can be a more stable source of revenue, and thus greater diversification of revenues should be considered along with potentially greater variability in revenues.

Solution to 2:

For both companies, the percentage of total revenues earned from premiums is greater in 2016 than in any of the previous four years. For Aegon, the increase in the proportion of revenue from premiums resulted in part from significant growth in premium income (15.4% in 2015) as well as a decline in investment income (−8.6%) in 2016. For MetLife, the increase in the proportion of revenue from premiums resulted primarily from the decline in investment income in 2015 and 2016 (−10.6% and −32.9%, respectively).

6.1.2 *Earnings Characteristics*

The major components of L&H insurers' expenses are for benefit payments to policyholders under life insurance, other types of insurance policies, annuity contracts, and other types of contracts. Some types of insurance products that accumulate a cash value include provisions for the policyholder to cancel the contract before its contractual maturity and receive the accumulated cash value. Such early cancellation is known as a contract surrender. Contract surrenders may result in additional expenses for L&H insurers.

Similar to P&C insurers, L&H insures' earnings reflect a number of accounting items that require a significant amount of judgement and estimates. L&H companies must estimate future policyholder benefits and claims based on actuarial assumptions (e.g., about life expectancy). The amounts expensed in a given period are affected by both policyholder benefits actually paid and interest on the estimated liability for future policyholder benefit. As another example of the importance of estimates, L&H companies capitalize the costs of acquiring new and renewal insurance business, which are then amortized on the basis of actual and expected future profits from that business. Another area where accounting judgement can significantly affect L&H companies' earnings—securities valuation—is discussed below in the section on investment returns.

Some general profitability measures can be applied to L&H companies, such as, for example, return on assets (ROA), return on equity (ROE), growth and volatility of capital, and book value per share. Other common profitability measures include pre- and post-tax operating margin (operating profit as a percentage of total revenues) and pre- and post-tax operating return on assets and return on equity.[38] However, most analysis goes beyond these general measures because of the complexity of L&H companies' earnings. Given the possibility of operational distortion and the importance of accounting estimates to L&H companies' reported earnings, a variety of earnings metrics specific to the insurance sector are helpful in providing a good understanding of performance. For example, the profitability ratios used by A.M. Best include (1) total benefits paid as a percentage of net premiums written and deposits and (2) commissions and expenses incurred as a percentage of net premiums written and deposits.[39]

Exhibit 34 shows return on average equity and pretax operating return on average equity for the US L&H sector and MetLife, Inc. In 2011, MetLife had a higher return on average equity than the industry average and a similar pretax operating return on average equity. After 2011, MetLife has not performed as well as the industry on these two measures. Further investigation into causes of the differences between MetLife and the industry and into the reason why the pretax operating return on average equity and return on average equity were similar for MetLife in 2014 and 2015 is needed.

Exhibit 34 Return on Equity—US L&H Sector and MetLife, Inc.

	2011	2012	2013	2014	2015	2016
US L&H Sector Return on Average Equity	4.70%	12.60%	12.90%	11.00%	11.20%	na*
US L&H Sector Pretax Operating Return on Average Equity	9.10%	18.70%	19.10%	14.30%	15.10%	na
MetLife, Inc., Return on Average Equity (Source: 10-K)	12.20%	2.00%	5.40%	9.40%	7.50%	1.00%
MetLife, Inc., Pretax Operating Return on Average Equity (Calculated)	9.00%	9.30%	9.90%	9.80%	7.80%	7.50%

Source for Sector Data: "Annual Report on the Insurance Industry," Federal Insurance Office (September 2016).

L&H companies' earnings can also be distorted by the accounting treatment of certain items. For example, mismatches between the valuation approach for assets and liabilities can introduce distortion when interest rate changes occur. In some cases, significant distortions to reported earnings have occurred because companies' assets are reported on the basis of current market values whereas liabilities are reported at fixed historical costs, which reflect assumptions in place at the time the liabilities were booked.[40]

39 A.M. Best is a widely known rating agency for insurance companies. "Best's Credit Rating Methodology: Global Life and Non-Life Insurance Edition" (28 April 2016) is available at www3.ambest.com/ambv/ratingmethodology/openpdf.aspx?ubcr=1&ri=1011.

40 See, for example, Alistair Gray, "MetLife Loss Raises Accounting 'Noise' Concerns," *Financial Times* (16 February 2017).

6.1.3 *Investment Returns*

Investment returns are an important source of income for L&H companies. Key aspects in evaluating L&H companies' investment activities include diversification, investment performance, and interest rate risk. Liquidity of the portfolio is also relevant for L&H companies and is discussed in the following section.

Investment diversification begins with an assessment of allocation across asset classes and an evaluation of how the allocation corresponds to the insurer's liabilities to policyholders. Compared to P&C companies, L&H companies' relative predictability of claims generally allows them to more often seek the higher returns offered by riskier investments. However, higher-yielding assets, such as equity or real estate investments, experience greater fluctuations in valuation than investments in debt. The insurance industry has also faced investment return challenges from the low-interest rate environment of the last 10 years. It has been harder to earn an adequate risk-adjusted return on financial assets because the low interest rates have limited the available opportunities. Overall, asset concentrations by type, maturity, low credit quality, industry, or geographic location or within single issuers can be a concern, particularly to rating agencies.[41]

Investment performance of L&H companies, as with any investment portfolio's performance, can be measured broadly as the amount of investment income divided by the amount of invested assets (cash and investments). The measure can use investment income plus realized gains (losses) with and without unrealized capital gains (losses). In addition, a common metric for evaluating interest rate risk of L&H companies is the comparison of the duration of the company's assets with the duration of its liabilities.

EXAMPLE 8

Investment Portfolio

Exhibit 35 presents information on the investment portfolio of AIA Group. AIA's portfolio of financial investments constitutes 82% of its total assets (and 84% including investment properties).

Exhibit 35 AIA Group Limited Investment Portfolio

	30-Nov-16		30-Nov-15	
	US$m	% Total	US$m	% Total
Loans and deposits	7,062	4.6%	7,211	5.1%
Debt securities	113,618	73.3%	104,640	73.3%
Equity securities	30,211	19.5%	27,159	19.0%
Derivative financial instruments	107	0.1%	73	0.1%
Total financial investments	150,998	97.5%	139,083	97.4%
Investment property	3,910	2.5%	3,659	2.6%
Total	154,908	100.0%	142,742	100.0%

41 Standard & Poor's, "Standard & Poor's Insurance Ratings Criteria: Life Edition" (2004): www.lifecriteria.standardandpoors.com. Note that Standard & Poor's makes ongoing updates to its ratings criteria.

AIA Group Limited Investment Income

	30-Nov-16
Investment Returns	**US$m**
Interest income	$5,290
Dividend income	654
Rental income	140
Investment income	6,084
Gains and losses	1,471
Total investment return	$7,555

Of the $1,471 million in gains and losses, approximately $127 million was related to debt securities.

1 Based on the information in Exhibit 35, describe AIA's investment allocation in 2016 and changes from the prior year.
2 Based on the information in Exhibit 35, estimate the return on average fixed-income assets. (For the purposes of this question, consider loans and deposits and debt securities as a single class of assets—namely, fixed-income assets.)

Solution to 1:

The portfolio, which is mainly invested in debt securities, shows a very small shift from loans and deposits to equity securities in 2016.

Solution to 2:

The return (in $ millions) can be estimated as Investment income on fixed-income securities divided by Average investment in fixed-income securities.

The Investment income on fixed-income securities equals Interest income plus Gains on debt securities = $5,290 + $127 = $5,417.

The average amounts invested in loans and deposits and debt securities was [($7,062 + $113,618) + ($7,211 +$104,640)]/2 = $232,531/2 = $116,265.5.

Therefore, the estimated return on the fixed-income investments was 4.7% (calculated as $5,417/$116,265.5).

6.1.4 *Liquidity*

An L&H company's requirements for liquidity are driven by its liabilities to creditors and, primarily, its liabilities to policyholders, including both benefits and policy surrenders. Historically, liquidity was less important to life insurers because of the long-term nature of traditional life insurance products; however, liquidity has become more important to life insurers as new products have been introduced.[42] An L&H company's sources of liquidity include its operating cash flow and the liquidity of its investment assets. An analysis of liquidity includes a review of the overall liquidity of the investment portfolio. Such investments as non-investment-grade bonds and equity real estate are typically less liquid than investment-grade fixed-income investments.[43]

42 "Insurance Regulatory Information Systems (IRIS) Manual: IRIS Ratios Manual for Property/Casualty, Life/Accident & Health, and Fraternal—2016 Edition," National Association of Insurance Commissioners (2016): www.naic.org/prod_serv/UIR-ZB-16_UIR_2016.pdf.

43 Standard & Poor's Liquidity Model for US and Canadian Life Insurers.

In general, liquidity measures compare the amount of the company's more liquid assets, such as cash and marketable securities, to the amount of its near-term liabilities. Other liquidity measures—for example, the liquidity model used by Standard & Poor's—compare the amount of the company's assets (individually adjusted for assumptions about ready convertibility to cash) with the amount of the company's obligations (individually adjusted for assumptions about potential for withdrawals).[44] The adjusted amounts are calculated under both normal market conditions and stress. The typical "current ratio" is not directly applicable to L&H companies because their balance sheets often do not include the classifications "current" and "non-current."

6.1.5 *Capitalization*

As noted with P&C insurers, L&H companies are not guided by a global risk-based capital standard. Various jurisdictions do, however, have standards specifying the amount of capital an insurer must have based on its risk profile. If an insurer's capital falls below the minimum requirement, generally, a supervisory authority intervenes.

Differences between the P&C and L&H businesses are reflected in differences in the risk-based capital requirement. For example, because L&H claims are considered more predictable than those of P&C insurers, L&H insurers do not need as high an equity cushion and can have lower capital requirements.[45] Another difference between the factors considered in establishing minimum capital requirements for L&H companies is that many life insurance products create material exposure to interest rate risk. Accordingly, the calculation of risk-based capital for an L&H company incorporates interest rate risk.[46]

SUMMARY

- Financial institutions' systemic importance results in heavy regulation of their activities.
- Systemic risk refers to the risk of impairment in some part of the financial system that then has the potential to spread throughout other parts of the financial system and thereby to negatively affect the entire economy.
- The Basel Committee, a standing committee of the Bank for International Settlements, includes representatives from central banks and bank supervisors from around the world.
- The Basel Committee's international regulatory framework for banks includes minimum capital requirements, minimum liquidity requirements, and stable funding requirements.
- Among the international organizations that focus on financial stability are the Financial Stability Board, the International Association of Insurance Supervisors, the International Association of Deposit Insurers, and the International Organization of Securities Commissions.
- Another distinctive feature of financial institutions (compared to manufacturing or merchandising companies) is that their productive assets are predominantly financial assets, such as loans and securities, creating greater direct exposures

44 "Annual Report on the Insurance Industry," Federal Insurance Office, US Department of the Treasury (September 2016).
45 Nissim, "Analysis and Valuation of Insurance Companies."
46 See www.naic.org/cipr_topics/topic_risk_based_capital.htm.

to a variety of risks, such as credit risk, liquidity risk, market risk, and interest rate risk. In general, the values of their assets are relatively close to fair market values.

- A widely used approach to analyzing a bank, CAMELS, considers a bank's **C**apital adequacy, **A**sset quality, **M**anagement capabilities, **E**arnings sufficiency, **L**iquidity position, and **S**ensitivity to market risk.
- "**C**apital adequacy," described in terms of the proportion of the bank's assets that is funded with capital, indicates that a bank has enough capital to absorb potential losses without severely damaging its financial position.
- "**A**sset quality" includes the concept of quality of the bank's assets—credit quality and diversification—and the concept of overall sound risk management.
- "**M**anagement capabilities" refers to the bank management's ability to identify and exploit appropriate business opportunities and to simultaneously manage associated risks.
- "**E**arnings" refers to the bank's return on capital relative to cost of capital and also includes the concept of earnings quality.
- "**L**iquidity" refers to the amount of liquid assets held by the bank relative to its near-term expected cash flows. Under Basel III, liquidity also refers to the stability of the bank's funding sources.
- "**S**ensitivity to market risk" pertains to how adverse changes in markets (including interest rate, exchange rate, equity, and commodity markets) could affect the bank's earnings and capital position.
- In addition to the CAMELS components, important attributes deserving analysts' attention include government support, the banking entity's mission, corporate culture and competitive environment, off-balance-sheet items, segment information, currency exposure, and risk disclosures.
- Insurance companies are typically categorized as property and casualty (P&C) or life and health (L&H).
- Insurance companies earn revenues from premiums (amounts paid by the purchaser of insurance products) and from investment income earned on the float (amounts collected as premiums and not yet paid out as benefits).
- P&C insurers' policies are usually short term, and the final cost will usually be known within a year of a covered event, whereas L&H insurers' policies are usually longer term. P&C insurers' claims are more variable, whereas L&H insurers' claims are more predictable.
- For both types of insurance companies, important areas for analysis include business profile, earnings characteristics, investment returns, liquidity, and capitalization. In addition, analysis of P&C companies' profitability includes analysis of loss reserves and the combined ratio.

PRACTICE PROBLEMS

The following information relates to questions 1–7

Viktoria Smith is a recently hired junior analyst at Aries Investments. Smith and her supervisor, Ingrid Johansson, meet to discuss some of the firm's investments in banks and insurance companies.

Johansson asks Smith to explain why the evaluation of banks is different from the evaluation of non-financial companies. Smith tells Johansson the following:

Statement 1 As intermediaries, banks are more likely to be systemically important than non-financial companies.

Statement 2 The assets of banks mostly consist of deposits, which are exposed to different risks than the tangible assets of non-financial companies.

Smith and Johansson also discuss key aspects of financial regulations, particularly the framework of Basel III. Johansson tells Smith:

> "Basel III specifies the minimum percentage of its risk-weighted assets that a bank must fund with equity. This requirement of Basel III prevents a bank from assuming so much financial leverage that it is unable to withstand loan losses or asset write-downs."

Johansson tells Smith that she uses the CAMELS approach to evaluate banks, even though it has some limitations. To evaluate P&C insurance companies, Johansson tells Smith that she places emphasis on the efficiency of spending on obtaining new premiums. Johansson and Smith discuss differences between P&C and L&H insurance companies. Smith notes the following differences:

Difference 1: L&H insurers' claims are more predictable than P&C insurers' claims.

Difference 2: P&C insurers' policies are usually short term, whereas L&H insurers' policies are usually longer term.

Difference 3: Relative to L&H insurers, P&C insurers often have lower capital requirements and can also seek higher returns offered by riskier investments.

Johansson asks Smith to review key performance ratios for three P&C insurers in which Aries is invested. The ratios are presented in Exhibit 1.

Exhibit 1 Key Performance Ratios for Selected P&C Insurers

	Insurer A	Insurer B	Insurer C
Loss and loss adjustment expense ratio	68.8%	65.9%	64.1%
Underwriting expense ratio	33.7%	37.8%	32.9%
Combined ratio	102.5%	103.7%	97.0%

© 2019 CFA Institute. All rights reserved.

Johansson also asks Smith to review key performance ratios for ABC Bank, a bank in which Aries is invested. The ratios are presented in Exhibit 2.

Exhibit 2 Key Performance Ratios for ABC Bank*

	2017	2016	2015
Common equity Tier 1 capital ratio	10.7%	11.5%	12.1%
Tier 1 capital ratio	11.5%	12.6%	13.4%
Total capital ratio	14.9%	14.8%	14.9%
Liquidity coverage ratio	123.6%	121.4%	119.1%
Net stable funding ratio	114.9%	113.2%	112.7%
Total trading VaR (all market risk factors)	$11	$13	$15
Total trading and credit portfolio VaR	$15	$18	$21

* *Note*: VaR amounts are in millions and are based on a 99% confidence interval and a single-day holding period.

1 Which of Smith's statements regarding banks is correct?
   A Only Statement 1
   B Only Statement 2
   C Both Statement 1 and Statement 2

2 The aspect of the Basel III framework that Johansson describes to Smith relates to minimum:
   A capital requirements.
   B liquidity requirements.
   C amounts of stable funding requirements.

3 One limitation of the approach used by Johansson to evaluate banks is that it fails to address a bank's:
   A sensitivity to market risk.
   B management capabilities.
   C competitive environment.

4 The best indicator of the operations of a P&C insurance company emphasized by Johansson when evaluating P&C insurance companies is the:
   A combined ratio.
   B underwriting loss ratio.
   C underwriting expense ratio.

5 Which of the differences between P&C insurers and L&H insurers noted by Smith is *incorrect*?
   A Difference 1
   B Difference 2
   C Difference 3

6 Based on Exhibit 1, Smith should conclude that the insurer with the most efficient underwriting operation is:
   A Insurer A.
   B Insurer B.
   C Insurer C.

7 Based on Exhibit 2, Smith and Johansson should conclude that over the past three years, ABC Bank's:

A liquidity position has declined.

B capital adequacy has improved.

C sensitivity to market risk has improved.

The following information relates to questions 8–14

Ivan Paulinic, an analyst at a large wealth management firm, meets with his supervisor to discuss adding financial institution equity securities to client portfolios. Paulinic focuses on Vermillion Insurance (Vermillion), a property and casualty company, and Cobalt Life Insurance (Cobalt). To evaluate Vermillion further, Paulinic compiles the information presented in Exhibit 1.

Exhibit 1 Select Financial Ratios for Vermillion Insurance

Ratio	2017	2016
Loss and loss adjustment expense	59.1%	61.3%
Underwriting expense	36.3%	35.8%
Combined	95.4%	97.1%
Dividend	2.8%	2.6%

In addition to the insurance companies, Paulinic gathers data on three national banks that meet initial selection criteria but require further review. This information is shown in Exhibits 2, 3, and 4.

Exhibit 2 Select Balance Sheet Data for National Banks—Trading: Contribution to Total Revenues

Bank	2017	2013	2009	2005
N-bank	4.2%	7.0%	10.1%	8.9%
R-bank	8.3%	9.1%	17.0%	7.9%
T-bank	5.0%	5.0%	11.9%	6.8%

Focusing on N-bank and T-bank, Paulinic prepares the following data.

Exhibit 3 2017 Select Data for N-bank and T-bank

	N-bank		T-bank	
	2017	2016	2017	2016
Average daily trading VaR ($ millions)	11.3	12.6	21.4	20.5
Annual trading revenue/average daily trading VaR	160×	134×	80×	80×

Paulinic investigates R-bank's risk management practices with respect to the use of credit derivatives to enhance earnings, following the 2008 financial crisis. Exhibit 4 displays R-bank's exposure over the last decade to credit derivatives not classified as hedges.

Exhibit 4 R-bank's Exposure to Freestanding Credit Derivatives

Credit Derivative Balances	2017	2012	2007
Notional amount ($ billions)	13.4	15.5	305.1

All of the national banks under consideration primarily make long-term loans and source a significant portion of their funding from retail deposits. Paulinic and the rest of the research team note that the central bank is unwinding a long period of monetary easing as evidenced by two recent increases in the overnight funding rate. Paulinic informs his supervisor that:

Statement 1 Given the recently reported stronger-than-anticipated macro-economic data, there is an imminent risk that the yield curve will invert.

Statement 2 N-bank is very active in the 30-day reverse repurchase agreement market during times when the bank experiences significant increases in retail deposits.

8 Paulinic's analysis of the two insurance companies *most likely* indicates that:

- **A** Cobalt has more-predictable claims than Vermillion.
- **B** Cobalt has a higher capital requirement than Vermillion.
- **C** Vermillion's calculated risk-based capital is more sensitive than Cobalt's to interest rate risk.

9 Based only on the information in Exhibit 1, in 2017 Vermillion *most likely*:

- **A** experienced a decrease in overall efficiency.
- **B** improved its ability to estimate insured risks.
- **C** was more efficient in obtaining new premiums.

10 Based only on Exhibit 2, which of the following statements is correct?

- **A** The quality of earnings for R-bank was the highest in 2009.
- **B** Relative to the other banks, N-bank has the highest quality of earnings in 2017.
- **C** Trading represented a sustainable revenue source for T-bank between 2005 and 2013.

11 Based only on Exhibit 3, Paulinic should conclude that:

- **A** trading activities are riskier at T-bank than N-bank.
- **B** trading revenue per unit of risk has improved more at N-bank than T-bank.
- **C** compared with duration, the metric used is a better measure of interest rate risk.

12 Based only on Exhibit 4, R-bank's use of credit derivatives since 2007 *most likely*:

- **A** increased posted collateral.
- **B** decreased the volatility of earnings from trading activities.
- **C** indicates consistent correlations among the relevant risks taken.

13 Based on Statement 1, the net interest margin for the three banks' *most likely* will:

- **A** decrease.
- **B** remain unchanged.
- **C** increase.

14 Based on Statement 2, the financial ratio *most* directly affected is the:

- **A** Tier 2 capital ratio.
- **B** net stable funding ratio.
- **C** liquidity coverage ratio.

The following information relates to questions 15–20

Judith Yoo is a financial sector analyst writing an industry report. In the report, Yoo discusses the relative global systemic risk across industries, referencing Industry A (international property and casualty insurance), Industry B (credit unions), and Industry C (global commercial banks).

Part of Yoo's analysis focuses on Company XYZ, a global commercial bank, and its CAMELS rating, risk management practices, and performance. First, Yoo considers the firm's capital adequacy as measured by the key capital ratios (common equity Tier 1 capital, total Tier 1 capital, and total capital) in Exhibit 1.

Exhibit 1 Company XYZ: Excerpt from Annual Report Disclosure

At 31 December	2017	2016	2015
Regulatory capital	**$m**	**$m**	**$m**
Common equity Tier 1 capital	146,424	142,367	137,100
Additional Tier 1 capital	22,639	20,443	17,600
Tier 2 capital	22,456	27,564	38,200
Total regulatory capital	191,519	190,374	192,900
Risk-weighted assets (RWAs) by risk type			
Credit risk	960,763	989,639	968,600

(continued)

Exhibit 1 (Continued)

At 31 December	2017	2016	2015
Regulatory capital	**$m**	**$m**	**$m**
Market risk	44,100	36,910	49,600
Operational risk	293,825	256,300	224,300
Total RWAs	1,298,688	1,282,849	1,242,500

Yoo turns her attention to Company XYZ's asset quality using the information in Exhibit 2.

Exhibit 2 Company XYZ: Asset Composition

At 31 December	2017	2016	2015
	$m	**$m**	**$m**
Total liquid assets	361,164	354,056	356,255
Investments	434,256	367,158	332,461
Consumer loans	456,957	450,576	447,493
Commercial loans	499,647	452,983	403,058
Goodwill	26,693	26,529	25,705
Other assets	151,737	144,210	121,780
Total assets	1,930,454	1,795,512	1,686,752

To assess Company XYZ's risk management practices, Yoo reviews the consumer loan credit quality profile in Exhibit 3 and the loan loss analysis in Exhibit 4.

Exhibit 3 Company XYZ: Consumer Loan Profile by Credit Quality

At 31 December	2017	2016	2015
	$m	**$m**	**$m**
Strong credit quality	338,948	327,345	320,340
Good credit quality	52,649	54,515	54,050
Satisfactory credit quality	51,124	55,311	56,409
Substandard credit quality	23,696	24,893	27,525
Past due but not impaired	2,823	2,314	2,058
Impaired	8,804	9,345	10,235
Total gross amount	478,044	473,723	470,617
Impairment allowances	–5,500	–4,500	–4,000
Total	472,544	469,223	466,617

Exhibit 4 Company XYZ: Loan Loss Analysis Data			
At 31 December	2017	2016	2015
	$m	$m	$m
Consumer loans			
Allowance for loan losses	11,000	11,500	13,000
Provision for loan losses	3,000	2,000	1,300
Charge-offs	3,759	3,643	4,007
Recoveries	1,299	1,138	1,106
Net charge-offs	2,460	2,505	2,901
Commercial loans			
Allowance for loan losses	1,540	1,012	169
Provision for loan losses	1,100	442	95
Charge-offs	1,488	811	717
Recoveries	428	424	673
Net charge-offs	1,060	387	44

Finally, Yoo notes the following supplementary information from Company XYZ's annual report:

- Competition in the commercial loan space has become increasingly fierce, leading XYZ managers to pursue higher-risk strategies to increase market share.
- The net benefit plan obligation has steadily decreased during the last three years.
- Company XYZ awards above-average equity-based compensation to its top managers.

15 Which of the following industries *most likely* has the highest level of global systemic risk?

A Industry A

B Industry B

C Industry C

16 Based on Exhibit 1, Company XYZ's capital adequacy over the last three years, as measured by the three key capital ratios, signals conditions that are:

A mixed.

B declining.

C improving.

17 Based only on Exhibit 2, asset composition from 2015 to 2017 indicates:

A declining liquidity.

B increasing risk based on the proportion of total loans to total assets.

C decreasing risk based on the proportion of investments to total assets.

18 Based on Exhibit 3, the trend in impairment allowances is reflective of the changes in:

A impaired assets.

B strong credit quality assets.

C past due but not impaired assets.

19 Based on Exhibit 4, a loan loss analysis for the last three years indicates that:

A Company XYZ has become less conservative in its provisioning for consumer loans.

B the provision for commercial loan losses has trailed the actual net charge-off experience.

C the cushion between the allowance and the net commercial loan charge-offs has declined.

20 Which of the following supplemental factors is consistent with a favorable assessment of Company XYZ's financial outlook?

A Competitive environment

B Net benefit plan obligation

C Equity-based compensation policy

SOLUTIONS

1 A is correct. Banks are more likely to be systemically important than non-financial companies because, as intermediaries, they create financial linkages across all types of entities, including households, banks, corporates, and governments. The network of linkages across entities means that the failure of one bank will negatively affect other financial and non-financial entities (a phenomenon known as financial contagion). The larger the bank and the more widespread its network of linkages, the greater its potential impact on the entire financial system. The assets of banks are predominantly financial assets, such as loans and securities (not deposits, which represent most of a bank's liabilities). Compared to the tangible assets of non-financial companies, financial assets create direct exposure to a different set of risks, including credit risks, liquidity risks, market risks, and interest rate risks.

2 A is correct. Basel III specifies the minimum percentage of its risk-weighted assets that a bank must fund with equity capital. This minimum funding requirement prevents a bank from assuming so much financial leverage that it is unable to withstand loan losses or asset write-downs.

3 C is correct. The approach used by Johansson to evaluate banks, the CAMELS approach, has six components: (1) capital adequacy, (2) asset quality, (3) management capabilities, (4) earnings sufficiency, (5) liquidity position, and (6) sensitivity to market risk. While the CAMELS approach to evaluating a bank is fairly comprehensive, some attributes of a bank are not addressed by this method. One such attribute is a bank's competitive environment. A bank's competitive position relative to its peers may affect how it allocates capital and assesses risks.

4 C is correct. The underwriting expense ratio is an indicator of the efficiency of money spent on obtaining new premiums. The underwriting loss ratio is an indicator of the quality of a company's underwriting activities—the degree of success an underwriter has achieved in estimating the risks insured. The combined ratio, a measure of the overall underwriting profitability and efficiency of an underwriting operation, is the sum of these two ratios.

5 C is correct. The products of the two types of insurance companies, P&C and L&H, differ in contract duration and claim variability. P&C insurers' policies are usually short term, and the final cost will usually be known within a year of the occurrence of an insured event, while L&H insurers' policies are usually longer term. P&C insurers' claims are more variable and "lumpier" because they arise from accidents and other less predictable events, while L&H insurers' claims are more predictable because they correlate closely with relatively stable, actuarially based mortality rates applied to large populations. The relative predictability of L&H insurers' claims generally allows these companies to have lower capital requirements and to seek higher returns than P&C insurers.

6 C is correct. The combined ratio, which is the sum of the underwriting expense ratio and the loss and loss adjustment expense ratio, is a measure of the efficiency of an underwriting operation. A combined ratio of less than 100% is considered efficient; a combined ratio greater than 100% indicates an underwriting loss. Insurer C is the only insurer that has a combined ratio less than 100%.

7 C is correct. Over the past three years, there has been a downward trend in the two VaR measures—total trading VaR (all market risk factors) and total trading and credit portfolio VaR. This trend indicates an improvement in ABC Bank's sensitivity, or a reduction in its exposure, to market risk. The two liquidity

measures—the liquidity coverage ratio and the net stable funding ratio—have increased over the past three years, indicating an improvement in ABC Bank's liquidity position. Trends in the three capital adequacy measures—common equity Tier 1 capital ratio, Tier 1 capital ratio, and total capital ratio—indicate a decline in ABC Bank's capital adequacy. While the total capital ratio has remained fairly constant over the past three years, the common equity Tier 1 capital ratio and the Tier 1 capital ratio have declined. This trend suggests that ABC Bank has moved toward using more Tier 2 capital and less Tier 1 capital, indicating an overall decline in capital adequacy.

8 A is correct. Claims associated with life and health insurance companies (Cobalt) are more predicable than those for property and casualty insurance companies (Vermillion). Property and casualty insurers' claims are more variable and "lumpier" because they arise from accidents and other unpredictable events, whereas life and health insurers' claims are more predictable because they correlate closely with relatively stable actuarially based mortality rates when applied to large populations.

9 B is correct. The loss and loss adjustment expense ratio decreased from 61.3% to 59.1% between 2016 and 2017. This ratio is calculated as follows: (Loss Expense + Loss Adjustment Expense)/Net Premiums Earned. The loss and loss adjustment expense ratio indicates the degree of success an underwriter has achieved in estimating the risks insured. A lower ratio indicates greater success in estimating insured risks.

10 B is correct. The quality of earnings is directly related to the level of sustainable sources of income. Trading income tends to be volatile and not necessarily sustainable. Higher-quality income would be net interest income and fee-based service income. Because N-bank's 2017 trading revenue contribution is the lowest relative to other banks, its quality of earnings would be considered the best of the three banks.

11 B is correct. Trading revenue per unit of risk can be represented by the ratio of annual trading revenue to average daily trading value at risk (VaR) and represents a measure of reward-to-risk. The trading revenue per unit of risk improved at N-bank (from 134× to 160×) between 2016 and 2017, and there was no change at T-bank (80×). VaR can be used for gauging trends in intra-company risk taking.

12 B is correct. Exhibit 4 indicates that exposure to free-standing credit derivatives dramatically declined from a peak during the global financial crisis in 2008. If a derivatives contract is classified as freestanding, changes in its fair value are reported as income or expense in the income statement at each reporting period. The immediate recognition of a gain or loss in earnings, instead of reporting it in other comprehensive income, can lead to unexpected volatility of earnings and missed earnings targets. As a result, earnings volatility from the use of credit derivatives most likely decreased.

13 A is correct. A bank's net interest revenue represents the difference between interest earned on loans and other interest-bearing assets and the level of interest paid on deposits and other interest-bearing liabilities. Banks typically borrow money for shorter terms (retail deposits) and lend to customers for longer periods (mortgages and car loans). If the yield curve unexpectedly inverts, the short-term funding costs will increase and the net interest margin will most likely decrease (not remain unchanged or increase).

14 C is correct. Reverse repurchase agreements represent collateralized loans between a bank and a borrower. A reverse repo with a 30-day maturity is a highly liquid asset and thus would directly affect the liquidity coverage ratio (LCR). LCR evaluates short-term liquidity and represents the percentage of a bank's expected cash outflows in relation to highly liquid assets.

15 C is correct. Industry C, representing global commercial banks, most likely has the highest level of global systemic risk because global commercial banks have the highest proportion of cross-border business. Unlike banks, the overall insurance market (of which Industry A is a subset) has a smaller proportion of cross-border business, and insurance companies' foreign branches are generally required to hold assets in a jurisdiction that are adequate to cover the related policy liabilities in that jurisdiction. As an international property and casualty (P&C) insurer, Company A provides protection against adverse events related to autos, homes, or commercial activities; many of these events have local, rather than international, impact. Industry B, credit unions, most likely has the lowest level of global systemic risk. Credit unions are depository institutions that function like banks and offer many of the same services, but they are owned by their members rather than being publicly traded as many banks are.

16 A is correct. Company XYZ's key capital adequacy ratios show mixed conditions. The ratios are calculated as follows:

$$\text{Common Equity Tier 1 Capital Ratio} = \frac{\text{Total Common Equity Tier 1 Capital}}{\text{Total Risk-Weighted Assets}}$$

$$\text{2015 Common Equity Tier 1 Capital Ratio} = \frac{137{,}100}{1{,}242{,}500} = 11.0\%$$

$$\text{2016 Common Equity Tier 1 Capital Ratio} = \frac{142{,}367}{1{,}282{,}849} = 11.1\%$$

$$\text{2017 Common Equity Tier 1 Capital Ratio} = \frac{146{,}424}{1{,}298{,}688} = 11.3\%$$

$$\text{Tier 1 Ratio} = \frac{\text{Common Equity Tier 1 Capital} + \text{Additional Tier 1 Capital}}{\text{Total Risk-Weighted Assets}}$$

$$\text{2015 Tier 1 Ratio} = \frac{137{,}100 + 17{,}600}{1{,}242{,}500} = 12.5\%$$

$$\text{2016 Tier 1 Ratio} = \frac{142{,}367 + 20{,}443}{1{,}282{,}849} = 12.7\%$$

$$\text{2017 Tier 1 Ratio} = \frac{146{,}424 + 22{,}639}{1{,}298{,}688} = 13.0\%$$

$$\text{Total Capital Ratio} = \frac{\text{Total Capital}}{\text{Total Risk-Weighted Assets}}$$

$$\text{2015 Total Capital Ratio} = \frac{192{,}900}{1{,}242{,}500} = 15.5\%$$

$$\text{2016 Total Capital Ratio} = \frac{190{,}374}{1{,}282{,}849} = 14.8\%$$

$$2017 \text{ Total Capital Ratio} = \frac{191{,}519}{1{,}298{,}688} = 14.7\%$$

	2017	2016	2015
Common equity Tier 1 capital ratio	11.3%	11.1%	11.0%
Tier 1 capital ratio	13.0%	12.7%	12.5%
Total capital ratio	14.7%	14.8%	15.5%

The common equity Tier 1 capital ratio and the Tier 1 capital ratio both strengthened from 2015 to 2017, but the total capital ratio weakened during that same period, signaling mixed conditions.

17 A is correct. Company XYZ's liquid assets as a percentage of total assets declined each year since 2015, indicating declining liquidity.

	2017		2016		2015	
	$m	% of Total Assets	$m	% of Total Assets	$m	% of Total Assets
Total liquid assets	361,164	18.7%	354,056	19.7%	356,255	21.1%
Investments	434,256	22.5%	367,158	20.4%	332,461	19.7%
Loans						
Consumer loans	456,957		450,576		447,493	
Commercial loans	499,647		452,983		403,058	
Total loans	956,604	49.6%	903,559	50.3%	850,551	50.4%
Goodwill	26,693	1.4%	26,529	1.5%	25,705	1.5%
Other assets	151,737	7.9%	144,210	8.0%	121,780	7.2%
Total assets	1,930,454	100%	1,795,512	100%	1,686,752	100%

18 C is correct. Impairment allowances have increased proportionately to the increases in the amount of past due but not impaired assets, which may be in anticipation of these past due assets becoming impaired. Impaired assets have decreased each year while strong credit quality assets have increased each year, which suggests lowering impairment allowances as a result of improving credit quality of these financial instruments.

At 31 December	2017	2016	2015
	$m	$m	$m
Strong credit quality	338,948	327,345	320,340
Good credit quality	52,649	54,515	54,050
Satisfactory credit quality	51,124	55,311	56,409
Substandard credit quality	23,696	24,893	27,525
Past due but not impaired	2,823	2,314	2,058
Impaired	8,804	9,345	10,235
Total gross amount	478,044	473,723	470,617
Impairment allowances	–5,500	–4,500	–4,000
Total	472,544	469,223	466,617
YoY change in impaired assets	–5.8%	–8.7%	
YoY change in strong credit quality assets	3.5%	2.2%	

At 31 December	2017	2016	2015
	$m	$m	$m
YoY change in past due but not impaired assets	22.0%	12.4%	
YoY change in impairment allowances	22.2%	12.5%	

Note: YoY = year-over-year

2015 to 2016 change in impaired assets: $\left(\frac{9,345}{10,235}\right) - 1 = -8.7\%$

2015 to 2016 change in strong credit quality assets: $\left(\frac{327,345}{320,340}\right) - 1 = 2.2\%$

2015 to 2016 change in past due but not impaired assets: $\left(\frac{2,314}{2,058}\right) - 1 = 12.4\%$

2015 to 2016 change in impairment allowances: $\left(\frac{-4,500}{-4,000}\right) - 1 = 12.5\%$

2016 to 2017 change in impaired assets: $\left(\frac{8,804}{9,345}\right) - 1 = -5.8\%$

2016 to 2017 change in strong credit quality assets: $\left(\frac{338,948}{327,345}\right) - 1 = 3.5\%$

2016 to 2017 change in past due but not impaired assets: $\left(\frac{2,823}{2.314}\right) - 1 = 22.0\%$

2016 to 2017 change in impairment allowances: $\left(\frac{-5,500}{-4,500}\right) - 1 = 22.2\%$

19 C is correct. The allowance for loan losses to net commercial loan charge-offs has been declining during the last three years, which indicates that the cushion between the allowance and the net commercial loan charge-offs has deteriorated.

2015 Consumer: $\frac{\text{Allowance for Loan Losses}}{\text{Net Loan Charge-Offs}} = \frac{13,000}{2,901} = 4.48$

2016 Consumer: $\frac{\text{Allowance for Loan Losses}}{\text{Net Loan Charge-Offs}} = \frac{11,500}{2,505} = 4.59$

2017 Consumer: $\frac{\text{Allowance for Loan Losses}}{\text{Net Loan Charge-Offs}} = \frac{11,000}{2,460} = 4.47$

2015 Commercial: $\frac{\text{Allowance for Loan Losses}}{\text{Net Loan Charge-Offs}} = \frac{169}{44} = 3.84$

$$\text{2016 Commercial: } \frac{\text{Allowance for Loan Losses}}{\text{Net Loan Charge-Offs}} = \frac{1{,}012}{387} = 2.61$$

$$\text{2017 Commercial: } \frac{\text{Allowance for Loan Losses}}{\text{Net Loan Charge-Offs}} = \frac{1{,}540}{1{,}060} = 1.45$$

$$\text{2015 Consumer: } \frac{\text{Provision for Loan Losses}}{\text{Net Loan Charge-Offs}} = \frac{1{,}300}{2{,}901} = 0.45$$

$$\text{2016 Consumer: } \frac{\text{Provision for Loan Losses}}{\text{Net Loan Charge-Offs}} = \frac{2{,}000}{2{,}505} = 0.80$$

$$\text{2017 Consumer: } \frac{\text{Provision for Loan Losses}}{\text{Net Loan Charge-Offs}} = \frac{3{,}000}{2{,}460} = 1.22$$

$$\text{2015 Commercial: } \frac{\text{Provision for Loan Losses}}{\text{Net Loan Charge-Offs}} = \frac{95}{44} = 2.16$$

$$\text{2016 Commercial: } \frac{\text{Provision for Loan Losses}}{\text{Net Loan Charge-Offs}} = \frac{442}{387} = 1.14$$

$$\text{2017 Commercial: } \frac{\text{Provision for Loan Losses}}{\text{Net Loan Charge-Offs}} = \frac{1{,}100}{1{,}060} = 1.04$$

	2017	2016	2015
	$m	$m	$m
Consumer loans			
Allowance for loan losses	11,000	11,500	13,000
Provision for loan losses	3,000	2,000	1,300
Charge-offs	3,759	3,643	4,007
Recoveries	1,299	1,138	1,106
Net charge-offs	2,460	2,505	2,901
Commercial loans			
Allowance for loan losses	1,540	1,012	169
Provision for loan losses	1,100	442	95
Charge-offs	1,488	811	717
Recoveries	428	424	673
Net charge-offs	1,060	387	44
Allowance for loan losses to net loan charge-offs: consumer	4.47	4.59	4.48
Allowance for loan losses to net loan charge-offs: commercial	1.45	2.61	3.84

	2017	2016	2015
	$m	$m	$m
Provision for loan losses to net loan charge-offs: consumer	1.22	0.80	0.45
Provision for loan losses to net loan charge-offs: commercial	1.04	1.14	2.16

20 B is correct. The net benefit plan obligation has steadily decreased during the last three years, which indicates a lower degree of risk posed by the benefit plan.

FINANCIAL STATEMENT ANALYSIS

STUDY SESSION

5

Financial Statement Analysis (2)

This study session focuses on evaluating financial reporting quality and applying financial analysis techniques to investment decisions. A conceptual framework for assessing the quality of a company's financial reports, including the quality of earnings, is provided. Indicators of low-quality reporting, including quality of earnings, cash flow, and balance sheet are examined. The session concludes with mini cases, which demonstrate the value in applying financial statement analysis to inform practical investment decisions.

READING ASSIGNMENTS

Reading 13	Evaluating Quality of Financial Reports by Jack T. Ciesielski, CPA, CFA, Elaine Henry, PhD, CFA, and Thomas I. Selling, PhD, CPA
Reading 14	Integration of Financial Statement Analysis Techniques by Jack T. Ciesielski, CPA, CFA

Note: Changes in accounting standards as well as new rulings and/or pronouncements issued after the publication of the readings on financial reporting and analysis may cause some of the information in these readings to become dated. Candidates are *not* responsible for anything that occurs after the readings were published. In addition, candidates are expected to be familiar with the analytical frameworks contained in the readings, as well as the implications of alternative accounting methods for financial analysis and valuation discussed in the readings. Candidates are also responsible for the content of accounting standards, but not for the actual reference numbers. Finally, candidates should be aware that certain ratios may be defined and calculated differently. When alternative ratio definitions exist and no specific definition is given, candidates should use the ratio definitions emphasized in the readings.

Evaluating Quality of Financial Reports

by Jack T. Ciesielski, CPA, CFA, Elaine Henry, PhD, CFA, and Thomas I. Selling, PhD, CPA

Jack T. Ciesielski, CPA, CFA, is at R.G. Associates, Inc., former publisher of The Analyst's Accounting Observer (USA). Elaine Henry, PhD, CFA, is at Stevens Institute of Technology (USA). Thomas I. Selling, PhD, CPA, is at the Cox School of Business, Southern Methodist University (USA).

LEARNING OUTCOMES

Mastery	*The candidate should be able to:*
☐	**a.** demonstrate the use of a conceptual framework for assessing the quality of a company's financial reports;
☐	**b.** explain potential problems that affect the quality of financial reports;
☐	**c.** describe how to evaluate the quality of a company's financial reports;
☐	**d.** evaluate the quality of a company's financial reports;
☐	**e.** describe the concept of sustainable (persistent) earnings;
☐	**f.** describe indicators of earnings quality;
☐	**g.** explain mean reversion in earnings and how the accruals component of earnings affects the speed of mean reversion;
☐	**h.** evaluate the earnings quality of a company;
☐	**i.** describe indicators of cash flow quality;
☐	**j.** evaluate the cash flow quality of a company;
☐	**k.** describe indicators of balance sheet quality;
☐	**l.** evaluate the balance sheet quality of a company;
☐	**m.** describe sources of information about risk.

1 INTRODUCTION

The ability to assess the quality of reported financial information can be a valuable skill. An analyst or investor who can recognize high-quality financial reporting can have greater confidence in analysis based on those financial reports and the resulting investment decisions. Similarly, an analyst or investor who can recognize poor financial reporting quality early—before deficiencies become widely known—is more likely to make profitable investment decisions or to reduce or even avoid losses.

An example of early recognition of an ultimate financial disaster is James Chanos's short position in Enron in November 2000 (Chanos 2002)—more than a year before Enron filed for bankruptcy protection (in December 2001). Despite Enron's high profile and reputation,[1] Chanos had a negative view of Enron based on both quantitative and qualitative factors. Chanos noted that Enron's return on capital was both lower than comparable companies' return on capital and lower than the company's own cost of capital. Qualitative factors contributing to Chanos's view included the company's aggressive revenue recognition policy, its complex and difficult-to-understand disclosures on related-party transactions, and one-time earnings-boosting gains. Later events that substantiated Chanos's perspective included sales of the company's stock by insiders and the resignation of senior executives.

Another example of early recognition of eventual financial troubles is June 2001 reports by analyst Enitan Adebonojo. These reports highlighted questionable accounting by Royal Ahold, a European food retailer. The questionable accounting included "claiming profits of acquired firms as 'organic growth,' booking capital gains from sale-and-leaseback deals as profit, and keeping billions in debt off its balance sheet."[2] In 2003, Royal Ahold announced that it had significantly overstated its profits in the prior two years. The CEO and CFO resigned, various regulators announced investigations, and Royal Ahold's market value dropped significantly.

This reading focuses on reporting quality and the interrelated attribute of results quality. *Reporting quality* pertains to the information disclosed in financial reports. High-quality reporting provides decision-useful information—information that is relevant and faithfully represents the economic reality of the company's activities during the reporting period and the company's financial condition at the end of the period. A separate, but interrelated, attribute of quality is *results* or *earnings quality*, which pertains to the earnings and cash generated by the company's actual economic activities and the resulting financial condition relative to expectations of current and future financial performance. Note that the term "earnings quality" is more commonly used in practice than "results quality," so throughout this reading, earnings quality is used broadly to encompass the quality of earnings, cash flow, and/or balance sheet items.

High-quality earnings reflect an adequate level of return on investment and are derived from activities that a company will likely be able to sustain in the future. Thus, high-quality earnings increase the value of a company more than low-quality earnings. When reported earnings are described as being high quality, it means that the company's underlying economic performance was good (i.e., value enhancing), and it also implies that the company had high reporting quality (i.e., that the information that the company calculated and disclosed was a good reflection of the economic reality).

Earnings can be termed "low quality" either because the reported information properly represents genuinely bad performance or because the reported information misrepresents economic reality. In theory, a company could have low-quality earnings while simultaneously having high reporting quality. Consider a company with

1 In October 2000, Enron was named in the top 25 on *Fortune* magazine's list of the World's Most Admired Companies.

2 "Ahold: Europe's Enron," *The Economist*, (27 February 2003).

low-quality earnings—for example, one whose only source of earnings in a period is a one-off settlement of a lawsuit without which the company would have reported huge losses. The company could nonetheless have high reporting quality if it calculated its results properly and provided decision-useful information. Although it is theoretically possible that a company could have low-quality earnings while simultaneously having high reporting quality, experiencing poor financial performance can motivate the company's management to misreport.

This reading begins in Sections 2–5 with a description of a conceptual framework for and potential problems with financial reporting quality. This is followed in Sections 6 and 7 with a discussion of how to evaluate financial reporting quality. Sections 8–16 focus on the quality of reported earnings, cash flows, and balance sheets, respectively. Sections 17–19 covers sources of information about risk. A summary and practice problems in the CFA Institute item set format complete the reading.

QUALITY OF FINANCIAL REPORTS: CONCEPTUAL FRAMEWORK

2

a demonstrate the use of a conceptual framework for assessing the quality of a company's financial reports;

This section reviews a conceptual framework for assessing the quality of financial reports and then outlines potential problems that affect the quality of financial reports.

2.1 Conceptual Framework for Assessing the Quality of Financial Reports

As indicated in the introduction, financial reporting quality and results or earnings quality are related attributes of quality. Exhibit 1 illustrates this relationship and its implications. Low financial reporting quality can make it difficult or impossible to assess a company's results, and as a result, it is difficult to make investment and other decisions, such as lending and extending credit to the company.

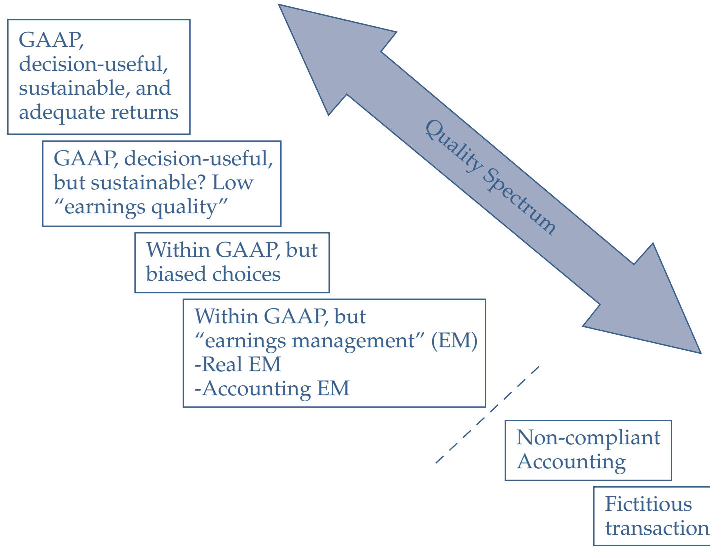
Exhibit 1 Relationships between Financial Reporting Quality and Earnings Quality

		Financial Reporting Quality: Low	Financial Reporting Quality: High
Earnings (Results) Quality	High	LOW financial reporting quality impedes assessment of earnings quality and impedes valuation.	HIGH financial reporting quality enables assessment. HIGH earnings quality increases company value.
	Low		HIGH financial reporting quality enables assessment. LOW earnings quality decreases company value.

Financial reporting quality varies across companies. Financial reports can range from those that contain relevant and faithfully representational information to those that contain information that is pure fabrication. Earnings (results) quality can range from high and sustainable to low and unsustainable. The presence of high-quality financial reporting is a necessary condition for enabling investors to evaluate results quality. High-quality financial reporting alone is an insufficient condition to ensure the presence of high-quality results, but the existence of high-quality financial reporting allows the investor to make such an assessment.

Combining the two aspects of quality—financial reporting and earnings—the overall quality of financial reports from a user perspective can be thought of as spanning a continuum from the highest to the lowest. Exhibit 2 presents a spectrum that provides a basis for evaluating better versus poorer quality reports.

Exhibit 2 Quality Spectrum of Financial Reports



Essentially, the analyst needs to consider two basic questions:

1 Are the financial reports GAAP-compliant and decision-useful?

2 Are the results (earnings) of high quality? In other words, do they provide an adequate level of return, and are they sustainable?

These two questions provide a basic conceptual framework to assess the quality of a company's financial reports and to locate the company's financial reports along the quality spectrum. At the top of the spectrum, labeled in Exhibit 2 as "GAAP, decision-useful, sustainable, and adequate returns" are high-quality reports that provide decision-useful information about high-quality earnings. "GAAP" refers generically to the generally accepted accounting principles or the accepted accounting standards of the jurisdiction under which the company reports. Examples of GAAP are International Financial Reporting Standards (IFRS), US GAAP, and other home-country accounting standards. *Decision-useful* information embodies the characteristics of relevance and faithful representation.[3] High-quality earnings provide an *adequate level of return* on investment (i.e., a return equal to or in excess of the cost of capital) and are sustainable. *Sustainable* indicates that the earnings are derived from activities that a company will likely be able to sustain in the future. Sustainable earnings that provide a high return on investment contribute to a higher valuation of a company and its securities.

Any deviation from the highest point on the quality spectrum can be assessed in terms of the two-question conceptual framework. For example, a company that provides GAAP-compliant, decision-useful information about low-quality earnings (they can be of low quality because they do not provide an adequate level of return and/or they are not sustainable) would appear lower on the quality spectrum. Even lower on the spectrum would be companies that provide GAAP-compliant information, which is less decision-useful because of biased choices.

Biased accounting choices result in financial reports that do not faithfully represent economic phenomena. Biased choices can be made not only in the context of reported amounts but also in the context of how information is presented. For example, companies can disclose information transparently and in a manner that facilitates analysis, or they can disclose information in a manner that aims to obscure unfavorable information and/or to emphasize favorable information.

The problem with bias in accounting choices, as with other deficiencies in financial reporting quality, is that it impedes an investor's ability to correctly assess a company's past performance, to accurately forecast future performance, and thus to appropriately value the company. Choices are deemed to be "aggressive" if they increase the company's reported performance and financial position in the current period. Aggressive choices may decrease the company's reported performance and financial position in later periods. In contrast, choices are deemed to be "conservative" if they decrease the company's reported performance and financial position in the current period. Conservative choices may increase the company's reported performance and financial position in later periods.

Another type of bias is "earnings management." An example of this bias is earnings "smoothing" to understate earnings volatility relative to the volatility if earnings were faithfully represented. Earnings volatility is decreased by understating earnings in periods when a company's operations are performing well and overstating in periods when the company's operations are struggling.

The next levels down on the spectrum mark a departure from GAAP. Financial reports that depart from GAAP can generally be considered low quality; they are of poor financial reporting quality and cannot be relied on to assess earnings quality. The lowest-quality financial reports portray fictitious transactions or omit actual transactions; such financial reports are fabrications.

---

3 These characteristics are from the *Conceptual Framework for Financial Reporting* (IASB 2010). The characteristics of decision-useful information are identical under IFRS and US GAAP. Relevant information is defined as information that can affect a decision and encompasses the notion of materiality. Faithful representation of economic events is complete, neutral, and free from error. The *Framework* also identifies enhancing characteristics of useful information: comparability, verifiability, timeliness, and understandability. High-quality information results when necessary trade-offs among these characteristics are made in an unbiased, skillful manner.

3 POTENTIAL PROBLEMS THAT AFFECT THE QUALITY OF FINANCIAL REPORTS AND REPORTED AMOUNTS AND TIMING OF RECOGNITION

b explain potential problems that affect the quality of financial reports;

The basic choices that give rise to potential problems with quality of financial reports include reported amounts and timing of recognition and classification. Remember that even GAAP-compliant financial reports can diverge from economic reality if GAAP allows for biased choices. In addition to GAAP-compliant choices, a financial statement preparer may choose to present fraudulent reports. This choice represents a divergence from GAAP and economic reality.

3.1 Reported Amounts and Timing of Recognition

The choice of the reported amount and timing of recognition may focus on a single financial statement element (assets, liabilities, owners' equity, revenue and gains [income], or expenses and losses). However, this choice may affect other elements and more than one financial statement because financial statements are interrelated.[4] It is useful to think of the impact of accounting choices in terms of the basic accounting equation (Assets = Liabilities + Equity). This equation can be restated as Assets – Liabilities = Equity, which is also equivalent to Net Assets = Equity. Choices related to income statement elements will affect the balance sheet through equity, and if equity is affected, then another balance sheet element(s) has to be affected or the balance sheet will not balance.

Following are some examples of choices—accounting choices that comply with GAAP, accounting choices that depart from GAAP, and operating choices—and their effects in the current period:

- Aggressive, premature, and fictitious revenue recognition results in overstated income and thus overstated equity. Assets, usually accounts receivable, are also overstated.
- Conservative revenue recognition, such as deferred recognition of revenue, results in understated net income, understated equity, and understated assets.
- Omission and delayed recognition of expenses results in understated expenses and overstated income, overstated equity, overstated assets, and/or understated liabilities. An understatement of bad debt expense results in overstated accounts receivable. Understated depreciation or amortization expense results in the overstatement of the related long-lived asset. Understated interest, taxes, or other expenses result in the understatement of the related liability: accrued interest payable, taxes payable, or other payable.
- Understatement of contingent liabilities is associated with overstated equity resulting from understated expenses and overstated income or overstated other comprehensive income.

4 Depending on management's motivation, poor-quality financial reports may either over-state or understate results. Fraudulent financial reports almost always overstate results.

- Overstatement of financial assets and understatement of financial liabilities, reported at fair value, are associated with overstated equity resulting from overstated unrealized gains or understated unrealized losses.
- Cash flow from operations may be increased by deferring payments on payables, accelerating payments from customers, deferring purchases of inventory, and deferring other expenditures related to operations, such as maintenance and research.

Example 1 describes events and choices at Satyam Computer Services Limited, which resulted in the issuance of fraudulent reports.

EXAMPLE 1

Fictitious Reports

Satyam Computer Services Limited

Satyam Computer Services Limited, an Indian information technology company, was founded in 1987 and grew rapidly by providing business process outsourcing (BPO) on a global basis. In 2007, its CEO, Ramalinga Raju, was named "Entrepreneur of the Year" by Ernst & Young, and in 2008, the World Council for Corporate Governance recognized the company for "global excellence in corporate accountability." In 2009, the CEO submitted a letter of resignation that outlined a massive financial fraud at the company. The company's decline was so rapid and significant that it came to be referred to as "India's Enron."

In late 2008, the World Bank terminated its relationship with the company after finding that Satyam gave kickbacks to bank staff and billed for services that were not provided. These initial revelations of wrongdoing had the effect of putting the company under increased scrutiny. Among other misconduct, the CEO eventually admitted that he created fictitious bank statements to inflate cash and to show interest income. The CEO also created fake salary accounts and took the money paid to those "employees." The company's head of internal auditing created fictitious customer accounts and invoices to inflate revenues.[5]

The external auditors did not independently verify much of the information provided by the company. Even when bank confirmations, which were sent to them directly as opposed to indirectly through Satyam, contained significantly different balances than those reported by Satyam, they did not follow up.

1 Based on the information provided, characterize Satyam's financial reports, with reference to the quality spectrum of financial reports.
2 Explain each of the following misconducts with reference to the basic accounting equation:
   A Transactions with World Bank
   B Fictitious interest income
   C CEO's embezzlement
   D Fictitious revenue
3 Based on the information provided, what documents were falsified to support the misconducts listed in Question 2?

5 See Bhasin (2012) for more information.

Solution to 1:

Based on the information provided, Satyam's financial reports were of the lowest quality. They clearly are at the bottom of the quality spectrum of financial reports: reports based on fictitious information.

Solution to 2:

The effects on the basic accounting equation of the different acts of misconduct are as follows:

A Upon billing for fictitious services, the company would increase an asset, such as accounts receivable, and a revenue account, such as service revenues. The kickbacks to the customer's staff, if recorded, would increase an expense account, such as commissions paid, and increase a liability, such as commissions payable, or decrease an asset, such as cash. The net effect of this misconduct is the overstatement of income, net assets, and equity.

B Fictitious interest income would result in overstated income; overstated assets, such as cash and interest receivable; and overstated equity. These overstatements were hidden by falsifying revenue and cash balances.

C The embezzlement by creating fictitious employees would increase an expense account, such as wages and salaries, and decrease the asset, cash. The resulting understatement of income and equity was offset by a real but fraudulent decrease in cash, which was hidden by falsifying revenue and cash balances.

D Fictitious revenues would result in overstated revenues and income; overstated assets, such as cash and accounts receivable; and overstated equity.

Solution to 3:

Based on the information provided, the documents that were falsified include

- invoices to the World Bank for services that were not provided,
- bank statements,
- employee records, and
- customer accounts and invoices.

The falsified documents were intended to mislead the external auditors.

An astute reader of financial statements may have identified a potential problem at Satyam by comparing the growth in revenue with the growth in assets on its balance sheet, such as short-term and long-term trade receivables and unbilled revenue. Long-term trade receivables and unbilled revenue accounts may have raised questions. Also, there was an account separate from cash, investments in bank deposits, which may have raised questions. However, fraudulent reports that are well constructed can be very challenging to identify.

4 CLASSIFICATION

b explain potential problems that affect the quality of financial reports;

Choices with respect to reported amounts and timing of recognition typically affect more than one financial element, financial statement, and financial period. Classification choices typically affect one financial statement and relate to how an item is classified within a particular financial statement. The balance sheet, the statement of comprehensive income, or the cash flow statement may be the primary focus of the choice.

With respect to the balance sheet, the concern may be to make the balance sheet ratios more attractive or to hide an issue. For example, a company may focus on accounts receivable because it wants to hide liquidity or revenue collection issues. Choices include removing the accounts receivable from the balance sheet by selling them externally or transferring them to a controlled entity, converting them to notes receivable, or reclassifying them within the balance sheet, such as by reporting them as long-term receivables. Although these amounts remain on the balance sheet as receivables of some sort, a result of their reclassification is a lower accounts receivable balance. This could imply to investors that a collection has taken place and also might favorably skew receivables measures, such as days' sales outstanding and receivables turnover.

In the 2003 Merck Annual Report, Merck & Co. reclassified a portion of its inventory to "Other assets," a long-term asset. This reclassification affects the balance sheet and financial ratios as demonstrated in Example 2.

EXAMPLE 2

Balance Sheet Reclassifications

Merck & Co., Inc. and Subsidiaries

In the 2002 Annual Report, inventory was reported at $3,411.8 million. In the 2003 Annual Report, the 2002 inventory value was reported at $2,964.3 million and $447.5 million of inventory was included in other assets. This information was contained in Note 6 to the financial statements, reproduced in Exhibit 3.

Exhibit 3 Note 6 to Consolidated Financial Statements

6. Inventories

Inventories at December 31 consisted of:

($ in millions)	2003	2002
Finished goods	$552.5	$1,262.3
Raw materials and work in process	2,309.8	2,073.8
Supplies	90.5	75.7
Total (approximate current cost)	$2,952.8	$3,411.8
Reduction to LIFO cost	—	—
	$2,952.8	$3,411.8
Recognized as:		
Inventories	$2,554.7	$2,964.3
Other assets	398.1	447.5

Inventories valued under the LIFO method comprised approximately 51% and 39% of inventories at December 31, 2003 and 2002, respectively. Amounts recognized as Other assets consist of inventories held

(continued)

Exhibit 3 (Continued)

in preparation for product launches and not expected to be sold within one year. The reduction in finished goods is primarily attributable to the spin-off of Medco Health in 2003.

1 The reclassification of a portion of inventory to other assets will *most likely* result in the days of inventory on hand:

A decreasing.

B staying the same.

C increasing.

2 As a result of the reclassification of a portion of inventory to other assets, the current ratio will *most likely*:

A decrease.

B stay the same.

C increase.

Solution to 1:

A is correct. The number of days of inventory on hand calculated using the reported inventory number will most likely decrease because the amount of inventory relative to cost of goods sold will decrease.

Solution to 2:

A is correct. The current ratio will decrease because current assets will decrease and current liabilities will stay the same.

From Exhibit 3, notice that the reclassification is described in the sentence, "Amounts recognized as Other assets consist of inventories held in preparation for product launches and not expected to be sold within one year." The reasoning behind the reclassification's explanation is logical: Current assets include assets to be consumed or converted into cash in a company's operating cycle, which is usually one year. The inventory items associated with product launches beyond one year are more appropriately classified as "other assets." Yet, the change in classification poses analytical problems. Inventory turnover is a key indicator of efficiency in managing inventory levels and is calculated as cost of sales divided by average inventory. Although the inventory turnover can be calculated for 2003, it cannot be calculated on a consistent basis for 2002, or any year before then, because the amount of inventory that would have been classified as "other assets" in those periods is not disclosed. An investor has to recognize that a time-series comparison of Merck's inventory turnover is going to produce an inconsistent history because of the lack of consistent information.

The classification of revenues between operating and non-operating may help the user to determine sustainability of a company's earnings, but the classification has potential for misuse by a company. The classification of revenues as being derived from core, continuing operations could mislead financial statement users into considering inflated amounts of income as being sustainable. Similarly, the classification of expenses as non-operating could mislead financial statement users into considering inflated amounts of income as being sustainable. In non-GAAP metrics reported outside of the financial statements, the classification of income-reducing items as non-recurring could also mislead financial statement users into considering inflated amounts of income as being sustainable.

Classifications that result in an item being reported in other comprehensive income rather than on the income statement can affect analysis and comparison. For example, if two otherwise identical companies classify investments differently, net income may differ because the change in value of the investments may flow through net income for one company and through other comprehensive income for the other company.

Classification issues also arise specifically with the statement of cash flows for which management may have incentives to maximize the amount of cash flows that are classified as "operating." Management may be motivated to classify activities, such as the sale of long-term assets, as operating activities rather than investing activities. Operating activities are part of the day-to-day functioning of a company, such as selling inventory or providing services. For most companies, the sale of property or other long-term assets are not operating activities, and including them in operating activities overstates the company's ability to generate cash from its operations. Management may capitalize rather than expense operating expenditures. As a result, the outflow may be classified as an investing activity rather than an operating activity.

Exhibit 4 presents a selection of potential issues, possible actions, and warning signs of possible deviations from high-quality financial reports, some of which will be specifically discussed in later sections of this reading. The warning signs may be visible in the financial statements themselves, in the notes to the financial statements, or in ratios calculated by the analyst that are assessed over time or compared with those of peer companies. Frequently, the chosen actions bias net income upward. However, a new management or management of a company in financial difficulty may be motivated to bias current income downward to enhance future periods.

Exhibit 4 Accounting Warning Signs

Potential Issues	Possible Actions/Choices	Warning Signs
■ Overstatement or non-sustainability of operating income and/or net income ● Overstated or accelerated revenue recognition ● Understated expenses ● Misclassification of revenue, gains, expenses, or losses	■ Contingent sales with right of return, "channel stuffing" (the practice of inducing customers to order products they would otherwise not order or order at a later date through generous terms), "bill and hold" sales (encouraging customers to order goods and retain them on seller's premises) ■ Fictitious (fraudulent) revenue ■ Capitalizing expenditures as assets ■ Classifying non-operating income or gains as part of operations ■ Classifying ordinary expenses as non-recurring or non-operating ■ Reporting gains through net income and losses through other comprehensive income	■ Growth in revenue higher than that of industry or peers ■ Increases in discounts to and returns from customers ■ Higher growth rate in receivables than revenue ■ Large proportion of revenue in final quarter of year for a non-seasonal business ■ Cash flow from operations is much lower than operating income ■ Inconsistency over time in the items included in operating revenues and operating expenses ■ Increases in operating margin ■ Aggressive accounting assumptions, such as long, depreciable lives ■ Losses in non-operating income or other comprehensive income and gains in operating income or net income ■ Compensation largely tied to financial results
■ Misstatement of balance sheet items (may affect income statement) ● Over- or understatement of assets ● Over- or understatement of liabilities ● Misclassification of assets and/or liabilities	■ Choice of models and model inputs to measure fair value ■ Classification from current to non-current ■ Over- or understating reserves and allowances ■ Understating identifiable assets and overstating goodwill	■ Models and model inputs that bias fair value measures ■ Inconsistency in model inputs when measuring fair value of assets compared with that of liabilities ■ Typical current assets, such as accounts receivable and inventory, included in non-current assets ■ Allowances and reserves that fluctuate over time or are not comparable with peers ■ High goodwill value relative to total assets ■ Use of special purpose vehicles ■ Large changes in deferred tax assets and liabilities ■ Significant off-balance-sheet liabilities

Exhibit 4 (Continued)

Potential Issues	Possible Actions/Choices	Warning Signs
■ Overstatement of cash flow from operations	■ Managing activities to affect cash flow from operations ■ Misclassifying cash flows to positively affect cash flow from operations	■ Increase in accounts payable and decrease in accounts receivable and inventory ■ Capitalized expenditures in investing activities ■ Sales and leaseback ■ Increases in bank overdrafts

5 QUALITY ISSUES AND MERGERS AND ACQUISITIONS & FINANCIAL REPORTING THAT DIVERGES FROM ECONOMIC REALITY DESPITE COMPLIANCE WITH ACCOUNTING RULES

b explain potential problems that affect the quality of financial reports;

Quality issues with respect to financial reports often arise in connection with mergers and acquisitions. Mergers and acquisitions provide opportunities and motivations to manage financial results. For accounting purposes, the business combination is accounted for using the acquisition method, and one company is identified as the acquirer. The financial results of the combined companies are reported on a consolidated basis.

Companies with faltering cash-generating ability may be motivated to acquire other companies to increase cash flow from operations. The acquisition will be reported in the investing cash flows if paid in cash, or not even appear on the cash flow statement if paid for with equity. The consolidated cash flow from operations will include the cash flow of the acquired company, effectively concealing the acquirer's own cash flow problems. Such an acquisition can provide a one-time boost to cash from operations that may or may not be sustainable. There are no required post-acquisition "with and without acquisitions" disclosures, making it impossible for investors to reliably assess whether or not the acquirer's cash flow problems are worsening.

A potential acquisition may create an incentive for a company to report using aggressive choices or even misreport. For example, an acquirer's managers may be motivated to make choices to increase earnings to make an acquisition on more favorable terms. Evidence indicates that acquirers making an acquisition for stock may manipulate their reported earnings prior to the acquisition to inflate the value of shares being used to pay for the acquisition (Erickson and Wang 1999). Similarly, the target company's managers may be motivated to make choices to increase earnings to secure a more favorable price for their company. As another example, the acquiring managers may try to manipulate earnings upward after an acquisition if they want to positively influence investors' opinion of the acquisition.[6]

In other cases, misreporting can be an incentive to make an acquisition. Acquisitions complicate a company's financial statements and thus can conceal previous accounting misstatements. Some evidence indicates that companies engaged in intentional

6 Findings consistent with this possibility are presented in Bens, Goodman, and Neamtiu (2012).

misreporting (specifically, companies that were subsequently accused of accounting fraud by the US SEC) are more likely than non-misreporting companies to make an acquisition. They are also more likely to acquire a company that would reduce the comparability and consistency of their financial statements, such as by targeting companies that have less public information and less similar operations (Erickson, Heitzman, and Zhang 2012).

There are also opportunities to make choices that affect the initial consolidated balance sheet and consolidated income statements in the future. When a business combination occurs, the acquirer must measure and recognize identifiable assets acquired and liabilities assumed at their fair values as of the acquisition date. These may include assets and liabilities that the acquired company had not previously recognized as assets and liabilities in its financial statements. For example, identifiable intangible assets that the acquired company developed internally and some contingent liabilities would be recognized by the acquirer. The excess of the purchase price over the recognized value of the identified assets acquired and liabilities assumed is reported as goodwill. Unlike other long-lived assets, goodwill is not amortized; however, it is subject to impairment testing. Because goodwill is not amortized, unless appropriate impairment charges are recorded, the capitalized goodwill amount continues indefinitely.

The default accounting treatment for goodwill—no future amortization expense—provides an incentive to acquirers to understate the value of amortizable intangibles when recording an acquisition. Being a residual amount, more of the value of an acquisition will thus be classified as goodwill, with its future earnings-friendly accounting treatment. That bias may result in postponement of the recognition of an uneconomic acquisition until impairment charges on the goodwill are recorded, which may be long after the acquisition. Managements may be willing to take this chance because they may be able to convince analysts and investors that a goodwill impairment charge is a non-recurring, non-cash charge—something that many will overlook. Nevertheless, the presence of goodwill should make an investor more inquisitive about a company's record in recognizing impairments and should also motivate an investor to evaluate a company's impairment testing process for goodwill. Fair value measurement, except in the case of assets and liabilities with quoted prices in active markets for identical assets or liabilities, presents an opportunity for the acquirer's management to exercise judgment and affect reported values. For example, they could understate fair value of assets to avoid future charges to expense. Understating the fair value of assets will result in a higher goodwill amount. In the absence of impairment of goodwill, there will be no charges associated with the goodwill. Many analysts question whether reported goodwill reflects economic reality.

5.1 Financial Reporting that Diverges from Economic Reality Despite Compliance with Accounting Rules

Certain accounting standards may give rise to financial reporting that an analyst may find less useful because he or she does not view it as reflective of economic reality. Examples 3 and 4 illustrate these types of situations. When possible, an analyst should adjust the reported information to better reflect his or her view of economic reality. If an adjustment is not possible because the relevant data are not disclosed, an analyst can instead make a qualitative assessment of the effect.

Example 3 describes one of the earlier cases of creative consolidation accounting that raised the need for an in-depth consideration of consolidation accounting and the related issue of control. Many entities are governed by the votes of shareholders under which the majority rules. However, exceptions may exist and both US GAAP and IFRS have endeavored to create regimes under which consolidation is required when it is appropriate to depict economic substance.

EXAMPLE 3

Treatment of Variable Interest (Special Purpose) Entities

SEC enforcement action regarding the financial statements of Digilog, Inc.

In order to develop and introduce a new product, Digilog created a separate business entity, DBS, that was capitalized with $10 million of convertible debt issued to Digilog. Upon conversion, Digilog would end up owning nearly 100% of DBS. Initially, owners' equity of DBS consisted of a few thousand dollars of common stock issued to DBS's manager.

During the first two years of DBS's operations, Digilog did not consolidate DBS; it argued that DBS was controlled by its manager, who owned 100% of the outstanding common shares. Even though DBS generated substantial losses over its first two years of existence, Digilog reported interest income on its investment in the convertible debt. After two years, when DBS started to generate profits, Digilog exercised its conversion option and consolidated from that point forward.

Although DBS had been set up as an "independent" corporation, the SEC took the position that the contractual and operating relationships between the two companies were such that they should have been viewed as constituting a single enterprise for financial reporting purposes. The defendants in the enforcement action, Digilog's auditors, consented to a settlement. The settlement included the opinion by the SEC that consolidation would have provided a user of the financial statements with the most meaningful presentation in accordance with GAAP—even though no specific GAAP at that time directly addressed Digilog's "creative" accounting solution.

Eventually, after many more years of debate, and in the wake of the Enron scandal, which also involved abuse of subsequent consolidation rules, the concept of a "variable interest entity" (VIE) was created. A key aspect is control for consolidation purposes; even in the absence of voting control, consolidation is necessary if the investor has the ability to exert influence on the financial and operating policy of the entity and is exposed, or has rights, to variable returns from its investment in the entity. Although the term VIE is not employed by IFRS, its provisions are similar.

Given the facts above and the consolidation rules for a variable interest entity, Digilog is *most likely* to try to argue that it does not need to consolidate DBS because:

A Digilog does not have voting control.

B Digilog's interest income from DBS is not variable.

C DBS's manager has operational and financial control.

Solution:

C is correct. Digilog is most likely to assert that operational and financial control rest with DBS's manager. However, the assertion is not likely to be accepted because the manager's investment is a few thousand dollars compared with $10 million by Digilog. Simply not having voting control is not sufficient to avoid consolidation. Digilog is exposed to variable returns because of possible losses and the convertibility option.

Example 4 considers asset impairments and restructuring charges and their implications.

EXAMPLE 4

Asset Impairments and Restructuring Charges

Two related topics that almost always require special consideration on the part of analysts are asset impairments and restructuring charges. Asset impairments are write-downs of assets required when circumstances indicate that the carrying amount of an asset is excessive compared with the expected future benefits.

The term "restructuring charge" is used under IFRS to indicate a sale or termination of a line of business, closure of business locations, changes in management structure, and/or a fundamental reorganization. All of these events could also give rise to the recognition of a liability (e.g., a commitment to make employee severance payments or to make a payment to settle a lease).

On 25 April 2013, Fuji Electric Co., Ltd, a Japanese company reporting under the GAAP of its home country, announced an impairment loss on land, buildings, structures, and leased assets employed in its "solar cell and module business" in the amount of ¥6.5 billion (Fuji Electric 2013). The entire loss was recorded in its 2012 fiscal year (ending 31 March). Assets and net income were reduced by ¥6.5 billion.

Elan Corporation, plc, a biotechnology company headquartered in Ireland, reported US$42.4 million in restructuring and other costs incurred during fiscal year 2012 related to its decision to close a research facility in San Francisco, with the loss of around 200 jobs, and to shift much of its operations back to Ireland because of changing business conditions. Some of these costs were associated with the obligation to make current and deferred employee severance payments (Leuty 2012).[7]

Recognizing an impairment loss and restructuring charges in a single period, although consistent with most GAAP, is *most likely* to overstate:

A prior periods' net incomes.

B current period's net income.

C future periods' net incomes.

Solution:

A is correct. The impairment and the restructuring were likely the result of past activities and should be taken into account when evaluating past net incomes. The current period's net income, unless the impairment or restructuring is expected to be repeated, is understated. Future period net income may be overstated if reversals occur, but such behavior is not likely. Charging the entire impairment loss and restructuring charge in the current period are examples of conservative accounting principles.

An analyst would likely consider it probable that the events giving rise to Fuji Electric's impairment loss (evidently, declining activity and future prospects for its solar business) had actually occurred over a longer period than that single year. Similarly, an analyst might view the restructuring charge at Elan as relating to previous periods.

When faced with a restructuring charge, an impairment charge, or a combination of the two, an analyst should consider whether similar events occur regularly enough such that they should be factored into estimates of permanent earnings, or whether they should be regarded as one-off items that provide little information about the future earnings of the remaining activities of the company. If it is the former, then the

7 See also Elan Corporation, plc, Form 20-F, filed 12 February 2013.

analyst should attempt to "normalize" earnings by essentially spreading the current restructuring/impairment charge(s) over past periods as well as the current period. If an item is truly one-off—say, the financial effects of a natural disaster—then the analyst is justified in "normalizing" earnings by excluding the item from earnings. This process will require a significant amount of judgment, best informed by knowledge of the underlying facts and circumstances.

Items that are commonly encountered by analysts include the following:

- Revisions to ongoing estimates, such as the remaining economic lives of assets, may lead an analyst to question whether an earlier change in estimate would have been more appropriate.
- Sudden increases to allowances and reserves could call into question whether the prior estimates resulted in overstatement of prior periods' earnings instead of an unbiased picture of economic reality.
- Large accruals for losses (e.g., environmental or litigation-related liabilities) suggest that prior periods' earnings may have been overstated because of the failure to accrue losses earlier.

Management may use items such as reserves and allowances to manage or smooth earnings. The application of accounting standards illustrated in Examples 3 and 4 results in financial statements that may not reflect economic reality. Accounting standards may result in some economic assets and liabilities not being reflected in the financial statements. An example is research and development (R&D) expense. Accounting standards do not permit the capitalization of expenditures for R&D expense, yet R&D produces assets that, in turn, produce future benefits. Accounting standards prohibit R&D's capitalization because of the difficulty in assessing which expenditures will actually produce future benefits and which expenditures will produce nothing. Accounting standards may also result in some information being reported in other comprehensive income rather than through net income. For example, classifying marketable securities as "available for sale" will result in their changes in fair value being reported in other comprehensive income. Contrast that reporting result against that for marketable securities classified as "trading": Their changes in fair value are reported in net income.

No basis of accounting can be expected to recognize all of the economic assets and liabilities for an entity. Consequently, figuring out what *is not* reported can be challenging. One frequently encountered example of an unrecognized asset is a company's sales order backlog. Under most GAAP, revenue is not recognized (and an asset is not created) until services have been performed and other criteria have been met. However, in certain industries, particularly large-scale manufacturing, such as airplane manufacturing, the order backlog can be a significant unrecognized asset. When the amount of backlog is significant, it is typically discussed in the management commentary, and an analyst can use this information to adjust reported amounts and to prepare forecasts.

Another dilemma for analysts is judging whether an item presented in other comprehensive income (OCI) should be included in their analysis as net income. Examples of items presented in OCI include the following:

- unrealized holding gains and losses on certain investments in equity securities,
- unrealized holding gains (and subsequent losses) on items of property and equipment for which the "revaluation option" is elected (IFRS only),
- effects on owners' equity resulting from the translation of the foreign currency-denominated financial statements of a foreign operation to the reporting currency of the consolidated entity,

- certain changes to net pension liability or asset, and
- gains and losses on derivative financial instruments (and certain foreign currency-denominated non-derivative financial instruments) accounted for as a hedge of future cash flows.

When an analyst decides that a significant item presented in OCI should be included in net income, the analyst can adjust reported and forecasted amounts accordingly.

6 EVALUATING THE QUALITY OF FINANCIAL REPORTS: GENERAL STEPS

c describe how to evaluate the quality of a company's financial reports;

Prior to beginning any financial analysis, an analyst should clarify the purpose and context and clearly understand the following:

- What is the purpose of the analysis? What questions will this analysis answer?
- What level of detail will be needed to accomplish this purpose?
- What data are available for the analysis?
- What are the factors or relationships that will influence the analysis?
- What are the analytical limitations, and will these limitations potentially impair the analysis?

In the context of evaluating the quality of financial reports, an analyst is attempting to answer two basic questions:

1. Are the financial reports GAAP-compliant and decision-useful?
2. Are the results (earnings) of high quality? Do they provide an adequate level of return, and are they sustainable?

General steps, which fit within the general framework just mentioned, are discussed first. Following these steps may help an analyst evaluate the quality of financial reports (answering the two basic questions). Then, quantitative tools for evaluating the quality of financial reports are discussed.

6.1 General Steps to Evaluate the Quality of Financial Reports

It is important to note that the steps presented here are meant to serve as a general guideline only. An analyst may choose to add steps, emphasize or deemphasize steps, or alter the order of the steps. Companies are unique, and variation in specific analytical projects will require specific approaches.

1. Develop an understanding of the company and its industry. Understanding the economic activities of a company provides a basis for understanding why particular accounting principles may be appropriate and why particular financial metrics matter. Understanding the accounting principles used by a company *and* its competitors provides a basis for understanding what constitutes the norm—and to assess whether a company's treatment is appropriate.
2. Learn about management. Evaluate whether the company's management has any particular incentives to misreport. Review disclosures about compensation and insider transactions, especially insiders' sales of the company's stock. Review the disclosures concerning related-party transactions.

3 Identify significant accounting areas, especially those in which management judgment or an unusual accounting rule is a significant determinant of reported financial performance.

4 Make comparisons:

   A Compare the company's financial statements and significant disclosures in the current year's report with the financial statements and significant disclosures in the prior year's report. Are there major differences in line items or in key disclosures, such as risk disclosures, segment disclosures, classification of specific expense, or revenue items? Are the reasons for the changes apparent?

   B Compare the company's accounting policies with those of its closest competitors. Are there significant differences? If so, what is the directional effect of the differences?

   C Using ratio analysis, compare the company's performance with that of its closest competitors.

5 Check for warnings signs of possible issues with the quality of the financial reports. For example,

   - declining receivables turnover could suggest that some revenues are fictitious or recorded prematurely or that the allowance for doubtful accounts is insufficient;
   - declining inventory turnover could suggest obsolescence problems that should be recognized; and
   - net income greater than cash provided by operations could suggest that aggressive accrual accounting policies have shifted current expenses to later periods.

6 For firms operating in multiple segments by geography or product—particularly multinational firms—consider whether inventory, sales, and expenses have been shifted to make it appear that a company is positively exposed to a geographic region or product segment that the investment community considers to be a desirable growth area. An analyst may suspect that this shift is occurring if the segment is showing strong performance while the consolidated results remain static or worsen.

7 Use appropriate quantitative tools to assess the likelihood of misreporting.

The first six steps listed describe a qualitative approach to evaluating the quality of financial reports. In addition to the qualitative approach, quantitative tools have been developed to help in evaluating financial reports.

QUANTITATIVE TOOLS TO ASSESS THE LIKELIHOOD OF MISREPORTING 7

c describe how to evaluate the quality of a company's financial reports;

d evaluate the quality of a company's financial reports;

This section describes some tools for assessing the likelihood of misreporting (Step 7 above). If the likelihood of misreporting appears high, an analyst should take special care in analyzing, including qualitatively analyzing, the financial reports of the company.

7.1 Beneish Model

Messod D. Beneish and colleagues conducted studies to identify quantitative indicators of earnings manipulation and to develop a model to assess the likelihood of misreporting (Beneish 1999; Beneish, Lee, and Nichols 2013). The following is the Beneish model and its variables. After the description of each variable, an intuitive explanation of why it is included is given.

The probability of manipulation (M-score) is estimated using a probit model:[8]

$$M\text{-score} = -4.84 + 0.920\ (\text{DSR}) + 0.528\ (\text{GMI}) + 0.404\ (\text{AQI}) + 0.892\ (\text{SGI}) + 0.115\ (\text{DEPI}) - 0.172\ (\text{SGAI}) + 4.679\ (\text{Accruals}) - 0.327\ (\text{LEVI})$$

where

M-score = Score indicating probability of earnings manipulation

DSR (days sales receivable index) = $(\text{Receivables}_t/\text{Sales}_t)/(\text{Receivables}_{t-1}/\text{Sales}_{t-1})$.

Changes in the relationship between receivables and sales could indicate inappropriate revenue recognition.

GMI (gross margin index) = $\text{Gross margin}_{t-1}/\text{Gross margin}_t$.

Deterioration in margins could predispose companies to manipulate earnings.

AQI (asset quality index) = $[1 - (\text{PPE}_t + \text{CA}_t)/\text{TA}_t]/[1 - (\text{PPE}_{t-1} + \text{CA}_{t-1})/\text{TA}_{t-1}]$, where PPE is property, plant, and equipment; CA is current assets; and TA is total assets.

Change in the percentage of assets other than in PPE and CA could indicate excessive expenditure capitalization.

SGI (sales growth index) = $\text{Sales}_t/\text{Sales}_{t-1}$.

Managing the perception of continuing growth and capital needs from actual growth could predispose companies to manipulate sales and earnings.

DEPI (depreciation index) = $\text{Depreciation rate}_{t-1}/\text{Depreciation rate}_t$, where Depreciation rate = Depreciation/(Depreciation + PPE).

Declining depreciation rates could indicate understated depreciation as a means of manipulating earnings.

SGAI (sales, general, and administrative expenses index) = $(\text{SGA}_t\ /\text{Sales}_t)/(\text{SGA}_{t-1}/\text{Sales}_{t-1})$.

An increase in fixed SGA expenses suggests decreasing administrative and marketing efficiency, which could predispose companies to manipulate earnings.

Accruals = (Income before extraordinary items[9] − Cash from operations)/Total assets.

Higher accruals can indicate earnings manipulation.

LEVI (leverage index) = $\text{Leverage}_t/\text{Leverage}_{t-1}$, where Leverage is calculated as the ratio of debt to assets.

Increasing leverage could predispose companies to manipulate earnings.

---

8 Variables that are statistically significant in the empirical results of Beneish (1999) include the days sales receivable index, gross margin index, asset quality index, sales growth index, and accruals.

9 US GAAP for fiscal periods beginning after December 15, 2015, will no longer include the concept of extraordinary items.

The *M*-score in the Beneish model is a normally distributed random variable with a mean of 0 and a standard deviation of 1.0. Consequently, the probability of earnings manipulation indicated by the model can be calculated by using the cumulative probabilities for a standard normal distribution or the NORMSDIST function in Excel. For example, *M*-scores of –1.49 and –1.78 indicate that the probability of earnings manipulation is 6.8% and 3.8%, respectively. Higher *M*-scores (i.e., less negative numbers) indicate an increased probability of earnings manipulation. The probability is given by the amount in the left side of the distribution.

The use of the *M*-score to classify companies as potential manipulators depends on the relative cost of Type I errors (incorrectly classifying a manipulator company as a non-manipulator) and Type II errors (incorrectly classifying a non-manipulator as a manipulator). The cutoff value for classification minimizes the cost of misclassification. Beneish considered that the likely relevant cutoff for investors is a probability of earnings manipulation of 3.8% (an *M*-score exceeding –1.78).[10] Example 5 shows an application of the Beneish model.

EXAMPLE 5

Application of the Beneish Model

Exhibit 5 presents the variables and Beneish's *M*-Score for XYZ Corporation (a hypothetical company).

Exhibit 5 XYZ Corporation *M*-Score

	Value of Variable	Coefficient from Beneish Model	Calculations
DSR	1.300	0.920	1.196
GMI	1.100	0.528	0.581
AQI	0.800	0.404	0.323
SGI	1.100	0.892	0.981
DEPI	1.100	0.115	0.127
SGAI	0.600	–0.172	–0.103
Accruals	0.150	4.679	0.702
LEVI	0.600	–0.327	–0.196
Intercept			–4.840
M-score			–1.231
Probability of manipulation			10.93%

1 Would the results of the Beneish model lead an analyst, using a –1.78 *M*-score as the cutoff, to flag XYZ as a likely manipulator?

2 The values of DSR, GMI, SGI, and DEPI are all greater than one. In the Beneish model, what does this indicate for each variable?

10 See Beneish (1999) for an explanation and derivation of the cutoff values. Beneish et al. (2013) use an *M*-score exceeding –1.78 as the cutoff value.

Solution to 1:

Yes, the model could be expected to lead an analyst to flag XYZ as a likely manipulator. The *M*-score is higher than the cutoff of −1.78, indicating a higher-than-acceptable probability of manipulation. For XYZ Corporation, the model estimates the probability of manipulation as 10.93%. Although the classification of companies as manipulators depends on the relative cost of Type I errors and Type II errors, the value of 10.93% greatly exceeds the cutoff of 3.8% that Beneish identified as the relevant cutoff.

Solution to 2:

Indications are as follows:

A The value greater than one for DSR indicates that receivables as a percentage of sales have increased; this change may be an indicator of inappropriate revenue recognition. XYZ may have shipped goods prematurely and recognized revenues belonging in later periods. Alternatively, it may be caused by customers with deteriorating credit-paying ability—still a problem for the analyst of XYZ.

B The value greater than one for GMI indicates that gross margins were higher last year; deteriorating margins could predispose companies to manipulate earnings.

C The value greater than one for SGI indicates positive sales growth relative to the previous year. Companies could be predisposed to manipulate earnings to manage perceptions of continuing growth and also to obtain capital needed to support growth.

D The value greater than one for DEPI indicates that the depreciation rate was higher in the prior year; a declining depreciation rate can indicate manipulated earnings.

7.2 Other Quantitative Models

Researchers have examined numerous factors that contribute to assessing the probability that a company is engaged in accounting manipulation. Variables that have been found useful for detecting misstatement include accruals quality; deferred taxes; auditor change; market-to-book value; whether the company is publicly listed and traded; growth rate differences between financial and non-financial variables, such as number of patents, employees, and products; and aspects of corporate governance and incentive compensation.[11]

7.3 Limitations of Quantitative Models

Accounting is a partial representation of economic reality. Consequently, financial models based on accounting numbers are only capable of establishing associations between variables. The underlying cause and effect can only be determined by a deeper analysis of actions themselves—perhaps through interviews, surveys, or investigations by financial regulators with enforcement powers.

An additional concern is that earnings manipulators are just as aware as analysts of the power of quantitative models to screen for possible cases of earnings manipulation. It is not surprising to learn, therefore, that Beneish et al.'s 2013 study found

11 A summary of research on predicting accounting misstatement is provided in Dechow, Ge, Larson, and Sloan (2011).

that the predictive power of the Beneish model is declining over time. Undoubtedly, many managers have learned to test the detectability of earnings manipulation tactics by using the model to anticipate analysts' perceptions. Thus, as useful as the Beneish model may be, the search for more powerful analytical tools continues. It is necessary for analysts to use qualitative, not just quantitative, means to assess quality.

EARNINGS QUALITY INDICATORS AND RECURRING EARNINGS 8

f describe indicators of earnings quality;

This section first discusses indicators of earnings quality and then describes how to evaluate the earnings quality of a company. Analytical tools related to identifying very poor earnings/results quality, such as quantitative approaches to assessing the probability of bankruptcy, are also discussed.

8.1 Indicators of Earnings Quality

In general, the term "earnings quality" can be used to encompass earnings, cash flow, and balance sheet quality. This section, however, focuses specifically on earnings quality. High earnings quality is often considered to be evidenced by earnings that are sustainable and represent returns equal to or in excess of the company's cost of capital.[12] High-quality earnings increase the value of the company more than low-quality earnings, and the term "high-quality earnings" assumes that reporting quality is high. In contrast, low-quality earnings are insufficient to cover the company's cost of capital and/or are derived from non-recurring, one-off activities. In addition, the term "low-quality earnings" can also be used when the reported information does not provide a useful indication of the company's performance.

A variety of alternatives have been used as indicators of earnings quality: recurring earnings, earnings persistence and related measures of accruals, beating benchmarks, and after-the-fact confirmations of poor-quality earnings, such as enforcement actions and restatements.

8.1.1 *Recurring Earnings*

When using a company's current and prior earnings as an input to forecast future earnings (for example, for use in an earnings-based valuation), an analyst focuses on the earnings that are expected to recur in the future. For example, earnings from subsidiaries that have been selected for disposal, which must be separately identified as "discontinued operations," are typically excluded from forecasting models. A wide range of other types of items may be non-recurring—for example, one-off asset sales, one-off litigation settlements, or one-off tax settlements. Reported earnings that contain a high proportion of non-recurring items are less likely to be sustainable and are thus considered lower quality.

Enron, an energy distribution company and a company famous for misreporting, presented non-recurring items, among other reporting issues, in such a way that they created an illusion of a solidly performing company. Example 6 shows aspects of Enron's reporting.

12 The residual income model of valuation is most closely linked to this concept of high earnings quality.

EXAMPLE 6

Non-Recurring Items

Enron Corp.

Exhibit 6 Excerpts from Enron and Subsidiaries Consolidated Income Statement, Year-Ended 31 December

(In millions, except per share amounts)	2000	1999	1998
Total revenues	$100,789	$40,112	$31,260
Total costs and expenses	98,836	39,310	29,882
Operating income	$1,953	$802	$1,378
Other income and deductions			
Equity in earnings of unconsolidated equity affiliates	$87	$309	$97
Gains on sales of non-merchant assets	146	541	56
Gain on the issuance of stock by TNPC, Inc.	121	0	0
Interest income	212	162	88
Other income, net	–37	181	–37
Income before interest, minority interests, and income taxes	$2,482	$1,995	$1,582

1 How does the trend in Enron's operating income compare with the trend in its income after other income and deductions (i.e., Income before interest, minority interests, and income taxes)?

2 What items appear to be non-recurring as opposed to being a result of routine operations? How significant are these items?

3 The Enron testimony of short seller James Chanos before US Congress referred to "a number of one-time gains that boosted Enron's earnings" as one of the items that "strengthened our conviction that the market was mispricing Enron's stock" (Chanos 2002). What does Chanos's statement indicate about how Enron's earnings information was being used in valuation?

Solution to 1:

Enron's operating income varied dramatically from year to year, declining from 1998 to 1999 and then more than doubling in 2000. In contrast, Enron's income before interest, minority interests, and income taxes shows a smooth, upward trend with significant increases each year. The increases were 24% and 26% for 2000 and 1999 relative to 1999 and 1998, respectively.

Solution to 2:

Items that appear to be non-recurring are gains on sales of non-merchant assets and the gain on the issuance of stock by TNPC. Although gains from sales of non-merchant assets do recur in each year, this type of activity is not a part of Enron's energy distribution operations. In addition, two other non-operating items—the amount of equity in earnings from unconsolidated subsidiaries and the amount of other income—are highly variable. Two aspects of these items are significant. First, the smooth, upward trend in Enron's income is the direct result of these items. Second, these items collectively represent a significant percentage of the company's income before interest, minority interests, and income taxes, particularly in 1999 when these items represent 52% of the total: ($309 + $541+ $181)/ $1,995 = $1,031/$1,995.

Solution to 3:

Chanos's statement suggests that at least some market participants were mistakenly using Enron's reported income as an input to earnings-based valuation, without adjusting for non-recurring items.

Although evaluating non-recurring items for inclusion in operating metrics is important for making appropriate historical comparisons and for developing appropriate inputs in valuation, another aspect of non-recurring items merits mention. Because classification of items as non-recurring is a subjective decision, classification decisions can provide an opportunity to inflate the amount potentially identified by a user of the income statement as repeatable earnings—those earnings expected from the company's business operations, which investors label as "recurring" or "core" earnings. In the absence of special or one-time items (such as restructuring charges, employee separation costs, goodwill impairment charges, or gains on disposals of assets), operating income is representative of these kinds of earnings. So-called classification shifting, which does not affect total net income, can inflate the amount reported as recurring or core earnings. This could be accomplished by re-classifying normal expenses to special items or by shifting operating expenses to income-decreasing discontinued operations. Anecdotal evidence of classification shifting exists (see Exhibit 7), but the evidence only emerges after the fact.[13] From an analyst's perspective, after-the-fact evidence of earnings management is not particularly useful for anticipating issues with earnings quality. Although it may not be possible to identify whether a company might be engaging in classification shifting, an analyst should nonetheless give special attention to income-decreasing special items, particularly if the company is reporting unusually high operating earnings for the period or if the classification of the item enabled the company to meet or beat forecasts for operating earnings.

Exhibit 7 Anecdotal Evidence of Classification Shifting

- Borden, a food and chemicals company: The SEC determined that the company had classified $146 million of operating expenses as part of a special item (restructuring charges) when the expenses should have been included in selling, general, and administrative expenses (Hwang 1994).
- AmeriServe Food Distribution Inc., which declared bankruptcy only four months after completing a $200 million junk bond issuance: A bankruptcy court–appointed examiner found that the company's financial statements "classified substantial operating expenses… as restructuring charges," which "masked the company's serious financial underperformance and delayed recognition by all parties of the severity of the problems faced by the company (Sherer 2000)."

(continued)

13 Archival evidence of classification shifting is presented in McVay (2006). McVay first models "expected core earnings" and then documents a relationship between reported-minus-expected core earnings and the number of special items. But in any given year, a company's management could attribute the unexpectedly high core earnings to economic improvements related to the special items; therefore, only the *ex post* evidence that unexpectedly high core earnings tend to reverse in the following year is suggestive of earnings management through classification shifting.

Exhibit 7 (Continued)

- Waste Management, which, in 1998, issued the then-largest restatement in SEC history: The enforcement documentation indicates that the company had improperly inflated operating income by netting non-operating gains from the sale of investments and discontinued operations against unrelated operating expenses (SEC 2001b).
- IBM: Revised disclosures, prompted by SEC scrutiny and analysts' requests, showed that the company had classified intellectual property income as an offset to selling, general, and administrative expenses. This classification resulted in an understatement of operating expenses and thus an overstatement of core earnings by $1.5 billion and $1.7 billion in 2001 and 2000, respectively (Bulkeley 2002).

Companies understand that investors differentiate between recurring and non-recurring items. Therefore, in addition to presenting components of income on the face of the income statement, many companies voluntarily disclose additional information to facilitate the differentiation between recurring and non-recurring items. Specifically, companies may disclose both total income and so-called *pro forma* income (or adjusted income, also referred to as non-GAAP measures, or non-IFRS measures if IFRS is applicable) that has been adjusted to exclude non-recurring items. Disclosures of *pro forma* income must be accompanied by a reconciliation between *pro forma* income and reported income. It is important to be aware, however, that determination of whether an item is non-recurring involves judgment, and some companies' managers may be motivated to consider an item non-recurring if it improves a performance metric relevant to investors. For example, Groupon, an online discount provider, included in its original initial public offering (IPO) filing a *pro forma* (i.e., non-GAAP) measure of operating income that excluded online marketing costs. The SEC determined that the measure was misleading and subsequently required the company to eliminate that measure as reported. Overall, although voluntarily disclosed adjustments to reported income can be informative, an analyst should review the information to ensure that excluded items are truly non-recurring.[14]

9 EARNINGS PERSISTENCE AND RELATED MEASURES OF ACCRUALS

e describe the concept of sustainable (persistent) earnings;

One property of high earnings quality is earnings persistence—that is, sustainability of earnings excluding items that are obviously non-recurring and persistence of growth in those earnings. The assumption is that, for equity valuation models involving earnings forecasts, more persistent earnings are more useful inputs. Persistence can be expressed as the coefficient on current earnings in a simple model:[15]

$$\text{Earnings}_{t+1} = \alpha + \beta_1 \text{Earnings}_t + \varepsilon$$

A higher coefficient (β_1) represents more persistent earnings.

14 A survey of non-GAAP earnings in the S&P 500 is presented in Ciesielski and Henry (2017). In the article, the authors provide key prescriptions in evaluating non-GAAP earnings disclosure.

15 Descriptions of certain indicators in this section follow Dechow, Ge, and Schrand (2010).

Earnings can be viewed as being composed of a cash component and an accruals component. The accrual component arises from accounting rules that reflect revenue in the period earned and expenses in the period incurred—not at the time of cash movement. For example, a sale of goods on account results in accounting income in the period the sale is made. If the cash collection occurs in a subsequent period, the difference between reported net income and cash collected constitutes an accrual. When earnings are decomposed into a cash component and an accruals component, research has shown that the cash component is more persistent (Sloan 1996). In the following model, the coefficient on cash flow (β_1) has been shown to be higher than the coefficient on accruals (β_2), indicating that the cash flow component of earnings is more persistent:

$$\text{Earnings}_{t+1} = \alpha + \beta_1\text{Cash flow}_t + \beta_2\text{Accruals}_t + \varepsilon$$

Because of the greater persistence of the cash component, indicators of earnings quality evolved to measure the relative size of the accruals component of earnings. Earnings with a larger component of accruals would be less persistent and thus of lower quality.

An important distinction is between accruals that arise from normal transactions in the period (called "non-discretionary") and accruals that result from transactions or accounting choices outside the normal, which are possibly made with the intent to distort reported earnings (called "discretionary accruals"). Outlier discretionary accruals are an indicator of possibly manipulated—and thus low-quality—earnings. One common approach to identifying abnormal accruals is first to model companies' normal accruals and then to determine outliers. A company's normal accruals are modeled as a function of economic factors, such as growth in credit sales and the amount of depreciable assets. Growth in credit sales would be expected to result in accounts receivable growth, and depreciable assets would be associated with the amount of depreciation. To apply this approach, total accruals are regressed on the factors expected to give rise to normal accruals, and the residual of the regression would be considered a proxy for abnormal accruals.

This approach was pioneered by academics and subsequently adopted in practice.[16] The SEC describes its approach to modeling abnormal accruals:

> Our Accounting Quality Model extends the traditional approach [often based on the popular Jones Model or the Modified Jones Model] by allowing discretionary accrual factors to be a part of the estimation. Specifically, we take filings information across all registrants and estimate total accruals as a function of a large set of factors that are proxies for discretionary and non-discretionary components…. Discretionary accruals are calculated from the model estimates and then used to screen firms that appear to be managing earnings most aggressively. (Lewis 2012)

One simplified approach to screening for abnormal accruals is to compare the magnitude of total accruals across companies. To make a relevant comparison, the accruals would be scaled—for example, by average assets or by average net operating income. Under this approach, high amounts of accruals are an indicator of possibly manipulated and thus low-quality earnings.

A more dramatic signal of questionable earnings quality is when a company reports positive net income but negative operating cash flows. This situation is illustrated in Example 7.

16 See Jones (1991) and Dechow, Sloan, and Sweeney (1995). These seminal academic papers produced the Jones Model and the Modified Jones Model.

EXAMPLE 7

Discrepancy between Net Income and Operating Cash Flows

Allou Health & Beauty Care, Inc.

Allou Health & Beauty Care, Inc. was a manufacturer and distributor of hair and skin care products. Exhibit 8 presents excerpts from the company's financial statements from 2000 to 2002. Following the periods reported in these statements, Allou's warehouses were destroyed by fire, for which the management was found to be responsible. Allou was subsequently shown to have fraudulently inflated the amount of its sales and inventories in those years.

Exhibit 8 Illustration of Fraudulent Reporting in which Reported Net Income Significantly Exceeded Reported Operating Cash Flow, Annual Data 10-K for Allou Health & Beauty Care, Inc., and Subsidiaries

Years ended 31 March	2002	2001	2000
Excerpt from Income Statement			
Revenues, net	$564,151,260	$548,146,953	$421,046,773
Costs of revenue	500,890,588	482,590,356	367,963,675
Gross profit	$63,260,672	$65,556,597	$53,083,098
	⋮	⋮	⋮
Income from operations	27,276,779	28,490,063	22,256,558
	⋮	⋮	⋮
Income from continuing operations*	$6,589,658	$2,458,367	$7,043,548
Excerpt from Statement of Cash Flows			
Cash flows from operating activities:			
Net income from continuing operations	$6,589,658	$2,458,367	$7,043,548
Adjustments to reconcile net income to net cash used in operating activities:			
[Portions omitted]	⋮	⋮	⋮
Decrease (increase) in operating assets:			
Accounts receivable	(24,076,150)	(9,725,776)	(25,691,508)
Inventories	(9,074,118)	(12,644,519)	(40,834,355)
Net cash used in operating activities	$(17,397,230)	$(34,195,838)	$(27,137,652)

* The difference between income from operations and income from continuing operations included deductions for interest expense and provision for income taxes in each year and for a $5,642,678 loss on impairment of investments in 2001.

Referring to Exhibit 8, answer the following questions:

1 Based on the income statement data, evaluate Allou's performance over the period shown.

2 Compare Allou's income from continuing operations and cash flows from operating activities.

3 Interpret the amounts shown as adjustments to reconcile income from continuing operations to net cash used in operating activities.

Solution to 1:

Based on the income statement, the following aspects of Allou's performance are notable. Revenues grew in each of the past three years, albeit more slowly in the latest year shown. The company's gross margin declined somewhat over the past three years but has been fairly stable. Similarly, the company's operating margin declined somewhat over the past three years but has been fairly stable at around 5%. The company's income from continuing operations was sharply lower in 2001 as a result of an impairment loss. The company showed positive net income in each year. Overall, the company showed positive net income in each year, and its performance appears to be reasonably stable based on the income statement data.

Note: Gross margin is gross profit divided by revenues. For example, for 2002, \$63,260,672 divided by \$564,151,260 is 11.2%. The ratios for 2001 and 2000 are 12.0% and 12.6%, respectively.

Operating margin is income from operations divided by revenues. For example, for 2002, \$27,276,779 divided by \$564,151,260 is 4.8%. The ratios for 2001 and 2000 are 5.2% and 5.3%, respectively.

Solution to 2:

Allou reported positive income from continuing operations but negative cash from operating activities in each of the three years shown. Persistent negative cash from operating activities is not sustainable for a going concern.

Solution to 3:

The excerpt from Allou's Statement of Cash Flows shows that accounts receivable and inventories increased each year. This increase can account for most of the difference between the company's income from continuing operations and net cash used in operating activities. The company seems to be accumulating inventory and not collecting on its receivables.

Note: The statement of cash flows, prepared using the indirect method, adjusts net income to derive cash from operating activities. An increase in current assets is subtracted from the net income number to derive the cash from operating activities.

Similar to Allou, the quarterly data for Enron shown in Exhibit 9 shows positive net income but negative cash from operating activities in quarters that were subsequently shown to have been misreported.

Exhibit 9

Quarterly Data 10-Q: Enron and Subsidiaries

Three months ended 31 March ($ millions)	2001	2000
Net income	425	338
Net cash used in operating activities	(464)	(457)

Annual Data 10-K: Enron and Subsidiaries

Year ended 31 December ($ millions)	2000	1999	1998
Net income	979	893	703
Net cash provided by operating activities	4,779	1,228	1,640

An analyst might also question why net cash provided by operating activities was more than double that of net income in 1998, almost 50% greater than net income in 1999, and almost five times net income in 2000.

Although sizable accruals (roughly, net income minus operating cash flow) can indicate possibly manipulated and thus low-quality earnings, it is not necessarily the case that fraudulently reporting companies will have such a profile. For example, as shown in Exhibit 9, Enron's annual operating cash flows exceeded net income in all three years during which fraudulent financial reporting was subsequently revealed. Some of the fraudulent transactions undertaken by Enron were specifically aimed at generating operating cash flow. It is advisable for investors to explore and understand why the differences exist. The company's ability to generate cash from operations ultimately affects investment and financing within the company.

Similarly, as shown in Exhibit 10, WorldCom showed cash from operating activities in excess of net income in each of the three years shown, although the company was subsequently found to have issued fraudulent reports. WorldCom's most significant fraudulent reporting was improperly capitalizing (instead of expensing) certain costs. Because capital expenditures are shown as investing cash outflows rather than operating cash outflows, the company's fraudulent reporting had the impact of inflating operating cash flows.

Exhibit 10 Example of Fraudulent Reporting in which Reported Net Income Did Not Significantly Exceed Reported Operating Cash Flow, WorldCom Inc. and Subsidiaries ($ millions)

For the years ended 31 December	1999	2000	2001
Net income (loss)	$4,013	$4,153	$1,501
Net cash provided by operating activities	11,005	7,666	7,994

In summary, although accrual measures (i.e., differences between net income and operating cash flows) can serve as indicators of earnings quality, they cannot be used in isolation or applied mechanically. WorldCom shows how comparing cash-basis measures, such as cash provided by operating activities, with net income may provide a false sense of confidence about net income. Net income is calculated using subjective estimates, such as expected life of long-term assets, that can be easily manipulated. In each year shown in Exhibit 10, the cash provided by operations exceeded net income (earnings), suggesting that the earnings were of high quality; an analyst looking at this without considering the investing activities would have felt a false sense of security in the reported net income.

MEAN REVERSION IN EARNINGS, BEATING BENCHMARKS AND EXTERNAL INDICATORS OF POOR-QUALITY EARNINGS

10

g explain mean reversion in earnings and how the accruals component of earnings affects the speed of mean reversion;

A key analyst responsibility is to forecast earnings for the purpose of valuation in making investment decisions. The accuracy and credibility of earnings forecasts should increase when a company's earnings stream possesses a high degree of persistence. As already discussed, earnings can be viewed as being composed of a cash flow element plus an accruals element. Sustainable, persistent earnings are driven by the cash flow element of earnings, whereas the accruals element adds information about the company's performance. At the same time, the accruals component can detract from the stability and persistence of earnings because of the estimation process involved in calculating them.

Academic research has shown empirically what we already know intuitively: Nothing lasts forever. Extreme levels of earnings, both high and low, tend to revert to normal levels over time. This phenomenon is known as "mean reversion in earnings" and is a natural attribute of competitive markets. A company experiencing poor earnings performance will shut down or minimize its losing operations and replace inferior managers with ones capable of executing an improved strategy, resulting in improved earnings. At the other extreme, a company experiencing abnormally high profits will attract competition unless the barriers to entry are insurmountable. New competitors may reduce their prices to gain a foothold in an existing company's markets, thereby reducing the existing company's profits over time. Whether a company is experiencing abnormally high or low earnings, the net effect over time is that a return to the mean should be anticipated.

Nissim and Penman (2001) demonstrated that the mean reversion principle exists across a wide variety of accounting-based measures. In a time-series study encompassing companies listed on the New York Stock Exchange and the American Stock Exchange between 1963 and 1999, they tracked such measures as residual income, residual operating income, return on common equity, return on net operating assets, growth in common equity, core sales profit margins, and others. Beginning with data from 1964, they sorted the companies into 10 equal portfolios based on their ranking for a given measure and tracked the median values in each portfolio in each of the next five-year periods. At the end of each fifth year, the portfolios were re-sorted. The process was extended through 1994, yielding means of portfolio medians over seven rankings. The findings were similar across the metrics, showing a clear reversion to the mean over time.

For example, looking at the pattern for return on net operating assets (RNOA),[17] they found that the range of observed RNOAs was between 35% and –5% at the start of the observations but had compressed to a range of 22% to 7% by the end of the study. Their work illustrates the point that extremely strong or weak performance cannot be sustained forever. They also found that the RNOAs of the portfolios that were not outliers in either direction in Year 1—outperformance or underperformance—did not stray over time, staying constant or nearly so over the entire observation period.

The lesson for analysts is clear: One cannot simply extrapolate either very high or very low earnings into the future and expect to construct useful forecasts. In order to be useful, analysts' forecasts need to take into account normalized earnings over the relevant valuation time frame. As discussed, earnings are the sum of cash flows and accruals, and they will be more sustainable and persistent when the cash flow component dominates earnings. If earnings have a significant accruals component, it may hasten the earnings' reversion to the mean, even more so when the accrual elements are outliers relative to the normal amount of accruals in a company's earnings. In constructing their forecasts of future earnings, analysts need to develop a realistic cash flow model and realistic estimates of accruals as well.

10.1 Beating Benchmarks

Announcements of earnings that meet or exceed benchmarks, such as analysts' consensus forecasts, typically result in share price increases. However, meeting or beating benchmarks is not necessarily an indicator of high-quality earnings. In fact, exactly meeting or only narrowly beating benchmarks has been proposed as an indicator of earnings manipulation and thus low-quality earnings. Academic research has documented a statistically large clustering slightly above zero of actual benchmark differences, and this clustering has been interpreted by some as evidence of earnings management.[18] There is, however, disagreement about whether exactly meeting or only narrowly beating is an indicator of earnings manipulation.[19] Nonetheless, a company that consistently reports earnings that exactly meet or only narrowly beat benchmarks can raise questions about its earnings quality.

10.2 External Indicators of Poor-Quality Earnings

Two external indicators of poor-quality earnings are enforcement actions by regulatory authorities and restatements of previously issued financial statements. From an analyst's perspective, recognizing poor earnings quality is generally more valuable if it can be done before deficiencies become widely known and confirmed. Therefore, the external indicators of poor earnings quality are relatively less useful to an analyst. Nonetheless, even though it might be better to recognize poor earnings quality early, an analyst should be alert to external indicators and be prepared to re-evaluate decisions.

---

17 Nissim and Penman define return on net operating assets as Operating income_t/Net operating assets_{t-1}. Net operating assets are operating assets (those assets used in operations) net of operating liabilities (those generated by operations).

EVALUATING THE EARNINGS QUALITY OF A COMPANY - REVENUE RECOGNITION CASE: SUNBEAM CORPORATION

11

h evaluate the earnings quality of a company;

The aim of analyzing earnings is to understand the persistence and sustainability of earnings. If earnings do not represent the financial realities faced by a company, then any forecast of earnings based on flawed reporting will also be flawed. Choices and estimates abound in financial reporting; and with those choices and estimates, the temptations for managers to improve their companies' performance by creative accounting are enormous. All too often, companies that appear to be extraordinary performers turn out to be quite ordinary or worse once their choice of accounting methods, including fraudulent choices, is uncovered by a regulator.

To avoid repeating the mistakes of the past, it may be helpful for analysts to learn how managers have used accounting techniques to enhance their companies' reported performance. Some cases provide useful lessons. In a study of 227 enforcement cases brought between 1997 and 2002, the SEC found that the most common accounting misrepresentation occurred in the area of revenue recognition (SEC 2003). Revenue is the largest single figure on the income statement and arguably the most important. Its sheer size and its effect on earnings, along with discretion in revenue recognition policies, have made it the most likely account to be intentionally misstated. For those reasons, investors should always thoroughly and skeptically analyze revenues. Too often, however, the chief concerns of analysts center on the quantitative aspects of revenues. They may ponder the growth of revenues and whether growth came from acquisitions or organically, but they rarely focus on the quality of revenues in the same way. A focus on the quality of revenues, including specifically on how it was generated, will serve analysts well. For example, was it generated by offering discounts or through bill-and-hold sales?

11.1 Revenue Recognition Case: Sunbeam Corporation

Premature/Fraudulent Revenue Recognition

Sunbeam Corporation was a consumer goods company focused on the production and sale of household appliances and outdoor products. In the mid- to late 1990s, it appeared that its new CEO, "Chainsaw Al" Dunlap, had engineered a turnaround at Sunbeam. He claimed to have done this through cutting costs and increasing revenues. The reality was different. Had more analysts performed basic but rigorous analysis of the financial statements in the earlier phases of Sunbeam's misreporting, they might have been more skeptical of the results produced by Chainsaw Al. Sunbeam engaged in numerous sales transactions that inflated revenues. Among them were the following:

- Sunbeam included one-time disposals of product lines in sales for the first quarter of 1997 without indicating that such non-recurring sales were included in revenues.
- At the end of the first quarter of 1997 (March), Sunbeam booked revenue and income from a sale of barbecue grills to a wholesaler. The wholesaler held the merchandise over the quarter's end without accepting ownership risks. The wholesaler could return the goods if it desired, and Sunbeam would pick up the cost of shipment both ways. All of the grills were returned to Sunbeam in the third quarter of 1997.

- Sunbeam induced customers to order more goods than they would normally through offers of discounts and other incentives. Often, the customers also had return rights on their purchases. This induced ordering had the effect of inflating current results by pulling future sales into the present. This practice is sometimes referred to as "channel stuffing." This policy was not disclosed by Sunbeam, which routinely made use of channel-stuffing practices at the end of 1997 and the beginning of 1998.
- Sunbeam engaged in bill-and-hold revenue practices. In a bill-and-hold transaction, revenue is recognized when the invoice is issued while the goods remain on the premises of the seller. These are unusual transactions, and the accounting requirements for them are very strict: The buyer must request such treatment, have a genuine business purpose for the request, and must accept ownership risks. Other criteria for justifying the use of this revenue recognition practice include the seller's past experience with bill-and-hold transactions, in which buyers took possession of the goods and the transactions were not reversed.

There was no real business purpose to the channel stuffing and bill-and-hold transactions at Sunbeam other than for the seller to accelerate revenue and for the buyers to take advantage of such eagerness without any risks on their part. In the words of the SEC, "these transactions were little more than projected orders disguised as sales" (SEC 2001a). Sunbeam did not make such transactions clear to analysts, and many of its disclosures from the fourth quarter of 1996 to the middle of 1998 were inadequate. Still, its methods of inflating revenue left indicators in the financial statements that should have alerted analysts to the low quality of its earnings and revenue reporting.

If customers are induced into buying goods they do not yet need through favorable payment terms or given substantial leeway in returning such goods to the seller, days' sales outstanding (DSO) may increase and returns may also increase. Furthermore, increases in revenue may exceed past increases and the increases of the industry and/or peers. Problems with and changes in collection, expressed through accounts receivable metrics, can give an analyst clues about the aggressiveness of the seller in making sales targets. Exhibit 11 contains relevant annual data on Sunbeam's sales and receivables from 1995 (before the misreporting occurred) through 1997 (when earnings management reached its peak level in the fourth quarter).

Exhibit 11 Information on Sunbeam's Sales and Receivables, 1995–1997

($ millions)	1995	1996	1997
Total revenue	$1,016.9	$984.2	$1,168.2
Change from prior year	—	–3.2%	18.7%
Gross accounts receivable	$216.2	$213.4	$295.6
Change from prior year	—	–1.3%	38.5%
Receivables/revenue	21.3%	21.7%	25.3%
Change in receivables/revenue	0.7%	0.4%	3.6%
Days' sales outstanding	77.6	79.1	92.4
Accounts receivable turnover	4.7	4.6	4.0

Source: Based on information in original company 10-K filings.

What can an analyst learn from the information in Exhibit 11?

- Although revenues dipped 3.2% in 1996, the year the misreporting began, they increased significantly in 1997 as Sunbeam's various revenue "enhancement" programs were implemented. The important factor to notice—the one that should have given an analyst insight into the quality of the revenues—is the simultaneous, and much greater, increase in the accounts receivable balance. Receivables increasing faster than revenues suggests that a company may be pulling future sales into current periods by offering favorable discounts or generous return policies. As it turned out, Sunbeam offered all of these inducements.
- The percentage relationship of receivables to revenue is another way of looking at the relationship between sales and the time it takes a company to collect cash from its customers. An increasing percentage of receivables to revenues means that a lesser percentage of sales has been collected. The decrease in collection on sales may indicate that customers' abilities to repay have deteriorated. It may also indicate that the seller created period-end sales by shipping goods that were not wanted by customers; the shipment would produce documentation, which serves as evidence of a sale. Receivables and revenue would increase by the same absolute amount, which would increase the percentage of receivables to revenue. Customers would return the goods to the seller in the following accounting period. The same thing would happen in the event of totally fictitious revenues. Revenues from a non-existent customer would simultaneously increase receivables by the same amount. An increase in the relationship between revenue and receivables provides analysts with a clue that collections on sales have declined or that there is a possible issue with revenue recognition.
- The number of days sales outstanding [Accounts receivable/(Revenues/365)] increased each year, indicating that the receivables were not being paid on a timely basis—or even that the revenues may not have been genuine in the first place. DSO figures increasing over time indicate that there are problems, either with collection or revenue recognition. The accounts receivable turnover (365/DSO) tells the same story in a different way: It is the number of times the receivables converted into cash each year, and the figure decreased each year. A trend of slower cash collections, as exhibited by Sunbeam, shows increasingly inefficient cash collections at best and should alert an analyst to the possibility of questionable sales or revenue recognition practices.
- The accounts receivable showed poor quality. In 1997, it increased 38.5% over the previous year, while revenues gained 18.7%. The simple fact that receivables growth greatly outstripped the revenue growth suggests receivables collection problems. Furthermore, analysts who paid attention to the notes might have found even more tiles to fit into the mosaic of accounting manipulations. According to a note in the 10-K titled "Accounts Receivable Securitization Facility," in December 1997 Sunbeam had entered into an arrangement for the sale of accounts receivable. The note said that "At December 28, 1997, the Company had received approximately $59 million from the sale of trade accounts receivable." Those receivables were not included in the year-end accounts receivable balance. As the *pro forma* column in Exhibit 12 shows, the accounts receivable would have shown an increase of 66.1% instead of 38.5%; the percentage of receivables to sales would have ballooned to 30.4%, and the days' sales outstanding would have been an attention-getting 110.8 days. Had this receivables sale not occurred, and the receivables been that large, perhaps analysts would have noticed a problem sooner. Careful attention to the notes might have alerted them to how this transaction improved the appearance of the financial statements and ratios.

Exhibit 12 Information on Sunbeam's Sales and Receivables, 1995–1997, and *Pro Forma* Information, 1997

($ millions)	1995	1996	1997	1997 *Pro Forma*
Total revenue	$1,016.9	$984.2	$1,168.2	*$1,168.2*
Change from prior year	—	−3.2%	18.7%	*18.7%*
Gross accounts receivable	$216.2	$213.4	$295.6	*$354.6*
Change from prior year	—	−1.3%	38.5%	*66.1%*
Receivables/revenue	21.3%	21.7%	25.3%	*30.4%*
Change in receivables/revenue	0.7%	0.4%	3.6%	*8.7%*
Days' sales outstanding	77.7	79.2	92.3	*110.8*
Accounts receivable turnover	4.7	4.6	4.0	*3.2*

Source: Based on information in original company 10-K filings.

Analysts observing the trend in days' sales outstanding would have been rightly suspicious of Sunbeam's revenue recognition practices, even if they were observing the days' sales outstanding simply in terms of Sunbeam's own history. If they took the analysis slightly further, they would have been even more suspicious. Exhibit 13 compares Sunbeam's DSO and accounts receivable turnover with those of an industry median based on the numbers from a group of other consumer products companies—Harman International, Jarden, Leggett & Platt, Mohawk Industries, Newell Rubbermaid, and Tupperware Brands.

Exhibit 13 Comparison of Sunbeam and Industry Median, 1995–1997

Sunbeam	1995	1996	1997
Days sales outstanding	77.7	79.2	92.3
Accounts receivable turnover	4.7	4.6	4.0
Industry median			
Days sales outstanding	44.6	46.7	50.4
Accounts receivable turnover	8.2	7.8	7.3
Sunbeam's underperformance relative to median			
Days sales outstanding	33.0	32.5	41.9
Accounts receivable turnover	(3.5)	(3.2)	(3.3)

Source: Based on information in company 10-K filings.

There was yet another clue that should have aroused suspicion in the analyst community. In the December 1997 annual report, the revenue recognition note had been expanded from the previous year's note:

> The Company recognizes revenues from product sales principally at the time of shipment to customers. *In limited circumstances, at the customer's request the Company may sell seasonal product on a bill and hold basis provided that the goods are completed, packaged and ready for shipment, such goods are segregated and the risks of ownership and legal title have passed to the customer.* ***The amount of such bill and hold sales at December 29, 1997 was approximately 3% of consolidated revenues.*** [Italics and emphasis added.]

Not only did Sunbeam hint at the fact that its revenue recognition policies included a method that was of questionable quality, a clue was dropped as to the degree to which it affected operations. That 3% figure may seem small, but the disclosure should have aroused suspicion in the mind of a thorough analyst. As shown in Exhibit 14, working through the numbers with some reasonable assumptions about the gross profit on the sales (28.3%) and the applicable tax rate (35%), an analyst would have seen that the bill-and-hold sales were significant to the bottom line.

Exhibit 14 Effect of Sunbeam's Bill-and-Hold Sales on Net Income ($ millions)

1997 revenue	$1,168.18
Bill-and-hold sales from note	3.0%
Bill-and-hold sales in 1997	$35.05
Gross profit margin	28.3%
Gross profit contribution	$9.92
After-tax earnings contribution	$6.45
Total earnings from continuing operations	$109.42
Earnings attributable to bill-and-hold sales	5.9%

An analyst questioning the genuineness of bill-and-hold sales and performing a simple test of the degree of exposure to their effects might have been disturbed to estimate that nearly 6% of net income depended on such transactions. This knowledge might have dissuaded an analyst from a favorable view of Sunbeam.

REVENUE RECOGNITION CASE: MICROSTRATEGY, INC. 12

h evaluate the earnings quality of a company;

12.1 Multiple-Element Contracts

MicroStrategy, Inc. was a fast-growing software and information services company that went public in 1998. After going public, the company engaged in more complex revenue transactions than it had previously. Its revenue stream increasingly involved less outright sales of software and began tilting more to transactions containing multiple deliverables, including obligations to provide services.

Product revenue is usually recognized immediately, depending on the delivery terms and acceptance by customers, whereas service revenue is recognized as the services are provided. The relevant accounting standards for multiple-deliverable arrangements at the time permitted recognition of revenue on a software delivery only if the software sale could be separated from the service portion of the contract and only if the service revenues were in fact accounted for separately.

Analysts studying MicroStrategy's financial statements should have understood the effects of such accounting conventions on the company's revenues. MicroStrategy's revenue recognition policy in the accounting policies note of its 1998 10-K stated that the standards' requirements were, in fact, its practice:

> Revenue from product licensing arrangements is generally recognized after execution of a licensing agreement and shipment of the product, provided that no significant Company obligations remain and the resulting receivable is deemed collectible by management… Services revenue, which includes training and consulting, is recognized at the time the service is performed. The Company defers and recognizes maintenance revenue ratably over the terms of the contract period, ranging from 12 to 36 months. (p. 49)

MicroStrategy took advantage of the ambiguity present in such arrangements, however, to mischaracterize service revenues and recognize them earlier than they should have as part of the software sale. For example, in the fourth quarter of 1998, MicroStrategy entered into a $4.5 million transaction with a customer for software licenses and a broad array of consulting services. Most of the software licenses acquired by the customer were intended to be used in applications that MicroStrategy would develop in the future, yet the company recognized all of the $4.5 million as software revenue (SEC 2000).

Similarly, in the fourth quarter of 1999, MicroStrategy entered into a multiple-deliverable arrangement with another customer that included the provision for extensive services. Again, the company improperly allocated the elements of the contract, skewing them toward an earlier-recognized software element and improperly recognizing $14.1 million of product revenue in the quarter, which was material.

How could analysts have recognized this pattern of behavior? Without in-depth knowledge of the contracts, it is not possible to approve or disapprove of the revenue allocation with certainty. The company still left a trail that could have aroused the suspicion of analysts, had they been familiar with MicroStrategy's stated revenue recognition policy.

Exhibit 15 shows the mix of revenues for 1996, 1997, and 1998 based on the income statement in MicroStrategy's 1998 10-K:

Exhibit 15 MicroStrategy's Mix of Licenses and Support Revenues, 1996–1998 ($ millions)

	1996	1997	1998
Licenses	$15,873	$36,601	$72,721
Support	6,730	16,956	33,709
Total	$22,603	$53,557	$106,430
Licenses	70.2%	68.3%	68.3%
Support	29.8	31.7	31.7
Total	100.0%	100.0%	100.0%

Between 1996 and 1997, the proportion of support revenues to total revenues increased slightly. It flattened out in 1998, which was the first year known to have mischaracterization between the support revenues and the software revenues. With perfect hindsight, had the $4.5 million of consulting services not been recognized at all, overall revenues would have been $101.930 million and support revenues would have been 33.1% of the total revenues. What could have alerted analysts that something was amiss, if they could not examine actual contracts?

Looking at the quarterly mix of revenues might have aroused analyst suspicions. Exhibit 16 shows the peculiar ebb and flow of revenues attributable to support services revenues.

Exhibit 16 MicroStrategy's Revenue Mix by Quarters, 1Q1998–4Q1999

Quarter	Licenses	Support
1Q98	71.8%	28.2%
2Q98	68.3	31.7
3Q98	62.7	37.3
4Q98	70.7	29.3
1Q99	64.6	35.4
2Q99	68.1	31.9
3Q99	70.1	29.9
4Q99	73.2	26.8

The support services revenue climbed in the first three quarters of 1998 and dropped sharply in the fourth quarter—the one in which the company characterized the $4.5 million of revenues that should have been deferred as software license revenue. Subsequently, the proportion rose again and then continued a downward trend, most sharply in the fourth quarter of 1999 when the company again mischaracterized $14.1 million of revenue as software license revenue.

There is no logical reason that the proportion of revenues from licensing and support services should vary significantly from quarter to quarter. The changes should arouse suspicions and generate questions to ask management. Management's answers, and the soundness of the logic embedded in them, might have made investors more comfortable or more skeptical.

If an analyst knows that a company has a policy of recognizing revenues for contracts with elements of multiple-deliverable arrangements—something apparent from a study of the accounting policy note—then the analyst should consider the risk that misallocation of revenue can occur. Observing trends and investigating deviations from observed trends become important habits for an analyst to practice in order to isolate exceptions. Although a study of revenue trends may not pinpoint a manipulated revenue transaction, it should be sufficient to raise doubts about the propriety of the accounting for transactions.

Enhancing the recognition of revenue is a way for managers to increase earnings, yet it can leave indicators that can be detected by analysts vigilant enough to look for them. Exhibit 17 provides a summary of how to assess the quality of revenues.

Exhibit 17 Summary: Looking for Quality in Revenues

Start with the basics

The first step should be to fully understand the revenue recognition policies as stated in the most recent annual report. Without context for the way revenue is recognized, an analyst will not understand the risks involved in the proper reporting of revenue. For instance, analysts should determine the following:

- What are the shipping terms?
- What rights of return does a customer have: limited or extensive?
- Do rebates affect revenues, and if so, how are they accounted for? What estimates are involved?
- Are there multiple deliverables to customers for one arrangement? If so, is revenue deferred until some elements are delivered late in the contract? If there are multiple deliverables, do deferred revenues appear on the balance sheet?

Age matters

A study of DSO can reveal much about their quality. Receivables do not improve with age. Analysts should seek reasons for exceptions appearing when they

- Compare the trend in DSOs or receivables turnover over a relevant time frame.
- Compare the DSO of one company with the DSOs of similar competitors over similar time frames.

Is it cash or accrual?

A high percentage of accounts receivable to revenues might mean nothing, but it might also mean that channel-stuffing has taken place, portending high future returns of inventory or decreased demand for product in the future. Analysts should

- Compare the percentage of accounts receivable to revenues over a relevant time frame.
- Compare the company's percentage of accounts receivable to revenues with that of competitors or industry measures over similar time frames.

Compare with the real world when possible

If a company reports non-financial data on a routine basis, try relating revenues to those data to determine whether trends in the revenue make sense. Examples include

- Airlines reporting extensive information about miles flown and capacity, enabling an analyst to relate increases in revenues to an increase in miles flown or capacity.
- Retailers reporting square footage used and number of stores open.
- Companies across all industries reporting employee head counts.

As always, analysts should compare any relevant revenue-per-unit measure with that of relevant competitors or industry measures.

Exhibit 17 (Continued)

Revenue trends and composition

Trend analysis, over time and in comparison with competitors, can prompt analysts to ask questions of managers, or it can simply evoke discomfort with the overall revenue quality. Some relationships to examine include

- The relationships between the kinds of revenue recognized. For example, how much is attributable to product sales or licenses, and how much is attributable to services? Have the relationships changed over time, and if so, why?
- The relationship between overall revenue and accounts receivable. Do changes in overall revenues make sense when compared with changes in accounts receivable?

Relationships

Does the company transact business with entities owned by senior officers or shareholders? This is a particularly sensitive area if the manager/shareholder-owned entities are private and there are revenues recognized from the private entity by a publicly owned company; it could be a dumping ground for obsolete or damaged inventory while inflating revenues.

Overstating revenues is not the only way to enhance earnings; according to the SEC study of enforcement cases brought between 1997 and 2002, the next most common financial misreporting was improper expense recognition (SEC 2003). Improper expense recognition typically involves understating expenses and has the same overstating effects on earnings as improper revenue recognition. Understating expenses also leaves indicators in the financial statements for the vigilant analyst to find and assess.

COST CAPITALIZATION CASE: WORLDCOM CORP. 13

h evaluate the earnings quality of a company;

13.1 Property/Capital Expenditures Analysis

WorldCom was a major global communications company, providing phone and internet services to both the business and consumer markets. It became a major player in the 1990s, largely through acquisitions. To keep delivering the earnings expected by analysts, the company engaged in the improper capitalization of operating expenses known as "line costs." These costs were fees paid by WorldCom to third-party telecommunications network providers for the right to use their networks, and the proper accounting treatment for them is to classify them as an operating expense. This improper treatment began in 1999 and continued through the first quarter of 2002. The company declared bankruptcy in July 2002; restatements of financial reports ensued.

The company was audited by Arthur Andersen, who had access to the company's records. According to the findings of the special committee that headed the investigation of the failure (Beresford, Katzenbach, and Rogers 2003), Arthur Andersen failed to identify the misclassification of line costs, among other things, because

> Andersen concluded—mistakenly in this case—that, year after year, the risk of fraud was minimal and thus it never devised sufficient auditing procedures to address this risk. Although it conducted a controls-based audit—relying on WorldCom's internal controls—it failed to recognize the nature and extent of senior management's top-side adjustments through reserve reversals with little or no support, highly questionable revenue items, and entries capitalizing line costs. Andersen did not conduct tests to corroborate the information it received in many areas. It assumed incorrectly that the absence of variances in the financial statements and schedules—in a highly volatile business environment—indicated there was no cause for heightened scrutiny. Andersen conducted only very limited auditing procedures in many areas where we found accounting irregularities. Even so, Andersen still had several chances to uncover problems we identify in this Report. (p. 230–231)

If auditors failed to detect fraud, could analysts really be expected to do better? Analysts may not have been able to pinpoint what was going on at WorldCom, all the way down to the under-reported line costs, but if they had focused on the company's balance sheet, they certainly could have been suspicious that all was not right. If they were looking for out-of-line relationships between accounts—something that the auditors would be expected to do—they might have uncovered questionable relationships that, if unsatisfactorily explained, should have led them to shun securities issued by WorldCom.

For an operating expense to be under-reported, an offsetting increase in the balance of another account must exist. A simple scan of an annual time-series common-size balance sheet, such as is shown in Exhibit 18, might identify the possibility that capitalization is being used to avoid expense recognition. An analyst might not have known that line costs were being under-reported, but simply looking at the time series in Exhibit 18 would have shown that something unusual was going on in gross property, plant, and equipment. The fraud began in 1999, and gross property, plant, and equipment had been 30% and 31% of total assets, respectively, in the two prior years. In 1999, property, plant, and equipment became a much more significant 37% of total assets and increased to 45% in 2000 and 47% in 2001. The company had not changed strategy or anything else to justify such an increase.

Exhibit 18 Common Size Asset Portion of Balance Sheet for WorldCom, 1997–2001

	1997	1998	1999	2000	2001

Note: NA is not available.
Source: Based on information from Standard & Poor's Research Insight database.

A curious analyst in 1999 might not have *specifically* determined that line costs were being understated, but the buildup of costs in property, plant, and equipment should have at least made the analyst suspicious that expenses were under-reported somewhere in the income statement.

Capitalizing costs is not the only possible way of understating expenses. Exhibit 19 provides a summary of how to assess the quality of expense recognition, including some things to consider.

Exhibit 19 Summary: Looking for Quality in Expense Recognition

Start with the basics

The first step should be to fully understand the cost capitalization policies as stated in the most recent annual report. Without context for the costs stored on the balance sheet, analysts will not be able to comprehend practice exceptions they may encounter. Examples of policies that should be understood include the following:

- What costs are capitalized in inventory? How is obsolescence accounted for? Are there reserves established for obsolescence that might be artificially raised or lowered?
- What are the depreciation policies, including depreciable lives? How do they compare with competitors' policies? Have they changed from prior years?

Trend analysis

Trend analysis, over time and in comparison with competitors, can lead to questions the analyst can ask managers, or it can simply evoke discomfort with overall earnings quality because of issues with expenses. Some relationships to examine include the following:

- Each quarter, non-current asset accounts should be examined for quarter-to-quarter and year-to-year changes to see whether there are any unusual increases in costs. If present, they might indicate that improper capitalization of costs has occurred.
- Profit margins—gross and operating—are often observed by analysts in the examination of quarterly earnings. They are not often related to changes in the balance sheet, but they should be. If unusual buildups of non-current assets have occurred and the profit margins are improving or staying constant, it could mean that improper cost capitalization is taking place. Recall WorldCom and its improper capitalization of "line costs": Profitability was maintained by capitalizing costs that should have been

(continued)

Exhibit 19 (Continued)

expensed. Also, the overall industry environment should be considered: Are margins stable while balance sheet accounts are growing and the industry is slumping?

- Turnover ratio for total assets; property, plant, and equipment; and other assets should be computed (with revenues divided by the asset classification). Does a trend in the ratios indicate a slowing in turnover? Decreasing revenues might mean that the assets are used to make a product with declining demand and portend future asset write-downs. Steady or rising revenues and decreasing turnover might indicate improper cost capitalization.
- Compute the depreciation (or amortization) expense compared to the relevant asset base. Is it decreasing or increasing over time without a good reason? How does it compare with that of competitors?
- Compare the relationship of capital expenditures with gross property, plant, and equipment over time. Is the proportion of capital expenditures relative to total property, plant, and equipment increasing significantly over time? If so, it may indicate that the company is capitalizing costs more aggressively to prevent their recognition as current expenses.

Relationships

Does the company transact business with entities owned by senior officers or shareholders? This is a particularly sensitive area if the manager/shareholder-owned entities are private. Dealings between a public company and the manager-owned entity might take place at prices that are unfavorable for the public company in order to transfer wealth from the public company to the manager-owned entity. Such inappropriate transfers of wealth can also occur through excessive compensation, direct loans, or guarantees. These practices are often referred to as "tunneling" (Johnson, LaPorta, Shleifer, and Lopez-de-Silanes 2000).

In some cases, sham dealings between the manager-owned entity and the public company might be falsely reported to improve reported profits of the public company and thus enrich the managers whose compensation is performance based. In a different type of transaction, the manager-owned entity could transfer resources to the public company to ensure its economic viability and thus preserve the option to misappropriate or to participate in profits in the future. These practices are often referred to as "propping" (Friedman, Johnson, and Mitton 2003).

Assessing earnings quality should be an established practice for all analysts. Earnings quality should not automatically be accepted as "high quality" until accounting problems emerge and it is too late. Analysts should consider the quality of earnings before assigning value to the growth in earnings. In many cases, high reported earnings growth, which turned out to be fraudulent, preceded bankruptcy.

BANKRUPTCY PREDICTION MODELS: ALTMAN MODEL, DEVELOPMENTS IN BANKRUPTCY PREDICTION MODELS

14

h evaluate the earnings quality of a company;

j evaluate the cash flow quality of a company;

k describe indicators of balance sheet quality;

l evaluate the balance sheet quality of a company;

Bankruptcy prediction models address more than just the quality of a company's earnings and include aspects of cash flow and the balance sheet as well.[20] Various approaches have been used to quantify the likelihood that a company will default on its debt and/or declare bankruptcy.

14.1 Altman Model

A well-known and early model to assess the probability of bankruptcy is the Altman model (Altman 1968). The model is built on research that used ratio analysis to identify likely failures. An important contribution of the Altman model is that it provided a way to incorporate numerous financial ratios into a single model to predict bankruptcy. The model overcame a limitation of viewing ratios independently (e.g., viewing a company with poor profitability and/or solvency position as potentially bankrupt without considering the company's strong liquidity position).

Using discriminant analysis, Altman developed a model to discriminate between two groups: bankrupt and non-bankrupt companies. Altman's Z-score is calculated as follows:

Z-score = 1.2 (Net working capital/Total assets) + 1.4 (Retained earnings/Total assets) + 3.3 (EBIT/Total assets) + 0.6 (Market value of equity/Book value of liabilities) + 1.0 (Sales/Total assets)

The ratios in the model reflect liquidity, profitability, leverage, and activity. The first ratio—net working capital/total assets—is a measure of short-term liquidity risk. The second ratio—retained earnings/total assets—reflects accumulated profitability and relative age because retained earnings accumulate over time. The third ratio—EBIT (earnings before interest and taxes)/total assets, which is a variant of return on assets (ROA)—measures profitability. The fourth ratio—market value of equity/book value of liabilities—is a form of leverage ratio; it is expressed as equity/debt, so a higher number indicates greater solvency. The fifth ratio—sales/total assets—indicates the company's ability to generate sales and is an activity ratio.

Note that Altman's discriminant function shown in his original article (1968) was

$$Z\text{-score} = 0.012X_1 + 0.014X_2 + 0.033X_3 + 0.006X_4 + 0.999X_5$$

with each of the X variables corresponding to the ratios just described. Altman (2000) explains that "due to the original computer format arrangement, variables X_1 through X_4 must be calculated as absolute percentage values. For instance, the company whose net working capital to total assets (X_1) is 10% should be included as 10.0% and not 0.10. Only variable X_5 (sales to total assets) should be expressed in a different manner: that

20 Recall that the term "earnings quality" is used broadly to encompass the quality of earnings, cash flow, and/or balance sheet items.

is, a S/TA [sales/total assets] ratio of 200 percent should be included as 2.0" (p. 14). For this reason, the *Z*-score model is often expressed as shown in the first equation of this section.

The interpretation of the score is that a higher *Z*-score is better. In Altman's application of the model to a sample of manufacturing companies that had experienced losses, scores of less than 1.81 indicated a high probability of bankruptcy, scores greater than 3.00 indicated a low probability of bankruptcy, and scores between 1.81 and 3.00 were not clear indicators.

14.2 Developments in Bankruptcy Prediction Models

Subsequent research addressed various shortcomings in the Altman prediction model. One shortcoming is the single-period, static nature of the Altman model; it uses only one set of financial measures, taken at a single point in time. Shumway (2001) addressed this shortcoming by using a hazard model, which incorporates all available years of data to calculate each company's bankruptcy risk at each point in time.

Another shortcoming of the Altman model (and other accounting-based bankruptcy prediction models) is that financial statements measure past performance and incorporate the going-concern assumption. The reported values on a company's balance sheet assume that the company is a going concern rather than one that might be failing. An alternative is to use market-based bankruptcy prediction models. For example, market-based prediction models building on Merton's concept of equity as a call option on the company's assets infer the default probability from the company's equity value, amount of debt, equity returns, and equity volatility (Kealhofer 2003). Credit default swap data and corporate bond data can also be used to derive default probabilities. Other research indicates that the most effective bankruptcy prediction models include both accounting-based data and market-based data as predictor variables. For example, Bharath and Shumway (2008) model default probability based on market value of equity, face value of debt, equity volatility, stock returns relative to market returns over the previous year, and the ratio of net income to total assets to identify companies likely to default.

15 CASH FLOW QUALITY

i. describe indicators of cash flow quality;

j. evaluate the cash flow quality of a company;

Cash flow statements are free of some of the discretion embedded in the financial statements based on accrual accounting. As a result, analysts may place a great deal of importance and reliance on the cash flow statement. However, there are opportunities for management to affect the cash flow statement.

15.1 Indicators of Cash Flow Quality

Operating cash flow (OCF) is the cash flow component that is generally most important for assessing a company's performance and valuing a company or its securities. Therefore, discussions of cash flow quality typically focus on OCF.

Similar to the term "earnings quality," when reported cash flows are described as being of high quality, it means that the company's underlying economic performance was good (i.e., value enhancing) and it also implies that the company had high reporting quality (i.e., that the information calculated and disclosed by the company was a reasonable reflection of economic reality). Cash flow can be described as "low quality" either because the reported information correctly represents bad economic performance (poor results quality) or because the reported information misrepresents economic reality (poor reporting quality).

From an economic perspective, the corporate life cycle and industry profile affect cash flow and must be considered when analyzing the statement of cash flows. For example, a start-up company might be expected to have negative operating and investing cash flows, which would be funded from borrowing or from equity issuance (i.e., financing cash flows). In contrast, an established company would typically have positive operating cash flow from which it would fund necessary investments and returns to providers of capital (i.e., dividends, share repurchases, or debt repayments—all of which are financing cash flows).

In general, for established companies, high-quality cash flow would typically have most or all of the following characteristics:

- Positive OCF
- OCF derived from sustainable sources
- OCF adequate to cover capital expenditures, dividends, and debt repayments
- OCF with relatively low volatility (relative to industry participants)

As always, high quality requires not only high results quality, as in the previous list, but also high reporting quality. The reported cash flows should be relevant and faithfully represent the economic reality of the company's activities. For example, classifying a financing inflow as an operating inflow would misrepresent the economic reality.

From the perspective of cash flow reporting quality, OCF is generally viewed as being less easily manipulated than operating or net income. Large differences between earnings and OCF or increases in such differences can be an indication of earnings manipulation. The statement of cash flows can be used to highlight areas of potential earnings manipulation.

Even though OCF is viewed as being less subject to manipulation than earnings, the importance of OCF may create incentives for managers to manipulate the amounts reported. Therefore, quality issues with cash flow reporting can exist. One issue that arises with regard to cash flow reporting quality is timing. For example, by selling receivables to a third party and/or by delaying paying its payables, a company can boost OCF. An increase in such activities would be reflected as a decrease in the company's days' sales outstanding and an increase in the company's days of payables. Thus, an analyst can potentially detect management choices to decrease current assets or increase current liabilities, choices that will increase OCF, by looking at asset utilization (activity) ratios, changes in balance sheet accounts, and disclosures in notes to the financial statements. Another issue that arises with regard to cash flow reporting quality is related to classification of cash flows: Management may try to shift positive cash flow items from investing or financing activities to operating activities to inflate operating cash flows.

15.2 Evaluating Cash Flow Quality

Because OCF is viewed as being less subject to manipulation than earnings, the statement of cash flows can be used to identify areas of potential earnings manipulation. The financial fraud at Satyam Computer Services, an Indian information technology company, was described earlier in this reading. In that case, the use of a computer model based on accruals may have failed to detect the fraud. A *New York Times* article (Kahn 2009) provides anecdotal evidence:

> In September, [an analyst] used a computer model to examine India's 500 largest public companies for signs of accounting manipulation. He found that more than 20 percent of them were potentially engaged in aggressive accounting, but Satyam was not on the list. This is because the automated screens that analysts … use to pick up signs of fraud begin by searching for large discrepancies between reported earnings and cash flow. In Satyam's case, the cash seemed to keep pace with profits.

In other words, a computer model that screened for companies with operating cash flow persistently lower than earnings would not have identified Satyam as a potential problem because its reported operating cash flow was relatively close to reported profits.

It may be helpful to examine pertinent indicators using a more qualitative approach. Exhibit 20 presents an excerpt from the statement of cash flows for Satyam for the quarter ended 30 June 2008.

Exhibit 20 Excerpt from Satyam's IFRS Consolidated Interim Cash Flow Statement (All amounts $ millions except per share data and as otherwise stated.)

	Quarter ended 30 June 2008 (unaudited)	Quarter ended 30 June 2007 (unaudited)	Year ended 31 March 2008 (audited)
Profit before income tax	**143.1**	**107.1**	**474.3**
Adjustments for			
Share-based payment expense	4.3	5.9	23.0
Financial costs	1.3	0.8	7.0
Finance income	(16.2)	(16.4)	(67.4)
Depreciation and amortisation	11.5	9.3	40.3
(Gain)/loss on sale of premises and equipment	0.1	0.1	0.6
Changes in value of preference shares designated at fair value through profit or loss	0.0	0.0	(1.6)
Gain/(loss) on foreign exchange forward and option contracts	53.0	(21.1)	(7.4)
Share of (profits)/losses of joint ventures, net of taxes	(0.1)	0.0	(0.1)
	197.0	**85.7**	**468.7**
Movements in working capital			
— Trade and other receivables	(81.4)	(64.9)	(184.3)
— Unbilled revenue	(23.5)	(6.0)	(39.9)
— Trade and other payables	34.1	2.2	48.8
— Unearned revenue	5.8	2.4	11.4
— Other liabilities	(6.3)	30.3	61.2
— Retirement benefit obligations	3.7	1.3	17.8
Cash generated from operations	**129.4**	**51.0**	**383.7**
Income taxes paid	–3.8	–9.8	–49.4
Net cash provided by operating activities	**125.6**	**41.2**	**334.3**

Source: Based on information from Satyam's Form 6-K, filed 25 July 2008.

One item of note on this statement of cash flows is the $53 million non-cash item labeled "Gain/(loss) on foreign exchange forward and options contracts" (i.e., derivative instruments) in the quarter ended 30 June 2008. The item appears to be shown as a gain based on the labeling; however, it would not be correct to add back a gain in this calculation of operating cash flow because it is already included in profit before tax. When the company was asked about this item in the quarterly conference call with analysts, no answer was readily available. Instead, the company's manager said that he would "get back to" the questioner. The fact that the company's senior executives could not explain the reason for an item that represented almost 40% of the total pre-tax profit for the quarter ($53/$143.1 = 37%) is clearly a signal of potential problems. Refer to Exhibit 21 for an excerpt from the conference call.

Exhibit 21 Excerpt from Conference Call regarding Quarterly Results of Satyam, 18 July 2008

George Price, analyst at Stifel Nicolaus:	One question which is on the cash flow statement. You had a—you had $53 million in unrealized gain on derivative financial instruments in the quarter and it's a line item that just, on quick check, I don't think we've seen in past quarters. Can you comment on exactly what that is? … On the comparison periods, there were more modest losses. What drove that large benefit? How should we think about timing of cash flow maybe over the next couple quarters? Any one-time issues like that?
Srinivas Vadlamani:	I—can you repeat that, please?
George Price:	Srinivas, there's was a $53 million unrealized gain in the cash flow statement, and I'm just wondering if you could explain that in a little bit more detail…. The magnitude is a little surprising.
Srinivas Vadlamani:	No, let me—let me check on that. I'll get back to you.

Another item of note on the statement of cash flows is the steady growth in receivables. Analysts examine a company's ratios, such as days' sales outstanding. Exhibit 22 presents selected annual data for Satyam. The large jump in days' sales outstanding from 2006 to 2007 could cause concern. Furthermore, the management commentary in the company's Form 20-F indicated that "Net accounts receivable… increased… primarily as a result of an increase in our revenues and increase in collection period." An increase in the collection period of receivables raises questions about the creditworthiness of the company's customers, about the efficiency of the company's collection efforts, and about the quality of the revenue recognized.

Exhibit 22 Selected Annual Data on Accounts Receivable for Satyam, 2005–2008

($ millions)	2008	2007	2006	2005
Total revenue	$2,138.1	$1,461.4	$1,096.3	$793.6
% Change from previous year	*46.3%*	*33.3%*	*38.1%*	
Gross accounts receivable	$539.1	$386.9	$238.1	$178.3
% Change from previous year	*39.3%*	*62.5%*	*33.5%*	

(continued)

Exhibit 22 (Continued)

($ millions)	2008	2007	2006	2005
Allowance for doubtful debts	$31.0	$22.8	$19.1	$17.5
% Change from previous year	*36.0%*	*19.4%*	*9.1%*	
Gross receivables/revenue	25.21%	26.47%	21.72%	22.47%
Change in receivables/revenue	*–4.8%*	*21.9%*	*–3.3%*	
Days' sales outstanding	92.0	96.6	79.3	82.0
Accounts receivable turnover	4.0	3.8	4.6	4.5

Source: Based on data from Satyam's 20-F filings.

A signal of problems related to cash, which would not have appeared on the statement of cash flows, was the purported use of the company's cash. Satyam reported increasing amounts invested in current accounts. On a conference call excerpted in Exhibit 23, an analyst asked for a specific reason why such large amounts would be held in non-interest-bearing accounts. Instead of providing a reason, the company officer instead stated that the amounts would be transferred to higher-earning accounts soon.

Exhibit 23 Excerpt from Conference Call regarding Quarterly Results for Satyam, 17 October 2008

Kawaljeet Saluja, analyst at Kotak Institutional Equities:	Hi, my questions are for Srinivas. Srinivas, any specific reason why you have $500m parked in current accounts which are not [gaining] any interest?
Srinivas Vadlamani:	No, that is basically—as on the quarter ending, but there is a statement to that [inaudible] to the deposit accounts. We have [inaudible] deposits now.
Kawaljeet Saluja:	But, Srinivas, if I look at the deposit accounts for the last four quarters, that number has remained absolutely flat. And most of the incremental cash that is parked in current accounts and this is not something which is this quarter changed. Would you highlight some of the reasons for it?
Srinivas Vadlamani:	No, basically, what will happen is these amounts will be basically in different countries. And then we will be bringing them to India based on the need. So we will be—basically, some of them are in overnight deposits and all that. So, now we have placing them into normal current deposits. So, next quarter onwards, we will see that as part of the deposits.

In Satyam CEO's January 2009 letter of resignation, he confessed that "the Balance Sheet carries as of September 30, 2008 [i]nflated (non-existent) cash and bank balances of Rs. 5,040 crore[21] (as against Rs. 5,361 crore reflected in the books)...."[22] In other words, of the amount shown as cash on the company's balance sheet, more than 90% was non-existent. It is suggested that some of the cash balances had existed but had been "siphoned off to a web of companies controlled by Mr. Raju and his family." (Kahn 2009)

Overall, the Satyam example illustrates how the statement of cash flows can suggest potential areas of misreporting. In Satyam's case, two items that raised questions were a large non-cash gain on derivatives and an increase in days' sales outstanding. Potential areas of misreporting can then be investigated by reference to the company's other financial reports. The following example illustrates how the statement of cash flows can highlight earnings manipulation and also illustrates how the cash flow information corresponds to information gleaned from analysis of the company's earnings.

Example 8 covers the application of cash flow evaluation to determine quality of earnings.

EXAMPLE 8

Sunbeam Statement of Cash Flows

As noted in the previous section, Sunbeam engaged in various improper accounting practices. Refer to the excerpt from Sunbeam's statement of cash flows in Exhibit 24 to answer the following questions:

1. One of the ways that Sunbeam misreported its financial statements was improperly inflating and subsequently reversing restructuring charges. How do these items appear on the statement of cash flows?
2. Another aspect of Sunbeam's misreporting was improper revenue recognition. What items on the statement of cash flow would primarily be affected by that practice?

Exhibit 24 Excerpt from Sunbeam's Consolidated Statement of Cash Flows, 1995–1997 ($ thousands)

Fiscal Years Ended	28 Dec. 1997	29 Dec. 1996	31 Dec. 1995
Operating Activities:			
Net earnings (loss)	109,415	(228,262)	50,511
Adjustments to reconcile net earnings (loss) to net cash provided by (used in) operating activities:			
Depreciation and amortization	38,577	47,429	44,174
Restructuring, impairment, and other costs	—	154,869	—
Other non-cash special charges	—	128,800	—
Loss on sale of discontinued operations, net of taxes	13,713	32,430	—
Deferred income taxes	57,783	(77,828)	25,146
Increase (decrease) in cash from changes in working capital:			

(continued)

21 Crore is used in India to denote 10,000,000.

22 From Mr. B. Ramalinga Raju's resignation letter attached to Form 6-K that was filed with the SEC on 7 January 2009.

Exhibit 24 (Continued)

Fiscal Years Ended	28 Dec. 1997	29 Dec. 1996	31 Dec. 1995
Receivables, net	(84,576)	(13,829)	(4,499)
Inventories	(100,810)	(11,651)	(4,874)
Account payable	(1,585)	14,735	9,245
Restructuring accrual	(43,378)	—	—
Prepaid expenses and other current assets and liabilities	(9,004)	2,737	(8,821)
Income taxes payable	52,844	(21,942)	(18,452)
Payment of other long-term and non-operating liabilities	(14,682)	(27,089)	(21,719)
Other, net	(26,546)	13,764	10,805
Net cash provided by (used in) operating activities	(8,249)	14,163	81,516

Note: The reason that an increase in sales is shown as a negative number on the statement of cash flows prepared using the indirect method is to reverse any sales reported in income for which cash has not yet been received.

Solution to 1:

Sunbeam's statement of cash flows is prepared using the indirect method (i.e., the operating section shows a reconciliation between reported net income and operating cash flow). This reconciliation highlights that the amount of non-cash charges recorded in 1996 for restructuring, impairment, and other costs totaled about $284 million ($154.869 million + $128.8 million). In the following year, the reversal of the restructuring accrual was $43 million. By inflating and subsequently reversing restructuring charges, the company's income would misleadingly portray significant improvements in performance following the arrival of its new CEO in mid-1996.

Solution to 2:

The items on the statement of cash flows that would primarily be affected by improper revenue recognition include net income, receivables, and inventories. Net income and receivables would be overstated. The statement of cash flows, in which an increase in receivables is shown as a negative number, highlights the continued growth of receivables. In addition, Sunbeam's practice of recording sales that lacked economic substance—because the purchaser held the goods over the end of an accounting period but subsequently returned all the goods—is highlighted in the substantial increase in inventory in 1997.

An issue that arises with regard to cash flow reporting quality is classification shifting: shifting positive cash flow items from investing or financing to inflate operating cash flows. A shift in classification does not change the total amount of cash flow, but it can affect investors' evaluation of a company's cash flows and investors' expectations for future cash flows.

Flexibility in classification exists within accounting standards. For example, IFRS permits companies to classify interest paid either as operating or as financing. IFRS also permits companies to classify interest and dividends received as operating or as investing. In contrast, US GAAP requires that interest paid, interest received, and dividends received all be classified as operating cash flows. Thus, an analyst comparing an IFRS-reporting company to a US GAAP-reporting company would want to ensure comparable classification of interest and dividends and would adjust the reported amounts, if necessary. In addition, an analyst examining an IFRS-reporting company should be alert to any year-to-year changes in classification of interest and dividends. For example, consider an IFRS-reporting company that changed its classification of interest paid from operating to financing. All else equal, the company's operating cash flow would appear higher than the prior period even if no other activities occurred in the period.

As another example of the flexibility permitted by accounting standards, cash flows from non-trading securities are classified as investing cash flows, whereas cash flows from trading securities are typically classified as operating cash flows. However, each company decides what constitutes trading and non-trading activities, depending on how it manages its securities holdings. This discretion creates an opportunity for managers to shift cash flows from one classification to another.

Example 9 illustrates a shift of cash flows from investing to operating.

EXAMPLE 9

Classification of Cash Flows

Nautica Enterprises[23]

An excerpt from the statement of cash flows from the fiscal 2000 annual report of Nautica Enterprises, an apparel manufacturer, is shown as Exhibit 25. An excerpt from the statement of cash flows from the company's fiscal 2001 annual report is shown in Exhibit 26. Use these two excerpts to answer the questions below.

Exhibit 25 Excerpt from Nautica Enterprises' Consolidated Statement of Cash Flow from Annual Report, filed 27 May 2000 (amounts in thousands)

	Year ended 4 March 2000
Cash flows from operating activities	
Net earnings	$46,163
Adjustments to reconcile net earnings to net cash provided by operating activities, net of assets and liabilities acquired	
Minority interest in net loss of consolidated subsidiary	—
Deferred income taxes	(1,035)
Depreciation and amortization	17,072
Provision for bad debts	1,424
Changes in operating assets and liabilities	
Accounts receivable	(6,562)
Inventories	(3,667)
Prepaid expenses and other current assets	(20)
Other assets	(2,686)
Accounts payable: trade	(548)

(continued)

23 Example adapted from Mulford and Comiskey (2005).

Exhibit 25 (Continued)

	Year ended 4 March 2000
Accrued expenses and other current liabilities	9,086
Income taxes payable	3,458
Net cash provided by operating activities	62,685
Cash flows from investing activities	
Purchase of property, plant, and equipment	(33,289)
Acquisitions, net of cash acquired	—
Sale (purchase) of short-term investments	21,116
Payments to register trademark	(277)
Net cash used in investing activities	(12,450)

Purchase of short-term investments	—	—
Payments to register trademark	(199)	(277)
Net cash used in investing activities	(41,911)	(33,566)

1. What amount does Nautica report as operating cash flow for the year ended 4 March 2000 in Exhibit 25? What amount does Nautica report as operating cash flow for the same year in Exhibit 26?
2. Exhibit 25 shows that the company had investing cash flows of $21,116 thousand from the sale of short-term investments for the year ended 4 March 2000. Where does this amount appear in Exhibit 26?
3. As actually reported (Exhibit 26), how did the company's operating cash flow for fiscal year 2001 compare with that for 2000? If Nautica had not changed the classification of its short-term investing activities, how would the company's operating cash flows for fiscal year 2001 have compared with that for 2000?

Solution to 1:

In Exhibit 25, Nautica reports operating cash flow for the year ended 4 March 2000 of $62,685 thousand. In Exhibit 26, Nautica reports operating cash flow for the same year of $83,801 thousand.

Solution to 2:

The $21,116 thousand (i.e., the difference between the amounts of operating cash flow reported in Exhibits 25 and 26) that appears in Exhibit 25 as investing cash flows from the sale of short-term investments for the year ended 4 March 2000 has been reclassified. In Exhibit 26, this amount appears under changes in operating assets and liabilities (i.e., as a component of operating cash flow).

Solution to 3:

As reported in Exhibit 26, the company's cash flows declined by 7% from fiscal year 2000 to fiscal year 2001 (= 78,018/83,801 − 1 = −7%). If Nautica had not changed the classification of its short-term investing activities, the company's operating cash flows for fiscal year 2001 would have been $49,573 thousand (=78,018 − 28,445), and would have shown a decline of 21% from fiscal year 2000 to fiscal year 2001 (= 49,573/62,685 − 1 = −21%).

An analyst could have identified Nautica's classification shift by comparing the statement of cash flows for 2000 in the fiscal year 2000 annual report with the statement in the fiscal year 2001 annual report. In general, comparisons of period-to-period reports issued by a company can be useful in assessing financial reporting quality.

If a company restates prior years' financial statements (because of an error), recasts prior years' financial statements (because of a change in accounting policy), omits some information that was previously voluntarily disclosed, or adds some item, such as a new risk disclosure that was not previously disclosed, an analyst should aim to understand the reasons for the changes.

16 BALANCE SHEET QUALITY

k describe indicators of balance sheet quality;

l evaluate the balance sheet quality of a company;

With regard to the balance sheet, high financial *reporting* quality is indicated by completeness, unbiased measurement, and clear presentation. High financial *results* quality (i.e., a strong balance sheet) is indicated by an optimal amount of leverage, adequate liquidity, and economically successful asset allocation. Balance sheet strength is assessed using ratio analysis, including common-size financial statements, which is covered by the financial statement analysis readings. There are no absolute values for ratio analysis that indicate adequate financial strength; such analysis must be undertaken in the context of a firm's earnings and cash flow outlook, coupled with an understanding of the environment in which the firm operates. In this section, the focus is on high financial reporting quality.

An important aspect of financial reporting quality for the balance sheet is *completeness*. Significant amounts of off-balance-sheet obligations could be a concern for an analyst because exclusion of these obligations could understate the company's leverage. One common source of off-balance-sheet obligation is purchase contracts, which may be structured as take-or-pay contracts. Analysts typically adjust reported financial statement information by constructively capitalizing, where material, purchase obligations. Constructive capitalization means that the analyst estimates the amount of the obligation as the present value of future purchase obligation payments and then adds the amount of the obligation to the company's reported assets and liabilities.

The use of unconsolidated joint ventures or equity-method investees may reflect off-balance-sheet liabilities. In addition, certain profitability ratios (return on sales, also called "net profit margin") may be overstated because the parent company's consolidated financial statements include its share of the investee's profits but not its share of the investee's sales. If disclosures are adequate, an analyst can adjust the reported amounts to better reflect the combined amounts of sales, assets, and liabilities. A company operating with numerous or material unconsolidated subsidiaries for which ownership levels approach 50% could be a warning sign of accounting issues. Understanding why a company structures its operations in such a manner—industry practice or need for strategic alliances in certain businesses or geographies—can allay concerns.

Another important aspect of financial reporting quality for the balance sheet is *unbiased measurement*. Unbiased measurement is particularly important for assets and liabilities for which valuation is subjective. The following list presents several examples:

- As previously discussed, understatement of impairment charges for inventory; plant, property, and equipment; or other assets not only results in overstated profits on the income statement but also results in overstatement of the assets on the balance sheet. A company with substantial amounts of reported goodwill but with a market value of equity less than the book value of shareholders' equity may indicate that appropriate goodwill impairments have not been taken.

- Similarly, understatement of valuation allowance for deferred tax assets would understate tax expenses and overstate the value of the assets on the balance sheet. (Overstatement would have the opposite effect.) Significant, unexplainable variations in the valuation account can signal biased measurement.
- A company's investments in the debt or equity securities of another company would ideally be based on observable market data. For some investments, no observable market data exist and the valuation must be based solely on management estimates. The balance sheet of a company with a substantial portion of its assets valued using non-observable inputs likely warrants closer scrutiny.
- A company's pension liabilities require various estimates, such as the discount rate at which future obligations are present valued. If pension obligations exist, the level and changes for the discount rate should be examined.

Example 10 shows a company with overstated goodwill.

EXAMPLE 10

Goodwill

Sealed Air Corporation

In August 2012, a *Wall Street Journal* article listed six companies that were carrying more goodwill on their balance sheets than the companies' market values (Thurm 2012). At the top of the list was Sealed Air Corporation, a company operating in the packaging and containers industry. Exhibit 27 presents an excerpt from the company's income statement for the following year, and Exhibit 28 presents an excerpt from the company's balance sheet.

Exhibit 27 Sealed Air Corporation and Subsidiaries Consolidated Statements of Operations ($ millions, except per share amounts)

Year ended 31 December	2012	2011	2010
Net sales	$7,648.1	$5,550.9	$4,490.1
Cost of sales	5,103.8	3,950.6	3,237.3
Gross profit	2,544.3	1,600.3	1,252.8

Other assets, net	415.1	455.0
Total assets	$9,437.2	$11,432.0

1 Sealed Air Corporation's financial statements indicate that the number of common shares issued and outstanding in 2011 was 192,062,185. The price per share of Sealed Air Corporation's common stock was around $18 per share in December 2011 and around $14 in August 2012; the *Wall Street Journal* article (Thurm 2012) was written in 2012. What was the company's market value?

2 How did the amount of goodwill as of 31 December 2011 compare with the company's market value?

3 Why did the *Wall Street Journal* article state that goodwill in excess of the company's market value is "a potential clue to future write-offs"?

4 Based on the information in Exhibit 28, does the *Wall Street Journal* article statement appear to be correct?

Solution to 1:

Sealed Air Corporation's market cap was about \$3,457 million (= 192,062,185 shares × \$18 per share) in December 2011 and around \$2,689 million (= 192,062,185 shares × \$14 per share) when the *Wall Street Journal* article was written in August 2012.

Solution to 2:

The amount of goodwill on Sealed Air Corporation's balance sheet as of 31 December 2011 was \$4,209.6 million. The amount of goodwill exceeded the company's market value. (Also note that goodwill and other intangible assets represented about 55% of Sealed Air Corporation's total assets as of 31 December 2011.)

Solution to 3:

If the market capitalization exactly equaled the reported amount of goodwill, the value implicitly assigned to all the company's other assets would equal zero. In this case, because the market capitalization is less than the reported amount of goodwill, the value implicitly attributed to all the company's other assets is less than zero. This suggests that the amount of goodwill on the balance sheet is overvalued, so a future write-off is likely.

Solution to 4:

Yes, based on the information in Exhibit 28, the *Wall Street Journal* article statement appears correct. In the fiscal year ending 31 December 2012 after the article, Sealed Air Corporation recorded impairment of goodwill and other intangible assets of \$1,892.3 million.

Finally, *clear presentation* is also important for financial reporting quality for the balance sheet. Although accounting standards specify many aspects of what appears on the balance sheet, companies have discretion, for example, in determining which line items should be shown separately and which should be aggregated into a single total. For items shown as a single total, an analyst can usually consult the notes for information about the components. For example, in consulting the inventory note, an analyst may learn that inventory is carried on a last-in, first-out basis and that, consequently, in an inflationary environment, the inventory is carried on the balance sheet at a cost that is significantly lower than its current cost. This information would provide the analyst with comfort that the inventory is unlikely to be overstated.

SOURCES OF INFORMATION ABOUT RISK AND LIMITED USEFULNESS OF AUDITOR'S REPORT 17

m describe sources of information about risk.

A company's financial statements can provide useful indicators of financial, operating, or other risk. For example, high leverage ratios (or, similarly, low coverage ratios) derived from financial statement data can signal financial risk. As described in a previous section, analytical models that incorporate various financial data can signal bankruptcy risk, and others can predict reporting risks (i.e., the risk of a company misreporting). Operating risks can be indicated by financial data, such as highly variable operating cash flows or negative trends in profit margins. Additional information about risk can be obtained from sources other than the financial statements.

An audit opinion(s) covering financial statements (and internal controls over financial reporting, where required) can provide some information about reporting risk. However, the content of an audit opinion is unlikely to be a timely source of information about risk. A related item that is potentially a signal of problems (and thus potentially represents information about risk) is a discretionary change in auditor. For example, Allou Health & Beauty Care, discussed in Example 7, had a different auditor for 2000, 2001, and 2002.

The notes are an integral part of the financial statements. They typically contain information that is useful in understanding a company's risk. Beyond the information about risk that can be derived from a company's financial statements and notes, various other disclosures can provide information about financial, operating, reporting, or other risks. An important source of information is the management commentary, which provides management's assessment of the important risks faced by the company. Although risk-related disclosures in the management commentary sometimes overlap with disclosures contained in the financial statement notes or elsewhere in regulatory filings, the commentary should reveal the management perspective, and its content often differs from the note disclosures.

Other required disclosures that are specific to an event, such as capital raising, non-timely filing of financial reports, management changes, or mergers and acquisitions, can provide important information relevant to assessing risk. Finally, the financial press, including online media, if used judiciously, can be a useful source of information about risk.

17.1 Limited Usefulness of Auditor's Opinion as a Source of Information about Risk

An auditor's opinion is unlikely to be an analyst's first source of information about a company's risk.[24] For financial statements, a clean audit opinion states that the financial statements present the information fairly and in conformity with the relevant accounting principles. For internal controls, a clean audit opinion states that the company maintained effective internal controls over financial reporting. A negative or going-concern audit opinion on financial statements or a report indicating an internal control weakness would clearly be a warning sign for an analyst. However, an audit opinion relates to historical information and would, therefore, typically not provide information on a timely enough basis to be a useful source of information about risk.

For example, Eastman Kodak Company filed for bankruptcy on 19 January 2012. The audit opinion for fiscal 2011 (dated 28 February 2012) is shown in Exhibit 29. The opinion is identical to the company's audit opinion for the prior fiscal year except for two differences: (1) the years have been updated, and (2) the paragraph highlighted in bold has been added. The added paragraph states that the financial statements were prepared under the "going-concern" assumption; the company has subsequently declared bankruptcy, which raises doubt about the company's ability to continue as a going concern; and the financial statements have not been adjusted to reflect the bankruptcy. An analyst would have learned about Eastman Kodak's bankruptcy on 19 January, so the audit opinion is not useful as a source of that information. In addition, the audit opinion addresses financial statements that had not been adjusted to reflect the bankruptcy, which would limit usefulness to an analyst.

24 Regulators globally are considering changes to increase the usefulness of audit reports. For example, the Financial Reporting Council in the UK requires auditors to include more information in their reports on risks identified during the audit and on how the concept of materiality was applied.

Exhibit 29 Post-Bankruptcy Audit Opinion for Eastman Kodak

Report of Independent Registered Public Accounting Firm

To the Board of Directors and Shareholders of Eastman Kodak Company:

In our opinion, the consolidated financial statements listed in the index appearing under Item 15(a)(1) present fairly, in all material respects, the financial position of Eastman Kodak Company and its subsidiaries at December 31, 2011 and 2010, and the results of their operations and their cash flows for each of the three years in the period ended December 31, 2011 in conformity with accounting principles generally accepted in the United States of America. In addition, in our opinion, the financial statement schedule listed in the index appearing under Item 15(a)(2) presents fairly, in all material respects, the information set forth therein when read in conjunction with the related consolidated financial statements. Also in our opinion, the Company maintained, in all material respects, effective internal control over financial reporting as of December 31, 2011, based on criteria established in *Internal Control - Integrated Framework* issued by the Committee of Sponsoring Organizations of the Treadway Commission (COSO). The Company's management is responsible for these financial statements and financial statement schedule, for maintaining effective internal control over financial reporting and for its assessment of the effectiveness of internal control over financial reporting, included in Management's Report on Internal Control over Financial Reporting appearing under Item 9A. Our responsibility is to express opinions on these financial statements, on the financial statement schedule, and on the Company's internal control over financial reporting based on our integrated audits. We conducted our audits in accordance with the standards of the Public Company Accounting Oversight Board (United States). Those standards require that we plan and perform the audits to obtain reasonable assurance about whether the financial statements are free of material misstatement and whether effective internal control over financial reporting was maintained in all material respects. Our audits of the financial statements included examining, on a test basis, evidence supporting the amounts and disclosures in the financial statements, assessing the accounting principles used and significant estimates made by management, and evaluating the overall financial statement presentation. Our audit of internal control over financial reporting included obtaining an understanding of internal control over financial reporting, assessing the risk that a material weakness exists, and testing and evaluating the design and operating effectiveness of internal control based on the assessed risk. Our audits also included performing such other procedures as we considered necessary in the circumstances. We believe that our audits provide a reasonable basis for our opinions.

The accompanying financial statements have been prepared assuming that the Company will continue as a going concern. As more fully discussed in Note 1 to the financial statements, on January 19, 2012, the Company and its US subsidiaries filed voluntary petitions for relief under chapter 11 of the United States Bankruptcy Code. Uncertainties inherent in the bankruptcy process raise substantial doubt about the Company's ability to continue as a going concern. Management's plans in regard to these matters are also described in Note 1. The accompanying financial statements do not include any adjustments that might result from the outcome of this uncertainty.

A company's internal control over financial reporting is a process designed to provide reasonable assurance regarding the reliability of financial reporting and the preparation of financial statements for external purposes in accordance with generally accepted accounting principles. A company's internal control over

(continued)

Exhibit 29 (Continued)

financial reporting includes those policies and procedures that (i) pertain to the maintenance of records that, in reasonable detail, accurately and fairly reflect the transactions and dispositions of the assets of the company; (ii) provide reasonable assurance that transactions are recorded as necessary to permit preparation of financial statements in accordance with generally accepted accounting principles, and that receipts and expenditures of the company are being made only in accordance with authorizations of management and directors of the company; and (iii) provide reasonable assurance regarding prevention or timely detection of unauthorized acquisition, use, or disposition of the company's assets that could have a material effect on the financial statements.

Because of its inherent limitations, internal control over financial reporting may not prevent or detect misstatements. Also, projections of any evaluation of effectiveness to future periods are subject to the risk that controls may become inadequate because of changes in conditions, or that the degree of compliance with the policies or procedures may deteriorate.

/s/ PricewaterhouseCoopers LLP

PricewaterhouseCoopers LLP
Rochester, New York
February 28, 2012

Note: Bold-face type is added for emphasis.

In the case of Kodak, an analyst would not have obtained very useful information about risk from the auditor's report. Other sources of information—financial and market data—would have provided clear and timely indications of the company's financial difficulty.

Groupon provides another example of the timing of availability of information about risk in external auditors' reports. Exhibit 30 presents a timeline of events related to the company's material weakness in internal controls. Note that no negative external auditor opinion appeared before or during the time frame in which the weakness existed. No external opinion was required for the first annual filing, and the weakness had been remedied by the second annual filing.

Exhibit 30 Material Weaknesses in Internal Controls at Groupon

November 2011:	The company goes public (initial public offering)
March 2012:	The company revises financial results and discloses that management concluded there was a "material weakness" in internal controls over financial reporting, as of 31 December. Shares fall 17%. (Because of an exemption for newly public companies, no external auditor opinion on the effectiveness of internal controls was required.)
May 2012:	In its first-quarter filing, the company discloses that it is "taking steps" to correct the weaknesses but cannot provide assurance that internal controls will be considered effective by the end of the year.
August 2012:	Second-quarter filing includes a disclosure similar to that in first-quarter filing.

Exhibit 30 (Continued)

November 2012:	Third-quarter filing includes a disclosure similar to that in first-quarter filing.
February 2013:	Full-year filing indicates that the company "concluded that we have remediated the previously identified material weakness as of December 31, 2012." (As required for public companies, the filing includes Groupon's first external auditor opinion on the effectiveness of internal controls. The company received a clean opinion.)

In the case of Groupon, an analyst would not have obtained any useful information from the auditor's report. Other data would have given more useful indicators of the company's reporting difficulties. For example, the company was required to change its revenue recognition policy and to restate the amount of revenue reported in its IPO filing—clearly a sign of reporting difficulties. Another item of information providing a signal of likely reporting difficulties was the company's extensive number of acquisitions and explosive growth. Groupon's reported revenues for 2009 were more than 300 times the amount of 2008 reported revenues, and 2010 reported revenues were 23 times larger than 2009 revenues. As described in an August 2011 accounting blog (Catanach and Ketz 2011):

> It is absolutely ludicrous to think that Groupon is anywhere close to having an effective set of internal controls over financial reporting having done 17 acquisitions in a little over a year. When a company expands to 45 countries, grows merchants from 212 to 78,466, and expands its employee base from 37 to 9,625 in only two years, there is little doubt that internal controls are not working somewhere.

The growth data, particularly coupled with disclosures in the IPO filing about management inexperience, are a warning sign of potential reporting risks. These reporting risks were observable many months before the company disclosed its internal control weakness, and the control weaknesses did not appear in an audit opinion.

Although the content of an audit opinion is unlikely to provide timely information about risk, a change in the auditor—and especially multiple changes in the auditor—can signal possible reporting problems. For example, one of the largest feeder funds for Bernie Madoff (the perpetrator of a multi-billion-dollar Ponzi scheme) had three different auditors for the three years from 2004 to 2006, a fact highlighted in testimony as a huge warning sign indicating "auditor shopping."[25] Similarly, the use of an auditor whose capabilities seem inadequate for the complexity of the company can indicate risk. For example, the accounting/auditing firm that audited Madoff's $50 billion operation consisted of three people (two principals and a secretary). The small size of the auditing firm relative to the size of Madoff's operations should have caused serious concern for any potential investor. In general, it is important to understand the relationship between the auditor and the firm. Any questions about the auditor's independence would be a cause for concern—for example, if the auditor and company management are particularly close or if the company represents a substantial portion of the auditing firm's revenue.

25 From the testimony of Harry Markopolos, CFA, given before the US House of Representatives Committee on Financial Services, 4 February 2009.

18 RISK-RELATED DISCLOSURES IN THE NOTES

m describe sources of information about risk.

The notes, an integral part of the financial statements, typically contain information that is useful in understanding a company's risk. For example, both IFRS and US GAAP require specific disclosures about risks related to contingent obligations, pension and post-employment benefits, and financial instrument risks.

Disclosures about contingent obligations include a description of the obligation, estimated amounts, timing of required payments, and related uncertainties.[26] Exhibit 31 shows excerpts from two of Royal Dutch Shell's financial statement notes disclosing information about provisions and contingencies. The year-to-year changes in management's estimated costs for items such as future decommissioning and restoration could have implications for risk evaluation. The disclosure also emphasizes the uncertain timing and amounts.

Exhibit 31 Disclosures about Contingent Obligations, Excerpt from Royal Dutch Shell's Note 19 and Note 25

19 Decommissioning and Other Provisions

	Current		Non-Current		Total	
	31 Dec 2012	31 Dec 2011	31 Dec 2012	31 Dec 2011	31 Dec 2012	31 Dec 2011
Decommissioning and restoration	1,356	894	14,715	13,072	16,071	13,966
Environmental	366	357	1,032	1,078	1,398	1,435
Redundancy	228	406	275	297	503	703
Litigation	390	256	307	330	697	586
Other	881	1,195	1,106	854	1,987	2,049
Total	3,221	3,108	17,435	15,631	20,656	18,739

The timing and amounts settled in respect of these provisions are uncertain and dependent on various factors that are not always within management's control. Additional provisions are stated net of reversals of provisions recognised in previous periods.

Of the decommissioning and restoration provision at December 31, 2012, an estimated $4,666 million is expected to be utilised within one to five years, $3,483 million within six to ten years, and the remainder in later periods.

Reviews of estimated decommissioning and restoration costs are carried out annually, which in 2012 resulted in an increase of $1,586 million …

26 Contingent losses are recognized (i.e., reported on the financial statements) when it is probable the loss will occur and the amount can be reasonably estimated. Contingencies are disclosed (but not recognized) when the occurrence of a loss is less than probable but greater than remote and/or the amount cannot be reliably estimated. The concepts are similar under IFRS and US GAAP despite differences in terminology. IFRS makes a distinction between "provisions," which are recognized as liabilities because they meet the definition of a liability, and "contingent liabilities," which are disclosed but not recognized.

Exhibit 31 (Continued)

25 Legal Proceedings and Other Contingencies

Groundwater contamination

Shell Oil Company (including subsidiaries and affiliates, referred to collectively as SOC), along with numerous other defendants, has been sued by public and quasi-public water purveyors, as well as governmental entities. The plaintiffs allege responsibility for groundwater contamination caused by releases of gasoline containing oxygenate additives. Most of these suits assert various theories of liability, including product liability, and seek to recover actual damages, including clean-up costs. Some assert claims for punitive damages. Fewer than 10 of these cases remain. On the basis of court rulings in SOC's favour in certain cases claiming damages from threats of contamination, the claims asserted in remaining matters, and Shell's track record with regard to amounts paid to resolve varying claims, the management of Shell currently does not believe that the outcome of the remaining oxygenate-related litigation pending, as at December 31, 2012, will have a material impact on Shell.

Nigerian claims

Shell subsidiaries and associates operating in Nigeria are parties to various environmental and contractual disputes. These disputes are at different stages in litigation, including at the appellate stage, where judgments have been rendered against Shell. If taken at face value, the aggregate amount of these judgments could be seen as material. The management of Shell, however, believes that these matters will ultimately be resolved in a manner favourable to Shell. While no assurance can be provided as to the ultimate outcome of any litigation, these matters are not expected to have a material effect on Shell.

Other

In the ordinary course of business, Shell subsidiaries are subject to a number of other loss contingencies arising from litigation and claims brought by governmental and private parties. The operations and earnings of Shell subsidiaries continue, from time to time, to be affected to varying degrees by political, legislative, fiscal and regulatory developments, including those relating to the protection of the environment and indigenous groups, in the countries in which they operate. The industries in which Shell subsidiaries are engaged are also subject to physical risks of various types. The nature and frequency of these developments and events, as well as their effect on future operations and earnings, are unpredictable.

Disclosures about pensions and post-employment benefits include information relevant to actuarial risks that could result in actual benefits differing from the reported obligations based on estimated benefits or investment risks that could result in actual assets differing from reported amounts based on estimates.

Disclosures about financial instruments include information about risks, such as credit risk, liquidity risk, and market risks that arise from the company's financial instruments, and how they have been managed.

EXAMPLE 11

Use of Disclosures

Use the excerpts from Royal Dutch Shell's note disclosing information about financial instruments in Exhibit 32 to answer the following questions:

1. Does Shell appear to take a centralized or decentralized approach to managing interest rate risk?
2. For the year ended 31 December 2012, Shell reported pre-tax income of $50,289 million. How significant is Shell's exposure to a 1% increase in interest rates?
3. For the year ended 31 December 2012, what would be the impact on Shell's pre-tax income of a 10% appreciation of the Australian dollar against the US dollar?

Exhibit 32 Disclosures about Financial Instruments, Excerpt from Royal Dutch Shell's Note 21

21 Financial Instruments and Other Derivative Contracts

A – Risks

In the normal course of business, financial instruments of various kinds are used for the purposes of managing exposure to interest rate, currency and commodity price movements.

....

Interest rate risk

Most debt is raised from central borrowing programmes. Interest rate swaps and currency swaps have been entered into to effectively convert most centrally issued debt to floating rate linked to dollar Libor (London Inter-Bank Offer Rate), reflecting Shell's policy to have debt principally denominated in dollars and to maintain a largely floating interest rate exposure profile. Consequently, Shell is exposed predominantly to dollar Libor interest rate movements. The financing of most subsidiaries is also structured on a floating-rate basis and, except in special cases, further interest rate risk management is discouraged.

On the basis of the floating rate net debt position at December 31, 2012, and assuming other factors (principally foreign exchange rates and commodity prices) remained constant and that no further interest rate management action were taken, an increase in interest rates of 1% would decrease pre-tax income by $27 million (2011: $146 million).

Foreign exchange risk

Many of the markets in which Shell operates are priced, directly or indirectly, in dollars. As a result, the functional currency of most Upstream companies and those with significant cross-border business is the dollar. For Downstream companies, the local currency is typically the functional currency. Consequently, Shell is exposed to varying levels of foreign exchange risk when it enters into transactions that are not denominated in the companies' functional currencies, when foreign currency monetary

Exhibit 32 (Continued)

assets and liabilities are translated at the reporting date and as a result of holding net investments in operations that are not dollar-functional. The main currencies to which Shell is exposed are sterling, the Canadian dollar, euro and Australian dollar. Each company has treasury policies in place that are designed to measure and manage its foreign exchange exposures by reference to its functional currency.

Exchange rate gains and losses arise in the normal course of business from the recognition of receivables and payables and other monetary items in currencies other than individual companies' functional currency. Currency exchange risk may also arise in connection with capital expenditure. For major projects, an assessment is made at the final investment decision stage whether to hedge any resulting exposure.

Hedging of net investments in foreign operations or of income that arises in foreign operations that are non-dollar functional is not undertaken.

Assuming other factors (principally interest rates and commodity prices) remained constant and that no further foreign exchange risk management action were taken, a 10% appreciation against the dollar at December 31 of the main currencies to which Shell is exposed would have the following pre-tax effects:

	Increase (decrease) in income		Increase in net assets	
$ millions	**2012**	**2011**	**2012**	**2011**
10% appreciation against the dollar of:				
Sterling	(185)	(58)	1,214	1,042
Canadian dollar	131	(360)	1,384	1,364
Euro	30	458	1,883	1,768
Australian dollar	246	153	142	120

The above sensitivity information is calculated by reference to carrying amounts of assets and liabilities at December 31 only. The pre-tax effect on income arises in connection with monetary balances denominated in currencies other than the relevant entity's functional currency; the pre-tax effect on net assets arises principally from the translation of assets and liabilities of entities that are not dollar-functional.

Solution to 1:

Shell appears to take a centralized approach to managing interest rate risk based on its statements that most debt is raised centrally and that interest rate swaps and currency swaps have been used to convert most interest rate exposure to dollar Libor. In addition, Shell states that apart from structuring subsidiary financing on a floating-rate basis, it discourages subsidiary's further interest rate risk management.

Solution to 2:

For the year ended 31 December 2012, Shell's exposure to a 1% increase in interest rates is relatively insignificant. An increase in interest rates of 1% would decrease pre-tax income by $27 million, which is less than 0.1% of Shell's 2012 reported pre-tax income of $50,289 million.

Solution to 3:

The impact on Shell's pre-tax income of a 10% appreciation of the Australian dollar against the US dollar would be an increase of $246 million, which is about 0.5% of Shell's 2012 reported pre-tax income of $50,289 million.

These disclosures, along with expectations about future market conditions, can help an analyst assess whether the company's exposures to interest rate risk and foreign exchange risks pose a significant threat to the company's future performance.

19 MANAGEMENT COMMENTARY (MD&A), OTHER REQUIRED DISCLOSURES, FINANCIAL PRESS

m describe sources of information about risk.

The IFRS Practice Statement, *Management Commentary*, issued in December 2010, is a non-binding framework for commentary related to financial statements prepared in accordance with IFRS. One purpose of the commentary is to help users of the financial reports in understanding the company's risk exposures, approach to managing risks, and effectiveness of risk management. The practice statement includes five elements that should be contained in the commentary: (1) nature of the business; (2) objectives and strategies; (3) resources, risks, and relationships; (4) results and prospects; and (5) performance measures and indicators. The section on risks can be particularly useful (IFRS 2010).

> Management should disclose its principal strategic, commercial, operational, and financial risks, which are those that may significantly affect the entity's strategies and progress of the entity's value. The description of the principal risks facing the entity should cover both exposures to negative consequences and potential opportunities.... The principal risks and uncertainties can constitute either a significant external or internal risk to the entity. (p. 13)

Public US companies are required to include an MD&A as Item 7 of Form 10-K. The MD&A disclosures include information about (1) liquidity, (2) capital resources, (3) results of operations, (4) off-balance-sheet arrangements, and (5) contractual arrangements. Information about off-balance-sheet arrangements and contractual arrangements can enable an analyst to anticipate future impact on cash flow. Companies are required to present quantitative and qualitative information about the company's exposure to market risks as Item 7A of the 10-K. This disclosure should enable analysts to understand the impact of fluctuations in interest rates, foreign exchange, and commodity prices.[27]

The IFRS Practice Statement states specifically that companies should present only the principal risks and not list all possible risks and uncertainties. Similarly, the SEC Division of Corporation Finance's internal reference document, *Financial Reporting Manual*, states, "MD&A should not consist of generic or boilerplate disclosure. Rather, it should reflect the facts and circumstances specific to each individual registrant" (p. 296). In practice, disclosures do not always reflect the intent. One challenge faced by analysts is identifying important risks and distinguishing between risks that are generic and thus relevant to all companies and risks that are more specific to an individual company.

This challenge is illustrated by an excerpt from the "Key Risks and Uncertainties" section of Autonomy Corporation's 2010 Annual Report, its last annual report before it was acquired by Hewlett-Packard Company (HP) for $11.1 billion in 2011.[28] As shown in Exhibit 33, Autonomy's risk disclosures contain many items that are arguably generic, such as the inability to maintain the competitive value of its technology, loss of key executives, and continued unfavorable economic conditions. These types of risks would be faced by any technology company. This significant amount of generic commentary (two pages) could potentially distract a reader whose aim was to identify the specific and important risks faced by the company.

Exhibit 33 Autonomy Corporation, Key Risks and Uncertainties

Risk	Description	Impact/Sensitivity	Mitigation/Comment
Technology	Business depends on our core technology, and our strategy concentrates on developing and marketing software based on our proprietary technology.	Since substantially all of revenues derive from licensing our core technology, if unable to maintain and enhance the competitive value of our core technology, our business will be adversely affected.	Continue to invest heavily in research and development to maintain competitive advantage. Monitor market to maintain competitiveness. Apply core technology to new and additional vertical market applications.
Competition	Technology which significantly competes with our technology.	Could render our products out of date and could result in rapid loss of market share.	Invest heavily in new product development to ensure that we have products at various stages of the product life cycle.

(continued)

27 Although not part of the MD&A, disclosures about risk factors relevant to the company's securities are also required as Item 1A of Form 10-K.

28 HP subsequently took a multi-billion-dollar write-down on its investment, which it attributed to misreporting by Autonomy Corporation, stating that "the majority of this impairment charge is linked to serious accounting improprieties, disclosure failures and outright misrepresentations at Autonomy Corporation plc that occurred prior to HP's acquisition of Autonomy and the associated impact of those improprieties, failures and misrepresentations on the expected future financial performance of the Autonomy business over the long-term" (HP earnings announcement, 20 November 2012). Of course, HP's due diligence prior to purchasing the company would have gone far beyond the published financial reports; HP would have had access to all of the company's internal reporting as well.

Exhibit 33 (Continued)

Risk	Description	Impact/Sensitivity	Mitigation/Comment
Variability and visibility	There may be fluctuations in results due to quarterly reporting, and variability in results due to late-in-the-quarter purchasing cycles common in the software industry.	Although quarter-to-quarter results may not be meaningful due to the short periods, negative sentiment may arise based on interpretation of results. Due to late purchasing cycles common in the software industry, variability in closure rates could become exaggerated resulting in a negative effect on operations.	Close management of sales pipelines on a quarterly basis to improve visibility in results expectations. Close monitoring of macro and micro economic conditions to understand variability in closure rates. Annual and quarterly target setting to enable results achievement.
Margins	Expenditures increasing without a commensurate increase in revenues, and rapid changes in market conditions.	If increased expenses are not accompanied by increased revenues, we could experience decreased margins or operating losses.	Close monitoring by management of revenue and cost forecasts. Adjustment to expenditures in the event of anticipated revenue shortfalls.
Average selling prices	The average selling prices of our products could decrease rapidly.	May negatively impact revenues and gross margins.	Monitor market prices on an ongoing basis. Pricing responsibility at a senior level of management for deviations from standard.
Market conditions	The continuation of unfavourable economic and market conditions.	Could result in a rapid deterioration of operating results.	Regular monitoring of economic conditions. Adjustments to costs and product offerings to anticipate and match market conditions.
Resellers	Our ability to expand sales through indirect sellers and our general reliance on sales of our products by third parties.	Inability to recruit and retain resellers who can successfully penetrate their markets could adversely affect our business.	Invest in training resources for resellers. Close monitoring of reseller sales cycles. Investment in direct sales channel.
Management	The continued service of our executive directors.	The loss of any key member of management may affect the leadership of the company.	Establish succession plan. Maintain effective management training programme. Attract and retain senior personnel.
Hiring	The hiring and retention of qualified personnel.	Without the appropriate quality and quantity of skills throughout the organisation, it would be difficult to execute the business plans and grow.	Use of external recruiters and internal bonuses. Rigorous talent management plans and reviews. Provide competitive compensation packages. Ensure that work is challenging and rewarding.
Product errors	Errors or defects in our products.	Could negatively affect our revenues and the market acceptance of our products and increase our costs.	Invest in quality control programmes. Monitor integrity and effectiveness of software. Solicit and act on customer feedback.
Acquisitions	Problems encountered in connection with potential acquisitions.	We may not successfully overcome problems in connection with potential acquisitions, which could lead to a deterioration in our results.	Carefully evaluate transactions. Conduct thorough due diligence on all targets. Carefully plan for post-acquisition integration.
IP infringement	Claims by others that we infringe on their intellectual property rights.	If our technology infringed on other parties' intellectual property rights, we could be exposed to costs and injunctive relief.	Monitor market developments closely to identify potential violations of our patents, and by the company, and take action where necessary. Maintain a significant number of patents to support our business and protect competitive advantage.

Exhibit 33 (Continued)

Risk	Description	Impact/Sensitivity	Mitigation/Comment
Growth	Our ability to effectively manage our growth.	Expansion places demands on management, engineering, support, operations, legal, accounting, sales and marketing personnel, and other resources. Failure to manage effectively will impact business and financial results	Recruitment and retention of key personnel. Investment in corporate infrastructure, including support, operations, legal, and accounting personnel. Focus on internal controls.
International risks	Additional operational and financial risks as we continue to expand our international operations.	Exposure to movements in exchange rates and lack of familiarity with local laws could lead to infractions.	Pricing of contracts in US dollars to the extent possible to minimise exchange risk. Retention of local staff and local advisors, reporting to headquarters, to manage risk.
Security breaches	Any breach of our security measures and unauthorised access to a customer's or our data.	Could result in significant legal liability and negative publicity.	Establish and maintain strict security standards. Test security standards on a regular basis.

19.1 Other Required Disclosures

Other required disclosures that are specific to an event, such as capital raising, non-timely filing of financial reports, management changes, or mergers and acquisitions, can provide important information relevant to assessing risk. In the United States, public companies would report such events to the SEC in a Form 8-K (and NT—"notification of inability to timely file"—when appropriate). Delays in filing are often the result of accounting difficulties. Such accounting difficulties could be internal disagreement on an accounting principle or estimate, the lack of adequate financial staff, or the discovery of an accounting fraud that requires further examination. In general, an NT filing is highly likely to signal problems with financial reporting quality.

For public companies in Europe, the Committee of European Securities Regulators (CESR)[29] has published guidance concerning the types of inside information that must be disclosed on an ad hoc basis to the market. Examples of such information include changes in control; changes in management and supervisory boards; mergers, splits, and spinoffs; legal disputes; and new licenses, patents, and registered trademarks. Companies use the disclosure mechanisms specified by their relevant national authorities to make such disclosures. For example, in the United Kingdom, a company would release an announcement to the market via an approved regulatory information service.

In these cases, an examination of the information announced would be necessary to determine whether reporting quality would be affected. For example, an announcement of the sudden resignation of a company's most senior financial officer or external auditor would clearly be a warning sign of potential problems with financial reporting quality. As another example, an announcement of a legal dispute related to one of the company's important assets or products would warrant attention because it could negatively affect the company's future earnings. Announcements of mergers and acquisitions, although they might indicate future positive developments for the company, could also indicate changes in the company's risk profile, particularly during the transaction.

29 CESR has been replaced by the European Securities and Markets Authority (ESMA).

19.2 Financial Press as a Source of Information about Risk

The financial press can be a useful source of information about risk when, for example, a financial reporter uncovers financial reporting issues that had not previously been recognized. For example, a *Wall Street Journal* financial reporter, Jonathan Weil (2000), was one of the first people to identify problems with the accounting at Enron (and other companies that were using "gain-on-sale" accounting, an aggressive policy allowing immediate revenue recognition on long-term contracts). Indeed, the well-known investor James (Jim) Chanos cites an article by Weil as the catalyst of his investigation of Enron (Chanos 2002).

It is important to emphasize that even if an initial idea comes from a news article, further investigation is essential—first, by using definitive sources (i.e., regulatory filings) to confirm any accounting and financial disclosures and, second, by seeking supporting information from other sources, where available. For example, although a financial press article was the initial source of information for Chanos, the first step in his research was to analyze Enron's annual SEC filings (Form 10-K and 10-Q). In addition, Chanos obtained information about insider stock sales, the company's business strategy and tactics, and stock analysts' perspectives.

It is also important—and likely will become increasingly important as electronic media via the internet expands—to consider the source of any particular news article. Information reported by a well-known financial news provider is more likely to be factual than information from less-established sources. Similarly, stories or blogs written by financial journalists are more likely to be unbiased than those written by individuals with a related service or product to sell.

SUMMARY

Assessing the quality of financial reports—both reporting quality and results quality—is an important analytical skill.

- The quality of financial reporting can be thought of as spanning a continuum from the highest quality to the lowest.
- Potential problems that affect the quality of financial reporting broadly include revenue and expense recognition on the income statement; classification on the statement of cash flows; and the recognition, classification, and measurement of assets and liabilities on the balance sheet.
- Typical steps involved in evaluating financial reporting quality include an understanding of the company's business and industry in which the company is operating; comparison of the financial statements in the current period and the previous period to identify any significant differences in line items; an evaluation of the company's accounting policies, especially any unusual revenue and expense recognition compared with those of other companies in the same industry; financial ratio analysis; examination of the statement of cash flows with particular focus on differences between net income and operating cash flows; perusal of risk disclosures; and review of management compensation and insider transactions.
- High-quality earnings increase the value of the company more than low-quality earnings, and the term "high-quality earnings" assumes that reporting quality is high.

- Low-quality earnings are insufficient to cover the company's cost of capital and/or are derived from non-recurring, one-off activities. In addition, the term "low-quality earnings" can be used when the reported information does not provide a useful indication of the company's performance.
- Various alternatives have been used as indicators of earnings quality: recurring earnings, earnings persistence and related measures of accruals, beating benchmarks, and after-the-fact confirmations of poor-quality earnings, such as enforcement actions and restatements.
- Earnings that have a significant accrual component are less persistent and thus may revert to the mean more quickly.
- A company that consistently reports earnings that exactly meet or only narrowly beat benchmarks can raise questions about its earnings quality.
- Cases of accounting malfeasance have commonly involved issues with revenue recognition, such as premature recognition of revenues or the recognition of fraudulent revenues.
- Cases of accounting malfeasance have involved misrepresentation of expenditures as assets rather than as expenses or misrepresentation of the timing or amount of expenses.
- Bankruptcy prediction models, used in assessing financial results quality, quantify the likelihood that a company will default on its debt and/or declare bankruptcy.
- Similar to the term "earnings quality," when reported cash flows are described as being high quality, it means that the company's underlying economic performance was satisfactory in terms of increasing the value of the firm, and it also implies that the company had high reporting quality (i.e., that the information calculated and disclosed by the company was a good reflection of economic reality). Cash flow can be described as "low quality" either because the reported information properly represents genuinely bad economic performance or because the reported information misrepresents economic reality.
- For the balance sheet, high financial *reporting* quality is indicated by completeness, unbiased measurement, and clear presentation.
- A balance sheet with significant amounts of off-balance-sheet debt would lack the completeness aspect of financial reporting quality.
- Unbiased measurement is a particularly important aspect of financial reporting quality for assets and liabilities for which valuation is subjective.
- A company's financial statements can provide useful indicators of financial or operating risk.
- The management commentary (also referred to as the management discussion and analysis, or MD&A) can give users of the financial statements information that is helpful in assessing the company's risk exposures and approaches to managing risk.
- Required disclosures regarding, for example, changes in senior management or inability to make a timely filing of required financial reports can be a warning sign of problems with financial reporting quality.
- The financial press can be a useful source of information about risk when, for example, a financial reporter uncovers financial reporting issues that had not previously been recognized. An analyst should undertake additional investigation of any issue identified.

PRACTICE PROBLEMS

The following information relates to Questions 1–4

Mike Martinez is an equity analyst who has been asked to analyze Stellar, Inc. by his supervisor, Dominic Anderson. Stellar exhibited strong earnings growth last year; however, Anderson is skeptical about the sustainability of the company's earnings. He wants Martinez to focus on Stellar's financial reporting quality and earnings quality.

After conducting a thorough review of the company's financial statements, Martinez concludes the following:

Conclusion 1	Although Stellar's financial statements adhere to generally accepted accounting principles (GAAP), Stellar understates earnings in periods when the company is performing well and overstates earnings in periods when the company is struggling.
Conclusion 2	Stellar most likely understated the value of amortizable intangibles when recording the acquisition of Solar, Inc. last year. No goodwill impairment charges have been taken since the acquisition.
Conclusion 3	Over time, the accruals component of Stellar's earnings is large relative to the cash component.
Conclusion 4	Stellar reported an unusually sharp decline in accounts receivable in the current year, and an increase in long-term trade receivables.

1 Based on Martinez's conclusions, Stellar's financial statements are *best* categorized as:

- A non-GAAP compliant.
- B GAAP compliant, but with earnings management.
- C GAAP compliant and decision useful, with sustainable and adequate returns.

2 Based on Conclusion 2, after the acquisition of Solar, Stellar's earnings are *most likely*:

- A understated.
- B fairly stated.
- C overstated.

3 In his follow-up analysis relating to Conclusion 3, Martinez should focus on Stellar's:

- A total accruals.
- B discretionary accruals.
- C non-discretionary accruals.

4 What will be the impact on Stellar in the current year if Martinez's belief in Conclusion 4 is correct? Compared with the previous year, Stellar's:

- A current ratio will increase.

© 2018 CFA Institute. All rights reserved.

B days sales outstanding (DSO) will decrease.

C accounts receivable turnover will decrease.

The following information relates to questions 5–11

Ioana Matei is a senior portfolio manager for an international wealth management firm. She directs research analyst Teresa Pereira to investigate the earnings quality of Miland Communications and Globales, Inc.

Pereira first reviews industry data and the financial reports of Miland Communications for the past few years. Pereira then makes the following three statements about Miland:

Statement 1 Miland shortened the depreciable lives for capital assets.

Statement 2 Revenue growth has been higher than that of industry peers.

Statement 3 Discounts to customers and returns from customers have decreased.

Pereira also observes that Miland has experienced increasing inventory turnover, increasing receivables turnover, and net income greater than cash flow from operations. She estimates the following regression model to assess Miland's earnings persistence:

$$\text{Earnings}_{t+1} = \alpha + \beta_1\text{Cash flow}_t + \beta_2\text{Accruals}_t + \varepsilon$$

Pereira and Matei discuss quantitative models such as the Beneish model, used to assess the likelihood of misreporting. Pereira makes the following two statements to Matei:

Statement 4 An advantage of using quantitative models is that they can determine cause and effect between model variables.

Statement 5 A disadvantage of using quantitative models is that their predictive power declines over time because many managers have learned to test the detectability of manipulation tactics by using the model.

Pereira concludes her investigation of Miland by examining the company's reported pre-tax income of $5.4 billion last year. This amount includes $1.2 billion of acquisition and divestiture-related expenses, $0.5 billion of restructuring expenses, and $1.1 billion of other non-operating expenses. Pereira determines that the acquisition and divestiture-related expenses as well as restructuring expenses are non-recurring expenses, but other expenses are recurring expenses.

Matei then asks Pereira to review last year's financial statements for Globales, Inc. and assess the effect of two possible misstatements. Upon doing so, Pereira judges that Globales improperly recognized EUR50 million of revenue and improperly capitalized EUR100 million of its cost of revenue. She then estimates the effect of these two misstatements on net income, assuming a tax rate of 25%.

Pereira compares Globales, Inc.'s financial statements with those of an industry competitor. Both firms have similar, above-average returns on equity (ROE), although Globales has a higher cash flow component of earnings. Pereira applies the mean reversion principle in her forecasts of the two firms' future ROE.

5 Which of Pereira's statements describes an accounting warning sign of potential overstatement or non-sustainability of operating and/or net income?

A Statement 1

B Statement 2

C Statement 3

6 Which of Pereira's statements about Miland Communications is *most likely* a warning sign of potential earnings manipulation?

A The trend in inventory turnover

B The trend in receivables turnover

C The amount of net income relative to cash flow from operations

7 Based on the regression model used by Pereira, earnings persistence for Miland would be highest if:

A β_1 is less than 0.

B β_1 is greater than β_2.

C β_2 is greater than β_1.

8 Which of Pereira's statements regarding the use of quantitative models to assess the likelihood of misreporting is correct?

A Only Statement 4

B Only Statement 5

C Both Statement 4 and Statement 5

9 Based on Pereira's determination of recurring and non-recurring expenses for Miland, the company's recurring or core pre-tax earnings last year is *closest* to:

A $4.3 billion.

B $4.8 billion.

C $7.1 billion.

10 After adjusting the Globales, Inc. income statement for the two possible misstatements, the decline in net income is *closest* to:

A EUR37.5 million.

B EUR112.5 million.

C EUR150.0 million.

11 Pereira should forecast that the ROE for Globales is likely to decline:

A more slowly than that of the industry competitor.

B at the same rate as the industry competitor.

C more rapidly than that of the industry competitor.

The following information relates to questions 12–18

Emmitt Dodd is a portfolio manager for Upsilon Advisers. Dodd meets with Sonya Webster, the firm's analyst responsible for the machinery industry, to discuss three established companies: BIG Industrial, Construction Supply, and Dynamic Production. Webster provides Dodd with research notes for each company that reflect trends during the last three years:

BIG Industrial:

Note 1 Operating income has been much lower than operating cash flow (OCF).

Note 2 Accounts payable has increased, while accounts receivable and inventory have substantially decreased.

Note 3 Although OCF was positive, it was just sufficient to cover capital expenditures, dividends, and debt repayments.

Construction Supply:

Note 4 Operating margins have been relatively constant.

Note 5 The growth rate in revenue has exceeded the growth rate in receivables.

Note 6 OCF was stable and positive, close to its reported net income, and just sufficient to cover capital expenditures, dividends, and debt repayments.

Dynamic Production:

Note 7 OCF has been more volatile than that of other industry participants.

Note 8 OCF has fallen short of covering capital expenditures, dividends, and debt repayments.

Dodd asks Webster about the use of quantitative tools to assess the likelihood of misreporting. Webster tells Dodd she uses the Beneish model, and she presents the estimated *M*-scores for each company in Exhibit 1.

Exhibit 1 Beneish Model *M*-scores

Company	2017	2016	Change in *M*-score
BIG Industrial	−1.54	−1.82	0.28
Construction Supply	−2.60	−2.51	−0.09
Dynamic Production	−1.86	−1.12	−0.74

Webster tells Dodd that Dynamic Production was required to restate its 2016 financial statements as a result of its attempt to inflate sales revenue. Customers of Dynamic Production were encouraged to take excess product in 2016, and they were then allowed to return purchases in the subsequent period, without penalty.

Webster's industry analysis leads her to believe that innovations have caused some of the BIG Industrial's inventory to become obsolete. Webster expresses concern to Dodd that although the notes to the financial statements for BIG Industrial are informative about its inventory cost methods, its inventory is overstated.

The BIG Industrial income statement reflects a profitable 49% unconsolidated equity investment. Webster calculates the return on sales of BIG Industrial based on the reported income statement. Dodd notes that industry peers consolidate similar investments. Dodd asks Webster to use a comparable method of calculating the return on sales for BIG Industrial.

12 Which of Webster's notes about BIG Industrial provides an accounting warning sign of a potential reporting problem?

A Only Note 1

B Only Note 2

C Both Note 1 and Note 2

13 Do either of Webster's Notes 4 or 5 about Construction Supply describe an accounting warning sign of potential overstatement or non-sustainability of operating income?-

A No

B Yes, Note 4 provides a warning sign

C Yes, Note 5 provides a warning sign

14 Based on Webster's research notes, which company would *most likely* be described as having high-quality cash flow?

A BIG Industrial

B Construction Supply

C Dynamic Production

15 Based on the Beneish model results for 2017 in Exhibit 1, which company has the highest probability of being an earnings manipulator?

A BIG Industrial

B Construction Supply

C Dynamic Production

16 Based on the information related to its restatement, Dynamic Production reported poor operating cash flow quality in 2016 by understating:

A inventories.

B net income.

C trade receivables.

17 Webster's concern about BIG Industrial's inventory suggests poor reporting quality, *most likely* resulting from a lack of:

A completeness.

B clear presentation.

C unbiased measurement.

18 In response to Dodd's request, Webster's recalculated return on sales will *most likely*:

A decrease.

B remain the same.

C increase.

SOLUTIONS

1 B is correct. Stellar's financial statements are GAAP compliant (Conclusion 1) but cannot be relied upon to assess earnings quality. There is evidence of earnings management: understating and overstating earnings depending upon the results of the period (Conclusion 1), understated amortizable intangibles (Conclusion 2), and a high accruals component in the company's earnings (Conclusion 3).

2 C is correct. Martinez believes that Stellar most likely understated the value of amortizable intangibles when recording the acquisition of a rival company last year. Impairment charges have not been taken since the acquisition (Conclusion 2). Consequently, the company's earnings are likely to be overstated because amortization expense is understated. This understatement has not been offset by an impairment charge.

3 B is correct. Martinez concluded that the accruals component of Stellar's earnings was large relative to the cash component (Conclusion 3). Earnings with a larger component of accruals are typically less persistent and of lower quality. An important distinction is between accruals that arise from normal transactions in the period (called non-discretionary) and accruals that result from transactions or accounting choices outside the normal (called discretionary accruals). The discretionary accruals are possibly made with the intent to distort reported earnings. Outlier discretionary accruals are an indicator of possibly manipulated—and thus low quality earnings. Thus, Martinez is primarily focused on discretionary accruals, particularly outlier discretionary accruals (referred to as abnormal accruals).

4 B is correct. Because accounts receivable will be lower than reported in the past, Stellar's DSO [Accounts receivable/(Revenues/365)] will decrease. Stellar's accounts receivable turnover (365/days' sales outstanding) will increase with the lower DSO, giving the false impression of a faster turnover. The company's current ratio will decrease (current assets will decrease with no change in current liabilities).

5 B is correct. Higher growth in revenue than that of industry peers is an accounting warning sign of potential overstatement or non-sustainability of operating income. Shortening the depreciable lives of capital assets is a conservative change and not a warning sign. An increase (not a decrease) in discounts and returns would be a warning sign.

6 C is correct. Net income being greater than cash flow from operations is a warning sign that the firm may be using aggressive accrual accounting policies that shift current expenses to future periods. Decreasing, not increasing, inventory turnover could suggest inventory obsolescence problems that should be recognized. Decreasing, not increasing, receivables turnover could suggest that some revenues are fictitious or recorded prematurely or that the allowance for doubtful accounts is insufficient.

7 B is correct. When earnings are decomposed into a cash component and an accruals component, research has shown that the cash component is more persistent. A beta coefficient (β_1) on the cash flow variable that is larger than the beta coefficient (β_2) on the accruals variable indicates that the cash flow component of earnings is more persistent than the accruals component. This result provides evidence of earnings persistence.

8 B is correct. Earnings manipulators have learned to test the detectability of earnings manipulation tactics by using the model to anticipate analysts' perceptions. They can reduce their likelihood of detection; therefore, Statement 5 is correct. As a result, the predictive power of the Beneish model can decline over time. An additional limitation of using quantitative models is that they cannot determine cause and effect between model variables. Quantitative models establish only associations between variables, and Statement 4 is incorrect.

A is incorrect because quantitative models cannot determine cause and effect between model variables. They are capable only of establishing associations between variables. Therefore, Statement 4 is incorrect.

9 C is correct. Recurring or core pre-tax earnings would be \$7.1 billion, which is the company's reported pre-tax income of \$5.4 billion plus the \$1.2 billion of non-recurring (i.e., one-time) acquisitions and divestiture expenses plus the \$0.5 billion of non-recurring restructuring expenses.

10 B is correct. The correction of the revenue misstatement would result in lower revenue by EUR50 million, and the correction of the cost of revenue misstatement would result in higher cost of revenue by EUR100 million. The result is a reduction in pre-tax income of EUR150 million. Applying a tax rate of 25%, the reduction in net income would be $150 \times (1 - 0.25)$ = EUR112.5 million.

11 A is correct. Based on the principle of mean reversion, the high ROE for both firms should revert towards the mean. Globales has a higher cash flow component to its return than the peer firm, however, so its high return on common equity should persist longer than that of the peer firm. The peer firm has a higher accruals component, so it is likely to revert more quickly.

12 B is correct. Only Note 2 provides a warning sign. The combination of increases in accounts payable with substantial decreases in accounts receivable and inventory are an accounting warning sign that management may be overstating cash flow from operations. Note 1 does not necessarily provide a warning sign. Operating income being greater than operating cash flow is a warning sign of a potential reporting problem. In this case, however, BIG Industrial's operating income is lower than its operating cash flow.

13 A is correct. Neither Note 4 nor Note 5 provides an accounting warning sign of potential overstatement or non-sustainability of operating income.

Increases in operating margins can be a warning sign of potential overstatement or non-sustainability of operating and/or net income. In this case, however, operating margins for Construction Supply have been relatively constant during the last three years.

A growth rate in receivables exceeding the growth rate in revenue is an accounting warning sign of potential overstatement or non-sustainability of operating income. In this case, however, Construction Supply's revenue growth exceeds the growth rate in receivables.

14 B is correct. High-quality OCF means the performance is of high reporting quality and also of high results quality. For established companies, high-quality operating cash flow would typically be positive; be derived from sustainable sources; be adequate to cover capital expenditures, dividends, and debt repayments; and have relatively low volatility compared with industry peers. Construction Supply reported positive OCF during each of the last three years. The OCF appears to be derived from sustainable sources, because it compares closely with reported net income. Finally, OCF was adequate to cover capital expenditures, dividends, and debt repayments. Although the OCF for BIG Industrial has been positive and just sufficient to cover capital expenditures, dividends, and debt repayments, the increases in accounts payable and substantial decreases in accounts receivable and inventory during the last three years are an accounting warning sign that management may be overstating cash flow from operations. For Dynamic Production, OCF has been more volatile than other industry participants, and it has fallen short of covering capital expenditures, dividends, and debt repayments for the last three years. Both of these conditions are warning signs for Dynamic Production.

15 A is correct. Higher *M*-scores indicate an increased probability of earnings manipulation. The company with the highest *M*-score in 2017 is BIG Industrial, with an *M*-score of −1.54. Construction Supply has the lowest *M*-score at −2.60, and Dynamic Production also has a lower *M*-score at −1.86. The *M*-score for BIG Industrial is above the relevant cutoff of −1.78.

16 A is correct. The items primarily affected by improper revenue recognition include net income, receivables, and inventories. When revenues are overstated, net income and receivables will be overstated and inventories will be understated.

17 C is correct. Webster is concerned that innovations have made some of BIG Industrial's inventory obsolete. This scenario suggests impairment charges for inventory may be understated and that the inventory balance does not reflect unbiased measurement.

18 A is correct. The use of unconsolidated joint ventures or equity-method investees may reflect an overstated return on sales ratio, because the parent company's consolidated financial statements include its share of the investee's profits but not its share of the investee's sales. An analyst can adjust the reported amounts to better reflect the combined amounts of sales. Reported net income divided by the combined amount of sales will result in a decrease in the net profit margin.

Integration of Financial Statement Analysis Techniques

by Jack T. Ciesielski, CPA, CFA

Jack T. Ciesielski, CPA, CFA, is at R.G. Associates, Inc., former publisher of The Analyst's Accounting Observer (USA).

LEARNING OUTCOMES

Mastery	*The candidate should be able to:*
☐	**a.** demonstrate the use of a framework for the analysis of financial statements, given a particular problem, question, or purpose (e.g., valuing equity based on comparables, critiquing a credit rating, obtaining a comprehensive picture of financial leverage, evaluating the perspectives given in management's discussion of financial results);
☐	**b.** identify financial reporting choices and biases that affect the quality and comparability of companies' financial statements and explain how such biases may affect financial decisions;
☐	**c.** evaluate the quality of a company's financial data and recommend appropriate adjustments to improve quality and comparability with similar companies, including adjustments for differences in accounting standards, methods, and assumptions;
☐	**d.** evaluate how a given change in accounting standards, methods, or assumptions affects financial statements and ratios;
☐	**e.** analyze and interpret how balance sheet modifications, earnings normalization, and cash flow statement related modifications affect a company's financial statements, financial ratios, and overall financial condition.

1 INTRODUCTION

a demonstrate the use of a framework for the analysis of financial statements, given a particular problem, question, or purpose (e.g., valuing equity based on comparables, critiquing a credit rating, obtaining a comprehensive picture of financial leverage, evaluating the perspectives given in management's discussion of financial results);

It is important to keep in mind that financial analysis is a means to an end and not the end itself. Rather than try to apply every possible technique and tool to every situation, it is essential for the investor to consider and identify the proper type of analysis to apply in a given situation.

The primary reason for performing financial analysis is to help in making an economic decision. Before making such decisions as whether to lend to a particular long-term borrower or to invest a large sum in a common stock, venture capital vehicle, or private equity candidate, an investor or financial decision-maker wants to make sure that the probability of a successful outcome is on his or her side. Rather than leave outcomes to chance, a financial decision-maker should use financial analysis to identify and make more visible potential favorable and unfavorable outcomes.

The purpose of this reading is to provide examples of the effective use of financial analysis in decision making. The framework for the analysis is shown in Exhibit 1. The case study follows the basic framework shown in Exhibit 1.

Exhibit 1 A Financial Statement Analysis Framework

Phase	Sources of Information	Examples of Output
1 Define the purpose and context of the analysis.	■ The nature of the analyst's function, such as evaluating an equity or debt investment or issuing a credit rating ■ Communication with client or supervisor on needs and concerns ■ Institutional guidelines related to developing specific work product	■ Statement of the purpose or objective of the analysis ■ A list (written or unwritten) of specific questions to be answered by the analysis ■ Nature and content of report to be provided ■ Timetable and budgeted resources for completion
2 Collect input data.	■ Financial statements, other financial data, questionnaires, and industry/economic data ■ Discussions with management, suppliers, customers, and competitors ■ Company site visits (e.g., to production facilities or retail stores)	■ Organized financial statements ■ Financial data tables ■ Completed questionnaires, if applicable
3 Process input data, as required, into analytically useful data.	■ Data from the previous phase	■ Adjusted financial statements ■ Common-size statements ■ Ratios and graphs ■ Forecasts
4 Analyze/interpret the data.	■ Input data and processed data	■ Analytical results

Exhibit 1 (Continued)

Phase	Sources of Information	Examples of Output
5 Develop and communicate conclusions and recommendations (e.g., with an analysis report).	■ Analytical results and previous reports ■ Institutional guidelines for published reports	■ Analytical report answering questions posed in Phase 1 ■ Recommendation regarding the purpose of the analysis, such as whether to make an investment or grant credit
6 Follow-up.	■ Information gathered by periodically repeating above steps, as necessary, to determine whether changes to holdings or recommendations are necessary	■ Updated reports and recommendations

CASE STUDY 1: LONG -TERM EQUITY INVESTMENT: EARLY PHASES OF THE ANALYSIS

2

a demonstrate the use of a framework for the analysis of financial statements, given a particular problem, question, or purpose (e.g., valuing equity based on comparables, critiquing a credit rating, obtaining a comprehensive picture of financial leverage, evaluating the perspectives given in management's discussion of financial results);

The portfolio manager for the food sector of a large public employee pension fund wants to take a long-term equity position in a publicly traded food company and has become interested in Nestlé S.A., a global company. In its 2014 annual report, Nestlé's management outlined its long-term objectives for organic growth, margin and earnings per share improvement, and capital efficiency. The management report indicated the following general strategic direction: "Our ambition is not just to be the leader but the industry reference for Nutrition, Health and Wellness. In recent years we have built on the strong foundations of our unrivalled food and beverage portfolio, exploring the benefits of nutrition's therapeutic role with Nestlé Health Science." Nestlé's stated objectives, including expansion of the company's mission into "nutrition's therapeutic role," captured the portfolio manager's attention: She became intrigued with Nestlé as an investment possibility. She asks an analyst to evaluate Nestlé for consideration as a large core holding. Before investing in the company, the portfolio manager has several concerns that she has conveyed to the analyst:

- What are Nestlé's sources of earnings growth? How sustainable is Nestlé's performance? Do the company's reported earnings represent its economic reality? And if Nestlé's performance is fairly reported, will it be sustainable for an extended period, such as 5 to 10 years, while the pension fund has the common stock as a core holding?
- In determining the quality of earnings over a long-term time frame, the portfolio manager wants to understand the relationship of earnings to cash flow.
- Having started out in the investment business as a lending officer, the portfolio manager wants to know how well Nestlé's balance sheet takes into account the company's full rights and obligations. She wants to know whether the capital structure of the company can support future operations and strategic plans. Even if the investor is primarily concerned with the earnings potential of a possible investee, the balance sheet matters. For example, if asset write-downs

or new legal liabilities decrease a company's financial position, it is difficult for a company to sustain profitability if it has to repair its balance sheet. Worse still for an investor: If "repairing the balance sheet" means the issuance of dilutive stock, it can be even more costly to existing investors.

The analyst develops a plan of analysis to address the portfolio manager's concerns by following the framework presented in Exhibit 1. Phases 3 and 4 will be the focus of most of the work.

Phase 1: Define a Purpose for the Analysis

The analyst states the purpose and context of the analysis as identifying the factors that have driven the company's financial success and assessing their sustainability. He also states the need to identify and understand the risks that may affect the sustainability of returns.

Phase 2: Collect Input Data

The analyst finds that Nestlé has an extensive collection of financial statements on its website. After gathering several years of annual reports, he is ready to begin processing the data.

3 PHASES 3 & 4: DUPONT ANALYSIS: ISOLATING "PURE NESTLE"

a demonstrate the use of a framework for the analysis of financial statements, given a particular problem, question, or purpose (e.g., valuing equity based on comparables, critiquing a credit rating, obtaining a comprehensive picture of financial leverage, evaluating the perspectives given in management's discussion of financial results);

b identify financial reporting choices and biases that affect the quality and comparability of companies' financial statements and explain how such biases may affect financial decisions;

c evaluate the quality of a company's financial data and recommend appropriate adjustments to improve quality and comparability with similar companies, including adjustments for differences in accounting standards, methods, and assumptions;

Phase 3: Process Data and Phase 4: Analyze/Interpret the Processed Data

The analyst intends to accomplish his purpose stated in Phase 1 through a series of financial analyses, including

- a DuPont analysis;[1]
- an analysis of the composition of Nestlé's asset base;
- an analysis of Nestlé's capital structure;
- a study of the company's segments and the allocation of capital among them;
- an examination of the company's accruals in reporting as they affect earnings quality;
- a study of the company's cash flows and their adequacy for the company's continued operations and strategies; and
- a decomposition and analysis of the company's valuation.

While processing the input data consistent with the needs of these analyses, the analyst plans to simultaneously interpret and analyze the resulting data. In his view, Phases 3 and 4 of the framework are best considered jointly.

DuPont Analysis

The analyst decides to start the assessment of Nestlé with a DuPont analysis. The investment is expected to be in the company's common stock, and ultimately, the DuPont analysis separates the components affecting the return on common equity. Furthermore, the disaggregation of return on equity (ROE) components leads to more trails to follow in assessing the drivers of Nestlé's performance. The analyst also intends to investigate the quality of the earnings and underlying cash flows, as well as to understand the common shareholders' standing in the Nestlé capital structure.

One basic premise underlying all research and analysis is to constantly look beneath the level of information presented—to constantly search for meaningful insights through disaggregation of the presented information, whether it is a single line on a financial statement or within segments of an entire entity. This constant reduction of information into smaller components can reveal a company's earnings drivers; it can also highlight weaker operations being concealed by stronger ones in the aggregate. That premise of "seeking granularity" underlies DuPont analysis: By isolating the different components of ROE, it helps the analyst discover a company's strengths and allows the analyst to assess their sustainability.[2] Seeking granularity also helps the analyst find potential operational flaws and provides an opening for dialogue with management about possible problems.

The analyst begins to process the data gathered in Phase 2 in order to assemble the information required for the DuPont analysis. Exhibit 2 shows the last three years of income statements for Nestlé; Exhibit 3 shows the last four years of Nestlé balance sheets.

1 A reminder to the reader: This case study is an example, and starting the financial statement analysis with a DuPont analysis is not a mandate. Alternatively, another analyst might be more interested in the trends of various income and expense categories than in the sources of returns on shareholder equity as a financial statement analysis starting point. This analyst might have preferred starting with a time-series common-size income statement. The starting point depends on the perspective of the individual analyst.

2 ROE can be decomposed in a variety of ways:

ROE = Return on assets × Leverage

ROE = Net profit margin × Asset turnover × Leverage

ROE = EBIT margin × Tax burden × Interest burden × Asset turnover × Leverage

From his study of the income statement, the analyst notes that Nestlé has a significant amount of "income from associates and joint ventures" (hereafter referred to in the text as income from associates) in all three years. In 2014, this income amounted to CHF8,003 million, or 53.7%, of Nestlé's net income (referred to by Nestlé as "profit for the year"). The income from associates[3] is a pure net income figure, presented after taxes and with no related revenue in the income statement. Much of the income from associates relates to Nestlé's 23.4% stock ownership of L'Oréal, a cosmetics company.

In 2014, L'Oréal affected the amount of income from associates in a variety of ways. In 2014, Nestlé reduced its L'Oréal ownership by selling 48.5 million shares of its holding back to L'Oréal. In return, Nestlé gained full ownership of Galderma, a joint venture it had with L'Oréal. The partial disposal of L'Oréal shares resulted in a net gain of CHF4,569 million. Income from associates included a revaluation gain of CHF2,817 million from the increase in ownership of Galderma. Nestlé had owned 50% of Galderma, with L'Oréal holding the other 50%. When Nestlé bought the remaining ownership from L'Oréal, its original 50% ownership position was revalued at current fair value, which was based on the price paid. As of July 2014, Galderma became an affiliated company that was fully consolidated. Because of its L'Oréal stock ownership, Nestlé recognizes a share of L'Oréal's net income.

The share of results at other companies that Nestlé included in income from associates was CHF828 million in 2014.

The analyst wants to decompose the company's financial results as much as possible in order to identify any problem operations or to find hidden opportunities. Including the net investments and returns of associates with the full reported value of Nestlé's own assets and income would introduce noise into the analytical signals produced by the DuPont analysis. Unlike the "pure Nestlé" operations and resources, the returns earned by associates are not under the direct control of Nestlé's management. To avoid making incorrect inferences about the profitability of Nestlé's operations, the analyst wants to remove the effects of the investments in associates from the balance sheet and income statement. Otherwise, such DuPont analysis components as net profit margin and total asset turnover would combine the impact of pure Nestlé operations with that of the operations of associated companies: Conclusions about Nestlé-only business would be flawed because they would be based on commingled information.

Exhibit 2 Nestlé S.A. Income Statements, 2014–2012 (CHF millions)

	2014	2013	2012 (restated)[d]
Sales	91,612	92,158	89,721
Other revenue	253	215	210
Cost of goods sold	(47,553)	(48,111)	(47,500)
Distribution expenses	(8,217)	(8,156)	(8,017)
Marketing and administration expenses	(19,651)	(19,711)	(19,041)
Research and development costs	(1,628)	(1,503)	(1,413)
Other trading income	110	120	141
Other trading expenses[a]	(907)	(965)	(637)
Trading operating profit[b]	**14,019**	**14,047**	**13,464**
Other operating income	154	616	146

3 Associates are companies in which Nestlé has the power to exercise significant influence but does not exercise control. Associates and joint ventures are accounted for by the equity method.

Exhibit 2 (Continued)

[a] The 2012 information came from the 2013 Annual Report; 2012 comparatives were restated by Nestlé following the implementation of IFRS 11 and IAS 19 revised, as described in Note 22.
[b] The analyst revised the 2011 balance sheet from that reported in the 2012 Consolidated Financial Statements of the Nestlé Group.

To keep the DuPont analysis as logically consistent as possible throughout all the periods of study, the analyst revises the 2011 balance sheet (from that reported in the 2012 Consolidated Financial Statements of the Nestlé Group) for the effects of implementing IFRS 11 and IAS 19 revised. He identifies the 1 January 2012 adjustments from the 2013 financial statements and revises the 31 December 2011 year-end balances accordingly. The analyst's revisions to the as-reported 2011 balance sheet are shown in Exhibit 4.

(1) IAS 19 Revised 2011—Employee Benefits was implemented in 2013, with comparative restatement made to 1 January 2012. This standard revised the calculation of benefit plan obligations. The 1 January 2012 adjustments were imposed on the 31 December 2011 balance sheet by the analyst, taken from Note 22 (Restatements and adjustments of 2012 comparatives) of the 2013 Annual Report.

(2) IFRS 11—Joint Arrangements was implemented in 2013, with comparative restatement made to 1 January 2012. Nestlé had used proportional consolidation for two of its joint arrangements (Cereal Partners Worldwide and Galderma), and the standard required that they be accounted for using the equity method of investments. The 1 January 2012 adjustments were imposed on the 31 December 2011 balance sheet by the analyst, taken from Note 22 (Restatements and adjustments of 2012 comparatives) of the 2013 Annual Report.

PHASES 3 & 4: DUPONT DECOMPOSITION

a demonstrate the use of a framework for the analysis of financial statements, given a particular problem, question, or purpose (e.g., valuing equity based on comparables, critiquing a credit rating, obtaining a comprehensive picture of financial leverage, evaluating the perspectives given in management's discussion of financial results);

c evaluate the quality of a company's financial data and recommend appropriate adjustments to improve quality and comparability with similar companies, including adjustments for differences in accounting standards, methods, and assumptions;

The analyst considers what information he needs for a DuPont analysis. He extracts the data shown in Exhibit 5 from Exhibits 2 and 3:

Exhibit 5 Data Needed for DuPont Analysis (CHF millions)

	2014	2013	2012	2011
Income Statement Data:				
Sales	91,612	92,158	89,721	
Operating profit (EBIT)	10,905	13,068	13,388	
Profit before taxes, associates, and joint ventures (EBT)	10,268	12,437	12,683	
Profit for the year	14,904	10,445	10,677	
Income from associates and joint ventures	8,003	1,264	1,253	
Profit, excluding associates and joint ventures	6,901	9,181	9,424	
Balance Sheet Data:				
Total assets	133,450	120,442	125,877	113,440
Investments in associates and joint ventures	8,649	12,315	11,586	10,317
Total assets, excluding associates and joint ventures	124,801	108,127	114,291	103,123
Total equity	71,884	64,139	62,664	58,342

The five-way decomposition of ROE is expanded to isolate the effects of the investment in associates in Nestlé's asset base and earnings. The necessary modifications to the reported financial data to isolate these effects are shown in Exhibit 5. Subtracting income from associates from the net income (profit for the year) gives the profits generated by Nestlé's own asset base. Subtracting the amount of investment in associates from total assets results in a figure that more closely represents Nestlé's own asset base. With this information, the analyst can assess the profitability and returns of the largest and most relevant part of the entire Nestlé entity: the core Nestlé company.

Exhibit 6 shows the results of expanding the DuPont analysis. The net profit margin component and the asset turnover component require adjustments to remove the impact of the associates on the return on assets. To adjust the net profit margin component, the analyst subtracts the associates' income from the net income and divides the result by sales. For 2014, the Nestlé-only net profit margin was 7.53% (= Profit excluding income from associates/Sales = 6,901/91,612). To adjust the asset turnover, the analyst subtracts the investment in associates from total assets to arrive at the assets used by the core Nestlé company. Sales divided by the average of the beginning and ending assets (excluding investment in associates) gives the Nestlé-only asset turnover. For 2014, the Nestlé-only asset turnover was 0.787 {= 91,612/[(108,127 + 124,801)/2] = 91,612/116,464}. Including the investment in associates in total assets, the asset turnover was 0.722 {= 91,612/[(120,442 + 133,450)/2] = 91,612/126,946}. The difference between the asset turnover based on unadjusted financial statement amounts and the Nestlé-only asset turnover gives the effect on total asset turnover of the investment in associates: a decrease of 0.065 in 2014.

The net profit margin can be decomposed into three components: EBIT margin × Tax burden × Interest burden. The tax and interest burdens indicate what is left for the company after the effects of taxes and interest, respectively. To adjust the tax burden component, the analyst divides profit (excluding income from associates) by profit before taxes and income from associates (EBT). For 2014, the tax burden was 67.21% (= 6,901/10,268). The interest burden is calculated by dividing the profit before taxes, associates, and joint ventures (EBT) by operating profit (EBIT). For 2014, the interest burden was 94.16% (= 10,268/10,905). The EBIT margin is earnings before interest and taxes (operating profit) divided by revenue (sales). For 2014, the EBIT margin was 11.90% (= 10,905/91,612).

Multiplying the three components together yields the Nestlé-only net profit margin. In 2014, the Nestlé-only net profit margin was 7.53% (= 67.21% × 94.16% × 11.90%). Calculating the net profit margin without excluding income from associates gives 16.27% (= Net income/ Revenue = Profit for the year/Sales = 14,904/91,612), which is not representative of the Nestlé-only operations. Dividing the net profit margin by the net profit margin *without* the associates' income (16.27%/7.53% = 216.07%) quantifies the magnifying effect of the associates' income on Nestlé's own margins. The "Nestlé-only" entity earned 7.53% on every sale, but including the associates' income in net profit increases the net profit margins by 116.07% [(100.00% + 116.07%) × 7.53% = 16.27%]. A 16.27% level of profitability is not representative of what Nestlé's core operations can generate.

Exhibit 6 Expanded DuPont Analysis

	2014	2013	2012
Tax burden (excl. associates)	67.21%	73.82%	74.30%
× Interest burden	94.16%	95.17%	94.73%
× EBIT margin	11.90%	14.18%	14.92%
= Net profit margin (excl. associates)	7.53%	9.96%	10.50%
× Associates' effect on net profit margin	216.07%	113.76%	113.33%
= Net profit margin	**16.27%**	**11.33%**	**11.90%**
Total asset turnover (excl. associates)	0.787	0.829	0.825
Effect of associates' investments on turnover	(0.065)	(0.081)	(0.075)
× Total asset turnover	**0.722**	**0.748**	**0.750**
= Return on assets	11.75%	8.47%	8.93%
× Leverage	**1.87**	**1.94**	**1.98**
= Return on equity (ROE)	**21.97%**	**16.44%**	**17.67%**

Traditional ROE calculation (CHF millions):

Exhibit 6 (Continued)

	2014	2013	2012
Net income	14,904	10,445	10,677
÷ Average total equity	68,012	63,402	60,503
= ROE	**21.91%**	**16.47%**	**17.65%**

Note: Differences in ROE calculations because of rounding.

PHASES 3 & 4: ADJUSTING FOR UNUSUAL CHARGES

5

a demonstrate the use of a framework for the analysis of financial statements, given a particular problem, question, or purpose (e.g., valuing equity based on comparables, critiquing a credit rating, obtaining a comprehensive picture of financial leverage, evaluating the perspectives given in management's discussion of financial results);

c evaluate the quality of a company's financial data and recommend appropriate adjustments to improve quality and comparability with similar companies, including adjustments for differences in accounting standards, methods, and assumptions;

d evaluate how a given change in accounting standards, methods, or assumptions affects financial statements and ratios;

e analyze and interpret how balance sheet modifications, earnings normalization, and cash flow statement related modifications affect a company's financial statements, financial ratios, and overall financial condition.

In 2012 and 2013, the net profit margin (including income from associates) was fairly stable at 11.90% and 11.33%, respectively. But it increased significantly in 2014—to 16.27%—as a result of the increase in income from associates attributable to the L'Oréal disposal and Galderma revaluation. The analyst, however, is interested in the ongoing operations of Nestlé, unaffected by such non-repeating types of gains. The net profit margin excluding income from associates shows a disturbing trend: It decreased each year in the 2012–2014 period. This finding prompts the analyst to try to identify a reason for the declining profitability of the Nestlé-only business. Searching the income statements and notes in the annual reports, he notices that Nestlé has recorded goodwill impairments over the period under study, with a particularly large one, CHF1,908 million, occurring in 2014. This impairment was related to Nestlé's acquisitions of ice cream and pizza businesses in the United States. He also notices that Nestlé has recorded provisions each year for restructuring activities, environmental liabilities, litigation reserves, and other activities. To see how much these events affected the Nestlé-only profitability, he constructs the table shown in Exhibit 7. He calls these events "unusual charges" for convenience of presentation.

Exhibit 7 Profitability Adjusted for Provisions and Impairment Charges (CHF millions)

	2014	2013	2012
Sales	91,612	92,158	89,721
Profit excluding income from associates (from Exhibit 5)	6,901	9,181	9,424
Impairment of goodwill	1,908	114	14
Total provisions for restructuring, environmental, litigation, and other (not tax-affected: assumed non-taxable in year of recognition)	920	862	618
Profit adjusted for unusual charges	9,729	10,157	10,056
Net profit margin: excl. associates, with all unusual charges incl.	7.53%	9.96%	10.50%
Net profit margin: excluding associates and unusual charges	10.62%	11.02%	11.21%
Profit margin consumed by unusual charges	3.09%	1.06%	0.71%

The analyst notices that the adjusted profits and the adjusted profit margins were more stable over the three-year period than the profits and profit margins excluding associates. However, the adjusted profits and profit margins and the profits and profit margins excluding associates decreased over the same period. Although the provisions and impairment charges potentially explain the significant decrease in the Nestlé-only profit margins, in particular from 2013 to 2014, the analyst decides *not* to adjust the remaining DuPont analysis to exclude these charges. They involve decisions by management, they recur regularly, and they affect the returns to shareholders. In assessing the company's prospects, he believes that these charges are important variables that should not to be ignored.

Returning to the DuPont analysis, he now realizes the significance of the associates' earnings to the entire Nestlé entity. The margin is greater in each year if the associates' earnings are included in net profit as opposed to looking at Nestlé alone. Consistently, the company's profit margins are smaller without the boost from associates' earnings. Asset turnover is consistently lower when assets include the investment in associates.

The adjustments thus far have isolated the operational aspects of Nestlé's performance and the assets that produced them from non-Nestlé operations. The financial leverage ratio has not been adjusted by the analyst in similar fashion to profit margin and asset turnover. The profit margin and asset turnover components of the DuPont analysis are relatively easy to consider when including or excluding associates: Both the Nestlé assets and the non-Nestlé assets produce a certain pre-tax return. Isolating those assets and their respective returns from each other makes it possible to see the contributions of each to the aggregate performance. It might be tempting to likewise adjust the financial leverage ratio by subtracting the investment in associates from total assets and equity, but the financial leverage component need not be adjusted. The analyst assumes that there will be no change in the Nestlé capital structure and that a similar blend of debt and equity in the company's capital structure finances the investment in associates' assets and the Nestlé-only assets.

From Exhibit 6, multiplying the three conventionally calculated components of ROE (net profit margin, total asset turnover, and leverage) yields the ROE when the effect of associates is included (top row of Exhibit 8). The ROE exhibits an overall increasing trend when examined without adjusting for investment in associates. The analyst wants to compare the ROE for Nestlé alone with the ROE including associates. Calculating the ROE on a Nestlé-only basis is done by multiplying the net profit margin excluding associates by the total asset turnover excluding associates by the financial leverage. For 2014, the Nestlé-only ROE was 11.08% (7.53% × 0.787 × 1.87 = 11.08%).

Exhibit 8 shows the ROE including and excluding the effects of associates. The difference between the two sets of ROE figures reveals the amount of ROE contribution from the associates. The trend in the ROE including associates, which shows a significant increase in 2014, is largely the result of the gains in 2014 from the transactions involving the investments in associates (exchange of L'Oréal shares for complete ownership of Galderma). Nestlé only shows a different trend: decreasing in each of the last two years.

Exhibit 8 ROE Performance Due to Investment in Associates

	2014 (%)	2013 (%)	2012 (%)
ROE including associates	21.97	16.44	17.67
Less Nestlé-only ROE	11.08	16.02	17.15
Associates' contribution to ROE	10.89	0.42	0.52

The analyst is particularly troubled by the sharp drop-off in the Nestlé-only ROE in 2014. He knows that there was an unusually large goodwill impairment charge in 2014, which may explain the sudden decrease. To see the role played by such unusual charges in the ROE trend, he reworks the Nestlé-only ROE figures on the basis of revised net profit margins (excluding associates and unusual charges) as shown in Exhibit 7. For 2014, the Nestlé-only ROE was 15.63% (10.62% × 0.787 × 1.87 = 15.63%). The results are shown in Exhibit 8A.

Exhibit 8A Nestlé-Only ROE, with Unusual Charges Removed from Pre-tax Margins

	2014	2013	2012
Nestlé-only ROE	15.63%	17.73%	18.31%

Absent the unusual charges, the magnitude of the Nestlé-only ROE improved significantly in all three years, but the trend remained on a downward slope. This trend is a genuine concern to the analyst; the investment in associates might provide incremental returns, but he believes the biggest part of the entire entity should be the most significant driver of returns.

Underscoring the significance of the investment in associates—and the deterioration of the Nestlé-only business—is the increasing spread between the as-reported and the Nestlé-only net profit margins in a with- and without-associates comparison (Exhibit 9). The profit margins include all the previously identified unusual charges because the analyst believes that they should not be excluded. They are real costs of doing business and seem to recur; they were actually incurred by the managers, who should be accountable for their stewardship of the shareholders' resources.

Exhibit 9 Net Profit Margin Spread

	2014	2013	2012
Consolidated net profit margin based on as-reported figures	16.27%	11.33%	11.90%
Nestlé-only profit margin	7.53%	9.96%	10.50%
Spread	8.74%	1.37%	1.40%

The analyst decides to focus on learning more about the drivers of Nestlé-only growth and revenues. He makes a note to himself to investigate the valuation aspects of the investment holdings later.

6 PHASES 3 & 4: ASSET BASE COMPOSITION

a demonstrate the use of a framework for the analysis of financial statements, given a particular problem, question, or purpose (e.g., valuing equity based on comparables, critiquing a credit rating, obtaining a comprehensive picture of financial leverage, evaluating the perspectives given in management's discussion of financial results);

Asset Base Composition

The analyst examines the composition of the balance sheet over time, as shown in Exhibit 10.

Exhibit 10 Asset Composition as a Percentage of Total Assets

	2014 (%)	2013 (%)	2012 (%)	2011 (%)
Cash and equivalents	5.6	5.3	4.5	4.2
Short-term investments	1.1	0.5	2.8	2.7
Inventories	6.9	7.0	7.1	8.0
Trade and other receivables	10.1	10.1	10.4	11.5
Other current	1.8	2.0	2.2	2.4
Total current	**25.5**	**24.9**	**27.0**	**28.8**
Property, plant, and equipment, net	21.3	22.3	21.1	20.7
Goodwill	25.9	25.8	26.0	25.2
Intangible assets	14.8	10.5	10.3	7.7
Other non-current	12.5	16.4	15.6	17.7
Total	**100.0**	**99.9***	**100.0**	**100.1***

* Does not add to 100% because of rounding.

Although he expected significant investments in current assets, inventory, and physical plant assets—given that Nestlé is a food manufacturer and marketer—he is surprised to see so much investment in intangible assets, indicating that Nestlé's success may depend, in part, on successful acquisitions. Apparently, the company has been actively acquiring companies in the last four years. Goodwill and intangible assets, hallmarks of a growth-by-acquisition strategy, composed 40.7% of total assets in 2014; at the end of 2011, they amounted to 32.9% of total assets. The investing section of the statement of cash flows (Exhibit 11) shows that there have been acquisitions.

Exhibit 11 Nestlé Investing Activities, 2012–2014 (CHF millions)

	Total	2014	2013	2012
Capital expenditure	(14,115)	(3,914)	(4,928)	(5,273)
Expenditure on intangible assets	(1,236)	(509)	(402)	(325)
Acquisition of businesses	(13,223)	(1,986)	(321)	(10,916)
Disposal of businesses	884	321	421	142
Investments (net of divestments) in associates and joint ventures	3,851	3,958	(28)	(79)
Outflows from non-current treasury investments	(573)	(137)	(244)	(192)
Inflows from non-current treasury investments	4,460	255	2,644	1,561
Inflows/(outflows) from short-term treasury investments	115	(962)	400	677
Other investing activities	668	(98)	852	(86)
Cash flow from investing activities	(19,169)	(3,072)	(1,606)	(14,491)
Acquisitions' percentage of total investing activities	69.0%	64.6%	20.0%	75.3%

Except for a slowdown in acquisitions in 2013, Nestlé had been very active in devoting resources to acquisitions. For the full three-year span, 69.0% of the cash expenditures for investing activities were devoted to acquisitions. The largest single acquisition occurred in 2012, when Nestlé acquired the nutritional business of Wyeth for CHF10,846 million; this acquisition was 74.8% (= 10,846/14,491) of the cash used for investing activities in 2012.

PHASES 3 & 4: CAPITAL STRUCTURE ANALYSIS

7

a demonstrate the use of a framework for the analysis of financial statements, given a particular problem, question, or purpose (e.g., valuing equity based on comparables, critiquing a credit rating, obtaining a comprehensive picture of financial leverage, evaluating the perspectives given in management's discussion of financial results);

Capital Structure Analysis

From the DuPont analysis, the analyst understands that Nestlé's overall financial leverage was rather stable over the last three years, which does not completely satisfy the analyst's curiosity regarding Nestlé's financing strategies. He knows that one shortcoming of financial leverage as a capital structure metric is that it says nothing about the nature, or riskiness, of the different financing instruments used by a company. For example, the financial burden imposed by bond debt is more onerous and bears more consequences in the event of default than do employee benefit plan obligations.

He decides to investigate Nestlé's capital structure more deeply by constructing a chart on a common-size basis, shown in Exhibit 12. The DuPont analysis indicated that the company's financial leverage remained within a narrow range over the last three years, from a low of 1.87 to a high of 1.98. A look at Exhibit 12, however, shows that Nestlé has been making its capital structure financially riskier over the last four years. Not only is the proportion of equity financing decreasing—from 74.2% in 2011 to 71.5% in 2014—but long-term financial liabilities have become a significantly greater part of the capital mix, increasing to 12.3% in 2014 from 7.8% in 2011. The "other long-term liabilities" (primarily employee benefit plan obligations and provisions) decreased from 17.9% in 2011 to 16.2% in 2014.

Exhibit 12 Percentages of Long-Term Capital Structure

	2014	2013	2012	2011
Long-term financial liabilities	12.3	11.8	10.3	7.8
Other long-term liabilities	16.2	14.9	17.9	17.9
Total equity	71.5	73.3	71.8	74.2
Total long-term capital	100.0	100.0	100.0	99.9*

* Does not add to 100% because of rounding.

Given the increased leverage in the long-term capital structure, the analyst wonders whether there have also been changes in the company's working capital accounts. He decides to examine Nestlé's liquidity situation. From the financial statements in Exhibits 2 and 3, he constructs the table shown in Exhibit 13.

Exhibit 13 Nestlé Working Capital Accounts and Ratios, 2011–2014

	2014	2013	2012	2011
Current ratio	1.03	0.91	0.88	0.93
Quick ratio	0.68	0.59	0.58	0.60
Defensive interval ratio*	106.6	91.9	110.0	110.5
Days sales outstanding (DSO)	51.1	50.0	53.0	54.7
Days on hand of inventory (DOH)	67.4	65.7	69.3	70.4
Number of days payables	(126.5)	(117.8)	(108.6)	(105.3)
Cash conversion cycle	(8.0)	(2.1)	13.7	19.8

* From Exhibit 2, for 2014: Daily cash expenditure = Expenses − Non-cash items = [Cost of goods sold + Distribution expenses + Marketing and administration expenses + R&D expenses − (Depreciation of PP&E + Amortisation of intangible assets) + Net trading expenses − (Impairment of PP&E and intangible assets) + (Net other operating expenses − Impairment of goodwill) + Net financial expenses]/365 = [47,553 + 8,217 + 19,651 + 1,628 − 3,058 + 797 − 159 + (3,114 − 1,908) + 637]/365 = 209.5. The defensive interval ratio is 22,340/209.5 = 106.6.

The analyst notices that the current and quick ratios improved slightly in 2014, after three years of relative stability. He also notices that the defensive interval ratio improved in 2014 after a significant decrease in 2013 from its prior levels. The improvements were modest; given the increase in long-term leverage, he was expecting more of a liquidity cushion in the working capital accounts. He found the cushion in that the speed of cash generation has been increasing: Since 2011, days' sales outstanding has decreased, as has days on hand of inventory, and the number of days payables has increased. In fact, the management of the working capital accounts has changed so much that Nestlé now has a negative eight days for its cash conversion cycle, mostly attributable to its steadily increasing delay in paying its vendors. In effect, Nestlé has been generating cash from its working capital accounts eight days before applying the cash to accounts payable.

PHASES 3 & 4: SEGMENT ANALYSIS: EARNINGS & CAPITAL

8

a demonstrate the use of a framework for the analysis of financial statements, given a particular problem, question, or purpose (e.g., valuing equity based on comparables, critiquing a credit rating, obtaining a comprehensive picture of financial leverage, evaluating the perspectives given in management's discussion of financial results);

d evaluate how a given change in accounting standards, methods, or assumptions affects financial statements and ratios;

Segment Analysis and Capital Allocation

The DuPont analysis showed the declining profitability of Nestlé in its core operations, leading the analyst to subsequently learn more about the composition of the assets and to study the company's financing. He knows that asset turnover has been slowing at Nestlé and that the company has been looking to acquisitions for growth. But he still wonders about the health of the different businesses under the Nestlé umbrella and how effectively management has allocated capital to them. DuPont analysis does not provide answers to these kinds of questions, and he knows there is more information in the financial statements that might shed light on how management allocates capital internally as opposed to making acquisitions.

To understand any geopolitical investment risks, as well as the economies in which Nestlé operates, the analyst wants to know which geographic areas are of the greatest importance to the company. One issue the analyst identifies is that Nestlé reports segment information by management responsibility and geographic area (hereafter referred to as "segment"), not by segments based exclusively on geographic areas. From the segment information in Exhibit 14, he notes that the sales and operating profit of the European segment decreased in absolute terms and as a percentage of total business in 2014 compared with 2012. The decrease in profits has been consistent over the period. The sales of the Americas segment have also become a smaller contributor to the whole company's revenue base in the same period and, like the European segment, have decreased slightly since 2012. The Americas operating profit has decreased consistently since 2012, and like the European segment, the Americas contribution to total operating profit in 2014 is a smaller proportion than in 2012. The Asia, Oceania, and Africa segment repeated the pattern: lower sales and operating profit, with a decrease in both measures in each of the two years following 2012. The smallest segment, Nestlé Waters, was not a true geographic segment. It showed minor growth in revenues and operating profit between 2012 and 2014 and contributed essentially the same proportion of sales and operating profit in 2014 as it did in

2012. Nestlé Nutrition grew significantly during the period: It contributed 10.5% of revenues in 2014 (only 8.8% in 2012), and its operating profit contributed 14.2% of revenues in 2014 compared with 11.2% in 2012. The analyst remembers that Nestlé acquired the Wyeth Nutritionals business in 2012, which would explain the solid growth. "Other businesses," which is a collectively large group of disparate businesses, also increased in importance between 2012 and 2014, accounting for 15.2% of sales in 2014 (13.2% in 2012) and 18.9% of operating profit (15.3% in 2012). Both measures (sales and operating profit) grew in 2014, and the analyst attributes that growth to Nestlé's gaining full control of Galderma in 2014.

Exhibit 14 Sales and EBIT by Segment (CHF millions)

	2014		2013		2012		Year-to-Year % Change

	14,019	100.0	14,047	100.0	13,464	100.0		

[a] Group mainly includes Nespresso, Nestlé Professional, Nestlé Health Science, and Nestlé Skin Health.

For several reasons, the analyst is somewhat frustrated by the segment information presented by Nestlé. He would like to look at trends over more than just three years, but the change in accounting principles in 2013 (for IFRS 11) was not carried back in the segment information prior to 2012. That accounting change eliminated the proportional consolidation method of accounting for joint ventures and made the 2011 segment information non-comparable with the figures presented for 2012 and later. The earlier amounts included proportional amounts of sales and operating profits for the segments, and a comparison with later years would be flawed.

Another problem with the segment information is that it is not defined by category with fully geographic information or product information. The analyst notes that three geographically classified segments accounted for 66.3% of revenues in 2014 and 70.1% in 2012; the operating profit for the same three segments amounted to 77.4% in 2014 and 83.9% in 2012. Thus, these segments are declining in importance to Nestlé as a whole, whereas Nestlé Waters and Other businesses are increasing in size and importance. Yet, it would seem likely that both of these segments have geographically different operations as well, which are not being accounted for in the other three geographic segments. These segments are growing in relevance, and more information about them would be useful. For instance, the Other businesses segment includes a coffee product line, professional products, health care products, and skin care products. Together, they amount to almost 19% of operating profit, yet they seem unlikely to have similar distribution channels, profitability levels, and growth potential.

PHASES 3 & 4: SEGMENT ANALYSIS: CASH FLOW & CAPITAL

9

a demonstrate the use of a framework for the analysis of financial statements, given a particular problem, question, or purpose (e.g., valuing equity based on comparables, critiquing a credit rating, obtaining a comprehensive picture of financial leverage, evaluating the perspectives given in management's discussion of financial results);

e analyze and interpret how balance sheet modifications, earnings normalization, and cash flow statement related modifications affect a company's financial statements, financial ratios, and overall financial condition.

The segment information is presented on the basis that management uses to make decisions. The analyst moves on with his segment analysis and evaluation of capital allocation, gathering the segment information shown in Exhibit 15 regarding Nestlé's capital expenditures and assets.

Exhibit 15 Asset and Capital Expenditure Segment Information (CHF millions)

	Assets*			Capital Expenditures		
	2014	2013	2012	2014	2013	2012
Europe	11,308	11,779	11,804	747	964	1,019
Americas	20,915	21,243	22,485	1,039	1,019	1,073

	99,313	85,314	88,347	3,727	4,712	5,039

* Assets do not equal total assets on the balance sheet because of inter-segment assets and non-segment assets.
[a] Group mainly includes Nespresso, Nestlé Professional, Nestlé Health Science, and Nestlé Skin Health.

Using the information from Exhibit 14 to calculate EBIT margins, as well as the information about the asset and capital expenditure distribution from Exhibit 15, the analyst constructs the table in Exhibit 16, ranking by descending order of EBIT profitability in 2014.

Exhibit 16 EBIT Margin, Asset, and Capital Expenditure Proportions by Segment

	EBIT Margin %			% of Total Assets			% of Total Capital Expenditures		
	2014	2013	2012	2014	2013	2012	2014	2013	2012
Nestlé Nutrition	20.77	19.96	19.20	24.6	26.4	27.5	9.7	9.1	8.5
Other businesses[a]	19.12	17.68	17.47	21.5	11.2	10.3	15.4	13.6	10.9
Americas	18.76	18.20	18.68	21.1	24.9	25.5	27.9	21.6	21.3
Asia, Oceania, and Africa	18.65	18.90	18.96	15.2	16.6	16.2	18.7	27.2	31.0
Europe	15.33	14.97	15.36	11.4	13.8	13.4	20.0	20.5	20.2
Nestlé Waters	9.66	9.16	8.92	6.2	7.1	7.2	8.3	8.0	8.1
				100.0	100.0	100.1*	100.0	100.0	100.0

* Does not add to 100% because of rounding.
[a] Group mainly includes Nespresso, Nestlé Professional, Nestlé Health Science, and Nestlé Skin Health.

Although the segmentation is not purely geographic, the analyst can still make some judgments about the allocation of capital. On the premise that the largest investments in assets require a similar proportion of capital expenditures, he calculates ratios of the capital expenditure proportion to the total asset proportion for the last three years and compares them with the current EBIT profitability ranking. The resulting table is shown in Exhibit 17.

Exhibit 17 Ratio of Capital Expenditure Percentage to Total Asset Percentage Ranked by EBIT Margin

	EBIT Margin %	Ratio of Total Capital Expenditure % to Total Asset %		
	2014	2014	2013	2012
Nestlé Nutrition	20.77	0.39	0.34	0.31
Other businesses[a]	19.12	0.72	**1.21**	**1.06**
Americas	18.76	**1.32**	0.87	0.84
Asia, Oceania, and Africa	18.65	**1.23**	**1.64**	**1.91**
Europe	15.33	**1.75**	**1.49**	**1.51**
Nestlé Waters	9.66	**1.34**	**1.13**	**1.13**

[a] Group mainly includes Nespresso, Nestlé Professional, Nestlé Health Science, and Nestlé Skin Health.

A ratio of 1 indicates that the segment's proportion of capital expenditures is the same as its proportion of total assets. A ratio of *less than* 1 indicates that the segment is being allocated a lesser proportion of capital expenditures than its proportion of total assets; if a trend develops, the segment will become less significant over time. A ratio of *greater than* 1 indicates the company is growing the segment; the segment is receiving a "growth allocation" of capital spending. Comparing the ratio with the EBIT margin percentage gives the analyst an idea of whether the company is investing its capital in the most profitable segments. (In Exhibit 17, the ratios greater than 1 are bolded for ease of viewing.)

Equipped with these premises, the analyst is puzzled by the capital allocation taking place within Nestlé. The most profitable segment is Nestlé Nutrition, but over the last three years, it has received the lowest proportion of capital expenditures. The company has invested in the nutrition segment by acquisition, such as the Wyeth Nutritionals business in 2012. One would expect that a more substantial operation would require more capital expenditures on maintenance. The capital expenditures for the nutrition segment have increased only nominally since 2012.

The Other businesses segment is the next most profitable segment in EBIT margin terms. The analyst has difficulty understanding just why the profit margins are high in this segment because of the variety of businesses it contains. It appears that the company's managers are allocating capital to it in a significant way. Although it did not receive a "growth allocation" of capital expenditures in 2014, it received a growth allocation in the previous two years. The Americas segment and the Asia, Oceania, and Africa segment have similar EBIT margins, which are in the same range as those of the Nestlé Nutrition and Other businesses segments. Given their profitability levels and substantial operations, the analyst is encouraged to see that they are receiving "growth allocations" of capital spending.

Less encouraging, however, is the past and continuing significant allocation of capital spending to the European segment. Even more questionable is the high proportional allocation of capital spending to the Nestlé Waters segment, which has had the lowest profit margins. The analyst is uncomfortable with growth investments in such a low-return business but notes that the absolute levels of capital expenditures are the lowest of all the segments in each year.

In a worst-case scenario, if the company were to continue making growth allocations of capital toward the lowest-margined businesses, such as Europe and Nestlé Waters, the overall Nestlé-only returns might be affected negatively. As a result, Nestlé might become more dependent on its investment in associates to sustain performance.

The analyst knows that accrual performance measures, such as EBIT, can produce results that do not indicate an entity's ability to generate cash flow, and he wonders whether this limitation has any effect on Nestlé management's capital allocation decisions. He also knows that at the segment level, cash flow information is not publicly available. He decides to at least approximate cash flow by adding depreciation expense to operating profit and then relate the approximated cash flow to the average total assets of each segment. This approach provides an approximation of cash return relative to the continued investment in a particular segment.

The analyst combines the segment operating profit from Exhibit 14 and the segment depreciation and amortisation in Exhibit 18 to estimate the segment cash generation shown in Exhibit 18. Because he wants to eliminate the effects of any investment peaks or valleys, he also averages the total assets for each segment in Exhibit 18. The average total assets in 2012 include the 2011 total assets that were prepared on a pre–IFRS 11 basis, for which no adjustment is available. The analyst is aware of the irreconcilable difference but believes that the averaging of the two years' amounts will help dilute the difference. He notes that if any resulting measures based on 2011 data points appear to be outliers, he will dismiss them.

Exhibit 18 Segment Depreciation and Amortisation, Segment Cash Generation, and Average Assets (CHF millions)

	Depreciation and Amortisation			Segment Cash Generation			Average Total Assets*		
	2014	2013	2012	2014	2013	2012	2014	2013	2012
Europe	473	517	533	2,800	2,848	2,896	11,544	11,792	11,683
Americas	681	769	899	5,798	5,931	6,245	21,079	21,864	22,783
Asia, Oceania, and Africa	510	520	553	3,918	4,082	4,132	14,630	14,247	14,068
Nestlé Waters	403	442	491	1,117	1,107	1,131	6,124	6,208	6,486
Nestlé Nutrition	330	337	176	2,327	2,298	1,685	23,483	23,398	18,564
Other businesses[a]	525	437	295	3,179	2,612	2,359	15,455	9,323	10,009

* Average of total assets at beginning and end of the year.
[a] Group mainly includes Nespresso, Nestlé Professional, Nestlé Health Science, and Nestlé Skin Health.

In Exhibit 19, the analyst computes each segment's cash operating return on total assets and compares the results with the 2014 ranking of capital expenditures (Exhibit 17) as well as the EBIT margins. They are ranked in descending order of the ratio of capital expenditure percentage to percentage of total assets. The lighter shading indicates the highest EBIT margin and cash return on assets for each year, and the darker shading indicates the lowest EBIT margin and cash return on assets for each year.

Exhibit 19 Segment Cash Operating Return on Assets

	2014		Segment Cash Return on Average Total Assets		
	Capex %/ Asset %	EBIT %	2014 (%)	2013 (%)	2012 (%)
Europe	1.75	15.3	24.3	24.2	24.8
Nestlé Waters	1.34	9.7	18.2	17.8	17.4
Americas	1.32	18.8	27.5	27.1	27.4
Asia, Oceania, and Africa	1.23	18.7	26.8	28.7	29.4
Other businesses[a]	0.72	19.1	20.6	28.0	23.6
Nestlé Nutrition	0.39	20.8	9.9	9.8	9.1

[a] Group mainly includes Nespresso, Nestlé Professional, Nestlé Health Science, and Nestlé Skin Health.

PHASES 3 & 4: SEGMENT ANALYSIS BY PRODUCT GROUP

10

a demonstrate the use of a framework for the analysis of financial statements, given a particular problem, question, or purpose (e.g., valuing equity based on comparables, critiquing a credit rating, obtaining a comprehensive picture of financial leverage, evaluating the perspectives given in management's discussion of financial results);

The analyst is surprised to see that the Nestlé Nutrition segment, which has the highest EBIT profit margin, consistently has the lowest cash return on total assets. When he looks at the segments with respect to EBIT margins, he is disappointed with the allocation of capital spending to Nestlé Nutrition, thinking that it is too low. When he looks at it using the cash return on total assets measure, the low allocation of spending makes much more sense. He is pleased to see that the segments with the highest cash return on total assets each year—the Americas and the Asia, Oceania, and Africa segments—are receiving growth allocations of capital spending. He is also encouraged that the European segment, though a poor performer with respect to EBIT margin, has cash returns on total assets that are competitive with the other segments and far ahead of Nestlé Waters and Nestlé Nutrition. Even Nestlé Waters, which had not appeared very attractive with respect to EBIT margin, is generating strong cash returns on total assets. The exercise restores the analyst's confidence that management is allocating capital in a rational manner. It makes sense to him that if management makes capital budgeting decisions on a cash flow basis, they should be evaluated on a cash flow basis also.

He decides to look at Nestlé's capital allocation process from a product group standpoint. The sales and EBIT information is shown in Exhibit 20. From the table, he notes that the Nutrition and Health Science product group is the only one with significant growth in either sales or EBIT, and that is the segment in which the company has been making its acquisitions in the last few years. He also notes that the EBIT margin for the Nutrition and Health Science product group has increased in each of the last two years, and although it is among the highest over the last three years, the Powdered and Liquid Beverages product group has consistently shown higher EBIT margins. The Powdered and Liquid Beverages product group EBIT margins far exceed the lowest-ranking EBIT margins of the Water product group.

Exhibit 20 Sales and EBIT Segment Information by Product Group (CHF millions)

	2014		2013		2012		Year-to-Year % Change	
Sales		**% Total**		**% Total**		**% Total**	**2014**	**2013**

Total	15.3%	15.2%	15.0%

Unfortunately for purposes of his analysis, Nestlé does not provide capital expenditure information by product group. Compared with the segment analysis he performed, the analyst's scope is more limited in examining product groups. All that can be done is to look at the return on assets with respect to EBIT rather than on a cash-generated basis. Nevertheless, the analyst decides to work with all the available information. To further examine capital allocation decisions, he gathers the asset information by product group from the financial statements, as shown in Exhibit 21. The reported total assets differ by segment and product group presentation because Nestlé reports its assets on an *average* basis for product groups and on a *year-end* basis for segments. A significant amount of assets is unallocated to segments, but there is no unallocated amount by product group. He calculates the EBIT return on assets as EBIT divided by average assets and determines the proportion of total average assets devoted to each product group. The highest EBIT percentage, EBIT return on assets, and percentage of total assets each year are lightly shaded, and the lowest are shaded darker.

Exhibit 21 Asset Segment Information by Product Group (CHF millions)

	Average Assets			EBIT %	EBIT Return on Assets			% Total Assets		
	2014	2013	2012	2014	2014	2013	2012	2014	2013	2012
Powdered and Liquid Beverages	11,599	11,044	10,844	23.1%	40.4%	42.1%	41.0%	11.6%	11.5%	12.4%
Water	5,928	6,209	6,442	10.3%	12.0%	10.9%	9.9%	6.0%	6.4%	7.4%
Milk Products and Ice Cream	14,387	14,805	14,995	16.1%	18.8%	17.8%	18.0%	14.4%	15.4%	17.1%
Nutrition and Health Science	32,245	28,699	19,469	20.9%	8.4%	7.8%	9.1%	32.4%	29.8%	22.2%
Prepared Dishes and Cooking Aids	13,220	13,289	13,479	13.4%	13.7%	14.1%	15.1%	13.3%	13.8%	15.4%
Confectionery	7,860	8,190	8,343	13.8%	17.1%	19.9%	21.2%	7.9%	8.5%	9.5%
Pet Care	14,344	14,064	13,996	19.8%	15.7%	15.4%	15.3%	14.4%	14.6%	16.0%
	99,583	96,300	87,568	15.3%	14.1%	14.6%	15.4%	100.0%	100.0%	100.0%

The analyst uses this information to make some important observations:

- The Nutrition and Health Science product group—which the company has been investing in over the last several years—has the lowest EBIT return on assets in each of the last three years and makes up the greatest portion of total assets.
- The EBIT return on assets for the Nutrition and Health Science product group is even lower than that of the Water product group, which has the lowest EBIT margin.
- The Nutrition and Health Science product group's EBIT return on assets is well below the total company's EBIT return on assets (8.4% versus 14.1% in 2014, 7.8% versus 14.6% in 2013, and 9.1% versus 15.4% in 2012).
- The Nutrition and Health Science product group drags down the overall return in each year as it becomes a bigger part of the whole.
- The EBIT return on assets is highest for the Powdered and Liquid Beverages product group, possibly because it might not need much in the way of assets or capital spending: It is one of the lesser components of total assets. Furthermore, it has the highest EBIT margin of all the product groups. Given the high EBIT margin, the high EBIT return on assets, and the low dedication of total assets, the analyst wonders whether the company is allocating capital among its product offerings effectively. It would make sense to devote as many resources as possible to where returns are best.
- He also wonders about management's capital allocation skills regarding acquisitions. The EBIT return on assets in the Nutrition and Health Science product group is weak, and the company has been making acquisitions in that group. He finds it troubling that Nestlé took a goodwill impairment charge of CHF1,908 million in 2014—something directly related to management's skill in making past acquisitions.

11 PHASES 3 & 4: ACCRUALS AND EARNINGS QUALITY

a demonstrate the use of a framework for the analysis of financial statements, given a particular problem, question, or purpose (e.g., valuing equity based on comparables, critiquing a credit rating, obtaining a comprehensive picture of financial leverage, evaluating the perspectives given in management's discussion of financial results);

b identify financial reporting choices and biases that affect the quality and comparability of companies' financial statements and explain how such biases may affect financial decisions;

c evaluate the quality of a company's financial data and recommend appropriate adjustments to improve quality and comparability with similar companies, including adjustments for differences in accounting standards, methods, and assumptions;

At this point, the information reviewed by the analyst has not increased his enthusiasm for Nestlé's operating and capital allocation prowess. He considers a worst-case possibility: Could the company try to make up for weak operating performance by manipulating accounting inputs? He makes it a point to understand whether accruals play a role in the company's performance.

He decides to examine the balance-sheet-based accruals and the cash-flow-based accruals over the last few years. From the Nestlé financial statements, he assembles the information and intermediate calculations shown in Exhibit 22.

Exhibit 22 Selected Information from Balance Sheet and Statement of Cash Flows (CHF millions)

	2014	2013	2012	2011
Balance Sheet Accrual Info:				
Total assets	133,450	120,442	125,877	113,440
Cash and short-term investments	8,881	7,053	9,296	7,782
Operating assets (A)	124,569	113,389	116,581	105,658
Total liabilities	61,566	56,303	63,213	55,098
Long-term debt	12,396	10,363	9,008	6,165
Debt in current liabilities	8,810	11,380	18,408	15,945
Operating liabilities (B)	40,360	34,560	35,797	32,988
Net operating assets (NOA) [(A) – (B)]	84,209	78,829	80,784	72,670
Balance-sheet-based aggregate accruals (year-to-year change in NOA)	5,380	(1,955)	8,114	6,218
Average NOA	81,519	79,807	76,727	69,561
Statement of Cash Flows Accrual Info:				
Profit from continuing operations	14,904	10,445	10,677	
Operating cash flow	(14,700)	(14,992)	(15,668)	
Investing cash flow	3,072	1,606	14,491	
Cash-flow-based aggregate accruals	3,276	(2,941)	9,500	

The analyst calculates the balance-sheet-based and cash-flow-based accruals ratios, which are measures of financial reporting quality.[4] The ratios are calculated as follows:

Balance sheet accruals ratio for time t = $(NOA_t - NOA_{t-1})/[(NOA_t + NOA_{t-1})/2]$, and

Cash flow accruals ratio for time t = $[NI_t - (CFO_t + CFI_t)]/[(NOA_t + NOA_{t-1})/2]$,

where NI is net income, CFO is cash flow from operations, and CFI is cash flow from investing.

The accruals ratios for the last three years are shown in Exhibit 23.

Exhibit 23 Accruals Ratios (CHF millions)

	2014	2013	2012
Balance-sheet-based aggregate accruals (year-to-year change in NOA)	5,380	(1,955)	8,114
Divided by: Average NOA	81,519	79,807	76,727
Balance-sheet-based accruals ratio	**6.6%**	**−2.4%**	**10.6%**
Cash-flow-based aggregate accruals	3,276	(2,941)	9,500
Divided by: Average NOA	81,519	79,807	76,727
Cash-flow-based accruals ratio	**4.0%**	**−3.7%**	**12.4%**

The analyst notes that the absolute level of accruals on the balance sheet is minor relative to the size of the operating assets, on either an ending balance basis or an average basis. Similarly, the fluctuation in the balance-sheet-based accruals ratio is low. The analyst would have been more concerned if the absolute levels of the accruals ratio were high; even more worrisome would have been if they were consistently trending higher. That was not the case. The cash-flow-based accruals ratio exhibits a similar pattern. For the most recent two years, both ratios are lower than in 2012 and indicate that accruals are not a large factor in the financial results. The analyst still decides to examine the quality of Nestlé's cash flow and its relationship to net income.

PHASES 3 & 4: CASH FLOW RELATIONSHIPS

12

a demonstrate the use of a framework for the analysis of financial statements, given a particular problem, question, or purpose (e.g., valuing equity based on comparables, critiquing a credit rating, obtaining a comprehensive picture of financial leverage, evaluating the perspectives given in management's discussion of financial results);

e analyze and interpret how balance sheet modifications, earnings normalization, and cash flow statement related modifications affect a company's financial statements, financial ratios, and overall financial condition.

4 If you are interested in subcomponents of accrual activity, simply focus on the relevant line item from the balance sheet. For example, looking at the change in net receivables over a fiscal period deflated by average NOA will give you a sense of the magnitude of accrued revenue attributable to net credit sales.

He begins his analysis with the compilation of Nestlé's statements of cash flows shown in Exhibit 24.

Exhibit 24 Nestlé's Statement of Cash Flows, 2012–2014 (CHF millions)

	2014	2013	2012
Operating activities			
Operating profit	10,905	13,068	13,388
Non-cash items of income and expense	6,323	4,352	3,217
Cash flow before changes in operating assets and liabilities	17,228	17,420	16,605
Decrease/(increase) in working capital	(114)	1,360	2,015
Variation of other operating assets and liabilities	85	(574)	(95)
Cash generated from operations	17,199	18,206	18,525
Net cash flows from treasury activities	(356)	(351)	(324)
Taxes paid	(2,859)	(3,520)	(3,118)
Dividends and interest from associates and joint ventures	716	657	585
Operating cash flow	**14,700**	**14,992**	**15,668**
Investing activities			
Capital expenditure	(3,914)	(4,928)	(5,273)
Expenditure on intangible assets	(509)	(402)	(325)
Acquisition of businesses	(1,986)	(321)	(10,916)
Disposal of businesses	321	421	142
Investments (net of divestments) in associates and joint ventures	3,958	(28)	(79)
Outflows from non-current treasury investments	(137)	(244)	(192)
Inflows from non-current treasury investments	255	2,644	1,561
Inflows/(outflows) from short-term treasury investments	(962)	400	677
Other investing activities	(98)	852	(86)
Cash flow from investing activities	**(3,072)**	**(1,606)**	**(14,491)**
Financing activities			
Dividends paid to shareholders of the parent	(6,863)	(6,552)	(6,213)
Dividends paid to non-controlling interests	(356)	(328)	(204)
Acquisition (net of disposal) of non-controlling interests	(49)	(337)	(165)
Purchase of treasury shares	(1,721)	(481)	(532)
Sale of treasury shares	104	60	1,199
Inflows from bonds and other non-current financial debt	2,202	3,814	5,226
Outflows from bonds and other non-current financial debt	(1,969)	(2,271)	(1,650)
Inflows/(outflows) from current financial debt	(1,985)	(6,063)	2,325
Cash flow from financing activities	**(10,637)**	**(12,158)**	**(14)**
Currency retranslations	42	(526)	(219)
Increase/(decrease) in cash and cash equivalents	**1,033**	**702**	**944**
Cash and cash equivalents at beginning of year	**6,415**	**5,713**	**4,769**
Cash and cash equivalents at end of year	**7,448**	**6,415**	**5,713**

The analyst's most pressing concerns include the following: Are Nestlé's operating earnings backed by cash flow? Are the accrual measures telling the whole story? Are the operating earnings the result of accounting choices? To convince himself of the representativeness of the Nestlé earnings, he first compares the cash generated by operations with the operating profit as shown in Exhibit 25. The amounts in Exhibit 25 are found in the cash flow statements in Exhibit 24.

Exhibit 25 Operating Cash Flow to Operating Profit, 2012–2014 (CHF millions)

	2014	2013	2012
Cash generated from operations	17,199	18,206	18,525
Operating profit	10,905	13,068	13,388
Cash generated from operations/Operating profit	**1.58**	**1.39**	**1.38**

The cash generated from operations is comparable to accrual basis operating income *but on a cash flow basis*. If the cash flow generated by operations was significantly or consistently less than operating profit, one would have reason to be suspicious about the quality of the operating profit. The analyst is encouraged by the fact that the cash generated from operations substantially exceeded the operating profit in each of the last three years.

Knowing that Nestlé has made a number of acquisitions, the analyst decides to examine the relationship between operating cash flow and total assets. *Cash flow* is a measure of the operational success of the company's investment projects: Successful investments generate cash rather than absorbing it. *Total assets* reflect the sum total of management's resource allocations over time. Cash generated by total assets indicates the kind of cash return that is generated by all investments. The relationship is shown in Exhibit 26.

Exhibit 26 Ratio of Operating Cash Flow to Total Assets, 2012–2014 (CHF millions)

	2014	2013	2012
Cash generated from operations	17,199	18,206	18,525
Average total assets	126,946	123,160	119,659
Cash return on total assets	13.5%	14.8%	15.5%

Again, the analyst finds himself concerned about the effectiveness of management's asset allocation decisions. Although the 13.5% cash return on total assets is a high return on investment, the trend is declining. The analyst thinks back to the 2014 goodwill impairment and the poor EBIT return on assets in the Nutrition and Health Science product group, in which acquisitions have been occurring lately.

Given the negative trend in asset returns, the analyst looks at Nestlé's liquidity and funding ability relative to cash flow. He decides to compare cash flow with reinvestment, debt, and debt-servicing capacity, as shown in Exhibit 27.

The analyst sees that reinvestment needs have been covered by cash flow by a factor of 3.89 in 2014, 3.42 in 2013, and 3.31 in 2012. Even better, the trend is improving.

He also sees that based on the relationship of cash flow to total debt, the company is not highly leveraged, with cash generated from operations at 78.3% of total debt at the end of 2014. The ratio is high enough to indicate that additional borrowing could be arranged should an investment opportunity arise. Furthermore, the analyst notes that Nestlé has the capacity to pay off its debt in approximately two years even while maintaining its current reinvestment policy [21,963/(17,199 – 4,423)].

Finally, the cash flow interest coverage ratio indicates more than satisfactory financial strength in the current year, with cash flow 33.2 times the interest paid. Like the ratio of cash flow to total debt, it indicates that the company has sufficient financial capacity to add more debt if there is an investment opportunity.

Exhibit 27 Ratio of Operating Cash Flow to Reinvestment, Debt, and Debt-Servicing Capacity, 2012–2014 (CHF millions)

	2014	2013	2012
*Cash flow to reinvestment:**			
Cash generated from operations	17,199	18,206	18,525
Capital expenditures	3,914	4,928	5,273
Expenditure on intangible assets	509	402	325
Total reinvestment spending	4,423	5,330	5,598
Ratio of cash flow to reinvestment	**3.89**	**3.42**	**3.31**
Cash flow to total debt:			
Cash generated from operations	17,199	18,206	18,525
Current debt (short-term financial liabilities)	8,810	11,380	18,408
Current derivative liabilities	757	381	423
Long-term debt (long-term financial liabilities)	12,396	10,363	9,008
Total debt	21,963	22,124	27,839
Ratio of cash flow to total debt	**78.3%**	**82.3%**	**66.5%**
Cash flow interest coverage:			
Cash generated from operations	17,199	18,206	18,525
Cash interest paid	518	505	559
Cash flow interest coverage	**33.2**	**36.1**	**33.1**

* Information is from Exhibit 24.

13 PHASES 3 & 4: DECOMPOSITION AND ANALYSIS OF THE COMPANY'S VALUATION

a demonstrate the use of a framework for the analysis of financial statements, given a particular problem, question, or purpose (e.g., valuing equity based on comparables, critiquing a credit rating, obtaining a comprehensive picture of financial leverage, evaluating the perspectives given in management's discussion of financial results);

c evaluate the quality of a company's financial data and recommend appropriate adjustments to improve quality and comparability with similar companies, including adjustments for differences in accounting standards, methods, and assumptions;

At this point, the analyst believes he has obtained sufficient information about the company's sources of earnings and returns on shareholders' equity, its capital structure, the results of its capital allocation decisions, and its earnings quality. Before he makes his report to the portfolio manager, he wants to study the company's market valuation. During his reading of the annual reports, he noted that Nestlé has a significant equity position (23.4%) in L'Oréal (Paris exchange: OR), a French cosmetics company. L'Oréal is accounted for in the financial statements as an investment in associates because Nestlé's ownership position does not give it control. Although L'Oréal contributes to the earnings of Nestlé as a whole, it is also valued separately in the public markets, and its discrete valuations may be very different from its embedded Nestlé valuation. To determine the value that the market places solely on Nestlé operations, the analyst first removes the value of the L'Oréal holding from the Nestlé market value, as shown in Exhibit 28.

Exhibit 28 Nestlé Market Value without L'Oréal as of 31 December 2014 (Currency in millions, except share prices)

L'Oréal value:	
31 Dec 2014 share price	€139.30
Shares held by Nestlé (millions)	129.881
L'Oréal holding value	€18,092
31 Dec CHF/EUR rate	1.202
L'Oréal holding value	CHF21,747
Nestlé market value, with and without L'Oréal:	
Nestlé 29 Dec 2014 share price	CHF72.95
Shares outstanding (millions)	3,168.400
Nestlé market capitalization	CHF231,135
Value of L'Oréal holding	(21,747)
Implied value of Nestlé operations	CHF209,388
Pro rata market value:	
L'Oréal	9.4%
Nestlé	90.6%
	100.0%

The value of the L'Oréal holding is slightly less than 10% of the value of Nestlé's market capitalization. The analyst now wants to remove the earnings of L'Oréal from the earnings of the combined entity (Exhibit 29) to make a price-to-earnings comparison for Nestlé earnings alone. For L'Oréal, this comparison is simple: Nestlé discloses in its annual report that L'Oréal has contributed CHF934 million to current year earnings. After isolating the different earnings sources, the analyst prepares the table shown in Exhibit 30, which compares the different market values and price-to-earnings ratios.

Exhibit 29 Calculation of Nestlé Earnings without L'Oréal as of 31 December 2014 (CHF millions)

Calculation of Nestlé standalone earnings:	2014
Nestlé consolidated earnings	14,904
Less: L'Oréal earnings	(934)
Nestlé standalone earnings	13,970
Less: Non-controlling interests	(448)
Nestlé standalone earnings to shareholders	13,522

At the time of the analysis (early 2015), Nestlé's common stock traded at a price-to-earnings multiple of 16.0 based on its year-end market value of CHF231,135 million and trailing earnings (attributable to controlling interests) of CHF14,456 million: a discount of 20% to the price-to-earnings multiple of 19.9 for the S&P 500 Index at year-end 2014. Once the earnings and available market value of the L'Oréal holding are taken out of the price-to-earnings valuation, the shares of the "Nestlé-only" company are selling at a slightly higher discount: At 15.5 times earnings, the discount to the overall market's price-to-earnings multiple was a steeper 22%. At first, the analyst is surprised by Nestlé's discount to the market multiple, given that the company has consistently demonstrated meaningful cash flows and earnings and possesses low financial leverage. He considers whether the discount might be attributable to Nestlé's slipping core profitability. The analyst concludes that Nestlé shares may be discounted by the market because investors may be developing a skeptical attitude toward the company.

Exhibit 30 Comparison of Decomposed Nestlé Earnings and Price-to-Earnings Ratios

Earnings (CHF millions)	Market Value	Earnings (Group Shareholder Level)	Respective Price-to-Earnings Ratios
L'Oréal	21,747	934	23.3
Implied Nestlé-only	209,388	13,522	15.5
Actual earnings available to Nestlé parent company shareholders	231,135	14,456	16.0

Recap (%):	Market Value	Earnings
L'Oréal	9.4	6.5
Implied Nestlé-only	90.6	93.5
	100.0	100.0

At this point, the analyst believes that he has processed and analyzed the data sufficiently to pull together his findings and make his report to the portfolio manager.

PHASES 5 & 6: DEVELOP AND COMMUNICATE CONCLUSIONS AND RECOMMENDATIONS AND FOLLOW-UP

14

a demonstrate the use of a framework for the analysis of financial statements, given a particular problem, question, or purpose (e.g., valuing equity based on comparables, critiquing a credit rating, obtaining a comprehensive picture of financial leverage, evaluating the perspectives given in management's discussion of financial results);

Phase 5: Develop and Communicate Conclusions and Recommendations (e.g., with an Analysis Report)

As a result of the analyses performed, the analyst has gathered sufficient evidence regarding many of Nestlé's operational and financial characteristics and believes he is able to address the concerns initially expressed by the portfolio manager. Summary points he will cover in his report are divided into two classes: support for an investment in Nestlé shares and causes for concern.

Support for an Investment in Nestlé Shares

- Nestlé has the financial stability to fund growth in its existing operations and carry out its growth-by-acquisition strategy. The company's current liquidity and cash flows are more than adequate for future operating and investment purposes. The company has low leverage, and the capital structure is capable of supporting future operations and strategic plans.
- The operating cash flows have consistently exceeded the operating earnings. The ratio of operating cash to operating profit has been consistently favorable, providing confidence in the quality of the earnings. Measures comparing cash flow with reinvestment, debt, and debt-servicing capacity indicate strength in financial capacity.
- Decomposing earnings into Nestlé-only and L'Oréal and considering the respective price-to-earnings ratios, it appears that the implied Nestlé-only portion is undervalued. The implied Nestlé-only portion has a far lower price-to-earnings ratio than L'Oréal or the market. This finding should be considered an opportunity, given Nestlé's demonstrated cash flows and low financial leverage.

Causes for Concern

- Although Nestlé has significant, world-class brands and global reach, its core business has deteriorated in profitability in the last several years, as shown by the decomposition of the ROE. Even when taking into account the unusual items affecting profit margins, core operations still show decreases in profitability.
- The negative trend also shows in the cash returns on total assets. They have decreased each year since 2012.
- The acquisition activities in the Nutrition and Health Science product group do not appear to build on the company's traditional strengths. They do not seem to provide a remedy for the deterioration in the core profitability.

- The company's priorities in the allocation of capital in making acquisitions are of some concern. Although the Nutrition and Health Science product group and the Nestlé Nutrition segment show excellent EBIT margins, they rank very low in return on assets. This finding raises the question of whether management is overpaying for acquired companies.
- The company's write-down of goodwill from earlier acquisitions may signal ineffective allocation of capital. It is troubling that Nestlé has taken write-downs on previous acquisitions while actively making new ones.

The analyst concludes that Nestlé is not clearly a good investment opportunity *at this time* and recommends waiting to see whether a further discount makes it more attractive or the operations improve.

Phase 6: Follow-up

The portfolio manager is surprised by the analyst's findings and recommendations. The portfolio manager is convinced that the purchase of shares is justified because of the discount and because, in her opinion, Nestlé is experiencing only temporary issues. She commits the pension fund to a cautious, less-than-core investment holding of Nestlé common stock. The size of the holding is less than originally anticipated because, despite her enthusiasm for the company, the portfolio manager is troubled by the analyst's observations about the resource allocation within the company. She wants him to continually re-evaluate the holding. Unproductive capital spending may be a trigger for eliminating the holding. The analyst is asked to update his findings in the initial research report at each reporting period, emphasizing the quality measures expressed by the accruals tests and the cash flow support of earnings, with particular regard to return on assets.

SUMMARY

The case study demonstrates the use of a financial analysis framework in investment decision making. Although each analysis undertaken may have a different focus, purpose, and context that result in the application of different techniques and tools, the case demonstrates the use of a common financial statement analysis framework. The analyst starts with a global, summarized view of a company and its attributes and digs below the surface of the financial statements to find economic truths that are not apparent from a superficial review. In the case of Nestlé, the analyst applied disaggregation techniques to review the company's performance in terms of ROE and then successively examined the drivers of ROE in increasing detail to evaluate management's skills in capital allocation.

An economic decision is reached, which is consistent with the primary reason for performing financial analysis: to facilitate an economic decision.

PRACTICE PROBLEMS

The following information relates to Questions 1–7

Quentin Abay, CFA, is an analyst for a private equity firm interested in purchasing Bickchip Enterprises, a conglomerate. His first task is to determine the trends in ROE and the main drivers of the trends using DuPont analysis. To do so he gathers the data in Exhibit 1.

Exhibit 1 Selected Financial Data for Bickchip Enterprises (€ Thousands)

	2020	2019	2018
Revenue	72,448	66,487	55,781
Earnings before interest and tax	6,270	4,710	3,609
Earnings before tax	5,101	4,114	3,168
Net income	4,038	3,345	2,576
Asset turnover	0.79	0.76	0.68
Assets/Equity	3.09	3.38	3.43

After conducting the DuPont analysis, Abay believes that his firm could increase the ROE without operational changes. Further, Abay thinks that ROE could improve if the company divested segments that were generating the lowest returns on capital employed (total assets less non-interest-bearing liabilities). Segment EBIT margins in 2020 were 11 percent for Automation Equipment, 5 percent for Power and Industrial, and 8 percent for Medical Equipment. Other relevant segment information is presented in Exhibit 2.

Exhibit 2 Segment Data for Bickchip Enterprises (€ Thousands)

	Capital Employed			Capital Expenditures (Excluding Acquisitions)		
Operating Segments	**2020**	**2019**	**2018**	**2020**	**2019**	**2018**
Automation Equipment	10,705	6,384	5,647	700	743	616
Power and Industrial	15,805	13,195	12,100	900	849	634
Medical Equipment	22,870	22,985	22,587	908	824	749
	49,380	42,564	40,334	2,508	2,416	1,999

Abay is also concerned with earnings quality, so he intends to calculate Bickchip's cash-flow-based accruals ratio and the ratio of operating cash flow before interest and taxes to operating income. To do so, he prepares the information in Exhibit 3.

Exhibit 3 Earnings Quality Data for Bickchip Enterprises (€ Thousands)

	2020	2019	2018
Net income	4,038	3,345	2,576
Net cash flow provided by (used in) operating activity[a]	9,822	5,003	3,198
Net cash flow provided by (used in) investing activity	(10,068)	(4,315)	(5,052)
Net cash flow provided by (used in) financing activity[b]	(5,792)	1,540	(2,241)
Average net operating assets	43,192	45,373	40,421
[a] includes cash paid for taxes of:	(1,930)	(1,191)	(1,093)
[b] includes cash paid for interest of:	(1,169)	(596)	(441)

1 Over the three-year period presented in Exhibit 1, Bickchip's return on equity is *best* described as:

A stable.

B trending lower.

C trending higher.

2 Based on the DuPont analysis, Abay's belief regarding ROE is *most likely* based on:

A leverage.

B profit margins.

C asset turnover.

3 Based on Abay's criteria, the business segment *best* suited for divestiture is:

A medical equipment.

B power and industrial.

C automation equipment.

4 Bickchip's cash-flow-based accruals ratio in 2020 is *closest* to:

A 9.9%.

B 13.4%.

C 23.3%.

5 The cash-flow-based accruals ratios from 2018 to 2020 indicate:

A improving earnings quality.

B deteriorating earnings quality.

C no change in earnings quality.

6 The ratio of operating cash flow before interest and taxes to operating income for Bickchip for 2020 is *closest* to:

A 1.6.

B 1.9.

C 2.1.

7 Based on the ratios for operating cash flow before interest and taxes to operating income, Abay should conclude that:

A Bickchip's earnings are backed by cash flow.

B Bickchip's earnings are not backed by cash flow.

C Abay can draw no conclusion due to the changes in the ratios over time.

SOLUTIONS

1 C is correct. The ROE has been trending higher. ROE can be calculated by multiplying (net profit margin) × (asset turnover) × (financial leverage). Net profit margin is net income/sales. In 2018 the net profit margin was 2,576/55,781 = 4.6% and the ROE = 4.6% × 0.68 × 3.43 = 10.8%. Using the same method, ROE was 12.9 percent in 2019 and 13.6 percent in 2020.

2 A is correct. The DuPont analysis shows that profit margins and asset turnover have both increased over the last three years, but leverage has declined. The reduction in leverage offsets a portion of the improvement in profitability and turnover. Thus, ROE would have been higher if leverage had not decreased.

3 B is correct. The Power and Industrial segment has the lowest EBIT margins but uses about 31 percent of the capital employed. Further, Power and Industrial's proportion of the capital expenditures has increased from 32 percent to 36 percent over the three years. Its capital intensity only looked to get worse, as the segment's percentage of total capital expenditures was higher than its percentage of total capital in each of the three years. If Abay is considering divesting segments that do not earn sufficient returns on capital employed, this segment is most suitable.

4 A is correct. The cash-flow-based accruals ratio = [NI – (CFO + CFI)]/(Average NOA) = [4,038 – (9,822 – 10,068)]/43,192 = 9.9%.

5 A is correct. The cash-flow-based accruals ratio falls from 11.0 percent in 2018 to 5.9 percent in 2019, and then rises to 9.9 percent in 2020. However, the change over the three-year period is a net modest decline, indicating a slight improvement in earnings quality.

6 B is correct. Net cash flow provided by (used in) operating activity has to be adjusted for interest and taxes, as necessary, in order to be comparable to operating income (EBIT). Bickchip, reporting under IFRS, chose to classify interest expense as a financing cash flow so the only necessary adjustment is for taxes. The operating cash flow before interest and taxes = 9,822 + 1,930 = 11,752. Dividing this by EBIT of 6,270 yields 1.9.

7 A is correct. Operating cash flow before interest and taxes to operating income rises steadily (not erratically) from 1.2 to 1.3 to 1.9. The ratios over 1.0 and the trend indicate that earnings are supported by cash flow.

Glossary

Abandonment option The ability to terminate a project at some future time if the financial results are disappointing.

Abnormal earnings See *residual income*.

Abnormal return The return on an asset in excess of the asset's required rate of return; the risk-adjusted return.

Absolute convergence The idea that developing countries, regardless of their particular characteristics, will eventually catch up with the developed countries and match them in per capita output.

Absolute valuation model A model that specifies an asset's intrinsic value.

Absolute version of PPP An extension of the law of one price whereby the prices of goods and services will not differ internationally once exchange rates are considered.

Accounting estimates Estimates used in calculating the value of assets or liabilities and in the amount of revenue and expense to allocate to a period. Examples of accounting estimates include, among others, the useful lives of depreciable assets, the salvage value of depreciable assets, product returns, warranty costs, and the amount of uncollectible receivables.

Accumulated benefit obligation The actuarial present value of benefits (whether vested or non-vested) attributed, generally by the pension benefit formula, to employee service rendered before a specified date and based on employee service and compensation (if applicable) before that date. The accumulated benefit obligation differs from the projected benefit obligation in that it includes no assumption about future compensation levels.

Accuracy The percentage of correctly predicted classes out of total predictions. It is an overall performance metric in classification problems.

Acquirer The company in a merger or acquisition that is acquiring the target.

Acquiring company See *acquirer*.

Acquisition The purchase of some portion of one company by another; the purchase may be for assets, a definable segment of another entity, or the entire company.

Activation function A functional part of a neural network's node that transforms the total net input received into the final output of the node. The activation function operates like a light dimmer switch that decreases or increases the strength of the input.

Active factor risk The contribution to active risk squared resulting from the portfolio's different-than-benchmark exposures relative to factors specified in the risk model.

Active return The return on a portfolio minus the return on the portfolio's benchmark.

Active risk The standard deviation of active returns.

Active risk squared The variance of active returns; active risk raised to the second power.

Active share A measure of how similar a portfolio is to its benchmark. A manager who precisely replicates the benchmark will have an active share of zero; a manager with no holdings in common with the benchmark will have an active share of one.

Active specific risk The contribution to active risk squared resulting from the portfolio's active weights on individual assets as those weights interact with assets' residual risk.

Adjusted funds from operations (AFFO) Funds from operations adjusted to remove any non-cash rent reported under straight-line rent accounting and to subtract maintenance-type capital expenditures and leasing costs, including leasing agents' commissions and tenants' improvement allowances.

Adjusted present value As an approach to valuing a company, the sum of the value of the company, assuming no use of debt, and the net present value of any effects of debt on company value.

Adjusted R^2 A measure of goodness-of-fit of a regression that is adjusted for degrees of freedom and hence does not automatically increase when another independent variable is added to a regression.

Administrative regulations or administrative law Rules issued by government agencies or other regulators.

Advanced set An arrangement in which the reference interest rate is set at the time the money is deposited.

Advanced settled An arrangement in which a forward rate agreement (FRA) expires and settles at the same time, at the FRA expiration date.

Agency costs Costs associated with the conflict of interest present when a company is managed by non-owners. Agency costs result from the inherent conflicts of interest between managers and equity owners.

Agency costs of equity The smaller the stake managers have in the company, the less their share in bearing the cost of excessive perquisite consumption—consequently, the less their desire to give their best efforts in running the company.

Agency issues Conflicts of interest that arise when the agent in an agency relationship has goals and incentives that differ from the principal to whom the agent owes a fiduciary duty. Also called *agency problems* or *principal–agent problems*.

Agglomerative clustering A bottom-up hierarchical clustering method that begins with each observation being treated as its own cluster. The algorithm finds the two closest clusters, based on some measure of distance (similarity), and combines them into one new larger cluster. This process is repeated iteratively until all observations are clumped into a single large cluster.

Allowance for loan losses A balance sheet account; it is a contra asset account to loans.

Alpha The return on an asset in excess of the asset's required rate of return; the risk-adjusted return.

American Depositary Receipt A negotiable certificate issued by a depositary bank that represents ownership in a non-US company's deposited equity (i.e., equity held in custody by the depositary bank in the company's home market).

Analysis of variance (ANOVA) The analysis that breaks the total variability of a dataset (such as observations on the dependent variable in a regression) into components representing different sources of variation. With reference to regression, ANOVA provides the inputs for an *F*-test of

the significance of the regression as a whole, as well as the inputs for the coefficient of determination and the standard error of the estimate.

Application programming interface (API) A set of well-defined methods of communication between various software components and typically used for accessing external data.

Arbitrage (1) The simultaneous purchase of an undervalued asset or portfolio and sale of an overvalued but equivalent asset or portfolio in order to obtain a riskless profit on the price differential. Taking advantage of a market inefficiency in a risk-free manner. (2) The condition in a financial market in which equivalent assets or combinations of assets sell for two different prices, creating an opportunity to profit at no risk with no commitment of money. In a well-functioning financial market, few arbitrage opportunities are possible. (3) A risk-free operation that earns an expected positive net profit but requires no net investment of money.

Arbitrage-free models Term structure models that project future interest rate paths that emanate from the existing term structure. Resulting prices are based on a no-arbitrage condition.

Arbitrage-free valuation An approach to valuation that determines security values consistent with the absence of any opportunity to earn riskless profits without any net investment of money.

Arbitrage opportunity An opportunity to conduct an arbitrage; an opportunity to earn an expected positive net profit without risk and with no net investment of money.

Arbitrage portfolio The portfolio that exploits an arbitrage opportunity.

Ask price The price at which a trader will sell a specified quantity of a security. Also called *ask*, *offer price*, or *offer*.

Asset-based approach Approach that values a private company based on the values of the underlying assets of the entity less the value of any related liabilities.

Asset-based valuation An approach to valuing natural resource companies that estimates company value on the basis of the market value of the natural resources the company controls.

Asset beta The unlevered beta; reflects the business risk of the assets; the asset's systematic risk.

Asset purchase An acquisition in which the acquirer purchases the target company's assets and payment is made directly to the target company.

Asymmetric information The differential of information between corporate insiders and outsiders regarding the company's performance and prospects. Managers typically have more information about the company's performance and prospects than owners and creditors.

At market contract When a forward contract is established, the forward price is negotiated so that the market value of the forward contract on the initiation date is zero.

Authorized participants (APs) A special group of institutional investors who are authorized by the ETF issuer to participate in the creation/redemption process. APs are large broker/dealers, often market makers.

Autocorrelations The correlations of a time series with its own past values.

Autoregressive model (AR) A time series regressed on its own past values in which the independent variable is a lagged value of the dependent variable.

Backtesting The process that approximates the real-life investment process, using historical data, to assess whether an investment strategy would have produced desirable results.

Backward integration A merger involving the purchase of a target ahead of the acquirer in the value or production chain; for example, to acquire a supplier.

Backward propagation The process of adjusting weights in a neural network, to reduce total error of the network, by moving backward through the network's layers.

Backwardation A condition in futures markets in which the spot price exceeds the futures price; also, the condition in which the near-term (closer to expiration) futures contract price is higher than the longer-term futures contract price.

Bag-of-words (BOW) A collection of a distinct set of tokens from all the texts in a sample dataset. BOW does not capture the position or sequence of words present in the text.

Bankruptcy A declaration provided for by a country's laws that typically involves the establishment of a legal procedure that forces creditors to defer their claims.

Barbell portfolio Fixed-income portfolio that combines short and long maturities.

Base error Model error due to randomness in the data.

Basic earnings per share (EPS) Net earnings available to common shareholders (i.e., net income minus preferred dividends) divided by the weighted average number of common shares outstanding during the period.

Basis The difference between the spot price and the futures price. As the maturity date of the futures contract nears, the basis converges toward zero.

Basis trade A trade based on the pricing of credit in the bond market versus the price of the same credit in the CDS market. To execute a basis trade, go long the "underpriced" credit and short the "overpriced" credit. A profit is realized as the implied credit prices converge.

Bear hug A tactic used by acquirers to circumvent target management's objections to a proposed merger by submitting the proposal directly to the target company's board of directors.

Bearish flattening Term structure shift in which short-term bond yields rise more than long-term bond yields, resulting in a flatter yield curve.

Benchmark value of the multiple In using the method of comparables, the value of a price multiple for the comparison asset; when we have comparison assets (a group), the mean or median value of the multiple for the group of assets.

Best ask The offer to sell with the lowest ask price. Also called *best offer* or *inside ask*.

Best bid The offer to buy with the highest bid price. Also called the *inside bid*.

Best offer See *best ask*.

Bias error Describes the degree to which a model fits the training data. Algorithms with erroneous assumptions produce high bias error with poor approximation, causing underfitting and high in-sample error.

Bid–ask spread The ask price minus the bid price.

Bid price The price at which a trader will buy a specified quantity of a security. Also called *bid*.

Bill-and-hold basis Sales on a bill-and-hold basis involve selling products but not delivering those products until a later date.

Blockage factor An illiquidity discount that occurs when an investor sells a large amount of stock relative to its trading volume (assuming it is not large enough to constitute a controlling ownership).

Bond indenture A legal contract specifying the terms of a bond issue.

Bond risk premium The expected excess return of a default-free long-term bond less that of an equivalent short-term bond.

Bond yield plus risk premium method An estimate of the cost of common equity that is produced by summing the before-tax cost of debt and a risk premium that captures the additional yield on a company's stock relative to its bonds. The additional yield is often estimated using historical spreads between bond yields and stock yields.

Bonding costs Costs borne by management to assure owners that they are working in the owners' best interest (e.g., implicit cost of non-compete agreements).

Bonus issue of shares *See stock dividend.*

Book value Shareholders' equity (total assets minus total liabilities) minus the value of preferred stock; common shareholders' equity.

Book value of equity Shareholders' equity (total assets minus total liabilities) minus the value of preferred stock; common shareholders' equity.

Book value per share The amount of book value (also called carrying value) of common equity per share of common stock, calculated by dividing the book value of shareholders' equity by the number of shares of common stock outstanding.

Bootstrap aggregating (or bagging) A technique whereby the original training dataset is used to generate *n* new training datasets or bags of data. Each new bag of data is generated by random sampling with replacement from the initial training set.

Bootstrapping The use of a forward substitution process to determine zero-coupon rates by using the par yields and solving for the zero-coupon rates one by one, from the shortest to longest maturities.

Bottom-up approach With respect to forecasting, an approach that usually begins at the level of the individual company or a unit within the company.

Breakup value The value derived using a sum-of-the-parts valuation.

Breusch–Pagan test A test for conditional heteroskedasticity in the error term of a regression.

Bullet portfolio A fixed-income portfolio concentrated in a single maturity.

Bullish flattening Term structure change in which the yield curve flattens in response to a greater decline in long-term rates than short-term rates.

Bullish steepening Term structure change in which short-term rates fall by more than long-term yields, resulting in a steeper term structure.

Buy-side analysts Analysts who work for investment management firms, trusts, bank trust departments, and similar institutions.

Buyback *See share repurchase.*

Callable bond Bond that includes an embedded call option that gives the issuer the right to redeem the bond issue prior to maturity, typically when interest rates have fallen or when the issuer's credit quality has improved.

Canceled shares Shares that were issued, subsequently repurchased by the company, and then retired (cannot be reissued).

Cannibalization Cannibalization occurs when an investment takes customers and sales away from another part of the company.

Capital charge The company's total cost of capital in money terms.

Capital deepening An increase in the capital-to-labor ratio.

Capital rationing A capital rationing environment assumes that the company has a fixed amount of funds to invest.

Capital structure The mix of debt and equity that a company uses to finance its business; a company's specific mixture of long-term financing.

Capitalization of earnings method In the context of private company valuation, a valuation model based on an assumption of a constant growth rate of free cash flow to the firm or a constant growth rate of free cash flow to equity.

Capitalization rate The divisor in the expression for the value of perpetuity. In the context of real estate, it is the divisor in the direct capitalization method of estimating value. The cap rate equals net operating income divided by value.

Capitalized cash flow method In the context of private company valuation, a valuation model based on an assumption of a constant growth rate of free cash flow to the firm or a constant growth rate of free cash flow to equity. Also called *capitalized cash flow model.*

Capitalized income method In the context of private company valuation, a valuation model based on an assumption of a constant growth rate of free cash flow to the firm or a constant growth rate of free cash flow to equity.

Capped floater Floating-rate bond with a cap provision that prevents the coupon rate from increasing above a specified maximum rate. It protects the issuer against rising interest rates.

Carry arbitrage model A no-arbitrage approach in which the underlying instrument is either bought or sold along with an opposite position in a forward contract.

Carry benefits Benefits that arise from owning certain underlyings; for example, dividends, foreign interest, and bond coupon payments.

Carry costs Costs that arise from owning certain underlyings. They are generally a function of the physical characteristics of the underlying asset and also the interest forgone on the funds tied up in the asset.

Cash available for distribution See *adjusted funds from operations.*

Cash-generating unit The smallest identifiable group of assets that generates cash inflows that are largely independent of the cash inflows of other assets or groups of assets.

Cash offering A merger or acquisition that is to be paid for with cash; the cash for the merger might come from the acquiring company's existing assets or from a debt issue.

Cash settlement A procedure used in certain derivative transactions that specifies that the long and short parties settle the derivative's difference in value between them by making a cash payment.

Catalyst An event or piece of information that causes the marketplace to re-evaluate the prospects of a company.

Categorical dependent variables An alternative term for qualitative dependent variables.

CDS spread A periodic premium paid by the buyer to the seller that serves as a return over a market reference rate required to protect against credit risk.

Ceiling analysis A systematic process of evaluating different components in the pipeline of model building. It helps to understand what part of the pipeline can potentially improve in performance by further tuning.

Centroid The center of a cluster formed using the *k*-means clustering algorithm.

Chain rule of forecasting A forecasting process in which the next period's value as predicted by the forecasting equation is substituted into the right-hand side of the equation to give a predicted value two periods ahead.

Cheapest-to-deliver The debt instrument that can be purchased and delivered at the lowest cost yet has the same seniority as the reference obligation.

Classification and regression tree A supervised machine learning technique that can be applied to predict either a categorical target variable, producing a classification tree, or a continuous target variable, producing a regression tree. CART is commonly applied to binary classification or regression.

Clean surplus relation The relationship between earnings, dividends, and book value in which ending book value is equal to the beginning book value plus earnings less dividends, apart from ownership transactions.

Club convergence The idea that only rich and middle-income countries sharing a set of favorable attributes (i.e., are members of the "club") will converge to the income level of the richest countries.

Cluster A subset of observations from a dataset such that all the observations within the same cluster are deemed "similar."

Clustering The sorting of observations into groups (clusters) such that observations in the same cluster are more similar to each other than they are to observations in other clusters.

Cobb–Douglas production function A function of the form $Y = K^{\alpha} L^{1-\alpha}$ relating output (Y) to labor (L) and capital (K) inputs.

Coefficient of determination The percentage of the variation of the dependent variable that is explained by the independent variable. Also referred to as the "*R*-squared" or "R^2."

Cointegrated Describes two time series that have a long-term financial or economic relationship such that they do not diverge from each other without bound in the long run.

Collateral return The component of the total return on a commodity futures position attributable to the yield for the bonds or cash used to maintain the futures position. Also called *collateral yield*.

Collection frequency (CF) The number of times a given word appears in the whole corpus (i.e., collection of sentences) divided by the total number of words in the corpus.

Commercial real estate properties Income-producing real estate properties; properties purchased with the intent to let, lease, or rent (in other words, produce income).

Commodity swap A type of swap involving the exchange of payments over multiple dates as determined by specified reference prices or indexes relating to commodities.

Common size statements Financial statements in which all elements (accounts) are stated as a percentage of a key figure, such as revenue for an income statement or total assets for a balance sheet.

Company fundamental factors Factors related to the company's internal performance, such as factors relating to earnings growth, earnings variability, earnings momentum, and financial leverage.

Company share-related factors Valuation measures and other factors related to share price or the trading characteristics of the shares, such as earnings yield, dividend yield, and book-to-market value.

Comparables Assets used as benchmarks when applying the method of comparables to value an asset. Also called *comps*, *guideline assets*, or *guideline companies*.

Competition laws A law that promotes or maintains market competition by regulating anti-competitive conduct. Known as "antitrust law" in the United States, "anti-monopoly law" in China and Russia, and often referred to as "trade practices law" in the United Kingdom and Australia.

Compiled financial statements Financial statements that are not accompanied by an auditor's opinion letter.

Complexity A term referring to the number of features, parameters, or branches in a model and to whether the model is linear or non-linear (non-linear is more complex).

Composite variable A variable that combines two or more variables that are statistically strongly related to each other.

Comprehensive income All changes in equity other than contributions by, and distributions to, owners; income under clean surplus accounting; includes all changes in equity during a period except those resulting from investments by owners and distributions to owners. Comprehensive income equals net income plus other comprehensive income.

Comps Assets used as benchmarks when applying the method of comparables to value an asset.

Concentrated ownership Ownership structure consisting of an individual shareholder or a group (controlling shareholders) with the ability to exercise control over the corporation.

Conditional convergence The idea that convergence of per capita income is conditional on the countries having the same savings rate, population growth rate, and production function.

Conditional heteroskedasticity Heteroskedasticity in the error variance that is correlated with the values of the independent variable(s) in the regression.

Conditional VaR (CVaR) The weighted average of all loss outcomes in the statistical (i.e., return) distribution that exceed the VaR loss. Thus, CVaR is a more comprehensive measure of tail loss than VaR is. Sometimes referred to as the *expected tail loss* or *expected shortfall*.

Confusion matrix A grid used for error analysis in classification problems, it presents values for four evaluation metrics including true positive (TP), false positive (FP), true negative (TN), and false negative (FN).

Conglomerate discount The discount possibly applied by the market to the stock of a company operating in multiple, unrelated businesses.

Conglomerate merger A merger involving companies that are in unrelated businesses.

Consolidation The combining of the results of operations of subsidiaries with the parent company to present financial statements as if they were a single economic unit. The assets, liabilities, revenues, and expenses of the subsidiaries are combined with those of the parent company, eliminating intercompany transactions.

Constant dividend payout ratio policy A policy in which a constant percentage of net income is paid out in dividends.

Constant returns to scale The condition that if all inputs into the production process are increased by a given percentage, then output rises by that same percentage.

Contango A condition in futures markets in which the spot price is lower than the futures price; also, the condition in which the near-term (closer to expiration) futures contract price is lower than the longer-term futures contract price.

Contingent consideration Potential future payments to the seller that are contingent on the achievement of certain agreed-on occurrences.

Continuing earnings Earnings excluding nonrecurring components. Also referred to as *core earnings*, *persistent earnings*, or *underlying earnings*.

Continuing residual income Residual income after the forecast horizon.

Continuing value The analyst's estimate of a stock's value at a particular point in the future.

Control premium An increment or premium to value associated with a controlling ownership interest in a company.

Convergence The property by which as expiration approaches, the price of a newly created forward or futures contract will approach the price of a spot transaction. At expiration, a forward or futures contract is equivalent to a spot transaction in the underlying.

Conversion period For a convertible bond, the period during which bondholders have the right to convert their bonds into shares.

Conversion price For a convertible bond, the price per share at which the bond can be converted into shares.

Conversion rate (or ratio) For a convertible bond, the number of shares of common stock that a bondholder receives from converting the bond into shares.

Conversion value For a convertible bond, the value of the bond if it is converted at the market price of the shares. Also called *parity value*.

Convertible bond Bond with an embedded conversion option that gives bondholders the right to convert their bonds into the issuer's common stock during a pre-determined period at a pre-determined price.

Convexity A measure of how interest rate sensitivity changes with a change in interest rates.

Core earnings Earnings excluding nonrecurring components. Also referred to as *continuing earnings*, *persistent earnings*, or *underlying earnings*.

Core real estate investment style Investing in high-quality, well-leased, core property types with low leverage (no more than 30% of asset value) in the largest markets with strong, diversified economies. It is a conservative strategy designed to avoid real estate–specific risks, including leasing, development, and speculation in favor of steady returns. Hotel properties are excluded from the core categories because of the higher cash flow volatility resulting from single-night leases and the greater importance of property operations, brand, and marketing.

Corpus A collection of text data in any form, including list, matrix, or data table forms.

Cost approach An approach that values a private company based on the values of the underlying assets of the entity less the value of any related liabilities. In the context of real estate, this approach estimates the value of a property based on what it would cost to buy the land and construct a new property on the site that has the same utility or functionality as the property being appraised.

Cost of carry model A model that relates the forward price of an asset to the spot price by considering the cost of carry (also referred to as future-spot parity model).

Cost of debt The cost of debt financing to a company, such as when it issues a bond or takes out a bank loan.

Cost of equity The required rate of return on common stock.

Covariance stationary Describes a time series when its expected value and variance are constant and finite in all periods and when its covariance with itself for a fixed number of periods in the past or future is constant and finite in all periods.

Covered bonds A senior debt obligation of a financial institution that gives recourse to the originator/issuer and a predetermined underlying collateral pool.

Covered interest rate parity The relationship among the spot exchange rate, the forward exchange rate, and the interest rates in two currencies that ensures that the return on a hedged (i.e., covered) foreign risk-free investment is the same as the return on a domestic risk-free investment. Also called *interest rate parity*.

Cox-Ingersoll-Ross model A general equilibrium term structure model that assumes interest rates are mean reverting and interest rate volatility is directly related to the level of interest rates.

Creation basket The list of securities (and share amounts) the authorized participant (AP) must deliver to the ETF manager in exchange for ETF shares. The creation basket is published each business day.

Creation/redemption The process in which ETF shares are created or redeemed by authorized participants transacting with the ETF issuer.

Creation units Large blocks of ETF shares transacted between the authorized participant (AP) and the ETF manager that are usually but not always equal to 50,000 shares of the ETF.

Credit correlation The correlation of credit (or default) risks of the underlying single-name CDS contained in an index CDS.

Credit curve The credit spreads for a range of maturities of a company's debt.

Credit default swap A derivative contract between two parties in which the buyer makes a series of cash payments to the seller and receives a promise of compensation for credit losses resulting from the default.

Credit derivative A derivative instrument in which the underlying is a measure of the credit quality of a borrower.

Credit event The event that triggers a payment from the credit protection seller to the credit protection buyer.

Credit protection buyer One party to a credit default swap; the buyer makes a series of cash payments to the seller and receives a promise of compensation for credit losses resulting from the default.

Credit protection seller One party to a credit default swap; the seller makes a promise to pay compensation for credit losses resulting from the default.

Credit risk The risk that the borrower will not repay principal and interest. Also called *default risk*.

Credit valuation adjustment The value of the credit risk of a bond in present value terms.

Cross-validation A technique for estimating out-of-sample error directly by determining the error in validation samples.

Current exchange rate For accounting purposes, the spot exchange rate on the balance sheet date.

Current rate method Approach to translating foreign currency financial statements for consolidation in which all assets and liabilities are translated at the current exchange rate. The current rate method is the prevalent method of translation.

Curvature One of the three factors (the other two are level and steepness) that empirically explain most of the changes in the shape of the yield curve. A shock to the curvature factor affects mid-maturity interest rates, resulting in the term structure becoming either more or less hump-shaped.

Curve trade Buying a CDS of one maturity and selling a CDS on the same reference entity with a different maturity.

Cyclical businesses Businesses with high sensitivity to business- or industry-cycle influences.

Data mining The practice of determining a model by extensive searching through a dataset for statistically significant patterns.

Data preparation (cleansing) The process of examining, identifying, and mitigating (i.e., cleansing) errors in raw data.

Data snooping The subconscious or conscious manipulation of data in a way that produces a statistically significant result (i.e., the *p*-value is sufficiently small or the *t*-statistic sufficiently large to indicate statistical significance), such as by running multiple simulations and naively accepting the best result. Also known as p-hacking.

Data wrangling (preprocessing) This task performs transformations and critical processing steps on cleansed data to make the data ready for ML model training (i.e., preprocessing), and includes dealing with outliers, extracting useful variables from existing data points, and scaling the data.

"Dead-hand" provision A poison pill provision that allows for the redemption or cancellation of a poison pill provision only by a vote of continuing directors (generally directors who were on the target company's board prior to the takeover attempt).

Debt rating An objective measure of the quality and safety of a company's debt based upon an analysis of the company's ability to pay the promised cash flows. It includes an analysis of any indentures.

Deep learning Algorithms based on deep neural networks, ones with many hidden layers (more than two), that address highly complex tasks, such as image classification, face recognition, speech recognition, and natural language processing.

Deep neural networks Neural networks with many hidden layers—at least 2 but potentially more than 20—that have proven successful across a wide range of artificial intelligence applications.

Default risk See *credit risk*.

Defined benefit pension plans Plan in which the company promises to pay a certain annual amount (defined benefit) to the employee after retirement. The company bears the investment risk of the plan assets.

Defined contribution pension plans Individual accounts to which an employee and typically the employer makes contributions, generally on a tax-advantaged basis. The amounts of contributions are defined at the outset, but the future value of the benefit is unknown. The employee bears the investment risk of the plan assets.

Definitive merger agreement A contract signed by both parties to a merger that clarifies the details of the transaction, including the terms, warranties, conditions, termination details, and the rights of all parties.

Delay costs Implicit trading costs that arise from the inability to complete desired trades immediately. Also called *slippage.*

Delta The relationship between the option price and the underlying price, which reflects the sensitivity of the price of the option to changes in the price of the underlying. Delta is a good approximation of how an option price will change for a small change in the stock.

Dendrogram A type of tree diagram used for visualizing a hierarchical cluster analysis; it highlights the hierarchical relationships among the clusters.

Dependent variable The variable whose variation about its mean is to be explained by the regression; the left-side variable in a regression equation. Also referred to as the *explained variable*.

Depository Trust and Clearinghouse Corporation A US-headquartered entity providing post-trade clearing, settlement, and information services.

Descriptive statistics The study of how data can be summarized effectively.

Diluted earnings per share (Diluted EPS)Net income, minus preferred dividends, divided by the weighted average number of common shares outstanding considering all dilutive securities (e.g., convertible debt and options); the EPS that would result if all dilutive securities were converted into common shares.

Dilution A reduction in proportional ownership interest as a result of the issuance of new shares.

Dimension reduction A set of techniques for reducing the number of features in a dataset while retaining variation across observations to preserve the information contained in that variation.

Diminishing marginal productivity When each additional unit of an input, keeping the other inputs unchanged, increases output by a smaller increment.

Direct capitalization method In the context of real estate, this method estimates the value of an income-producing property based on the level and quality of its net operating income.

Discount To reduce the value of a future payment in allowance for how far away it is in time; to calculate the present value of some future amount. Also, the amount by which an instrument is priced below its face value.

Discount factor The present value or price of a risk-free single-unit payment when discounted using the appropriate spot rate.

Discount for lack of control An amount or percentage deducted from the pro rata share of 100% of the value of an equity interest in a business to reflect the absence of some or all of the powers of control.

Discount for lack of marketability An amount of percentage deducted from the value of an ownership interest to reflect the relative absence of marketability.

Discount function Discount factors for the range of all possible maturities. The spot curve can be derived from the discount function and vice versa.

Discount rate Any rate used in finding the present value of a future cash flow.

Discounted abnormal earnings model A model of stock valuation that views intrinsic value of stock as the sum of book value per share plus the present value of the stock's expected future residual income per share.

Discounted cash flow (DCF) analysis In the context of merger analysis, an estimate of a target company's value found by discounting the company's expected future free cash flows to the present.

Discounted cash flow method Income approach that values an asset based on estimates of future cash flows discounted to present value by using a discount rate reflective of the risks associated with the cash flows. In the context of real estate, this method estimates the value of an income-producing property based on discounting future projected cash flows.

Discounted cash flow model A model of intrinsic value that views the value of an asset as the present value of the asset's expected future cash flows.

Discriminant analysis A multivariate classification technique used to discriminate between groups, such as companies that either will or will not become bankrupt during some time frame.

Dispersed ownership Ownership structure consisting of many shareholders, none of which has the ability to individually exercise control over the corporation.

Divestiture The sale, liquidation, or spin-off of a division or subsidiary.

Dividend A distribution paid to shareholders based on the number of shares owned.

Dividend coverage ratio The ratio of net income to dividends.

Dividend discount model (DDM) A present value model of stock value that views the intrinsic value of a stock as present value of the stock's expected future dividends.

Dividend displacement of earnings The concept that dividends paid now displace earnings in all future periods.

Dividend imputation tax system A taxation system that effectively assures corporate profits distributed as dividends are taxed just once and at the shareholder's tax rate.

Dividend index point A measure of the quantity of dividends attributable to a particular index.

Dividend payout ratio The ratio of cash dividends paid to earnings for a period.

Dividend policy The strategy a company follows with regard to the amount and timing of dividend payments.

Dividend rate The annualized amount of the most recent dividend.

Dividend yield Annual dividends per share divided by share price.

Divisive clustering A top-down hierarchical clustering method that starts with all observations belonging to a single large cluster. The observations are then divided into two clusters based on some measure of distance (similarity). The algorithm then progressively partitions the intermediate clusters into smaller ones until each cluster contains only one observation.

Document frequency (DF) The number of documents (texts) that contain a particular token divided by the total number of documents. It is the simplest feature selection method and often performs well when many thousands of tokens are present.

Document term matrix (DTM) A matrix where each row belongs to a document (or text file), and each column represents a token (or term). The number of rows is equal to the number of documents (or text files) in a sample text dataset. The number of columns is equal to the number of tokens from the BOW built using all the documents in the sample dataset. The cells typically contain the counts of the number of times a token is present in each document.

Dominance An arbitrage opportunity when a financial asset with a risk-free payoff in the future must have a positive price today.

Double taxation system Corporate earnings are taxed twice when paid out as dividends. First, corporate pretax earnings are taxed regardless of whether they will be distributed as dividends or retained at the corporate level. Second, dividends are taxed again at the individual shareholder level.

Downstream A transaction between two related companies, an investor company (or a parent company) and an associate company (or a subsidiary) such that the investor company records a profit on its income statement. An example is a sale of inventory by the investor company to the associate or by a parent to a subsidiary company.

Dual-class shares Shares that grant one share class superior or even sole voting rights, whereas the other share class has inferior or no voting rights.

Due diligence Investigation and analysis in support of a recommendation; the failure to exercise due diligence may sometimes result in liability according to various securities laws.

Dummy variable A type of qualitative variable that takes on a value of 1 if a particular condition is true and 0 if that condition is false.

Duration A measure of the approximate sensitivity of a security to a change in interest rates (i.e., a measure of interest rate risk).

Dutch disease A situation in which currency appreciation driven by strong export demand for resources makes other segments of the economy (particularly manufacturing) globally uncompetitive.

Earnings surprise The difference between reported EPS and expected EPS. Also referred to as *unexpected earnings*.

Earnings yield EPS divided by price; the reciprocal of the P/E.

Economic profit See *residual income*.

Economic sectors Large industry groupings.

Economic value added (EVA®) A commercial implementation of the residual income concept; the computation of EVA® is the net operating profit after taxes minus the cost of capital, where these inputs are adjusted for a number of items.

Economies of scale A situation in which average costs per unit of good or service produced fall as volume rises. In reference to mergers, the savings achieved through the consolidation of operations and elimination of duplicate resources.

Edwards–Bell–Ohlson model A model of stock valuation that views intrinsic value of stock as the sum of book value per share plus the present value of the stock's expected future residual income per share.

Effective convexity Sensitivity of duration to changes in interest rates.

Effective duration Sensitivity of the bond's price to a 100 bps parallel shift of the benchmark yield curve, assuming no change in the bond's credit spread.

Effective spread Two times the difference between the execution price and the midpoint of the market quote at the time an order is entered.

Eigenvalue A measure that gives the proportion of total variance in the initial dataset that is explained by each eigenvector.

Eigenvector A vector that defines new mutually uncorrelated composite variables that are linear combinations of the original features.

Embedded options Contingency provisions found in a bond's indenture or offering circular representing rights that enable their holders to take advantage of interest rate movements. They can be exercised by the issuer, by the bondholder, or automatically depending on the course of interest rates.

Ensemble learning A technique of combining the predictions from a collection of models to achieve a more accurate prediction.

Ensemble method The method of combining multiple learning algorithms, as in ensemble learning.

Enterprise value Total company value (the market value of debt, common equity, and preferred equity) minus the value of cash and investments.

Enterprise value multiple A valuation multiple that relates the total market value of all sources of a company's capital (net of cash) to a measure of fundamental value for the entire company (such as a pre-interest earnings measure).

Equilibrium The condition in which supply equals demand.

Equity carve-out A form of restructuring that involves the creation of a new legal entity and the sale of equity in it to outsiders.

Equity charge The estimated cost of equity capital in money terms.

Equity REITs REITs that own, operate, and/or selectively develop income-producing real estate.

Equity swap A swap transaction in which at least one cash flow is tied to the return on an equity portfolio position, often an equity index.

Error autocorrelations The autocorrelations of the error term.

Error term The difference between an observation and its expected value, where the expected value is based on the true underlying population relation between the dependent and independent variables. Also known simply as the *error*.

ESG integration An ESG investment approach that focuses on systematic consideration of material ESG factors in asset allocation, security selection, and portfolio construction decisions for the purpose of achieving the product's stated investment objectives.

Estimated parameters With reference to a regression analysis, the estimated values of the population intercept and population slope coefficients in a regression.

***Ex ante* tracking error** A measure of the degree to which the performance of a given investment portfolio might be expected to deviate from its benchmark; also known as *relative VaR*.

***Ex ante* version of PPP** The hypothesis that expected changes in the spot exchange rate are equal to expected differences in national inflation rates. An extension of relative purchasing power parity to expected future changes in the exchange rate.

Ex-dividend Trading ex-dividend refers to shares that no longer carry the right to the next dividend payment.

Ex-dividend date The first date that a share trades without (i.e., "ex") the right to receive the declared dividend for the period.

Excess earnings method Income approach that estimates the value of all intangible assets of the business by capitalizing future earnings in excess of the estimated return requirements associated with working capital and fixed assets.

Exchange ratio The number of shares that target stockholders are to receive in exchange for each of their shares in the target company.

Exercise date The date when employees actually exercise stock options and convert them to stock.

Exercise value The value of an option if it were exercised. Also sometimes called *intrinsic value*.

Expanded CAPM An adaptation of the CAPM that adds to the CAPM a premium for small size and company-specific risk.

Expectations approach A procedure for obtaining the value of an option derived from discounting at the risk-free rate its expected future payoff based on risk neutral probabilities.

Expected exposure The projected amount of money an investor could lose if an event of default occurs, before factoring in possible recovery.

Expected holding-period return The expected total return on an asset over a stated holding period; for stocks, the sum of the expected dividend yield and the expected price appreciation over the holding period.

Expected shortfall See *conditional VaR*.

Expected tail loss See *conditional VaR*.

Exploratory data analysis (EDA) The preliminary step in data exploration, where graphs, charts, and other visualizations (heat maps and word clouds) as well as quantitative methods (descriptive statistics and central tendency measures) are used to observe and summarize data.

Exposure to foreign exchange risk The risk of a change in value of an asset or liability denominated in a foreign currency due to a change in exchange rates.

Extendible bond Bond with an embedded option that gives the bondholder the right to keep the bond for a number of years after maturity, possibly with a different coupon.

External growth Company growth in output or sales that is achieved by buying the necessary resources externally (i.e., achieved through mergers and acquisitions).

Extra dividend *See special dividend.*

F1 score The harmonic mean of precision and recall. F1 score is a more appropriate overall performance metric (than accuracy) when there is unequal class distribution in the dataset and it is necessary to measure the equilibrium of precision and recall.

Factor A common or underlying element with which several variables are correlated.

Factor betas An asset's sensitivity to a particular factor; a measure of the response of return to each unit of increase in a factor, holding all other factors constant.

Factor portfolio See *pure factor portfolio*.

Factor price The expected return in excess of the risk-free rate for a portfolio with a sensitivity of 1 to one factor and a sensitivity of 0 to all other factors.

Factor risk premium The expected return in excess of the risk-free rate for a portfolio with a sensitivity of 1 to one factor and a sensitivity of 0 to all other factors. Also called *factor price*.

Factor sensitivity See *factor betas*.

Failure to pay When a borrower does not make a scheduled payment of principal or interest on any outstanding obligations after a grace period.

Fair market value The market price of an asset or liability that trades regularly.

Fair value The amount at which an asset (or liability) could be bought (or incurred) or sold (or settled) in a current transaction between willing parties, that is, other than in a forced or liquidation sale. As defined in IFRS and US GAAP, it is the price that would be received to sell an asset or paid to transfer a liability in an orderly transaction between market participants at the measurement date.

Feature engineering A process of creating new features by changing or transforming existing features.
Feature selection A process whereby only pertinent features from the dataset are selected for model training. Selecting fewer features decreases model complexity and training time.
Features The independent variables (X's) in a labeled dataset.
Financial contagion A situation in which financial shocks spread from their place of origin to other locales. In essence, a faltering economy infects other, healthier economies.
Financial distress Heightened uncertainty regarding a company's ability to meet its various obligations because of lower or negative earnings.
Financial transaction A purchase involving a buyer having essentially no material synergies with the target (e.g., the purchase of a private company by a company in an unrelated industry or by a private equity firm would typically be a financial transaction).
First-differencing A transformation that subtracts the value of the time series in period $t - 1$ from its value in period t.
First-order serial correlation Correlation between adjacent observations in a time series.
Fitting curve A curve which shows in- and out-of-sample error rates (E_{in} and E_{out}) on the y-axis plotted against model complexity on the x-axis.
Fixed price tender offer Offer made by a company to repurchase a specific number of shares at a fixed price that is typically at a premium to the current market price.
Fixed-rate perpetual preferred stock Non-convertible, non-callable preferred stock with a specified dividend rate that has a claim on earnings senior to the claim of common stock, and no maturity date.
Flight to quality During times of market stress, investors sell higher-risk asset classes such as stocks and commodities in favor of default-risk-free government bonds.
Flip-in pill A poison pill takeover defense that dilutes an acquirer's ownership in a target by giving other existing target company shareholders the right to buy additional target company shares at a discount.
Flip-over pill A poison pill takeover defense that gives target company shareholders the right to purchase shares of the acquirer at a significant discount to the market price, which has the effect of causing dilution to all existing acquiring company shareholders.
Float Amounts collected as premium and not yet paid out as benefits.
Floored floater Floating-rate bond with a floor provision that prevents the coupon rate from decreasing below a specified minimum rate. It protects the investor against declining interest rates.
Flotation cost Fees charged to companies by investment bankers and other costs associated with raising new capital.
Forced conversion For a convertible bond, when the issuer calls the bond and forces bondholders to convert their bonds into shares, which typically happens when the underlying share price increases above the conversion price.
Foreign currency transactions Transactions that are denominated in a currency other than a company's functional currency.
Forward curve The term structure of forward rates for loans made on a specific initiation date.
Forward dividend yield A dividend yield based on the anticipated dividend during the next 12 months.
Forward integration A merger involving the purchase of a target that is farther along the value or production chain; for example, to acquire a distributor.
Forward P/E A P/E calculated on the basis of a forecast of EPS; a stock's current price divided by next year's expected earnings.
Forward price The fixed price or rate at which the transaction, scheduled to occur at the expiration of a forward contract, will take place. This price is agreed to at the initiation date of the forward contract.
Forward pricing model The model that describes the valuation of forward contracts.
Forward propagation The process of adjusting weights in a neural network, to reduce total error of the network, by moving forward through the network's layers.
Forward rate An interest rate determined today for a loan that will be initiated in a future period.
Forward rate agreement An over-the-counter forward contract in which the underlying is an interest rate on a deposit. A forward rate agreement (FRA) calls for one party to make a fixed interest payment and the other to make an interest payment at a rate to be determined at contract expiration.
Forward rate model The forward pricing model expressed in terms of spot and forward interest rates.
Forward rate parity The proposition that the forward exchange rate is an unbiased predictor of the future spot exchange rate.
Forward value The monetary value of an existing forward contract.
Franking credit A tax credit received by shareholders for the taxes that a corporation paid on its distributed earnings.
Free cash flow The actual cash that would be available to the company's investors after making all investments necessary to maintain the company as an ongoing enterprise (also referred to as free cash flow to the firm); the internally generated funds that can be distributed to the company's investors (e.g., shareholders and bondholders) without impairing the value of the company.
Free cash flow hypothesis The hypothesis that higher debt levels discipline managers by forcing them to make fixed debt service payments and by reducing the company's free cash flow.
Free cash flow method Income approach that values an asset based on estimates of future cash flows discounted to present value by using a discount rate reflective of the risks associated with the cash flows.
Free cash flow to equity The cash flow available to a company's common shareholders after all operating expenses, interest, and principal payments have been made and necessary investments in working and fixed capital have been made.
Free cash flow to equity model A model of stock valuation that views a stock's intrinsic value as the present value of expected future free cash flows to equity.
Free cash flow to the firm The cash flow available to the company's suppliers of capital after all operating expenses (including taxes) have been paid and necessary investments in working and fixed capital have been made.
Free cash flow to the firm model A model of stock valuation that views the value of a firm as the present value of expected future free cash flows to the firm.
Frequency analysis The process of quantifying how important tokens are in a sentence and in the corpus as a whole. It helps in filtering unnecessary tokens (or features).

Friendly transaction A potential business combination that is endorsed by the managers of both companies.

Functional currency The currency of the primary economic environment in which an entity operates.

Fundamental factor models A multifactor model in which the factors are attributes of stocks or companies that are important in explaining cross-sectional differences in stock prices.

Fundamentals Economic characteristics of a business, such as profitability, financial strength, and risk.

Funds available for distribution (FAD) See *adjusted funds from operations*.

Funds from operations (FFO) Net income (computed in accordance with generally accepted accounting principles) *plus* (1) gains and losses from sales of properties and (2) depreciation and amortization.

Futures price The price at which the parties to a futures contract agree to exchange the underlying (or cash). In commodity markets, the price agreed on to deliver or receive a defined quantity (and often quality) of a commodity at a future date.

Futures value The monetary value of an existing futures contract.

FX carry trade An investment strategy that involves taking long positions in high-yield currencies and short positions in low-yield currencies.

Gamma A measure of how sensitive an option's delta is to a change in the underlying. The change in a given instrument's delta for a given small change in the underlying's value, holding everything else constant.

Generalize When a model retains its explanatory power when predicting out-of-sample (i.e., using new data).

Generalized least squares A regression estimation technique that addresses heteroskedasticity of the error term.

Going-concern assumption The assumption that the business will maintain its business activities into the foreseeable future.

Going-concern value A business's value under a going-concern assumption.

Goodwill An intangible asset that represents the excess of the purchase price of an acquired company over the value of the net identifiable assets acquired.

Grant date The day that stock options are granted to employees.

Green bond Bonds in which the proceeds are designated by issuers to fund a specific project or portfolio of projects that have environmental or climate benefits.

Greenmail The purchase of the accumulated shares of a hostile investor by a company that is targeted for takeover by that investor, usually at a substantial premium over market price.

Greenwashing The risk that a green bond's proceeds are not actually used for a beneficial environmental or climate-related project.

Grid search A method of systematically training a model by using various combinations of hyperparameter values, cross validating each model, and determining which combination of hyperparameter values ensures the best model performance.

Gross domestic product A money measure of the goods and services produced within a country's borders over a stated period.

Gross lease A lease under which the tenant pays a gross rent to the landlord, who is responsible for all operating costs, utilities, maintenance expenses, and real estate taxes relating to the property.

Ground truth The known outcome (i.e., target variable) of each observation in a labelled dataset.

Growth accounting equation The production function written in the form of growth rates. For the basic Cobb–Douglas production function, it states that the growth rate of output equals the rate of technological change plus α multiplied by the growth rate of capital plus $(1 - \alpha)$ multiplied by the growth rate of labor.

Growth capital expenditures Capital expenditures needed for expansion.

Growth option The ability to make additional investments in a project at some future time if the financial results are strong. Also called *expansion option*.

Guideline assets Assets used as benchmarks when applying the method of comparables to value an asset.

Guideline companies Assets used as benchmarks when applying the method of comparables to value an asset.

Guideline public companies Public-company comparables for the company being valued.

Guideline public company method A variation of the market approach; establishes a value estimate based on the observed multiples from trading activity in the shares of public companies viewed as reasonably comparable to the subject private company.

Guideline transactions method A variation of the market approach; establishes a value estimate based on pricing multiples derived from the acquisition of control of entire public or private companies that were acquired.

Harmonic mean A type of weighted mean computed by averaging the reciprocals of the observations and then taking the reciprocal of that average.

Hazard rate The probability that an event will occur, given that it has not already occurred.

Hedonic index Unlike a repeat-sales index, a hedonic index does not require repeat sales of the same property. It requires only one sale. The way it controls for the fact that different properties are selling each quarter is to include variables in the regression that control for differences in the characteristics of the property, such as size, age, quality of construction, and location.

Heteroskedastic With reference to the error term of regression, having a variance that differs across observations.

Heteroskedasticity The property of having a nonconstant variance; refers to an error term with the property that its variance differs across observations.

Heteroskedasticity-consistent standard errors Standard errors of the estimated parameters of a regression that correct for the presence of heteroskedasticity in the regression's error term.

Hierarchical clustering An iterative unsupervised learning procedure used for building a hierarchy of clusters.

Highest and best use The concept that the best use of a vacant site is the use that would result in the highest value for the land. Presumably, the developer that could earn the highest risk-adjusted profit based on time, effort, construction and development cost, leasing, and exit value would be the one to pay the highest price for the land.

Historical exchange rates For accounting purposes, the exchange rates that existed when the assets and liabilities were initially recorded.

Historical scenario analysis A technique for exploring the performance and risk of investment strategies in different structural regimes.

Historical simulation A simulation method that uses past return data and a random number generator that picks observations from the historical series to simulate an asset's future returns.

Historical simulation method The application of historical price changes to the current portfolio.

Historical stress testing The process that tests how investment strategies would perform under some of the most negative (i.e., adverse) combinations of events and scenarios.

Ho–Lee model The first arbitrage-free term structure model. The model is calibrated to market data and uses a binomial lattice approach to generate a distribution of possible future interest rates.

Holding period return The return that an investor earns during a specified holding period; a synonym for total return.

Holdout samples Data samples that are not used to train a model.

Homoskedasticity The property of having a constant variance; refers to an error term that is constant across observations.

Horizontal merger A merger involving companies in the same line of business, usually as competitors.

Horizontal ownership Companies with mutual business interests (e.g., key customers or suppliers) that have cross-holding share arrangements with each other.

Hostile transaction An attempt to acquire a company against the wishes of the target's managers.

Human capital The accumulated knowledge and skill that workers acquire from education, training, or life experience.

Hybrid approach With respect to forecasting, an approach that combines elements of both top-down and bottom-up analyses.

Hyperparameter A parameter whose value must be set by the researcher before learning begins.

I-spreads Shortened form of "interpolated spreads" and a reference to a linearly interpolated yield.

Illiquidity discount A reduction or discount to value that reflects the lack of depth of trading or liquidity in that asset's market.

Impairment Diminishment in value as a result of carrying (book) value exceeding fair value and/or recoverable value.

Impairment of capital rule A legal restriction that dividends cannot exceed retained earnings.

Implementation shortfall The difference between the money return (or value) on a notional or paper portfolio and the actual portfolio return (or value).

Implied volatility The standard deviation that causes an option pricing model to give the current option price.

In-sample forecast errors The residuals from a fitted time-series model within the sample period used to fit the model.

iNAVs "Indicated" net asset values are intraday "fair value" estimates of an ETF share based on its creation basket.

Income approach A valuation approach that values an asset as the present discounted value of the income expected from it. In the context of real estate, this approach estimates the value of a property based on an expected rate of return. The estimated value is the present value of the expected future income from the property, including proceeds from resale at the end of a typical investment holding period.

Incremental VaR (IVaR) A measure of the incremental effect of an asset on the VaR of a portfolio by measuring the difference between the portfolio's VaR while including a specified asset and the portfolio's VaR with that asset eliminated.

Indenture A written contract between a lender and borrower that specifies the terms of the loan, such as interest rate, interest payment schedule, or maturity.

Independent board directors Directors with no material relationship with the company with regard to employment, ownership, or remuneration.

Independent regulators Regulators recognized and granted authority by a government body or agency. They are not government agencies per se and typically do not rely on government funding.

Independent variable A variable used to explain the dependent variable in a regression; a right-side variable in a regression equation. Also referred to as the *explanatory variable*.

Index CDS A type of credit default swap that involves a combination of borrowers.

Indicator variable A variable that takes on only one of two values, 0 or 1, based on a condition. In simple linear regression, the slope is the difference in the dependent variable for the two conditions. Also referred to as a *dummy variable*.

Industry structure An industry's underlying economic and technical characteristics.

Information gain A metric which quantifies the amount of information that the feature holds about the response. Information gain can be regarded as a form of non-linear correlation between Y and X.

Information ratio (IR) Mean active return divided by active risk; or alpha divided by the standard deviation of diversifiable risk.

Informational frictions Forces that restrict availability, quality, and/or flow of information and its use.

Inside ask See *best ask*.

Inside bid See *best bid*.

Inside spread The spread between the best bid price and the best ask price. Also called the *market bid-ask spread*, *inside bid-ask spread*, or *market spread*.

Insiders Corporate managers and board directors who are also shareholders of a company.

Inter-temporal rate of substitution The ratio of the marginal utility of consumption s periods in the future (the numerator) to the marginal utility of consumption today (the denominator).

Intercept The expected value of the dependent variable when the independent variable in a simple linear regression is equal to zero.

Interest rate risk The risk that interest rates will rise and therefore the market value of current portfolio holdings will fall so that their current yields to maturity then match comparable instruments in the marketplace.

Interlocking directorates Corporate structure in which individuals serve on the board of directors of multiple corporations.

Internal rate of return Abbreviated as IRR. Rate of return that discounts future cash flows from an investment to the exact amount of the investment; the discount rate that makes the present value of an investment's costs (outflows) equal to the present value of the investment's benefits (inflows).

International Fisher effect The proposition that nominal interest rate differentials across currencies are determined by expected inflation differentials.

Intrinsic value The value of an asset given a hypothetically complete understanding of the asset's investment characteristics; the value obtained if an option is exercised based on current conditions. The difference between the spot exchange rate and the strike price of a currency.

Inverse price ratio The reciprocal of a price multiple—for example, in the case of a P/E, the "earnings yield" E/P (where P is share price and E is earnings per share).

Investment value The value to a specific buyer, taking account of potential synergies based on the investor's requirements and expectations.

ISDA Master Agreement A standard or "master" agreement published by the International Swaps and Derivatives Association. The master agreement establishes the terms for each party involved in the transaction.

Judicial law Interpretations of courts.

Justified (fundamental) P/E The price-to-earnings ratio that is fair, warranted, or justified on the basis of forecasted fundamentals.

Justified price multiple The estimated fair value of the price multiple, usually based on forecasted fundamentals or comparables.

***K*-fold cross-validation** A technique in which data (excluding test sample and fresh data) are shuffled randomly and then are divided into k equal sub-samples, with $k - 1$ samples used as training samples and one sample, the kth, used as a validation sample.

***K*-means** A clustering algorithm that repeatedly partitions observations into a fixed number, k, of non-overlapping clusters.

***K*-nearest neighbor** A supervised learning technique that classifies a new observation by finding similarities ("nearness") between this new observation and the existing data.

Kalotay–Williams–Fabozzi (KWF) model An arbitrage-free term structure model that describes the dynamics of the log of the short rate and assumes constant drift, no mean reversion, and constant volatility.

Key rate durations Sensitivity of a bond's price to changes in specific maturities on the benchmark yield curve. Also called *partial durations*.

***k*th-order autocorrelation** The correlation between observations in a time series separated by k periods.

Labeled dataset A dataset that contains matched sets of observed inputs or features (X's) and the associated output or target (Y).

Labor force Everyone of working age (ages 16 to 64) who either is employed or is available for work but not working.

Labor force participation rate The percentage of the working age population that is in the labor force.

Labor productivity The quantity of real GDP produced by an hour of labor. More generally, output per unit of labor input.

Labor productivity growth accounting equation States that potential GDP growth equals the growth rate of the labor input plus the growth rate of labor productivity.

Lack of marketability discount An extra return to investors to compensate for lack of a public market or lack of marketability.

LASSO Least absolute shrinkage and selection operator is a type of penalized regression which involves minimizing the sum of the absolute values of the regression coefficients. LASSO can also be used for regularization in neural networks.

Latency The elapsed time between the occurrence of an event and a subsequent action that depends on that event.

Law of one price A principle that states that if two investments have the same or equivalent future cash flows regardless of what will happen in the future, then these two investments should have the same current price.

Leading dividend yield Forecasted dividends per share over the next year divided by current stock price.

Leading P/E A P/E calculated on the basis of a forecast of EPS; a stock's current price divided by next year's expected earnings.

Learning curve A curve that plots the accuracy rate (= 1 – error rate) in the validation or test samples (i.e., out-of-sample) against the amount of data in the training sample, which is thus useful for describing under- and overfitting as a function of bias and variance errors.

Learning rate A parameter that affects the magnitude of adjustments in the weights in a neural network.

Level One of the three factors (the other two are steepness and curvature) that empirically explain most yield curve shape changes. A shock to the level factor changes the yield for all maturities by an almost identical amount.

Leveraged buyout A transaction whereby the target company management team converts the target to a privately held company by using heavy borrowing to finance the purchase of the target company's outstanding shares.

Leveraged recapitalization A post-offer takeover defense mechanism that involves the assumption of a large amount of debt that is then used to finance share repurchases. The effect is to dramatically change the company's capital structure while attempting to deliver a value to target shareholders in excess of a hostile bid.

Libor–OIS spread The difference between Libor and the overnight indexed swap rate.

Limit order book The book or list of limit orders to buy and sell that pertains to a security.

Lin-log model A regression model in which the independent variable is in logarithmic form.

Linear classifier A binary classifier that makes its classification decision based on a linear combination of the features of each data point.

Linear regression Regression that models the straight-line relationship between the dependent and independent variables. Also known as *least squares regression* and *ordinary least squares regression*.

Linear trend A trend in which the dependent variable changes at a constant rate with time.

Liquidating dividend A dividend that is a return of capital rather than a distribution from earnings or retained earnings.

Liquidation To sell the assets of a company, division, or subsidiary piecemeal, typically because of bankruptcy; the form of bankruptcy that allows for the orderly satisfaction of creditors' claims after which the company ceases to exist.

Liquidation value The value of a company if the company were dissolved and its assets sold individually.

Liquidity preference theory A term structure theory that asserts liquidity premiums exist to compensate investors for the added interest rate risk they face when lending long term.

Liquidity premium The premium or incrementally higher yield that investors demand for lending long term.

Local currency The currency of the country where a company is located.

Local expectations theory A term structure theory that contends the return for all bonds over short periods is the risk-free rate.

Log-lin model A regression model in which the dependent variable is in logarithmic form.

Log-linear model With reference to time-series models, a model in which the growth rate of the time series as a function of time is constant.

Log-log model A regression model in which both the dependent and independent variables are in logarithmic form. Also known as the *double-log model*.

Log-log regression model A regression that expresses the dependent and independent variables as natural logarithms.

Logistic regression (logit model) A qualitative-dependent-variable multiple regression model based on the logistic probability distribution.

Long/short credit trade A credit protection seller with respect to one entity combined with a credit protection buyer with respect to another entity.

Look-ahead bias The bias created by using information that was unknown or unavailable in the time periods over which backtesting is conducted, such as company earnings and macroeconomic indicator values.

Lookback period The time period used to gather a historical data set.

Loss given default The amount that will be lost if a default occurs.

Macroeconomic factor model A multifactor model in which the factors are surprises in macroeconomic variables that significantly explain equity returns.

Macroeconomic factors Factors related to the economy, such as the inflation rate, industrial production, or economic sector membership.

Maintenance capital expenditures Capital expenditures needed to maintain operations at the current level.

Majority shareholders Shareholders that own more than 50% of a corporation's shares.

Majority-vote classifier A classifier that assigns to a new data point the predicted label with the most votes (i.e., occurrences).

Managerialism theories Theories that posit that corporate executives are motivated to engage in mergers to maximize the size of their company rather than shareholder value (a form of agency cost).

Marginal VaR (MVaR) A measure of the effect of a small change in a position size on portfolio VaR.

Market approach Valuation approach that values an asset based on pricing multiples from sales of assets viewed as similar to the subject asset.

Market conversion premium per share For a convertible bond, the difference between the market conversion price and the underlying share price, which allows investors to identify the premium or discount payable when buying a convertible bond rather than the underlying common stock.

Market conversion premium ratio For a convertible bond, the market conversion premium per share expressed as a percentage of the current market price of the shares.

Market efficiency A finance perspective on capital markets that deals with the relationship of price to intrinsic value. The **traditional efficient markets formulation** asserts that an asset's price is the best available estimate of its intrinsic value. The **rational efficient markets formulation** asserts that investors should expect to be rewarded for the costs of information gathering and analysis by higher gross returns.

Market fragmentation Trading the same instrument in multiple venues.

Market impact The effect of the trade on transaction prices. Also called *price impact.*

Market timing Asset allocation in which the investment in the market is increased if one forecasts that the market will outperform T-bills.

Market value of invested capital The market value of debt and equity.

Mature growth rate The earnings growth rate in a company's mature phase; an earnings growth rate that can be sustained long term.

Maximum drawdown The worst cumulative loss ever sustained by an asset or portfolio. More specifically, maximum drawdown is the difference between an asset's or a portfolio's maximum cumulative return and its subsequent lowest cumulative return.

Mean reversion The tendency of a time series to fall when its level is above its mean and rise when its level is below its mean; a mean-reverting time series tends to return to its long-term mean.

Mean square error (MSE) The sum of squares error divided by the degrees of freedom, $n - k - 1$; in a simple linear regression, $n - k - 1 = n - 2$.

Mean square regression (MSR) The sum of squares regression divided by the number of independent variables k; in a simple linear regression, $k = 1$.

Merger The absorption of one company by another; two companies become one entity and one or both of the pre-merger companies ceases to exist as a separate entity.

Metadata Data that describes and gives information about other data.

Method based on forecasted fundamentals An approach to using price multiples that relates a price multiple to forecasts of fundamentals through a discounted cash flow model.

Method of comparables An approach to valuation that involves using a price multiple to evaluate whether an asset is relatively fairly valued, relatively undervalued, or relatively overvalued when compared to a benchmark value of the multiple.

Midquote price The average, or midpoint, of the prevailing bid and ask prices.

Minority interest The proportion of the ownership of a subsidiary not held by the parent (controlling) company.

Minority shareholders Shareholders that own less than 50% of a corporation's shares.

Mispricing Any departure of the market price of an asset from the asset's estimated intrinsic value.

Mixed offering A merger or acquisition that is to be paid for with cash, securities, or some combination of the two.

Model specification With reference to regression, the set of variables included in the regression and the regression equation's functional form.

Molodovsky effect The observation that P/Es tend to be high on depressed EPS at the bottom of a business cycle and tend to be low on unusually high EPS at the top of a business cycle.

Momentum indicators Valuation indicators that relate either price or a fundamental (such as earnings) to the time series of their own past values (or in some cases to their expected value).

Monetary assets and liabilities Assets and liabilities with value equal to the amount of currency contracted for, a fixed amount of currency. Examples are cash, accounts receivable, accounts payable, bonds payable, and mortgages payable. Inventory is not a monetary asset. Most liabilities are monetary.

Monetary/non-monetary method Approach to translating foreign currency financial statements for consolidation in which monetary assets and liabilities are translated at the current exchange rate. Non-monetary assets and liabilities are translated at historical exchange rates (the exchange rates that existed when the assets and liabilities were acquired).

Monetizing Unwinding a position to either capture a gain or realize a loss.

Monitoring costs Costs borne by owners to monitor the management of the company (e.g., board of director expenses).

Monte Carlo simulation A technique that uses the inverse transformation method for converting a randomly generated uniformly distributed number into a simulated value of a random variable of a desired distribution. Each key decision variable in a Monte Carlo simulation requires an assumed statistical distribution; this assumption facilitates incorporating non-normality, fat tails, and tail dependence as well as solving high-dimensionality problems.

Mortgages Loans with real estate serving as collateral for the loans.

Multicollinearity A regression assumption violation that occurs when two or more independent variables (or combinations of independent variables) are highly but not perfectly correlated with each other.

Multiple linear regression Linear regression involving two or more independent variables.

Multiple linear regression model A linear regression model with two or more independent variables.

Mutual information Measures how much information is contributed by a token to a class of texts. MI will be 0 if the token's distribution in all text classes is the same. MI approaches 1 as the token in any one class tends to occur more often in only that particular class of text.

Mutually exclusive projects Mutually exclusive projects compete directly with each other. For example, if Projects A and B are mutually exclusive, you can choose A or B, but you cannot choose both.

N-grams A representation of word sequences. The length of a sequence varies from 1 to n. When one word is used, it is a unigram; a two-word sequence is a bigram; and a 3-word sequence is a trigram; and so on.

***n*-Period moving average** The average of the current and immediately prior $n - 1$ values of a time series.

Naked credit default swap A position where the owner of the CDS does not have a position in the underlying credit.

Name entity recognition An algorithm that analyzes individual tokens and their surrounding semantics while referring to its dictionary to tag an object class to the token.

Negative serial correlation Serial correlation in which a positive error for one observation increases the chance of a negative error for another observation, and vice versa.

Net asset balance sheet exposure When assets translated at the current exchange rate are greater in amount than liabilities translated at the current exchange rate. Assets exposed to translation gains or losses exceed the exposed liabilities.

Net asset value The difference between assets and liabilities, all taken at current market values instead of accounting book values.

Net asset value per share Net asset value divided by the number of shares outstanding.

Net lease A lease under which the tenant pays a net rent to the landlord and an additional amount based on the tenant's pro rata share of the operating costs, utilities, maintenance expenses, and real estate taxes relating to the property.

Net liability balance sheet exposure When liabilities translated at the current exchange rate are greater assets translated at the current exchange rate. Liabilities exposed to translation gains or losses exceed the exposed assets.

Net operating income Gross rental revenue minus operating costs but before deducting depreciation, corporate overhead, and interest expense. In the context of real estate, a measure of the income from the property after deducting operating expenses for such items as property taxes, insurance, maintenance, utilities, repairs, and insurance but before deducting any costs associated with financing and before deducting federal income taxes. It is similar to EBITDA in a financial reporting context.

Net regulatory burden The private costs of regulation less the private benefits of regulation.

Network externalities The impact that users of a good, a service, or a technology have on other users of that product; it can be positive (e.g., a critical mass of users makes a product more useful) or negative (e.g., congestion makes the product less useful).

Neural networks Highly flexible machine learning algorithms that have been successfully applied to a variety of supervised and unsupervised tasks characterized by nonlinearities and interactions among features.

No-arbitrage approach A procedure for obtaining the value of an option based on the creation of a portfolio that replicates the payoffs of the option and deriving the option value from the value of the replicating portfolio.

No-growth company A company without positive expected net present value projects.

No-growth value per share The value per share of a no-growth company, equal to the expected level amount of earnings divided by the stock's required rate of return.

Non-cash rent An amount equal to the difference between the average contractual rent over a lease term (the straight-line rent) and the cash rent actually paid during a period. This figure is one of the deductions made from FFO to calculate AFFO.

Non-convergence trap A situation in which a country remains relatively poor, or even falls further behind, because it fails to implement necessary institutional reforms and/or adopt leading technologies.

Non-monetary assets and liabilities Assets and liabilities that are not monetary assets and liabilities. Non-monetary assets include inventory, fixed assets, and intangibles, and non-monetary liabilities include deferred revenue.

Non-renewable resources Finite resources that are depleted once they are consumed; oil and coal are examples.

Non-residential properties Commercial real estate properties other than multi-family properties, farmland, and timberland.

Nonearning assets Cash and investments (specifically cash, cash equivalents, and short-term investments).

Nonstationarity With reference to a random variable, the property of having characteristics, such as mean and variance, that are not constant through time.

Normal EPS The EPS that a business could achieve currently under mid-cyclical conditions. Also called *normalized EPS*.

Normalized earnings The expected level of mid-cycle earnings for a company in the absence of any unusual or temporary factors that affect profitability (either positively or negatively).

Normalized EPS The EPS that a business could achieve currently under mid-cyclical conditions. Also called *normal EPS*.

Normalized P/E P/E based on normalized EPS data.

Notional amount The amount of protection being purchased in a CDS.

NTM P/E Next 12-month P/E: current market price divided by an estimated next 12-month EPS.

Off-the-run A series of securities or indexes that were issued/created prior to the most recently issued/created series.

On-the-run The most recently issued/created series of securities or indexes.

One hot encoding The process by which categorical variables are converted into binary form (0 or 1) for machine reading. It is one of the most common methods for handling categorical features in text data.

One-sided durations Effective durations when interest rates go up or down, which are better at capturing the interest rate sensitivity of bonds with embedded options that do not react symmetrically to positive and negative changes in interest rates of the same magnitude.

One-tier board Board structure consisting of a single board of directors, composed of executive (internal) and non-executive (external) directors.

Opportunity cost The value that investors forgo by choosing a particular course of action; the value of something in its best alternative use.

Optimal capital structure The capital structure at which the value of the company is maximized.

Option-adjusted spread (OAS) Constant spread that, when added to all the one-period forward rates on the interest rate tree, makes the arbitrage-free value of the bond equal to its market price.

Orderly liquidation value The estimated gross amount of money that could be realized from the liquidation sale of an asset or assets, given a reasonable amount of time to find a purchaser or purchasers.

Organic growth Company growth in output or sales that is achieved by making investments internally (i.e., excludes growth achieved through mergers and acquisitions).

Other comprehensive income Changes to equity that bypass (are not reported in) the income statement; the difference between comprehensive income and net income.

Other post-employment benefits Promises by the company to pay benefits in the future, such as life insurance premiums and all or part of health care insurance for its retirees.

Out-of-sample forecast errors The differences between actual and predicted values of time series outside the sample period used to fit the model.

Overfitting When a model fits the training data too well and so does not generalize well to new data.

Overnight indexed swap (OIS) rate An interest rate swap in which the periodic floating rate of the swap equals the geometric average of a daily unsecured overnight rate (or overnight index rate).

Pairs trading An approach to trading that uses pairs of closely related stocks, buying the relatively undervalued stock and selling short the relatively overvalued stock.

Par curve A hypothetical yield curve for coupon-paying Treasury securities that assumes all securities are priced at par.

Par swap A swap in which the fixed rate is set so that no money is exchanged at contract initiation.

Parametric method A method of estimating VaR that uses the historical mean, standard deviation, and correlation of security price movements to estimate the portfolio VaR. Generally assumes a normal distribution but can be adapted to non-normal distributions with the addition of skewness and kurtosis. Sometimes called the *variance–covariance method* or the *analytical method*.

Partial regression coefficients The slope coefficients in a multiple regression. Also called *partial slope coefficients*.

Partial slope coefficients The slope coefficients in a multiple regression. Also called *partial regression coefficients*.

Parts of speech An algorithm that uses language structure and dictionaries to tag every token in the text with a corresponding part of speech (i.e., noun, verb, adjective, proper noun, etc.).

Payout amount The loss given default times the notional.

Payout policy The principles by which a company distributes cash to common shareholders by means of cash dividends and/or share repurchases.

Payouts Cash dividends and the value of shares repurchased in any given year.

Pecking order theory The theory that managers consider how their actions might be interpreted by outsiders and thus order their preferences for various forms of corporate financing. Forms of financing that are least visible to outsiders (e.g., internally generated funds) are most preferable to managers and those that are most visible (e.g., equity) are least preferable.

PEG ratio The P/E-to-growth ratio, calculated as the stock's P/E divided by the expected earnings growth rate.

Penalized regression A regression that includes a constraint such that the regression coefficients are chosen to minimize the sum of squared residuals *plus* a penalty term that increases in size with the number of included features.

Pension obligation The present value of future benefits earned by employees for service provided to date.

Perfect capital markets Markets in which, by assumption, there are no taxes, transaction costs, or bankruptcy costs and in which all investors have equal ("symmetric") information.

Perpetuity A perpetual annuity, or a set of never-ending level sequential cash flows, with the first cash flow occurring one period from now.

Persistent earnings Earnings excluding nonrecurring components. Also referred to as *core earnings*, *continuing earnings*, or *underlying earnings*.

Pet projects Projects in which influential managers want the corporation to invest. Often, unfortunately, pet projects are selected without undergoing normal capital budgeting analysis.

Physical settlement Involves actual delivery of the debt instrument in exchange for a payment by the credit protection seller of the notional amount of the contract.

Point-in-time data Data consisting of the exact information available to market participants as of a given point in time. Point-in-time data is used to address look-ahead bias.

Poison pill A pre-offer takeover defense mechanism that makes it prohibitively costly for an acquirer to take control of a target without the prior approval of the target's board of directors.

Poison puts A pre-offer takeover defense mechanism that gives target company bondholders the right to sell their bonds back to the target at a pre-specified redemption price, typically at or above par value; this defense increases the need for cash and raises the cost of the acquisition.

Portfolio balance approach A theory of exchange rate determination that emphasizes the portfolio investment decisions of global investors and the requirement that global investors willingly hold all outstanding securities denominated in each currency at prevailing prices and exchange rates.

Positive serial correlation Serial correlation in which a positive error for one observation increases the chance of a positive error for another observation; a negative error for one observation increases the chance of a negative error for another observation.

Potential GDP The maximum amount of output an economy can sustainably produce without inducing an increase in the inflation rate. The output level that corresponds to full employment with consistent wage and price expectations.

Precision In error analysis for classification problems it is ratio of correctly predicted positive classes to all predicted positive classes. Precision is useful in situations where the cost of false positives (FP), or Type I error, is high.

Preferred habitat theory A term structure theory that contends that investors have maturity preferences and require yield incentives before they will buy bonds outside of their preferred maturities.

Premise of value The status of a company in the sense of whether it is assumed to be a going concern or not.

Premium leg The series of payments the credit protection buyer promises to make to the credit protection seller.

Premiums Amounts paid by the purchaser of insurance products.

Present value model A model of intrinsic value that views the value of an asset as the present value of the asset's expected future cash flows.

Present value of growth opportunities The difference between the actual value per share and the no-growth value per share. Also called *value of growth*.

Presentation currency The currency in which financial statement amounts are presented.

Price improvement When trade execution prices are better than quoted prices.

Price momentum A valuation indicator based on past price movement.

Price multiples The ratio of a stock's market price to some measure of value per share.

Price-setting option The operational flexibility to adjust prices when demand varies from what is forecast. For example, when demand exceeds capacity, the company could benefit from the excess demand by increasing prices.

Price-to-earnings ratio (P/E) The ratio of share price to earnings per share.

Priced risk Risk for which investors demand compensation for bearing (e.g., equity risk, company-specific factors, macroeconomic factors).

Principal components analysis (PCA) An unsupervised ML technique used to transform highly correlated features of data into a few main, uncorrelated composite variables.

Principle of no arbitrage In well-functioning markets, prices will adjust until there are no arbitrage opportunities.

Prior transaction method A variation of the market approach; considers actual transactions in the stock of the subject private company.

Private market value The value derived using a sum-of-the-parts valuation.

Probability of default The probability that a bond issuer will not meet its contractual obligations on schedule.

Probability of survival The probability that a bond issuer will meet its contractual obligations on schedule.

Procedural law The body of law that focuses on the protection and enforcement of the substantive laws.

Production-flexibility option The operational flexibility to alter production when demand varies from forecast. For example, if demand is strong, a company may profit from employees working overtime or from adding additional shifts.

Project sequencing To defer the decision to invest in a future project until the outcome of some or all of a current project is known. Projects are sequenced through time, so that investing in a project creates the option to invest in future projects.

Projection error The vertical (perpendicular) distance between a data point and a given principal component.

Prospective P/E A P/E calculated on the basis of a forecast of EPS; a stock's current price divided by next year's expected earnings.

Protection leg The contingent payment that the credit protection seller may have to make to the credit protection buyer.

Protection period Period during which a bond's issuer cannot call the bond.

Provision for loan losses An income statement expense account that increases the amount of the allowance for loan losses.

Proxy fight An attempt to take control of a company through a shareholder vote.

Proxy statement A public document that provides the material facts concerning matters on which shareholders will vote.

Prudential supervision Regulation and monitoring of the safety and soundness of financial institutions to promote financial stability, reduce system-wide risks, and protect customers of financial institutions.

Pruning A regularization technique used in CART to reduce the size of the classification or regression tree—by pruning, or removing, sections of the tree that provide little classifying power.

Purchasing power gain A gain in value caused by changes in price levels. Monetary liabilities experience purchasing power gains during periods of inflation.

Purchasing power loss A loss in value caused by changes in price levels. Monetary assets experience purchasing power loss during periods of inflation.

Purchasing power parity (PPP) The idea that exchange rates move to equalize the purchasing power of different currencies.

Pure expectations theory A term structure theory that contends the forward rate is an unbiased predictor of the future spot rate. Also called the *unbiased expectations theory*.

Pure factor portfolio A portfolio with sensitivity of 1 to the factor in question and a sensitivity of 0 to all other factors.

Putable bond Bond that includes an embedded put option, which gives the bondholder the right to put back the bonds to the issuer prior to maturity, typically when interest rates have risen and higher-yielding bonds are available.

Qualitative dependent variables Dummy variables used as dependent variables rather than as independent variables.

Quality of earnings analysis The investigation of issues relating to the accuracy of reported accounting results as reflections of economic performance. Quality of earnings analysis is broadly understood to include not only earnings management but also balance sheet management.

Random forest classifier A collection of a large number of decision trees trained via a bagging method.

Random walk A time series in which the value of the series in one period is the value of the series in the previous period plus an unpredictable random error.

Rational efficient markets formulation See *market efficiency.*

Readme files Text files provided with raw data that contain information related to a data file. They are useful for understanding the data and how they can be interpreted correctly.

Real estate investment trusts Tax-advantaged entities (companies or trusts) that own, operate, and—to a limited extent—develop income-producing real estate property.

Real estate operating companies Regular taxable real estate ownership companies that operate in the real estate industry in countries that do not have a tax-advantaged REIT regime in place or that are engage in real estate activities of a kind and to an extent that do not fit in their country's REIT framework.

Real interest rate parity The proposition that real interest rates will converge to the same level across different markets.

Real options Options that relate to investment decisions such as the option to time the start of a project, the option to adjust its scale, or the option to abandon a project that has begun.

Rebalance return A return from rebalancing the component weights of an index.

Recall Also known as *sensitivity*, in error analysis for classification problems it is the ratio of correctly predicted positive classes to all actual positive classes. Recall is useful in situations where the cost of false negatives (FN), or Type II error, is high.

Reconstitution When dealers recombine appropriate individual zero-coupon securities and reproduce an underlying coupon Treasury.

Recovery rate The percentage of the loss recovered.

Redemption basket The list of securities (and share amounts) the authorized participant (AP) receives when it redeems ETF shares back to the ETF manager. The redemption basket is published each business day.

Reference entity The borrower (debt issuer) covered by a single-name CDS.

Reference obligation A particular debt instrument issued by the borrower that is the designated instrument being covered.

Regime With reference to a time series, the underlying model generating the times series.

Regression analysis A tool for examining whether a variable is useful for explaining another variable.

Regression coefficients The intercept and slope coefficient(s) of a regression.

Regular expression (regex) A series of texts that contains characters in a particular order. Regex is used to search for patterns of interest in a given text.

Regularization A term that describes methods for reducing statistical variability in high-dimensional data estimation problems.

Regulatory arbitrage Entities identify and use some aspect of regulations that allows them to exploit differences in economic substance and regulatory interpretation or in foreign and domestic regulatory regimes to their (the entities') advantage.

Regulatory burden The costs of regulation for the regulated entity.

Regulatory capture Theory that regulation often arises to enhance the interests of the regulated.

Regulatory competition Regulators may compete to provide a regulatory environment designed to attract certain entities.

Reinforcement learning Machine learning in which a computer learns from interacting with itself or data generated by the same algorithm.

Relative-strength indicators Valuation indicators that compare a stock's performance during a period either to its own past performance or to the performance of some group of stocks.

Relative valuation models A model that specifies an asset's value relative to the value of another asset.

Relative VaR See *ex ante tracking error*.

Relative version of PPP The hypothesis that changes in (nominal) exchange rates over time are equal to national inflation rate differentials.

Renewable resources Resources that can be replenished, such as a forest.

Rental price of capital The cost per unit of time to rent a unit of capital.

Repeat sales index As the name implies, this type of index relies on repeat sales of the same property. In general, the idea supporting this type of index is that because it is the same property that sold twice, the change in value between the two sale dates indicates how market conditions have changed over time.

Replacement cost In the context of real estate, the value of a building assuming it was built today using current construction costs and standards.

Reporting unit For financial reporting under US GAAP, an operating segment or one level below an operating segment (referred to as a component).

Required rate of return The minimum rate of return required by an investor to invest in an asset, given the asset's riskiness.

Residential properties Properties that provide housing for individuals or families. Single-family properties may be owner-occupied or rental properties, whereas multi-family properties are rental properties even if the owner or manager occupies one of the units.

Residual The difference between an observation and its predicted value, where the predicted value is based on the estimated linear relation between the dependent and independent variables using sample data.

Residual autocorrelations The sample autocorrelations of the residuals.

Residual income Earnings for a given period, minus a deduction for common shareholders' opportunity cost in generating the earnings. Also called *economic profit* or *abnormal earnings*.

Residual income method Income approach that estimates the value of all intangible assets of the business by capitalizing future earnings in excess of the estimated return requirements associated with working capital and fixed assets.

Residual income model (RIM) A model of stock valuation that views intrinsic value of stock as the sum of book value per share plus the present value of the stock's expected future residual income per share. Also called *discounted abnormal earnings model* or *Edwards–Bell–Ohlson model*.

Residual loss Agency costs that are incurred despite adequate monitoring and bonding of management.

Restructuring Reorganizing the capital structure of a firm.

Return on capital employed Operating profit divided by capital employed (debt and equity capital).

Return on invested capital A measure of the after-tax profitability of the capital invested by the company's shareholders and debtholders.

Reverse carry arbitrage A strategy involving the short sale of the underlying and an offsetting opposite position in the derivative.

Reverse stock split A reduction in the number of shares outstanding with a corresponding increase in share price but no change to the company's underlying fundamentals.

Reverse stress testing A risk management approach in which the user identifies key risk exposures in the portfolio and subjects those exposures to extreme market movements.

Reviewed financial statements A type of non-audited financial statements; typically provide an opinion letter with representations and assurances by the reviewing accountant that are less than those in audited financial statements.

Rho The change in a given derivative instrument for a given small change in the risk-free interest rate, holding everything else constant. Rho measures the sensitivity of the option to the risk-free interest rate.

Risk budgeting The allocation of an asset owner's total risk appetite among groups or divisions (in the case of a trading organization) or among strategies and managers (in the case of an institutional or individual investor).

Risk decomposition The process of converting a set of holdings in a portfolio into a set of exposures to risk factors.

Risk factors Variables or characteristics with which individual asset returns are correlated. Sometimes referred to simply as *factors*.

Risk parity A portfolio allocation scheme that weights stocks or factors based on an equal risk contribution.

Robust standard errors Standard errors of the estimated parameters of a regression that correct for the presence of heteroskedasticity in the regression's error term.

Roll When an investor moves its investment position from an older series to the most current series.

Roll return The component of the return on a commodity futures contract attributable to rolling long futures positions forward through time. Also called *roll yield*.

Rolling down the yield curve A maturity trading strategy that involves buying bonds with a maturity longer than the intended investment horizon. Also called *riding the yield curve*.

Rolling windows A backtesting method that uses a rolling-window (or walk-forward) framework, rebalances the portfolio after each period, and then tracks performance over time. As new information arrives each period, the investment manager optimizes (revises and tunes) the model and readjusts stock positions.

Root mean squared error (RMSE) The square root of the average squared forecast error; used to compare the out-of-sample forecasting performance of forecasting models.

Sale-leaseback A situation in which a company sells the building it owns and occupies to a real estate investor and the company then signs a long-term lease with the buyer to continue to occupy the building. At the end of the lease, use of the property reverts to the landlord.

Sales comparison approach In the context of real estate, this approach estimates value based on what similar or comparable properties (comparables) transacted for in the current market.

Scaled earnings surprise Unexpected earnings divided by the standard deviation of analysts' earnings forecasts.

Scaling The process of adjusting the range of a feature by shifting and changing the scale of the data. Two of the most common ways of scaling are normalization and standardization.

Scatter plot A chart in which two variables are plotted along the axis and points on the chart represent pairs of the two variables. In regression, the dependent variable is plotted on the vertical axis and the independent variable is plotted along the horizontal axis. Also known as a scattergram and a *scatter diagram*.

Scenario analysis A technique for exploring the performance and risk of investment strategies in different structural regimes.

Scree plots A plot that shows the proportion of total variance in the data explained by each principal component.

Screening The application of a set of criteria to reduce a set of potential investments to a smaller set having certain desired characteristics.

Seasonality A characteristic of a time series in which the data experience regular and predictable periodic changes; for example, fan sales are highest during the summer months.

Secured overnight financing rate (SOFR) A daily volume-weighted index of rates on qualified cash borrowings collateralized by US Treasuries that is expected to replace Libor as a floating reference rate for swaps.

Securities offering A merger or acquisition in which target shareholders are to receive shares of the acquirer's common stock as compensation.

Security selection risk See *active specific risk*.

Segmented markets theory A term structure theory that contends yields are solely a function of the supply and demand for funds of a particular maturity.

Self-regulating organizations (SROs) Self-regulating bodies that are given recognition and authority, including enforcement power, by a government body or agency.

Self-regulatory bodies Private, non-governmental organizations that both represent and regulate their members. Some self-regulating organizations are also independent regulators.

Sell-side analysts Analysts who work at brokerages.

Sensitivity analysis A technique for exploring how a target variable (e.g., portfolio returns) and risk profiles are affected by changes in input variables (e.g., the distribution of asset or factor returns).

Sentence length The number of characters, including spaces, in a sentence.

Serially correlated With reference to regression errors, errors that are correlated across observations.

Service period For employee stock options, usually the period between the grant date and the vesting date.

Settled in arrears An arrangement in which the interest payment is made (i.e., settlement occurs) at the maturity of the underlying instrument.

Settlement In the case of a credit event, the process by which the two parties to a CDS contract satisfy their respective obligations.

Shaping risk The sensitivity of a bond's price to the changing shape of the yield curve.

Share repurchase A transaction in which a company buys back its own shares. Unlike stock dividends and stock splits, share repurchases use corporate cash.

Shareholder activism Strategies used by shareholders to attempt to compel a company to act in a desired manner.

Shareholders' equity Total assets minus total liabilities.

Shark repellents A pre-offer takeover defense mechanism involving the corporate charter (e.g., staggered boards of directors and supermajority provisions).

Simple linear regression (SLR) A regression that summarizes the relation between the dependent variable and a single independent variable.

Simulation A technique for exploring how a target variable (e.g. portfolio returns) would perform in a hypothetical environment specified by the user, rather than a historical setting.

Single-name CDS Credit default swap on one specific borrower.

Sinking fund bond A bond that requires the issuer to set aside funds over time to retire the bond issue, thus reducing credit risk.

Slope coefficient The coefficient of an independent variable that represents the average change in the dependent variable for a one-unit change in the independent variable.

Soft margin classification An adaptation in the support vector machine algorithm which adds a penalty to the objective function for observations in the training set that are misclassified.

Special dividend A dividend paid by a company that does not pay dividends on a regular schedule or a dividend that supplements regular cash dividends with an extra payment.

Spin-off A form of restructuring in which shareholders of a parent company receive a proportional number of shares in a new, separate entity; shareholders end up owning stock in two different companies where there used to be one.

Split-off A form of restructuring in which shareholders of the parent company are given shares in a newly created entity in exchange for their shares of the parent company.

Split-rate tax system In reference to corporate taxes, a split-rate system taxes earnings to be distributed as dividends at a different rate than earnings to be retained. Corporate profits distributed as dividends are taxed at a lower rate than those retained in the business.

Spot curve The term structure of spot rates for loans made today.

Spot price The current price of an asset or security. For commodities, the current price to deliver a physical commodity to a specific location or purchase and transport it away from a designated location.

Spot rate The interest rate that is determined today for a risk-free, single-unit payment at a specified future date.

Spot yield curve The term structure of spot rates for loans made today.

Stabilized NOI In the context of real estate, the expected NOI when a renovation is complete.

Stable dividend policy A policy in which regular dividends are paid that reflect long-run expected earnings. In contrast to a constant dividend payout ratio policy, a stable dividend policy does not reflect short-term volatility in earnings.

Standard error of the estimate A measure of the fit of a regression line, calculated as the square root of the mean square error. Also known as the *standard error of the regression* and the *root mean square error*.

Standard error of the forecast A measure of the uncertainty associated with a forecasted value of the dependent variable that depends on the standard error of the estimate, the variability of the independent variable, the deviation of the forecasted independent variable from the mean in the regression, and the number of observations.

Standard error of the slope coefficient The standard error of the slope, which in a simple linear regression is the ratio of the model's standard error of the estimate (s_e) to the square root of the variation of the independent variable.

Standardized beta With reference to fundamental factor models, the value of the attribute for an asset minus the average value of the attribute across all stocks, divided by the standard deviation of the attribute across all stocks.

Standardized unexpected earnings Unexpected earnings per share divided by the standard deviation of unexpected earnings per share over a specified prior time period.

Static trade-off theory of capital structure A theory pertaining to a company's optimal capital structure. The optimal level of debt is found at the point where additional debt would cause the costs of financial distress to increase by a greater amount than the benefit of the additional tax shield.

Statistical factor model A multifactor model in which statistical methods are applied to a set of historical returns to determine portfolios that best explain either historical return covariances or variances.

Statutes Laws enacted by legislative bodies.

Statutory merger A merger in which one company ceases to exist as an identifiable entity and all its assets and liabilities become part of a purchasing company.

Steady-state rate of growth The constant growth rate of output (or output per capita) that can or will be sustained indefinitely once it is reached. Key ratios, such as the capital–output ratio, are constant on the steady-state growth path.

Steepness The difference between long-term and short-term yields that constitutes one of the three factors (the other two are level and curvature) that empirically explain most of the changes in the shape of the yield curve.

Stock dividend A type of dividend in which a company distributes additional shares of its common stock to shareholders instead of cash.

Stock purchase An acquisition in which the acquirer gives the target company's shareholders some combination of cash and securities in exchange for shares of the target company's stock.

Stop-loss limit Constraint used in risk management that requires a reduction in the size of a portfolio, or its complete liquidation, when a loss of a particular size occurs in a specified period.

Straight bond An underlying option-free bond with a specified issuer, issue date, maturity date, principal amount and repayment structure, coupon rate and payment structure, and currency denomination.

Straight-line rent The average annual rent under a multi-year lease agreement that contains contractual increases in rent during the life of the lease.

Straight-line rent adjustment See *non-cash rent.*

Straight voting Voting structure in which shareholders are granted the right of one vote for each share owned.

Stranded assets Assets that are obsolete or not economically viable.

Strategic transaction A purchase involving a buyer that would benefit from certain synergies associated with owning the target firm.

Stress tests A risk management technique that assesses the portfolio's response to extreme market movements.

Stripping A dealer's ability to separate a bond's individual cash flows and trade them as zero-coupon securities.

Subsidiary merger A merger in which the company being purchased becomes a subsidiary of the purchaser.

Substantive law The body of law that focuses on the rights and responsibilities of entities and relationships among entities.

Succession event A change of corporate structure of the reference entity, such as through a merger, a divestiture, a spinoff, or any similar action, in which ultimate responsibility for the debt in question is unclear.

Sum of squares error (SSE) The sum of the squared deviations of (1) the value of the dependent variable and (2) the value of the dependent variable based on the estimated regression line. Also referred to as the *residual sum of squares.*

Sum of squares regression (SSR) The sum of the squared deviations of (1) the value of the dependent variable based on the estimated regression line and (2) the mean of the dependent variable.

Sum of squares total (SST) The sum of the squared deviations of the dependent variable from its mean; the variation of the dependent variable. Also referred to as the *total sum of squares.*

Sum-of-the-parts valuation A valuation that sums the estimated values of each of a company's businesses as if each business were an independent going concern.

Summation operator A functional part of a neural network's node that multiplies each input value received by a weight and sums the weighted values to form the total net input, which is then passed to the activation function.

Supernormal growth Above-average or abnormally high growth rate in earnings per share.

Supervised learning Machine learning where algorithms infer patterns between a set of inputs (the *X*'s) and the desired output (*Y*). The inferred pattern is then used to map a given input set into a predicted output.

Support vector machine A linear classifier that determines the hyperplane that optimally separates the observations into two sets of data points.

Survivorship bias The bias that results when data as of a given date reflects only those entities that have survived to that date. Entities can include any element of an index or list that is constituted through time: stocks, investment funds, etc. Survivorship bias is a form of look-ahead bias.

Sustainable growth rate The rate of dividend (and earnings) growth that can be sustained over time for a given level of return on equity, keeping the capital structure constant and without issuing additional common stock.

Swap curve The term structure of swap rates.

Swap rate The "price" that swap traders quote among one another. It is the rate at which the present value of all the expected floating-rate payments received over the life of the floating-rate bond equal the present value of all the expected fixed-rate payments made over the life of the fixed-rate bond.

Swap rate curve The term structure of swap rates.

Swap spread The difference between the fixed rate on an interest rate swap and the rate on a Treasury note with equivalent maturity; it reflects the general level of credit risk in the market.

Systematic risk Risk that affects the entire market or economy; it cannot be avoided and is inherent in the overall market. Systematic risk is also known as non-diversifiable or market risk.

Systemic risk The risk of failure of the financial system.

Tail risk The risk that losses in extreme events could be greater than would be expected for a portfolio of assets with a normal distribution.

Takeover A merger; the term may be applied to any transaction but is often used in reference to hostile transactions.

Takeover premium The amount by which the takeover price for each share of stock must exceed the current stock price in order to entice shareholders to relinquish control of the company to an acquirer.

Tangible book value per share Common shareholders' equity minus intangible assets reported on the balance sheet, divided by the number of shares outstanding.

Target In machine learning, the dependent variable (*Y*) in a labeled dataset; the company in a merger or acquisition that is being acquired.

Target capital structure A company's chosen proportions of debt and equity.

Target company See *target.*

Target payout ratio A strategic corporate goal representing the long-term proportion of earnings that the company intends to distribute to shareholders as dividends.

Taxable REIT subsidiaries Subsidiaries that pay income taxes on earnings from non-REIT-qualifying activities like merchant development or third-party property management.

Technical indicators Momentum indicators based on price.

TED spread A measure of perceived credit risk determined as the difference between Libor and the T-bill yield of matching maturity.

Temporal method A variation of the monetary/non-monetary translation method that requires not only monetary assets and liabilities, but also non-monetary assets and liabilities that are measured at their current value on the balance sheet date to be translated at the current exchange rate. Assets and liabilities are translated at rates consistent with the timing of their measurement value. This method is typically used when the functional currency is other than the local currency.

Tender offer A public offer whereby the acquirer invites target shareholders to submit ("tender") their shares in return for the proposed payment.

Term frequency (TF) Ratio of the number of times a given token occurs in all the texts in the dataset to the total number of tokens in the dataset.

Term premium The additional return required by lenders to invest in a bond to maturity net of the expected return from continually reinvesting at the short-term rate over that same time horizon.

Terminal price multiples The price multiple for a stock assumed to hold at a stated future time.

Terminal share price The share price at a particular point in the future.

Terminal value of the stock The analyst's estimate of a stock's value at a particular point in the future. Also called *continuing value of the stock*.

Test sample A data sample that is used to test a model's ability to predict well on new data.

Theta The change in a derivative instrument for a given small change in calendar time, holding everything else constant. Specifically, the theta calculation assumes nothing changes except calendar time. Theta also reflects the rate at which an option's time value decays.

Time series A set of observations on a variable's outcomes in different time periods.

Tobin's *q* The ratio of the market value of debt and equity to the replacement cost of total assets.

Token The equivalent of a word (or sometimes a character).

Tokenization The process of splitting a given text into separate tokens. Tokenization can be performed at the word or character level but is most commonly performed at word level.

Top-down approach With respect to forecasting, an approach that usually begins at the level of the overall economy. Forecasts are then made at more narrowly defined levels, such as sector, industry, and market for a specific product.

Total factor productivity (TFP) A multiplicative scale factor that reflects the general level of productivity or technology in the economy. Changes in total factor productivity generate proportional changes in output for any input combination.

Total invested capital The sum of market value of common equity, book value of preferred equity, and face value of debt.

Tracking error The standard deviation of the differences between a portfolio's returns and its benchmark's returns; a synonym of active risk. Also called *tracking risk*.

Tracking risk The standard deviation of the differences between a portfolio's returns and its benchmark's returns; a synonym of active risk. Also called *tracking error*.

Trailing dividend yield The reciprocal of current market price divided by the most recent annualized dividend.

Trailing P/E A stock's current market price divided by the most recent four quarters of EPS (or the most recent two semi-annual periods for companies that report interim data semi-annually). Also called *current P/E*.

Training sample A data sample that is used to train a model.

Tranche CDS A type of credit default swap that covers a combination of borrowers but only up to pre-specified levels of losses.

Transaction exposure The risk of a change in value between the transaction date and the settlement date of an asset of liability denominated in a foreign currency.

Treasury shares/stock Shares that were issued and subsequently repurchased by the company.

Trend A long-term pattern of movement in a particular direction.

Triangular arbitrage An arbitrage transaction involving three currencies that attempts to exploit inconsistencies among pairwise exchange rates.

Trimming Also called truncation, it is the process of removing extreme values and outliers from a dataset.

Triple-net leases Common leases in the United States and Canada that require each tenant to pay its share of the following three operating expenses: common area maintenance and repair expenses; property taxes; and building insurance costs. Also known as *NNN leases*.

Two-tier board Board structure consisting of a supervisory board that oversees a management board.

Unbiased expectations theory A term structure theory that contends the forward rate is an unbiased predictor of the future spot rate. Also called the *pure expectations theory*.

Unconditional heteroskedasticity Heteroskedasticity of the error term that is not correlated with the values of the independent variable(s) in the regression.

Uncovered interest rate parity The proposition that the expected return on an uncovered (i.e., unhedged) foreign currency (risk-free) investment should equal the return on a comparable domestic currency investment.

Underlying earnings Earnings excluding nonrecurring components. Also referred to as *continuing earnings*, *core earnings*, or *persistent earnings*.

Unexpected earnings The difference between reported EPS and expected EPS. Also referred to as an *earnings surprise*.

Unit root A time series that is not covariance stationary is said to have a unit root.

Unsupervised learning Machine learning that does not make use of labeled data.

Upfront payment The difference between the credit spread and the standard rate paid by the protection buyer if the standard rate is insufficient to compensate the protection seller. Also called *upfront premium*.

Upfront premium See *upfront payment*.

Upstream A transaction between two related companies, an investor company (or a parent company) and an associate company (or a subsidiary company) such that the associate company records a profit on its income statement. An example is a sale of inventory by the associate to the investor company or by a subsidiary to a parent company.

Validation sample A data sample that is used to validate and tune a model.

Valuation The process of determining the value of an asset or service either on the basis of variables perceived to be related to future investment returns or on the basis of comparisons with closely similar assets.

Value additivity An arbitrage opportunity when the value of the whole equals the sum of the values of the parts.

Value at risk (VaR) The minimum loss that would be expected a certain percentage of the time over a certain period of time given the assumed market conditions.

Value of growth The difference between the actual value per share and the no-growth value per share.

Variance error Describes how much a model's results change in response to new data from validation and test samples. Unstable models pick up noise and produce high variance error, causing overfitting and high out-of-sample error.

Vasicek model A partial equilibrium term structure model that assumes interest rates are mean reverting and interest rate volatility is constant.

Vega The change in a given derivative instrument for a given small change in volatility, holding everything else constant. A sensitivity measure for options that reflects the effect of volatility.

Venture capital investors Private equity investors in development-stage companies.

Vertical merger A merger involving companies at different positions of the same production chain; for example, a supplier or a distributor.

Vertical ownership Ownership structure in which a company or group that has a controlling interest in two or more holding companies, which in turn have controlling interests in various operating companies.

Vested benefit obligation The actuarial present value of vested benefits.

Vesting date The date that employees can first exercise stock options.

Visibility The extent to which a company's operations are predictable with substantial confidence.

Voting caps Legal restrictions on the voting rights of large share positions.

Web spidering (scraping or crawling) programs Programs that extract raw content from a source, typically web pages.

Weighted average cost of capital (WACC) A weighted average of the after-tax required rates of return on a company's common stock, preferred stock, and long-term debt, where the weights are the fraction of each source of financing in the company's target capital structure.

Weighted harmonic mean See *harmonic mean*.

White-corrected standard errors A synonym for robust standard errors.

White knight A third party that is sought out by the target company's board to purchase the target in lieu of a hostile bidder.

White squire A third party that is sought out by the target company's board to purchase a substantial minority stake in the target—enough to block a hostile takeover without selling the entire company.

Winner's curse The tendency for the winner in certain competitive bidding situations to overpay, whether because of overestimation of intrinsic value, emotion, or information asymmetries.

Winsorization The process of replacing extreme values and outliers in a dataset with the maximum (for large value outliers) and minimum (for small value outliers) values of data points that are not outliers.

Write-down A reduction in the value of an asset as stated in the balance sheet.

Yield curve factor model A model or a description of yield curve movements that can be considered realistic when compared with historical data.

Zero A bond that does not pay a coupon but is priced at a discount and pays its full face value at maturity.

Zero-coupon bond A bond that does not pay a coupon but is priced at a discount and pays its full face value at maturity.

WILEY

CONTENTS

How to Use the CFA Program Curriculum

Congratulations on your decision to enter the Chartered Financial Analyst (CFA®) Program. This exciting and rewarding program of study reflects your desire to become a serious investment professional. You are embarking on a program noted for its high ethical standards and the breadth of knowledge, skills, and abilities (competencies) it develops. Your commitment should be educationally and professionally rewarding.

The credential you seek is respected around the world as a mark of accomplishment and dedication. Each level of the program represents a distinct achievement in professional development. Successful completion of the program is rewarded with membership in a prestigious global community of investment professionals. CFA charterholders are dedicated to life-long learning and maintaining currency with the ever-changing dynamics of a challenging profession. CFA Program enrollment represents the first step toward a career-long commitment to professional education.

The CFA exam measures your mastery of the core knowledge, skills, and abilities required to succeed as an investment professional. These core competencies are the basis for the Candidate Body of Knowledge (CBOK™). The CBOK consists of four components:

- A broad outline that lists the major CFA Program topic areas (www.cfainstitute.org/programs/cfa/curriculum/cbok);
- Topic area weights that indicate the relative exam weightings of the top-level topic areas (www.cfainstitute.org/programs/cfa/curriculum);
- Learning outcome statements (LOS) that advise candidates about the specific knowledge, skills, and abilities they should acquire from readings covering a topic area (LOS are provided in candidate study sessions and at the beginning of each reading); and
- CFA Program curriculum that candidates receive upon exam registration.

Therefore, the key to your success on the CFA exams is studying and understanding the CBOK. The following sections provide background on the CBOK, the organization of the curriculum, features of the curriculum, and tips for designing an effective personal study program.

BACKGROUND ON THE CBOK

CFA Program is grounded in the practice of the investment profession. CFA Institute performs a continuous practice analysis with investment professionals around the world to determine the competencies that are relevant to the profession, beginning with the Global Body of Investment Knowledge (GBIK®). Regional expert panels and targeted surveys are conducted annually to verify and reinforce the continuous feedback about the GBIK. The practice analysis process ultimately defines the CBOK. The CBOK reflects the competencies that are generally accepted and applied by investment professionals. These competencies are used in practice in a generalist context and are expected to be demonstrated by a recently qualified CFA charterholder.

© 2021 CFA Institute. All rights reserved.

The CFA Institute staff—in conjunction with the Education Advisory Committee and Curriculum Level Advisors, who consist of practicing CFA charterholders—designs the CFA Program curriculum in order to deliver the CBOK to candidates. The exams, also written by CFA charterholders, are designed to allow you to demonstrate your mastery of the CBOK as set forth in the CFA Program curriculum. As you structure your personal study program, you should emphasize mastery of the CBOK and the practical application of that knowledge. For more information on the practice analysis, CBOK, and development of the CFA Program curriculum, please visit www.cfainstitute.org.

ORGANIZATION OF THE CURRICULUM

The Level II CFA Program curriculum is organized into 10 topic areas. Each topic area begins with a brief statement of the material and the depth of knowledge expected. It is then divided into one or more study sessions. These study sessions should form the basic structure of your reading and preparation. Each study session includes a statement of its structure and objective and is further divided into assigned readings. An outline illustrating the organization of these study sessions can be found at the front of each volume of the curriculum.

The readings are commissioned by CFA Institute and written by content experts, including investment professionals and university professors. Each reading includes LOS and the core material to be studied, often a combination of text, exhibits, and in-text examples and questions. End of Reading Questions (EORQs) followed by solutions help you understand and master the material. The LOS indicate what you should be able to accomplish after studying the material. The LOS, the core material, and the EORQs are dependent on each other, with the core material and EORQs providing context for understanding the scope of the LOS and enabling you to apply a principle or concept in a variety of scenarios.

The entire readings, including the EORQs, are the basis for all exam questions and are selected or developed specifically to teach the knowledge, skills, and abilities reflected in the CBOK.

You should use the LOS to guide and focus your study because each exam question is based on one or more LOS and the core material and practice problems associated with the LOS. As a candidate, you are responsible for the entirety of the required material in a study session.

We encourage you to review the information about the LOS on our website (www.cfainstitute.org/programs/cfa/curriculum/study-sessions), including the descriptions of LOS "command words" on the candidate resources page at www.cfainstitute.org.

FEATURES OF THE CURRICULUM

End of Reading Questions/Solutions *All End of Reading Questions (EORQs) as well as their solutions are part of the curriculum and are required material for the exam.* In addition to the in-text examples and questions, these EORQs help demonstrate practical applications and reinforce your understanding of the concepts presented. Some of these EORQs are adapted from past CFA exams and/or may serve as a basis for exam questions.

Glossary For your convenience, each volume includes a comprehensive Glossary. Throughout the curriculum, a **bolded** word in a reading denotes a term defined in the Glossary.

Note that the digital curriculum that is included in your exam registration fee is searchable for key words, including Glossary terms.

LOS Self-Check We have inserted checkboxes next to each LOS that you can use to track your progress in mastering the concepts in each reading.

Source Material The CFA Institute curriculum cites textbooks, journal articles, and other publications that provide additional context or information about topics covered in the readings. As a candidate, you are not responsible for familiarity with the original source materials cited in the curriculum.

Note that some readings may contain a web address or URL. The referenced sites were live at the time the reading was written or updated but may have been deactivated since then.

Some readings in the curriculum cite articles published in the *Financial Analysts Journal®*, which is the flagship publication of CFA Institute. Since its launch in 1945, the *Financial Analysts Journal* has established itself as the leading practitioner-oriented journal in the investment management community. Over the years, it has advanced the knowledge and understanding of the practice of investment management through the publication of peer-reviewed practitioner-relevant research from leading academics and practitioners. It has also featured thought-provoking opinion pieces that advance the common level of discourse within the investment management profession. Some of the most influential research in the area of investment management has appeared in the pages of the *Financial Analysts Journal*, and several Nobel laureates have contributed articles.

Candidates are not responsible for familiarity with *Financial Analysts Journal* articles that are cited in the curriculum. But, as your time and studies allow, we strongly encourage you to begin supplementing your understanding of key investment management issues by reading this, and other, CFA Institute practice-oriented publications through the Research & Analysis webpage (www.cfainstitute.org/en/research).

Errata The curriculum development process is rigorous and includes multiple rounds of reviews by content experts. Despite our efforts to produce a curriculum that is free of errors, there are times when we must make corrections. Curriculum errata are periodically updated and posted by exam level and test date online (www.cfainstitute.org/en/programs/submit-errata). If you believe you have found an error in the curriculum, you can submit your concerns through our curriculum errata reporting process found at the bottom of the Curriculum Errata webpage.

DESIGNING YOUR PERSONAL STUDY PROGRAM

Create a Schedule An orderly, systematic approach to exam preparation is critical. You should dedicate a consistent block of time every week to reading and studying. Complete all assigned readings and the associated problems and solutions in each study session. Review the LOS both before and after you study each reading to ensure that

you have mastered the applicable content and can demonstrate the knowledge, skills, and abilities described by the LOS and the assigned reading. Use the LOS self-check to track your progress and highlight areas of weakness for later review.

Successful candidates report an average of more than 300 hours preparing for each exam. Your preparation time will vary based on your prior education and experience, and you will probably spend more time on some study sessions than on others.

You should allow ample time for both in-depth study of all topic areas and additional concentration on those topic areas for which you feel the least prepared.

CFA INSTITUTE LEARNING ECOSYSTEM (LES)

As you prepare for your exam, we will email you important exam updates, testing policies, and study tips. Be sure to read these carefully.

Your exam registration fee includes access to the CFA Program Learning Ecosystem (LES). This digital learning platform provides access, even offline, to all of the readings and End of Reading Questions found in the print curriculum organized as a series of shorter online lessons with associated EORQs. This tool is your one-stop location for all study materials, including practice questions and mock exams.

The LES provides the following supplemental study tools:

Structured and Adaptive Study Plans The LES offers two ways to plan your study through the curriculum. The first is a structured plan that allows you to move through the material in the way that you feel best suits your learning. The second is an adaptive study plan based on the results of an assessment test that uses actual practice questions.

Regardless of your chosen study path, the LES tracks your level of proficiency in each topic area and presents you with a dashboard of where you stand in terms of proficiency so that you can allocate your study time efficiently.

Flashcards and Game Center The LES offers all the Glossary terms as Flashcards and tracks correct and incorrect answers. Flashcards can be filtered both by curriculum topic area and by action taken—for example, answered correctly, unanswered, and so on. These Flashcards provide a flexible way to study Glossary item definitions.

The Game Center provides several engaging ways to interact with the Flashcards in a game context. Each game tests your knowledge of the Glossary terms a in different way. Your results are scored and presented, along with a summary of candidates with high scores on the game, on your Dashboard.

Discussion Board The Discussion Board within the LES provides a way for you to interact with other candidates as you pursue your study plan. Discussions can happen at the level of individual lessons to raise questions about material in those lessons that you or other candidates can clarify or comment on. Discussions can also be posted at the level of topics or in the initial Welcome section to connect with other candidates in your area.

Practice Question Bank The LES offers access to a question bank of hundreds of practice questions that are in addition to the End of Reading Questions. These practice questions, only available on the LES, are intended to help you assess your mastery of individual topic areas as you progress through your studies. After each practice question, you will receive immediate feedback noting the correct response and indicating the relevant assigned reading so you can identify areas of weakness for further study.

Mock Exams The LES also includes access to three-hour Mock Exams that simulate the morning and afternoon sessions of the actual CFA exam. These Mock Exams are intended to be taken after you complete your study of the full curriculum and take practice questions so you can test your understanding of the curriculum and your readiness for the exam. If you take these Mock Exams within the LES, you will receive feedback afterward that notes the correct responses and indicates the relevant assigned readings so you can assess areas of weakness for further study. We recommend that you take Mock Exams during the final stages of your preparation for the actual CFA exam. For more information on the Mock Exams, please visit www.cfainstitute.org.

PREP PROVIDERS

You may choose to seek study support outside CFA Institute in the form of exam prep providers. After your CFA Program enrollment, you may receive numerous solicitations for exam prep courses and review materials. When considering a prep course, make sure the provider is committed to following the CFA Institute guidelines and high standards in its offerings.

Remember, however, that there are no shortcuts to success on the CFA exams; reading and studying the CFA Program curriculum *is* the key to success on the exam. The CFA Program exams reference only the CFA Institute assigned curriculum; no prep course or review course materials are consulted or referenced.

SUMMARY

Every question on the CFA exam is based on the content contained in the required readings and on one or more LOS. Frequently, an exam question is based on a specific example highlighted within a reading or on a specific practice problem and its solution. To make effective use of the CFA Program curriculum, please remember these key points:

1. All pages of the curriculum are required reading for the exam.
2. All questions, problems, and their solutions are part of the curriculum and are required study material for the exam. These questions are found at the end of the readings in the print versions of the curriculum. In the LES, these questions appear directly after the lesson with which they are associated. The LES provides immediate feedback on your answers and tracks your performance on these questions throughout your study.
3. We strongly encourage you to use the CFA Program Learning Ecosystem. In addition to providing access to all the curriculum material, including EORQs, in the form of shorter, focused lessons, the LES offers structured and adaptive study planning, a Discussion Board to communicate with other candidates, Flashcards, a Game Center for study activities, a test bank of practice questions, and online Mock Exams. Other supplemental study tools, such as eBook and PDF versions of the print curriculum, and additional candidate resources are available at www.cfainstitute.org.
4. Using the study planner, create a schedule and commit sufficient study time to cover the study sessions. You should also plan to review the materials, answer practice questions, and take Mock Exams.
5. Some of the concepts in the study sessions may be superseded by updated rulings and/or pronouncements issued after a reading was published. Candidates are expected to be familiar with the overall analytical framework contained in the assigned readings. Candidates are not responsible for changes that occur after the material was written.

FEEDBACK

At CFA Institute, we are committed to delivering a comprehensive and rigorous curriculum for the development of competent, ethically grounded investment professionals. We rely on candidate and investment professional comments and feedback as we work to improve the curriculum, supplemental study tools, and candidate resources.

Please send any comments or feedback to info@cfainstitute.org. You can be assured that we will review your suggestions carefully. Ongoing improvements in the curriculum will help you prepare for success on the upcoming exams and for a lifetime of learning as a serious investment professional.

Corporate Issuers

STUDY SESSIONS

TOPIC LEVEL LEARNING OUTCOME

The candidate should be able to evaluate capital budget projects, capital structure policy, dividend policy, corporate governance, and mergers and acquisitions.

Capital investments, corporate structure, payout policies, corporate governance and ESG considerations, as well as mergers and acquisitions can significantly affect a company's operations, financials, and performance. Companies having strong leadership, well managed operations, sound corporate governance policies, and profitable investment activities are more likely to add value for their shareholders and other stakeholders.

CORPORATE ISSUERS
STUDY SESSION

6

Corporate Issuers (1)

This study session covers the capital budgeting process with emphasis on its principles and investment decision criteria. Project evaluation through the use of spreadsheet modeling is presented. Other income and valuation model approaches are compared. The subject of capital structure is introduced with the classic Modigliani–Miller irrelevance theory, which proposes that capital structure decisions should have no effect on company value. Additional considerations of taxes, agency costs, and financial distress are introduced. The session concludes with discussion on dividend policies, factors affecting distribution or reinvestment, and dividend payout or share repurchase decisions.

READING ASSIGNMENTS

Reading 15	Capital Structure by Raj Aggarwal, PhD, CFA, Pamela Peterson Drake, PhD, CFA, Adam Kobor, PhD, CFA, and Gregory Noronha, PhD, CFA
Reading 16	Analysis of Dividends and Share Repurchases by Gregory Noronha, PhD, CFA, and George H. Troughton, PhD, CFA

© 2021 CFA Institute. All rights reserved.

READING

15

Capital Structure

by Raj Aggarwal, PhD, CFA, Pamela Peterson Drake, PhD, CFA, Adam Kobor, PhD, CFA, and Gregory Noronha, PhD, CFA

Raj Aggarwal, PhD, CFA, is at the Kent State University Foundation Board (USA). Pamela Peterson Drake, PhD, CFA, is at James Madison University (USA). Adam Kobor, PhD, CFA, is at New York University (USA). Gregory Noronha, PhD, CFA, is at the University of Washington, Tacoma (USA).

LEARNING OUTCOMES

Mastery	*The candidate should be able to:*
☐	**a.** explain the Modigliani–Miller propositions regarding capital structure;
☐	**b.** explain the effects on costs of capital and capital structure decisions of taxes, financial distress, agency costs, and asymmetric information;
☐	**c.** explain factors an analyst should consider in evaluating the effect of capital structure policy on valuation;
☐	**d.** describe international differences in the use of financial leverage, factors that explain these differences, and implications of these differences for investment analysis.

INTRODUCTION

1

The most important decision a company makes in pursuit of maximizing its value is typically the decision concerning what products to manufacture and/or what services to offer. The decision on how to finance investments (e.g., in factories and equipment), the so-called capital structure decision, is often seen as less important, even secondary. As we will see in this reading, the importance of the capital structure decision depends on the assumptions one makes about capital markets and the agents operating in it.

Under the most restrictive set of assumptions, the capital structure decision—the choice between how much debt and how much equity a company uses in financing its investments—is irrelevant. That is, any level of debt is as good as any other. The capital structure decision is not only secondary but also irrelevant. However, as some of the underlying assumptions are relaxed, the choice of how much debt to have in

© 2020 CFA Institute. All rights reserved.

the capital structure becomes meaningful. Under a particular set of assumptions, it is even possible to have an optimal level of debt in the capital structure—that is, a level of debt at which company value is maximized.

In this reading, we first discuss the capital structure decision and the assumptions and theories that lead to alternative capital structures. We then present important practical issues for the analyst, such as differences in capital structure policies arising from country-specific factors. We conclude with a summary of key points from the reading.

2 MODIGLIANI-MILLER PROPOSITION I WITHOUT TAXES: CAPITAL STRUCTURE IRRELEVANCE

a explain the Modigliani–Miller propositions regarding capital structure;

A company's **capital structure** is the mix of debt and equity the company uses to finance its business. The goal of a company's capital structure decision is to determine the financial leverage or capital structure that maximizes the value of the company by minimizing the weighted average cost of capital. The **weighted average cost of capital (WACC)** is given by the weighted average of the marginal costs of financing for each type of financing used. For a company with both debt and equity in its capital structure for which interest expense is tax deductible at a rate t, the WACC, which we will denote r_{wacc}, is

$$r_{wacc} = \left(\frac{D}{V}\right) r_d (1 - t) + \left(\frac{E}{V}\right) r_e \quad (1)$$

where

r_{wacc} = the weighted average cost of capital of the company
r_d = the before-tax marginal cost of debt capital
r_e = the marginal cost of equity capital
t = the company's marginal tax rate
D = the market value of shareholders' outstanding debt
E = the market value of shareholders' outstanding equity
V = the value of the company, which is equal to $D + E$

The ratios of D/V and E/V are the proportions of debt and equity in the capital structure, respectively. These are weights applied to the respective costs and are often indicated as w_d, representing the proportion of debt in the capital structure, and w_e, representing the proportion of equity. For simplicity, this discussion ignores preferred stock. You will notice that the debt and equity costs of capital and the tax rate are all understood to be "marginal" rates. The overall cost of capital is therefore a marginal cost also: what it costs the company to raise additional capital using the specified mixture of debt and equity. Further, this is the current cost: what it would cost the company today. What it cost in the past is not relevant. Therefore, the cost of equity, the cost of debt, and the tax rate that we use throughout the remainder of this reading are marginal: the cost or tax rate for additional capital.

In the following section, we first consider the theoretical relationship between leverage and a company's value. We then examine the practical relationship between leverage and company value in equal depth.

2.1 Proposition I without Taxes: Capital Structure Irrelevance

In a now-classic paper, Nobel Prize–winning economists Franco Modigliani and Merton Miller (1958) argued the important theory that given certain assumptions, a company's choice of capital structure does not affect its value. The assumptions relate to expectations and markets:

1 Investors agree on the expected cash flows from a given investment. This means that all investors have the same expectations with respect to the cash flows from an investment in bonds or stocks. In other words, expectations are homogeneous.

2 Bonds and shares of stock are traded in **perfect capital markets**. This means that there are no transaction costs, no taxes, no bankruptcy costs, and everyone has the same information. In a perfect capital market, any two investments with identical cash flow streams and risk must trade for the same price.

3 Investors can borrow and lend at the risk-free rate.

4 There are no agency costs. This means that managers always act to maximize shareholder wealth.

5 The financing decision and the investment decision are independent of each other. This means that operating income is unaffected by changes in the capital structure.

Many of these assumptions are unrealistic, and we will examine the consequences of relaxing some of them later in this section. The important point is that Modigliani and Miller provided a basis for thinking about capital structure and the starting point for analysis. Consider the capital of a company to be a pie: Each slice represents how much of total capital is provided by a specific type of capital (e.g., common equity). One can split it in any number of ways, but the size of the pie remains the same. Saying that the pie remains the same size is equivalent to saying that the present value of cash flows to the company remains the same. This can only happen if the future cash flow stream is expected to remain the same and if the risk of that cash flow stream, as reflected by the cost of capital, remains the same. Modigliani and Miller prove that under these conditions, and given their assumptions, changing the capital structure (i.e., how the pie is sliced) does not affect value. In other words, in a perfect capital market with risk-free borrowing and lending and with investment and financing decisions independent of each other, investors can create the capital structure which they individually prefer for the company by borrowing and lending on their own accounts. The capital structure chosen by management does not matter because it can be adjusted to the desired capital structure by investors at no cost.

Suppose that a company has a capital structure consisting of 50% debt and 50% equity and that an investor would prefer that the company's capital structure be 70% debt and 30% equity. The investor uses borrowed money to finance his or her share purchases so that effectively ownership of company assets reflects the preferred 70% debt financing. To the extent this changing capital structure has no effect on the company's expected operating cash flows, the capital structure decision has no impact on company value. Modigliani and Miller use the concept of arbitrage to demonstrate their point: If the value of an unlevered company—that is, a company without any debt—is not equal to that of a levered company, investors could make an arbitrage profit. The arbitrage operation (selling the overvalued asset and using the proceeds to buy the undervalued asset) would quickly force the values to be equivalent.

The importance of the Modigliani and Miller theory is that it demonstrates that managers cannot create value simply by changing the company's capital structure. Consider why this might be true. The operating earnings of a business are available to the providers of its capital. In an all-equity company (that is, a company with no debt), all of the operating earnings are available to the equityholders and the value of the company is the present value of these operating earnings. If a company is partially financed by debt, however, these operating earnings are split between the providers of capital: the equityholders and the debtholders. Under market equilibrium, the sum of the values of debt and equity in such a case should equal the value of the all-equity company. In other words, the value of a company is determined solely by its cash flows, not by the relative reliance on debt and equity capital.

This principle does not change the fact of the relative risks of leverage to debtholders versus equityholders. Adding leverage does increase the risk faced by the equityholders. In such a case, equityholders seek compensation for this extra risk by requiring a higher return. Indeed, in equilibrium the increase in equity returns is exactly offset by increases in the risk and the associated increase in the required rate of return on equity; there is no change in the value of the company. Finally, in the absence of taxes the capital structure irrelevance result holds whether debt is assumed to be risk-free (as Modigliani and Miller assumed in their 1958 article) or risky—as long as there are no bankruptcy costs.

Modigliani and Miller (MM) first illustrated the capital structure irrelevance proposition under the condition of no taxes:

> *MM Proposition I:*
>
> The market value of a company is not affected by the capital structure of the company.

In other words, the value of the company levered (V_L) is equal to the value unlevered (V_U), or $V_L = V_U$. A crucial implication of MM Proposition I is that the weighted average cost of capital for a company in the no-tax case is unaffected by its capital structure.

To understand this proposition, we can think about two companies with the same expected, perpetual cash flows and uncertainty and, hence, the same discount rate applied to value these cash flows. Even if the companies have different capital structures, these two companies must have the same present value using discounted cash flow models. If capital structure changes were to have any effect on a company's value, there would be an arbitrage opportunity to make riskless profits.

In a perfect market, investors can substitute their own leverage for a company's leverage by borrowing or lending appropriate amounts in addition to holding shares of the company. Because this process is costless for investors (assuming perfect markets), a company's financial leverage should have no impact on its value. Therefore, a company's capital structure is irrelevant in perfect markets (which assume no taxes).

3 MODIGLIANI-MILLER PROPOSITION II WITHOUT TAXES: HIGHER FINANCIAL LEVERAGE RAISES THE COST OF EQUITY

a explain the Modigliani–Miller propositions regarding capital structure;

Modigliani and Miller's second proposition focuses on the cost of capital of the company:

> *MM Proposition II:*
>
> The cost of equity is a linear function of the company's debt-to-equity ratio.

Assuming that financial distress has no costs and that debtholders have prior claim to assets and income relative to equityholders, the cost of debt is less than the cost of equity. According to this proposition, as the company increases its use of debt financing, the cost of equity rises. We know from MM Proposition I that the value of the company is unchanged and the weighted average cost of capital remains constant if the company changes its capital structure. What Proposition II means is that the cost of equity increases in such a manner as to exactly offset the increased use of cheaper debt in order to maintain a constant WACC.

The risk of the equity depends on two factors: the risk of the company's operations (business risk) and the degree of financial leverage (financial risk). Business risk determines the cost of capital, whereas the capital structure determines financial risk.

The weighted average cost of capital, or r_{wacc}, *ignoring taxes*, is simply Equation 1 with t (the company's marginal tax rate) = 0:

$$r_{wacc} = \left(\frac{D}{V}\right)r_d + \left(\frac{E}{V}\right)r_e \tag{2}$$

Let us define r_0 as the cost of capital for a company financed only by equity (an "all-equity company"). Then, by MM Proposition I, $r_{wacc} = r_0$, so

$$r_{wacc} = \left(\frac{D}{V}\right)r_d + \left(\frac{E}{V}\right)r_e = r_0 \tag{3}$$

Recalling that $D + E = V$ and using this to substitute for V, we can rearrange Equation 3 to solve for the cost of equity:

$$r_e = r_0 + \left(r_0 - r_d\right)\frac{D}{E} \tag{4}$$

Equation 4 is the precise expression for the cost of equity in MM Proposition II. As shown in Equation 4, the cost of equity is a linear function of the debt-to-equity ratio (D/E), with the intercept equal to r_0 and the slope coefficient equal to the positive quantity ($r_0 - r_d$). We know that ($r_0 - r_d$) is positive because the cost of equity must be an increasing function of the debt-to-equity ratio for WACC to be unchanged as the use of debt in financing is increased, as required by Proposition I. Thus, as the debt-to-equity ratio increases, the cost of equity capital also increases. See Exhibit 1 later in this section.

Consider the example of the Leverkin Company, which currently has an all-equity capital structure. Leverkin has an expected operating income of \$5,000 and a cost of equity, which is also its WACC, of 10%. Adopting a common practice, we represent operating income by earnings before interest and taxes, EBIT. For simplicity, we will assume that the EBIT and other cash flows are perpetual. Let us suppose that Leverkin is planning to issue \$15,000 in debt at a cost of 5% in order to buy back \$15,000 worth of its equity.

Because there are no taxes and the EBIT is a perpetuity, we can compute the value of the all-equity Leverkin as the present value of its expected cash flows:

$$V = \frac{\text{EBIT}}{r_{wacc}} = \frac{\$5{,}000}{0.10} = \$50{,}000$$

Under MM Proposition I, because $V_L = V_U$, the value of Leverkin remains the same whether it is all-equity financed or has \$15,000 of debt. When it issues the debt, Leverkin pays an interest charge of 5% on this debt. That is, Leverkin's interest payment is 0.05(\$15,000) = \$750.

By MM Proposition II, the cost of Leverkin's equity when it has \$15,000 debt and \$50,000 – \$15,000 = \$35,000 equity is

$$r_e = 0.10 + \left(0.10 - 0.05\right)\frac{\$15{,}000}{\$35{,}000} \approx 0.12143 = 12.143\%$$

The value of Leverkin with \$15,000 debt in its capital structure must equal the sum of the present value of cash flows to debtholders and equityholders. With \$15,000 debt, Leverkin makes an interest payment of \$750 to debtholders, leaving \$5,000 – \$750 = \$4,250 for equityholders.

$$V = D + E = \frac{\$750}{0.05} + \frac{\$4{,}250}{0.12143} = \$15{,}000 + \$34{,}999.59 \approx \$50{,}000$$

It is straightforward to demonstrate that Leverkin's value remains at \$50,000 at any level of debt. Note that this statement is true even with 100% debt financing because in that case the debtholders are effectively the company's owners (i.e., equityholders). We can also confirm, using Equation 3, that Leverkin's WACC with the new capital structure remains at 10% as required by Proposition I:

$$r_{wacc} = \left(\frac{\$15{,}000}{\$50{,}000}\right)0.05 + \left(\frac{\$35{,}000}{\$50{,}000}\right)0.12143 = 0.10 = 10\%$$

Just as we can express the beta of any investment portfolio as a market-value-weighted average of the betas of the investments in that portfolio, we can express the systematic risk of each of the sources of a company's capital in a similar manner using the Hamada equation (see Hamada 1972). In other words, we can represent the systematic risk of the assets of the entire company as a weighted average of the systematic risk of the company's debt and equity:

$$\beta_a = \left(\frac{D}{V}\right)\beta_d + \left(\frac{E}{V}\right)\beta_e \tag{5}$$

where β_a is the asset's systematic risk, or **asset beta**, β_d is the beta of debt, and β_e is the equity beta. The asset beta represents the amount of the assets' risk that is non-diversifiable (i.e., cannot be eliminated by holding those assets as part of a large, well-diversified portfolio).

According to Modigliani and Miller, the company's cost of capital does not depend on its capital structure but rather is determined by the business risk of the company. As the level of debt rises, however, the risk of the company defaulting on its debt increases. These costs are borne by the equityholders. So, as the proportionate use of debt rises, the equity's beta, β_e, also rises. By reordering the formula of β_a to solve for β_e, we get

$$\beta_e = \beta_a + (\beta_a - \beta_d)\left(\frac{D}{E}\right) \tag{6}$$

In the next section, we look at the decision to use debt financing given the taxes and market imperfections found in the real world.

4 MODIGLIANI-MILLER PROPOSITIONS WITH TAXES: TAXES, COST OF CAPITAL AND VALUE OF THE COMPANY

a explain the Modigliani–Miller propositions regarding capital structure;

b explain the effects on costs of capital and capital structure decisions of taxes, financial distress, agency costs, and asymmetric information;

Taxes are the first practical consideration in modifying the results of the MM propositions. In the following discussion, we present MM Propositions I and II with taxes.

Because interest paid is deductible from income for tax purposes in most countries, the use of debt provides a tax shield that translates into savings that enhance the value of a company. Indeed, ignoring other practical realities of costs of financial distress and bankruptcy, the value of the company increases with increasing levels of debt. In effect, by making the interest costs deductible for income taxes, the government subsidizes companies' use of debt. The actual cost of debt is reduced by the level of the company's tax benefit:

After-tax cost of debt = Before-tax cost of debt × (1 − Marginal tax rate).

Modigliani and Miller show that in the presence of corporate taxes (but not personal taxes), the value of the company with debt is greater than that of the all-equity company by an amount equal to the tax rate multiplied by the value of the debt. That is, MM Proposition I with corporate taxes is:

$$V_L = V_U + tD, \quad (7)$$

where t is the marginal tax rate. The term tD is often referred to as the debt tax shield.

By introducing corporate tax, we adjust the weighted average cost of capital formula to reflect the impact of the tax benefit:

$$r_{wacc} = \left(\frac{D}{V}\right) r_d (1 - t) + \left(\frac{E}{V}\right) r_e \quad (8)$$

Because by Proposition I with taxes the value of a company with debt is greater than that of the same company without debt *for the same level of operating income*, it must follow that the WACC for the company with debt *must be lower* than that for the all-equity company. If we continue to define r_0 as the cost of capital for an all-equity company, MM show that the cost of equity for the same company with debt is:

$$r_e = r_0 + (r_0 - r_d)(1 - t)\frac{D}{E} \quad (9)$$

This is MM Proposition II when there are corporate taxes. Notice that the difference between Equation 9 and MM Proposition II in the no-tax case (Equation 4) is the presence of the term $(1 - t)$. When t is not zero, the term $(1 - t)$ is less than 1 and serves to lower the cost of leveraged (or levered) equity when compared to the no-tax case. That is, the cost of equity becomes greater as the company increases the amount of debt in its capital structure, but the cost of equity does not rise as fast as it does in the no-tax case. Equivalently, the slope coefficient is $(r_0 - r_d)(1 - t)$, which is smaller than the slope coefficient $(r_0 - r_d)$ in the case of no taxes. As a consequence, the WACC for the leveraged company falls as debt increases and overall company value increases. Therefore, if taxes are considered but financial distress and bankruptcy costs are not, debt financing is highly advantageous. In the extreme, a company's optimal capital structure is all debt.

Let us return to the example of the Leverkin Company, which is currently all-equity, has an EBIT of \$5,000, and a WACC (which is also its cost of equity) of 10%. As before, Leverkin is planning to issue \$15,000 of debt in order to buy back an equivalent amount of equity. Now, however, Leverkin pays corporate taxes at a rate of 25%.

Because Leverkin must pay taxes, the after-tax cash flow available to its shareholders is earnings before tax, EBT, times $(1 - t)$, or EBT$(1 - t)$. EBT$(1 - t)$ is the same here as EBIT$(1 - t)$ because I = 0. If we continue to assume perpetual cash flows, the value of the all-equity, or unlevered, Leverkin is:

$$V_U = \frac{\text{EBT}(1 - t)}{\text{WACC}} = \frac{\$5{,}000(1 - 0.25)}{0.10} = \$37{,}500$$

Note that the value of Leverkin when there are corporate taxes is less than its value in the no-tax case. This is simply because a new claimant on Leverkin's cash flows, the government through its ability to impose taxes, has entered the picture.

Let us now see what happens to Leverkin's value when it issues \$15,000 in debt and buys back stock. According to MM Proposition I, when there are corporate taxes (i.e., Equation 7), then

$$V_L = V_U + tD = \$37{,}500 + 0.25(\$15{,}000) = \$41{,}250.$$

Because the value of the debt is \$15,000, the value of the equity (after the buyback) must be (\$41,250 – \$15,000) = \$26,250. According to MM Proposition II with corporate taxes (Equation 9), the cost of the levered equity is:

$$r_e = 0.10 + (0.10 - 0.05)(1 - 0.25)\frac{\$15{,}000}{\$26{,}250} = 0.12143 = 12.143\%$$

Because the value of the company must equal the present value of cash flows to debt and to equity,

$$\begin{aligned} V_L &= D + E = \frac{r_d D}{r_d} + \frac{(\text{EBIT} - r_d D)(1 - t)}{r_e} \\ &= \frac{\$750}{0.05} + \frac{(\$5{,}000 - \$750)(1 - 0.25)}{0.12143} \approx \$41{,}250 \end{aligned}$$

This is the value of the company as given by MM Proposition I. As a further check, using Equation 8 the WACC for the levered Leverkin is:

$$\begin{aligned} r_{wacc} &= \frac{\$15{,}000}{\$41{,}250}(0.05)(1 - 0.25) + \frac{\$26{,}250}{\$41{,}250}(0.12143) \\ &= 0.09091 = 9.091\% \end{aligned}$$

As expected, this is lower than the unlevered WACC of 10%. Because after taxes are paid whatever is left of the cash flows can be claimed by debtholders and equityholders, we must also have:

$$V_L = \frac{\text{EBIT}(1 - t)}{\text{WACC}} = \frac{\$5{,}000(1 - 0.25)}{0.09091} \approx \$41{,}250$$

We can see the effect of taxes on the cost of capital in Exhibit 1. Here, we see that if there are no taxes, as shown in Panel B, the cost of capital is constant at $r_{wacc} = r_0$. If interest is tax deductible, however, the cost of capital declines for ever-increasing use of debt financing, as shown in Panel C.

Exhibit 1

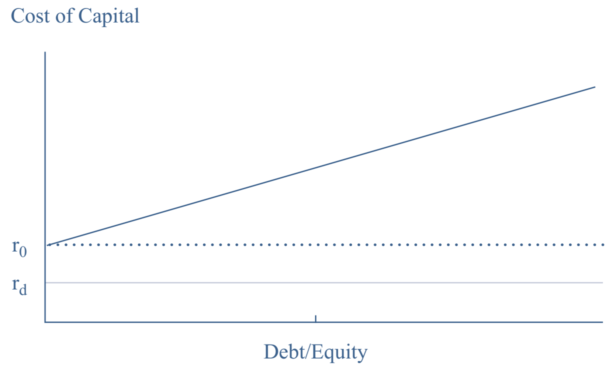
Modigliani and Miller Propositions

A. Value of the Company and Cost of Capital for Propositions without and with Taxes

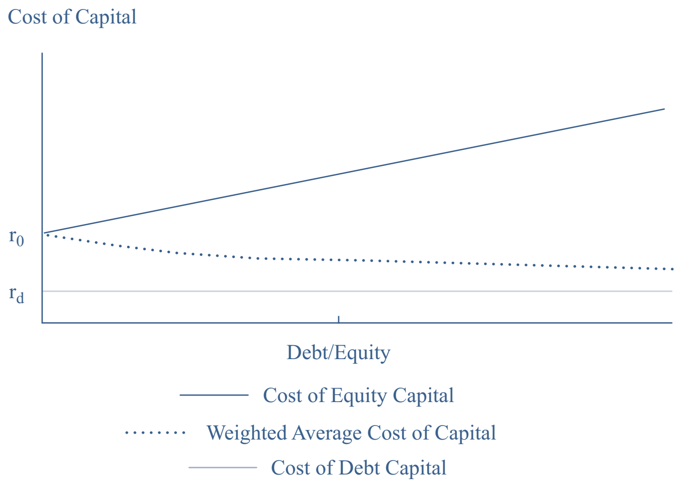
	Without Taxes	With Taxes
Proposition I	$V_L = V_U$	$V_L = V_U + tD$
Proposition II	$r_e = r_0 + (r_0 - r_d)\frac{D}{E}$	$r_e = r_0 + (r_0 - r_d)(1 - t)\frac{D}{E}$

Exhibit 1 (Continued)

B. Costs of Capital with No Taxes



C. Costs of Capital with Taxes



Miller (1977) introduced another aspect into the analysis of the tax benefits from the use of debt financing. He argued that if investors face different tax rates on dividend and interest income for their personal taxes, this situation may reduce the advantage of debt financing somewhat. If investors face a higher personal rate of tax on income from debt investments relative to stock investments, they will demand a higher return on debt—driving up the cost of debt to the company. Thus in the Miller model, whether or not financing with debt adds value to the company depends on the corporate tax rate, the personal tax rate on interest income, and the personal tax rate on dividend income. It is therefore possible in the Miller model, depending on the levels of the various tax rates, for debt to add value, lower value, or to have no effect on value.

In practice, however, the value of a levered company is affected by more than the tax issues surrounding the use of debt. The analysis gets more complicated once we introduce such factors as the cost of financial distress, agency costs, and asymmetric information. We address these additional factors next.

5 OTHER CAPITAL STRUCTURE COST CONSIDERATIONS: COSTS OF FINANCIAL DISTRESS

b explain the effects on costs of capital and capital structure decisions of taxes, financial distress, agency costs, and asymmetric information;

The downside of operating and financial leverage is that earnings are magnified downward during economic slowdowns. Lower or negative earnings put companies under stress, and this **financial distress** adds costs—both explicit and implicit—to a company. Even before taking the drastic step of filing for bankruptcy, companies under stress may lose customers, creditors, suppliers, and valuable employees to more secure competitors.

EXAMPLE 1

Costs of Financial Distress

The Carillion Plc liquidation provides an example of the costs of financial distress and the loss of shareholder value. Carillion was a UK-based construction and services entity that employed 43,000, had revenues of almost £4.4 billion, and was involved in many projects. These projects included ongoing projects with the UK government for the maintenance of roads and for catering and cleaning contracts at hundreds of schools. Carillion's share price was £308 per share at the end of 2015 and £236 at the end of 2016.

The first sign of trouble came in mid-2017 when Carillion warned on its full-year profit, citing issues with payment problems in several of its construction contracts. This announcement was followed soon after with a 30% loss of shareholder value in the market. Even as it faced these collection problems on its contracts, however, it was awarded more contracts, including those for railway and military projects.

Subsequent profit warnings sent share value further downward. The second profit warning of that year was followed by new credit facilities and deferrals of debt repayments. The third profit warning, which included concern over violating debt covenants, resulted in a further decline in the value of its shares, with shares trading around £21 per share.

Discussions with creditors in December 2017 and January 2018 did not result in an agreement. The company was put in compulsory liquidation on 15 January 2018, and share trading was suspended.

The primary causes of Carillion's problems were its many overreaching, unprofitable projects and the inability to collect quickly on its projects. Moreover, goodwill—an intangible asset associated with the purchase of one company by another—comprised a significant portion of assets. In FY2016, alone, goodwill was over 35% of the company's assets.

The costs of this financial distress included:

- the loss of all shareholder value from a market capitalization of over £2 billion in 2016;[1]

1 BBC News, "Carillion Collapse to Cost Taxpayers £148m" (7 June 2018): https://www.bbc.com/news/business-44383224.

- £44.2 million paid to an accounting firm as special managers of the insolvency;[2]
- costs to the UK government as it grappled with nationalizing contracts, at least on a temporary basis;[3] and
- creditors paid potentially a small fraction of what was owed to them.

The expected cost of financial distress is composed of two key ingredients: 1) the costs of financial distress and bankruptcy, in the event they happen, and 2) the probability that financial distress and bankruptcy happen. We can classify the costs of financial distress into direct and indirect costs. Direct costs of financial distress include the actual cash expenses associated with the bankruptcy process, such as legal and administrative fees. Indirect costs of financial distress include forgone investment opportunities, impaired ability to conduct business, and agency costs associated with the debt during periods in which the company is near or in bankruptcy.

Companies whose assets have a ready secondary market have lower costs associated with financial distress. Companies with relatively marketable tangible assets—such as airlines, shipping companies, and steel manufacturers—incur lower costs from financial distress because such assets are usually more readily marketable. In contrast, companies with few tangible assets—such as high-tech growth companies, pharmaceutical companies, information technology companies, and others in the service industry—have less to liquidate and therefore have a higher cost associated with financial distress.

The probability of bankruptcy increases as the degree of leverage increases. The probability of bankruptcy for a given company depends on how the fixed costs of debt service interact with the instability of the business environment and the reserves available to the company to delay bankruptcy. In other words, the probability of bankruptcy depends, in part, on the company's business risk. Other factors that affect the likelihood of bankruptcy include the company's corporate governance structure and the management of the company.

OTHER CAPITAL STRUCTURE COSTS: AGENCY COSTS AND COSTS OF ASYMMETRIC INFORMATION 6

b explain the effects on costs of capital and capital structure decisions of taxes, financial distress, agency costs, and asymmetric information;

Agency costs are the costs associated with the fact that all public companies and the larger private companies are managed by non-owners. Agency costs are the incremental costs arising from conflicts of interest when an agent makes decisions for a principal. In the context of a corporation, agency costs arise from conflicts of interest between managers, shareholders, and bondholders. In the following, "perquisite consumption" refers to items that executives may legally authorize for themselves that have a cost to shareholders, such as subsidized dining, a corporate jet fleet, and chauffeured limousines.

---

2 Mark Cobley,, "PwC to Reap £44m from Carillion Bankruptcy," *Financial News* (6 February 2019): https://www.fnlondon.com/articles/pwc-to-reap-44m-from-carillion-bankruptcy-20190206.

3 Hallie Detrick, "What You Need to Know about the Collapse of Carillion, a U.K. Construction Giant," *Fortune* (15 January 2018): http://fortune.com/2018/01/15/what-you-need-to-know-about-the-collapse-of-carillion-a-u-k-construction-giant/.

The smaller the stake managers have in the company, the less their share in bearing the cost of excessive perquisite consumption—consequently, the less their desire to give their best efforts in running the company. The costs arising from this conflict of interest have been called the **agency costs of equity**. Given that outside shareholders are aware of this conflict, they will take actions to minimize the loss, such as requiring audited financial statements. The net agency costs of equity, therefore, have three components (Jensen and Meckling 1976):

1 **Monitoring costs**. These are the costs borne by owners to monitor the management of the company and include the expenses of the annual report, board of director expenses, and the cost of the annual meeting.

2 **Bonding costs**. These are the costs borne by management to assure owners that they are working in the owners' best interest. These include the implicit cost of noncompete employment contracts and the explicit cost of insurance to guarantee performance.

3 **Residual loss**. This consists of the costs that are incurred even when there is sufficient monitoring and bonding, because monitoring and bonding mechanisms are not perfect.

The better a company is governed, the lower the agency costs. Good governance practices translate into higher shareholder value because managers' interests are better aligned with those of shareholders. Additionally, agency theory predicts that a reduction in net agency costs of equity results from an increase in the use of debt versus equity. That is, there are savings in the agency costs of equity associated with the use of debt. Similarly, the more financially leveraged a company is, the less freedom managers have to either take on more debt or unwisely spend cash. This is the foundation of Michael Jensen's **free cash flow hypothesis**. According to Jensen (1986), higher debt levels discipline managers by forcing them to manage the company efficiently so the company can make its interest and principal payments and by reducing the company's free cash flow and thus management's opportunities to misuse cash. Harvey, Lins, and Roper (2004) observe that this discipline is especially important in emerging markets, in which there is a tendency to overinvest.

6.1 Costs of Asymmetric Information

Asymmetric information (an unequal distribution of information) arises from the fact that managers have more information about a company's performance and prospects (including future investment opportunities) than do outsiders, such as owners and creditors. Whereas all companies have a certain level of asymmetric information, companies with comparatively high asymmetry in information are those with complex products. These include high-tech companies, companies with little transparency in financial accounting information, or companies with lower levels of institutional ownership. Providers of both debt and equity capital demand higher returns from companies with higher asymmetry in information because they have a greater likelihood of agency costs.

Some degree of asymmetric information always exists because investors never know as much as managers and other insiders. Consequently, investors often closely watch manager behavior for insight into insider opinions on the company's future prospects. Aware of this scrutiny, managers take into account how their actions might be interpreted by outsiders. The signaling model of capital structure suggests a hierarchy ("pecking order") to the selection of methods for financing new investments.

The **pecking order theory**, developed by Myers and Majluf (1984), suggests that managers choose methods of financing according to a hierarchy that gives first preference to methods with the least potential information content (internally generated funds) and lowest preference to the form with the greatest potential information content (public equity offerings). Public equity offerings are, in general, closely scrutinized because investors are typically skeptical that existing owners would share ownership of a company with a great future with other investors. In brief, managers prefer internal financing. If internal financing is insufficient, managers next prefer debt, then equity. Another implication of the work of Myers and Majluf is that financial managers tend to issue equity when they believe the stock is overvalued but are reluctant to issue equity if they believe the stock is undervalued. Thus, additional issuance of stock is often interpreted by investors as a negative signal.

We can read the signals that managers provide in their choice of financing method. For example, commitments to fixed payments, such as dividends and debt service payments, may be interpreted as the company's management having confidence in the company's future prospects of making payments. Such signals are considered too costly for poorly performing companies to afford. Alternatively, the signal of raising money at the top of the pecking order and issuing equity at the bottom of the pecking order holds other clues. If, for instance, the company's cost of capital increases after an equity issuance, we may interpret this effect as an indication that management needed capital beyond what comes cheaply; in other words, this is a negative signal regarding the company's future prospects.

OPTIMAL CAPITAL STRUCTURE: STATIC TRADE-OFF THEORY

7

c explain factors an analyst should consider in evaluating the effect of capital structure policy on valuation;

When companies make decisions about financial leverage, they must weigh the value-enhancing effects of leverage from the tax deductibility of interest against the value-reducing impact of the costs of financial distress or bankruptcy, agency costs of debt, and asymmetric information. Putting together all the pieces of the Modigliani and Miller theory—along with the taxes, costs of financial distress, debt agency costs, and asymmetric information—we see that as financial leverage is increased, there comes a point beyond which further increases in value from value-enhancing effects are offset completely by value-reducing effects. This point is known as the **optimal capital structure**. In other words, the optimal capital structure is that capital structure at which the value of the company is maximized.

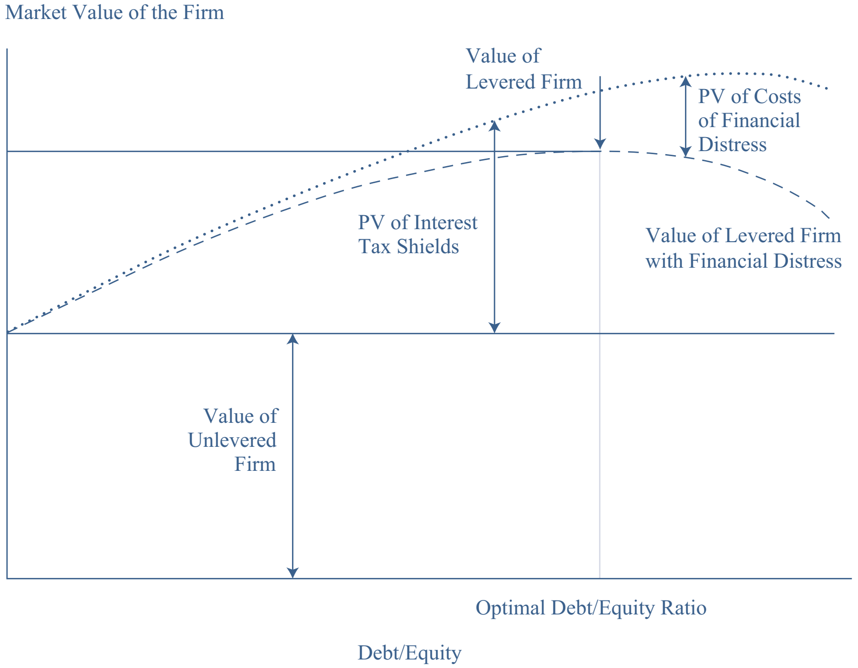
Considering only the tax shield provided by debt and the costs of financial distress, the expression for the value of a leveraged company becomes

$$V_L = V_U + tD - PV(\text{Costs of financial distress}). \quad (10)$$

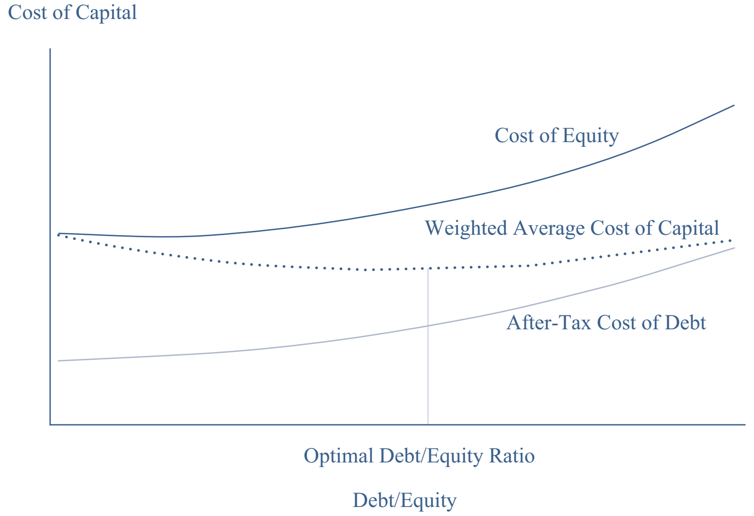
Equation 10 represents the **static trade-off theory of capital structure**. It results in an optimal capital structure such that debt constitutes less than 100% of a company's capital structure. We diagram this optimum in Exhibit 2.

Exhibit 2 Trade-off Theory with Taxes and Cost of Financial Distress

A. Value of the Company and the Debt/Equity Ratio



B. Cost of Capital and the Debt/Equity Ratio



The static trade-off theory of capital structure is based on balancing the expected costs from financial distress against the tax benefits of debt service payments, as shown in Panel A of Exhibit 2. Unlike the Modigliani and Miller proposition of no optimal capital structure, or a structure with almost all debt when the tax shield is considered, static trade-off theory puts forth an optimal capital structure with an optimal proportion of debt. Optimal debt usage is found at the point where any additional debt would cause the costs of financial distress to increase by a greater amount than the benefit of the additional tax shield.

We cannot say precisely at which level of debt financing a company reaches its optimal capital structure. The optimal capital structure depends on the company's business risk combined with its tax situation, corporate governance, and financial accounting information transparency, among other factors. However, what we can say, based on this theory, is that a company should consider a number of factors, including its business risk and the possible costs of financial distress, in determining its capital structure.

A company's management uses these tools to decide the level of debt appropriate for the company. The tax benefit from the deductibility of the interest expense on debt must be balanced against the risk associated with the use of debt. The extent of financial leverage used should thus depend on owners' and management's appetites for risk and the stability of the company's business environment. Indeed, as we show in Panel B of Exhibit 2, as the proportion of debt in a business rises, the costs of both debt and equity are likely to rise to offset the higher risks associated with higher levels of debt. These cost increases reduce or even negate the cost savings due to the greater use of debt, the cheaper source of financing. The result is a U-shaped weighted average cost of capital curve.

When the company recognizes its most appropriate or best capital structure, it may adopt this as its **target capital structure**. Because management may exploit short-term opportunities in one or another financing source and because market-value fluctuations continuously affect the company's capital structure, a company's capital structure at any point in time may differ from the target. In addition, it may be impractical (due to market conditions making it inadvisable to raise capital) and expensive (because of flotation costs) for a company to continuously maintain its target structure. Nevertheless, so long as the assumptions of the analysis and the target are unchanged, analysts and management should focus on the target capital structure.

CAPITAL STRUCTURE POLICY: PRACTICAL ISSUES AND EVALUATION 8

c explain factors an analyst should consider in evaluating the effect of capital structure policy on valuation;

Although capital structure theories should serve to inform an analyst's decision-making process in valuing a company, there are several practical aspects of capital structure to consider. These include an assessment of company creditworthiness, an understanding of the industry to which the company belongs, and an analysis of the legal, institutional, and macroeconomic environment in which the company operates. We consider these factors next.

8.1 Debt Ratings

Debt ratings are an important consideration in the practical management of leverage. As leverage rises, rating agencies tend to lower the ratings of the company's debt to reflect the higher credit risk resulting from the increasing leverage. Lower ratings signify higher risk to both equity and debt capital providers, who therefore demand higher returns.

Most large companies pay one or more rating services to provide debt ratings for their bonds. Debt issues are rated for creditworthiness by these credit rating agencies after they perform a financial analysis of the company's ability to pay the promised cash flows as well as an analysis of the bond's indenture (i.e., the set of complex legal documents associated with the issuance of debt instruments).

These agencies evaluate a wealth of information about the issuer and the bond, including the bond's characteristics and indenture agreement, and provide investors with an assessment of the company's ability to pay the interest and principal on the bond as promised.

Thus, in practice, most managers consider the company's debt rating in their policies regarding capital structure because the cost of capital is tied so closely to bond ratings.

8.2 Evaluating Capital Structure Policy

In evaluating a company's capital structure, the financial analyst must look at the capital structure of the company over time, the company's business risk, the capital structure of competitors that have similar business risk, and company-specific factors, such as the quality of corporate governance, that may affect agency costs. Good corporate governance should lower the net agency costs of equity. The financial analyst is not privy to the company's target capital structure but rather can evaluate the company's ability to handle its financial obligations and the potential role of costs of financial distress in determining how much financial leverage a company can handle.

Several practical considerations are important in this regard, such as the industry in which a company operates, the volatility of the company's cash flows, and its need for financial flexibility. Regulatory aspects can also play a role. For example, companies in the utility industry have relatively stable cash flows because they have a natural monopoly. Such companies usually also have a low degree of information asymmetry. As a result, utility companies tend to have much more debt than companies in other industries. Similarly, the guarantee afforded by deposit insurance in the United States, for example, allows banks in the United States to have debt levels in excess of 80% of assets.[4] In contrast, companies in the technology or pharmaceutical industries tend to have little or no debt for the following three reasons. 1) They have few tangible assets (their assets are chiefly human capital, patents, ideas, etc.). 2) There is a high degree of information asymmetry (such companies spend a lot on research and development and are very secretive about their products). 3) They have a great need for financial flexibility (they need to respond quickly to competitive and other changes in their operating environment).

A common goal of capital structure decisions is to finance at the lowest cost of capital. Analysts can use a scenario approach to assess this point for a particular company, starting with the current cost of capital for a company and considering various changes, to answer the following questions:

1 How do possible changes in capital structure affect changes in bond ratings, and how may this likely affect the cost of capital?

2 Are there anticipated events, such as an acquisition or merger, that may alter the company's business risk?

3 Is the company's capital structure in line with its peers and competitors? Why or why not?

4 Board of Governors of the Federal Reserve System, "Assets and Liabilities of Commercial Banks in the United States – H.8" (Release Date 22 March 2019): https://www.federalreserve.gov/releases/h8/20190322/.

4 Does the company tend to maintain a consistent capital structure, or does this appear to be changing over time to be more or less levered?

5 Do any recent or anticipated changes in tax rates affect the costs of capital?

INTERNATIONAL CAPITAL STRUCTURE DIFFERENCES: COUNTRY-SPECIFIC FACTORS

9

d describe international differences in the use of financial leverage, factors that explain these differences, and implications of these differences for investment analysis.

Modigliani and Miller told us that under several conditions the market value of a company is independent of its capital structure. However, we know that a company's capital structure is indeed relevant in the real world because of the effects of taxation, the costs of financial distress, and agency costs. The static trade-off theory suggests that the optimal level of leverage should be the level at which the value of the company is maximized; this is the level of debt financing at which any additional debt increases the costs of financial distress by an amount greater than the benefit from interest deductibility.

A company's capital structure largely depends on company-specific factors, such as the probability of bankruptcy, profitability, quality and structure of assets, and growth opportunities. Beyond these factors, the company's industry affiliation and the characteristics of the country where the company operates can also account for differences in capital structure.

The general business environment differs from one country to another. While researchers show that country-specific factors are becoming less of an influence on capital structure decisions over time, a meaningful comparison of financial leverage indicators of a US-based energy company and a Japanese energy company still requires us to take country-specific differences into account. Tradition, tax policy, and regulation may largely explain the different degrees of leverage in the two countries.

In examining the capital structure and debt maturity structure of corporations in an international context, researchers generally find that differences in the capital structures exist between developed and emerging markets as well as across the developed countries. Moreover, the debt maturity structure—another important capital structure decision—also tends to vary across the international setting. Therefore, when analysts focus on the capital structure of companies in an international setting, they must consider both the relative use of debt and the maturity structure of debt.

In fact, short-term and long-term debt ratios follow very different patterns in international comparisons. Whereas such characteristics of corporations as profitability and the degree to which total assets are tangible affect capital structure decisions globally, country-specific characteristics—and, to a lesser degree, global factors—affect capital structure decisions. For example, greater growth in GDP and greater property rights are associated with longer bond maturities. Further, capital structure decisions are affected by such global factors as risk aversion, where greater risk aversion is associated with shorter maturities.

Beyond the pure comparison of the capital structures, it is equally or even more important to identify and understand the country-specific factors that explain the cross-country differences. Three major types of factors may be used to explain most capital structure differences in an international comparison:

1 *Institutional and legal environment*: These factors represent the legal and regulatory environment in which companies operate and the requirements related to financial reporting. These institutional factors—including accounting standards, information transparency, taxation, and even the presence or lack of corruption—may affect a company's optimal capital structure.

2 *Financial markets and banking sector*: These factors include characteristics of the banking sector and the size and activity of the financial markets. Financial institutions are crucial for companies' access to financing.

3 *Macroeconomic environment*: These factors capture the general economic and business environment, addressing the influence of economic growth and inflation on the capital structure.

9.1 Institutional and Legal Environment

Taxation, financial legislation, the content of laws (e.g., bankruptcy law), and the quality of enforcement all differ from one country to another. These differences may influence the capital structures of companies and explain many of the differences that we observe across countries.

The apparent conflict of interest between a company's management and outside investors has already been addressed as the agency problem. This problem is, in fact, one of the key determinants of a company's ability to obtain capital; hence, agency costs are one of the major factors determining the capital structure. This conflict may be mitigated by carefully prepared contracts. The quality of investors' legal protections depends on both the content and the enforcement of the contracts and laws. As a result, we expect to see higher financial leverage in those countries that have weaker, less-efficient legal systems. Further, in countries with weaker legal systems, we expect a greater use of short-term debt financing versus long-term debt financing. Researchers find that companies operating in countries with an efficient legal system tend to use more long-term debt than short-term debt and exhibit lower leverage than comparable companies in countries with weaker legal systems.

Some researchers assume that legal systems based on common law offer external capital providers (both equity and debt providers) better protection compared to the legal systems of civil-law countries. Common law originated in England and is also followed in other countries, such as the United States, Canada, Australia, New Zealand, and Singapore. Civil law has origins going back to ancient Rome; the countries of continental Europe and South America and most of the rest of the world have legal systems based on this tradition. Researchers find mixed and limited evidence that companies operating in common-law countries tend to have longer debt maturity structures compared to their peers in civil-law countries. Further, in countries with a legal system based on common law, companies tend to use less debt and more equity in their capital structure. Further, some researchers observe that companies in countries with greater property rights tend to have longer debt maturities. In countries with stronger creditor rights, researchers find that companies tend to use less debt.

Similar to the rationale described in the case of legal system efficiency, a high level of information asymmetry favoring insiders over outsiders encourages a greater use of debt relative to equity as well as a greater reliance on short-term debt than on long-term debt in the capital structure. This is likely due to the fact that enforcing the debt contract is easier than enforcing the less clearly contracted shareholders' rights. Auditors and financial analysts can help reduce information asymmetries and increase the level of transparency. Researchers confirm that the presence of auditors and analysts is associated with lower financial leverage. The importance of auditors is usually strongest in emerging markets, whereas the presence of analysts is more important in developed markets. Researchers also observe that companies tend to use more equity to finance investments in countries with stronger information transparency.

As discussed earlier, taxes affect the capital structure decision by lowering the cost of debt financing to the issuer in those jurisdictions in which interest expense is tax deductible. In the absence of debt agency costs and bankruptcy costs, the benefit from the tax deductibility of interest encourages companies to use debt financing instead of equity financing. However, if dividend income is taxed at lower rates than interest income, some of the advantage of debt versus equity financing may be reduced from the corporate perspective because the price at which equity can be sold should reflect that advantage. In general, researchers observe that both corporate and personal tax rates influence a company's capital structure decisions.

9.2 Financial Markets and the Banking Sector

The size, activity, and liquidity of capital markets are crucial for corporations' access to capital. Several researchers have analyzed the impact of capital markets' characteristics on companies' capital structures. Some find that liquid and active capital markets affect companies' debt maturity structure. Specifically, they find that companies in countries that have liquid and active capital markets tend to use more long-term (as opposed to short-term) debt with longer maturity (30-year maturity is preferred to 15-year maturity). Researchers attribute this finding to the heightened external monitoring of companies by financial analysts and other market participants in active markets.

The banking sector is one of the primary sources of funds for the corporate sector in many countries, and its role is especially significant in countries that do not have a corporate bond market. The importance of the banking sector relative to the capital markets can vary from one country to another, however. Countries with a common-law tradition in which the shareholders' rights are stronger tend to be more market-based, whereas civil-law countries tend to be more bank-based. Because the relationship between a bank and a company is stronger and closer than between a company and a bondholder, banks can handle information asymmetries more efficiently. This effect may partly explain why civil-law countries are more bank-oriented. Researchers find a difference in the role of capital structure determinants based on whether the country's economy is bank-oriented (such as in France, Germany, and Japan) or capital market-oriented (such as in the United States and the United Kingdom). For example, the tangibility of assets plays a bigger role in capital structure decisions in bank-oriented economies; that is, bank-oriented economies focus on such tangible assets as plants and equipment rather than on such intangible assets as patents or goodwill.

An element of the role of the type of market—bank-oriented or market-oriented—is the resultant information available to stakeholders. De Fiore and Uhlig (2011) find that the increased availability of information about credit risk in the euro area may result in high debt, while the better availability of public information on market participants in the United States may reduce agency costs.

The presence of institutional investors may also affect the companies' capital structure choice. Some institutional investors may have preferred debt maturities ("preferred habitats"), and these preferences may affect companies' debt maturity structure. Insurance companies and pension plans, for example, may prefer investing in long-term debt securities to align with the interest rate risk of their long-term liabilities.

9.3 Macroeconomic Environment

Macroeconomic factors may affect both the relative use of debt and debt maturity. For example, researchers examining the effects of the 2007–2008 global financial crisis observed reduced reliance on debt financing and reduced debt maturity in both developed and developing countries as a result of the crisis, even for countries not directly affected by the crisis. Additionally, researchers observe that countries with companies that have higher debt and a greater ability to substitute bonds for loans recover faster from the trough of a business cycle.

Inflation is a widely recognized macroeconomic indicator. High inflation has a negative impact on both the level of debt financing and the use of long-maturity debt. Companies in higher-inflation countries usually exhibit lower levels of financial leverage, rely more on equity financing, and have a shorter debt maturity structure compared to their peers in lower-inflation countries.

Researchers have also found that the growth in gross domestic product is associated with longer debt maturity in developed markets. In addition, researchers focusing on developing countries find that companies in countries with high growth rely more on equity financing.

9.4 Conclusions

Financial analysts must consider country-specific factors when analyzing and comparing companies that operate in different countries. We have summarized these factors in Exhibit 3.

Exhibit 3 Country-Specific Factors and Their Assumed Impacts on the Companies' Capital Structure

Country-Specific Factor	If a Country	. . . Then D/E Ratio Is Potentially	. . . And Debt Maturity Is Potentially
Institutional framework			
Legal system efficiency	Is more efficient	Lower	Longer
Legal system origin	Has common law as opposed to civil law	Lower	
Information asymmetries	Has greater shareholder rights	Lower	Longer
Information intermediaries	Has auditors and analysts	Lower	Longer
Taxation	Has taxes that favor equity	Lower	
Banking system, financial markets			
Equity and bond markets	Has active bond and stock markets		Longer
Bank-based or market-based country	Has a bank-based financial system	Higher	
Investors	Has large institutional investors	Lower	Longer
Macroeconomic environment			
Inflation	Has high inflation	Lower	Shorter
Growth	Has high GDP growth	Lower	Longer

These factors include the differences in the business and legal environments in other countries, taxes, and macroeconomic factors, among others. Companies' optimal capital structures may differ simply as a consequence of these many country-specific differences. In addition to presenting challenges for international financial and credit analysis, these international differences in debt ratios present some challenges in developing debt policies for the foreign subsidiaries of multinational companies. Theory provides little guidance, and corporate practices in this area seem to vary widely.

SUMMARY

In this reading, we have reviewed theories of capital structure and considered practical aspects that an analyst should examine when making investment decisions.

- The goal of the capital structure decision is to determine the financial leverage that maximizes the value of the company (or minimizes the weighted average cost of capital).
- In the Modigliani and Miller theory developed without taxes, capital structure is irrelevant and has no effect on company value.
- The deductibility of interest lowers the cost of debt and the cost of capital for the company as a whole. Adding the tax shield provided by debt to the Modigliani and Miller framework suggests that the optimal capital structure is all debt.
- In the Modigliani and Miller propositions with and without taxes, increasing a company's relative use of debt in the capital structure increases the risk for equity providers and, hence, the cost of equity capital.
- When there are bankruptcy costs, a high debt ratio increases the risk of bankruptcy.
- Using more debt in a company's capital structure reduces the net agency costs of equity.
- The costs of asymmetric information increase as more equity is used versus debt, suggesting the pecking order theory of leverage in which new equity issuance is the least preferred method of raising capital.
- According to the static trade-off theory of capital structure, in choosing a capital structure, a company balances the value of the tax benefit from deductibility of interest with the present value of the costs of financial distress. At the optimal target capital structure, the incremental tax shield benefit is exactly offset by the incremental costs of financial distress.
- A company may identify its target capital structure, but its capital structure at any point in time may not be equal to its target for many reasons.
- Many companies have goals for maintaining a certain credit rating, and these goals are influenced by the relative costs of debt financing among the different rating classes.
- In evaluating a company's capital structure, the financial analyst must look at such factors as the capital structure of the company over time, the business risk of the company, the capital structure of competitors that have similar business risk, and company-specific factors (e.g., the quality of corporate governance, which may affect agency costs).

- Good corporate governance and accounting transparency should lower the net agency costs of equity.
- When comparing capital structures of companies in different countries, an analyst must consider a variety of characteristics that might differ and affect both the typical capital structure and the debt maturity structure. The major characteristics fall into three categories: institutional and legal environment, financial markets and banking sector, and macroeconomic environment.

PRACTICE PROBLEMS

1 If investors have homogeneous expectations, the market is efficient, and there are no taxes, no transaction costs, and no bankruptcy costs, the Modigliani and Miller Proposition I states that:

A bankruptcy risk rises with more leverage.

B managers cannot change the value of the company by using more or less debt.

C managers cannot increase the value of the company by employing tax saving strategies.

2 According to Modigliani and Miller's Proposition II without taxes:

A the capital structure decision has no effect on the cost of equity.

B investment and the capital structure decisions are interdependent.

C the cost of equity increases as the use of debt in the capital structure increases.

3 The current weighted average cost of capital (WACC) for Van der Welde is 10%. The company announced a debt offering that raises the WACC to 13%. The *most likely* conclusion is that for Van der Welde:

A the company's prospects are improving.

B equity financing is cheaper than debt financing.

C the company's debt/equity has moved beyond the optimal range.

4 All else equal, the use of long-maturity debt is expected to be *greater* in those markets in which:

A inflation is low.

B capital markets are passive and illiquid.

C the legal system's protection of bondholders' interests is weak.

5 According to the pecking order theory:

A new debt is preferable to new equity.

B new debt is preferable to internally generated funds.

C new equity is always preferable to other sources of capital.

6 According to the static trade-off theory:

A debt should be used only as a last resort.

B companies have an optimal level of debt.

C the capital structure decision is irrelevant.

The following information relates to Questions 7–9

Barbara Andrade is an equity analyst who covers the entertainment industry for Greengable Capital Partners, a major global asset manager. Greengable owns a significant position with a large unrealized capital gain in Mosely Broadcast Group (MBG). On a recent conference call, MBG's management states that they plan to increase the

© 2020 CFA Institute. All rights reserved.

proportion of debt in the company's capital structure. Andrade is concerned that any changes in MBG's capital structure will negatively affect the value of Greengable's investment.

To evaluate the potential impact of such a capital structure change on Greengable's investment, she gathers the information about MBG given in Exhibit 1.

Exhibit 1 Current Selected Financial Information for MBG

Yield to maturity on debt	8.00%
Market value of debt	$100 million
Number of shares of common stock	10 million
Market price per share of common stock	$30
Cost of capital if all equity-financed	10.3%
Marginal tax rate	35%

Andrade expects that an increase in MBG's financial leverage will increase its costs of debt and equity. Based on an examination of similar companies in MBG's industry, Andrade estimates MBG's cost of debt and cost of equity at various debt-to-total capital ratios, as shown in Exhibit 2.

Exhibit 2 Estimates of MBG's Before-Tax Costs of Debt and Equity

Debt-to-Total Capital Ratio (%)	Cost of Debt (%)	Cost of Equity (%)
20	7.7	12.5
30	8.4	13.0
40	9.3	14.0
50	10.4	16.0

7 MBG is *best* described as currently:

A 25% debt-financed and 75% equity-financed.

B 33% debt-financed and 66% equity-financed.

C 75% debt-financed and 25% equity-financed.

8 Holding operating earnings constant, an increase in the marginal tax rate to 40% would:

A result in a lower cost of debt capital.

B result in a higher cost of debt capital.

C not affect the company's cost of capital.

9 According to the pecking order theory, MBG's announced capital structure change may be optimal:

A because debt is cheaper than equity on an after-tax basis.

B if new equity is issued before new debt as a source of capital.

C if new debt is issued after all internally generated funds are first used as sources of capital.

The following information relates to Questions 10–11

Lindsay White, CFA, is an analyst with a firm in London. She is responsible for covering five companies in the Consumer Staples industry. White believes that over the next two years the domestic and global economies will grow slightly below average, but she is also concerned about the possibility of a mild recession during the same period. She has been asked to review the companies that she covers, and she has collected information about them, presented in Exhibit 1. White has estimated that earnings before interest and taxes (EBIT) will remain constant for all five companies for the foreseeable future. Currency is in terms of the British pound (£). The marginal corporate tax rate is 30% for all five companies.

Exhibit 1 Selected Company Financial Data

	Aquarius	Bema	Garth	Holte	Vega
EBIT (£)	600,000	600,000	400,000	400,000	400,000
Debt-to-equity ratio (market value)	0.60	0.00	0.00	0.71	0.62
Debt (market value) (£)	2,000,000	0	0	2,000,000	2,000,000
S&P debt rating	A+	n.a.	n.a.	A–	A
Weighted average cost of capital	—	10%	10%	—	—

Based on conversations with management of the five companies and her own independent research and analysis, White notes the following:

Aquarius:

- has lower bonding costs than does Bema.
- has a higher percentage of tangible assets to total assets than does Bema.
- has a higher degree of operating leverage than does Bema.

Garth:

- invests significantly less in research and development than does Holte.
- has a more highly developed corporate governance system than does Holte.
- has more business risk than does Holte.

In addition, White has reached various conclusions regarding announcements by Bema, Garth, and Vega:

Announcement	Bema has announced that it will issue debt and use the proceeds to repurchase shares. As a result of this debt-financed share repurchase program, Bema indicates that its debt/equity will increase to 0.6 and its before-tax cost of debt will be 6%.
Conclusion	As a result of the announced program, Bema's total market value should decrease relative to Aquarius's.

Announcement	Garth has announced that it plans to abandon the prior policy of all-equity financing by the issuance of £1 million in debt in order to buy back an equivalent amount of equity. Garth's before-tax cost of debt is 6%.
Conclusion	This change in capital structure is reasonable, but Garth should take care subsequently to maintain a lower D/E than Holte.
Announcement	Vega has announced that it intends to raise capital next year, but it is unsure of the appropriate method of raising capital.
Conclusion	White has concluded that Vega should apply the pecking order theory to determine the appropriate method of raising capital.

10 Based on Exhibit 1 and White's notes, which of the following is *most* consistent with White's conclusion regarding Garth's announcement?

A Garth has more business risk than does Holte.

B Garth invests significantly less in research and development than does Holte.

C Garth has a more highly developed corporate governance system than does Holte.

11 Based on White's third conclusion, regarding determining the appropriate method of raising capital, Vega should raise capital in the following order:

A debt, internal financing, equity.

B equity, debt, internal financing.

C internal financing, debt, equity.

SOLUTIONS

1 B is correct. Proposition I, or the capital structure irrelevance theorem, states that the level of debt versus equity in the capital structure has no effect on company value in perfect markets.

2 C is correct. The cost of equity rises with the use of debt in the capital structure (e.g., with increasing financial leverage).

3 C is correct. If the company's WACC increases as a result of taking on additional debt, the company has moved beyond the optimal capital range. The costs of financial distress may outweigh any tax benefits to the use of debt.

4 A is correct. The use of long-maturity debt is expected to be inversely related to the level of inflation.

5 A is correct. According to the pecking order theory, internally generated funds are preferable to both new equity and new debt. If internal financing is insufficient, managers next prefer new debt, then new equity.

6 B is correct. The static trade-off theory indicates that there is a trade-off between the tax shield from interest on debt and the costs of financial distress, leading to an optimal amount of debt in a company's capital structure.

7 A is correct. The market value of equity is ($30)(10,000,000) = $300,000,000. With the market value of debt equal to $100,000,000, the market value of the company is $100,000,000 + $300,000,000 = $400,000,000. Therefore, the company is $100,000,000/$400,000,000 = 0.25 or 25% debt-financed.

8 A is correct. The after-tax cost of debt decreases as the marginal tax rate increases.

9 C is correct. If internally generated funds have already been fully used, the use of new debt may be optimal according to the pecking order theory of capital structure.

10 A is correct. The statement implies that Garth possesses a lower ability to assume debt than does Holte, all else being equal.

11 C is correct. According to the pecking order theory, managers prefer internal financing. If internal financing is not sufficient, managers next prefer debt, then equity.

Analysis of Dividends and Share Repurchases

by Gregory Noronha, PhD, CFA, and George H. Troughton, PhD, CFA

Gregory Noronha, PhD, CFA, is at the University of Washington, Tacoma (USA). George H. Troughton, PhD, CFA (USA).

LEARNING OUTCOMES

Mastery	*The candidate should be able to:*
☐	**a.** describe the expected effect of regular cash dividends, extra dividends, liquidating dividends, stock dividends, stock splits, and reverse stock splits on shareholders' wealth and a company's financial ratios;
☐	**b.** compare theories of dividend policy and explain implications of each for share value given a description of a corporate dividend action;
☐	**c.** describe types of information (signals) that dividend initiations, increases, decreases, and omissions may convey;
☐	**d.** explain how agency costs may affect a company's payout policy;
☐	**e.** explain factors that affect dividend policy in practice;
☐	**f.** calculate and interpret the effective tax rate on a given currency unit of corporate earnings under double taxation, dividend imputation, and split-rate tax systems;
☐	**g.** compare stable dividend with constant dividend payout ratio, and calculate the dividend under each policy;
☐	**h.** compare share repurchase methods;
☐	**i.** calculate and compare the effect of a share repurchase on earnings per share when 1) the repurchase is financed with the company's surplus cash and 2) the company uses debt to finance the repurchase;
☐	**j.** calculate the effect of a share repurchase on book value per share;
☐	**k.** explain the choice between paying cash dividends and repurchasing shares;

(continued)

LEARNING OUTCOMES

Mastery	The candidate should be able to:
☐	**l.** describe broad trends in corporate payout policies;
☐	**m.** calculate and interpret dividend coverage ratios based on 1) net income and 2) free cash flow;
☐	**n.** identify characteristics of companies that may not be able to sustain their cash dividend.

1 DIVIDENDS: FORMS AND EFFECTS ON SHAREHOLDER WEALTH AND FINANCIAL RATIOS

a describe the expected effect of regular cash dividends, extra dividends, liquidating dividends, stock dividends, stock splits, and reverse stock splits on shareholders' wealth and a company's financial ratios;

This reading covers the features and characteristics of dividends and share repurchases as well as the theory and practice of corporate payout policy. A **dividend** is a distribution paid to shareholders. Dividends are declared (i.e., authorized) by a corporation's board of directors, whose actions may require approval by shareholders (e.g., in most of Europe) or may not require such approval (e.g., in the United States). Shares trading **ex-dividend** refers to shares that no longer carry the right to the next dividend payment. The **ex-dividend date** is the first date that a share trades without (i.e., "ex") this right to receive the declared dividend for the period. All else holding constant, on the ex-dividend date the share price can be expected to drop by the amount of the dividend. In contrast to the payment of interest and principal on a bond by its issuer, the payment of dividends is discretionary rather than a legal obligation and may be limited in amount by legal statutes and debt contract provisions. Dividend payments and interest payments in many jurisdictions are subject to different tax treatment at both the corporate and personal levels.

In this reading, we focus on dividends on common shares (as opposed to preferred shares) paid by publicly traded companies. A company's **payout policy** is the set of principles guiding cash dividends and the value of shares repurchased in any given year. Payout policy (also called distribution policy) is more general than dividend policy because it reflects the fact that companies can return cash to shareholders by means of share repurchases and cash dividends. One of the longest running debates in corporate finance concerns the impact of a company's payout policy on common shareholders' wealth. Payout decisions, along with financing (capital structure) decisions, generally involve the board of directors and senior management and are closely watched by investors and analysts.

Dividends and share repurchases concern analysts because, as distributions to shareholders, they affect investment returns and financial ratios. The contribution of dividends to total return for stocks is formidable. For example, the total compound annual return for the S&P 500 Index with dividends reinvested from the beginning of 1926 to the end of 2018 was 10.0%, as compared with 5.9% on the basis of price alone. Similarly, from 1950 to 2018 the total compound annual return for the Nikkei 225 Index with dividends reinvested was 11.1%, as compared with 8.0% on the basis of price alone. Dividends also may provide important information about future company performance and investment returns. Analysts should strive to become familiar with all investment-relevant aspects of dividends and share repurchases.

This reading is organized as follows. Section 1 reviews the features and characteristics of cash dividends, liquidating dividends, stock dividends, stock splits, and reverse stock splits and describes their expected effect on shareholders' wealth and a company's financial ratios. Sections 2–4 present theories of the effects of dividend policy on company value. In Section 5, we discuss factors that affect dividend policy in practice and presents global trends in payout policy. In Section 6, we cover three major types of dividend policies. Sections 7–9 present share repurchases, including their income statement and balance sheet effects and equivalence to cash dividends (under certain assumptions). Section 10 covers analysis of dividend safety. The reading concludes with a summary.

1.2 Dividends: Forms and Effects on Shareholder Wealth and Issuing Company's Financial Ratios

Companies can pay dividends in a number of ways. Cash dividends can be distributed to shareholders through regular, extra (also called special or irregular), or liquidating dividends. Other forms of dividends include stock dividends and stock splits. In this section, we review the different forms that dividends can take and explain their impact on both the shareholder and the issuing company.

1.2.1 *Regular Cash Dividends*

Many companies choose to distribute cash to their shareholders on a regular schedule. The customary frequency of payment, however, may vary among markets. In the United States and Canada, most companies that pay dividends choose a quarterly schedule of payments, whereas in Europe and Japan, the most common choice is to pay dividends twice a year (i.e., semiannually). Elsewhere in Asia, companies often favor paying dividends once a year (i.e., annually). Exhibit 1 summarizes typical dividend payment schedules for selected markets.

Exhibit 1 Geographic Differences in Frequency of Payment of Cash Dividends

Market	Most Common Frequency
Canada, United States	Quarterly
Australia, Japan, Saudi Arabia	Semiannually
Egypt, Germany, Thailand	Annually

Most companies that pay cash dividends strive to maintain or increase their dividends. A record of consistent dividends over a long period of time is important to many companies and shareholders because it is widely interpreted as evidence of consistent profitability. At a minimum, most dividend-paying companies strive not to reduce dividends when they are experiencing temporary problems.

Regular dividends, and especially increasing regular dividends, also signal to investors that their company is growing and will share profits with its shareholders. Perhaps more importantly, management can use dividend announcements to communicate confidence in the company's future. Accordingly, an increase in the regular dividend (especially if it is unexpected) often has a positive effect on share price.

1.2.2 *Extra or Special (Irregular) Dividends*

An **extra dividend** or **special dividend** (also known as an irregular dividend) is either a dividend paid by a company that does not pay dividends on a regular schedule or a dividend that supplements regular cash dividends with an extra payment. These extra dividend payments may be brought about by special circumstances. For example, in December 2018 Hong Kong Stock Exchange (HKEX)-listed Tencent Holdings, a leading provider of internet value-added services, declared a special dividend of HKD250 million to its shareholders after its spin-off Tencent Music went public in New York. This special dividend was approximately 3.5% of Tencent's annual dividend. Like many high-growth technology companies, Tencent had a history of paying very low dividends—with a yield of just 0.26% for 2018 (compared to an average of 4.6% for all stocks listed on the Hong Kong Stock Exchange).

Companies, particularly in cyclical industries, have sometimes chosen to use special dividends as a means of distributing more earnings only during strong earnings years. During economic downturns, when earnings are low or negative, cash that might otherwise be used for dividends is conserved. For example, a company may choose to declare a small regular dividend, and then when operating results are good, it may declare an extra dividend at the end of the year. In May 2018, Mumbai-listed Ingersoll-Rand (India) Ltd, a diversified industrial manufacturer, declared a special "second interim" dividend of Rs202 in addition to the regular annual Rs6 dividend, whereas for the prior 2 decades, the company had paid only the regular Rs6 dividend (excepting a special 2011 Rs24 dividend). The 2018 second interim dividend was paid out of current year profits and accumulated surpluses from earlier years. At the time, the company's reported year-on-year net profit growth was 25%.

Example 1 concerns a hypothetical company with a stated **dividend policy**—the strategy a company follows to determine the amount and timing of dividend payments—regarding the payment of extra dividends. In the example, the **dividend payout ratio** refers to common share cash dividends divided by net income available to common shares over the same time period.

EXAMPLE 1

AfriSage Technologies' Dividend Policy

AfriSage Technologies (AST), a hypothetical company, is a leading provider of commercial and enterprise software solutions in Southern African Development Community (SADC) countries. AST's financial data are reported in South African Rand (ZAR). In November 2017, AfriSage's board of directors modified its dividend policy, stating:

> The company will target an investment-grade, long-term credit rating to secure strategic financial flexibility for investments in future growth. The ordinary dividend shall be at least 35% of net income. Excess capital will be returned to shareholders after the board has taken into consideration the company's cash at hand, projected cash flow, and planned investment from a medium-term perspective as well as capital market conditions.

Selected AfriSage Financial per Share Data

	2018	2017
Shares outstanding	632.5 million	632.5 million
Earnings per share	ZAR14.23	ZAR12.65
Cash dividends per share	ZAR7.61	ZAR10.68

1. Calculate the cash dividend payout ratio for 2018 and 2017.
2. Assuming the board's new dividend policy became effective in 2018, calculate the amount of the annual ordinary dividend on the basis of AfriSage's minimum payout policy in 2018 and the amount that could be considered an extra dividend.

Solution to 1:

With the same number of shares outstanding, the dividend payout ratio on a per share basis is dividends per share divided by earnings per share.

For 2018: ZAR7.61/ZAR14.23 = 53.5%.

For 2017: ZAR10.68/ZAR12.65 = 84.4%.

Solution to 2:

Under a policy of 35% of earnings, the minimum amount of dividends would be ZAR14.23 × 0.35 = ZAR4.98. The amount of the extra dividend would then be ZAR7.61 − ZAR4.98 = ZAR2.63.

1.2.3 *Liquidating Dividends*

A dividend may be referred to as a **liquidating dividend** when a company:

- goes out of business and the net assets of the company (after all liabilities have been paid) are distributed to shareholders;
- sells a portion of its business for cash and the proceeds are distributed to shareholders; or
- pays a dividend that exceeds its accumulated retained earnings (impairs stated capital).

These points illustrate that a liquidating dividend is a return of capital rather than a distribution from earnings or retained earnings.

1.2.4 *Stock Dividends*

Stock dividends are a non-cash form of dividends. With a **stock dividend** (also known as a **bonus issue of shares** or a scrip dividend), the company distributes additional shares (typically 2–10% of the shares then outstanding) of its common stock to shareholders instead of cash. Although the shareholder's total cost basis remains the same, the cost per share held is reduced. For example, if a shareholder owns 100 shares with a purchase price of US$10 per share, the total cost basis would be US$1,000. After a 5% stock dividend, the shareholder would own 105 shares of stock at a total cost of US$1,000. However, the cost per share would decline to US$9.52 (US$1,000/105).

Superficially, the stock dividend might seem an improvement on the cash dividend from both the shareholders' and the company's point of view. Each shareholder ends up with more shares, which did not have to be paid for, and the company did not have to spend any actual money issuing a dividend. Furthermore, stock dividends are generally not taxable to shareholders because a stock dividend merely divides the "pie" (the market value of shareholders' equity) into smaller pieces. The stock dividend, however, does not affect the shareholder's proportionate ownership in the company because other shareholders receive the same proportionate increase in shares. Additionally, the stock dividend does not change the value of each shareholder's ownership position because the increase in the number of shares held is accompanied by an offsetting decrease in earnings per share, and other measures of value per share, resulting from the greater number of shares outstanding.

The second point is illustrated in Exhibit 2, which shows the impact of a 3% stock dividend to a shareholder who owns 10% of a company with a market value of US$20 million. As one can see, the market value of the shareholder's wealth does not change, assuming an unchanged **price-to-earnings ratio** (the ratio of share price, P, to earnings per share, E, or P/E). That assumption is reasonable because a stock dividend does not alter a company's asset base or earning power. (As the reader will see shortly, the same is true of a stock split.) The total market value of the company is unaffected by the stock dividend because the decrease in the share price is exactly offset by the increase in the number of shares outstanding.

Exhibit 2 Illustration of the Effect of a Stock Dividend

	Before Dividend	After Dividend
Shares outstanding	1,000,000	1,030,000
Earnings per share	US$1.00	US$0.97 (1,000,000/1,030,000)
Stock price	US$20.00	US$19.4175 (20 × 0.9709)
P/E	20	20
Total market value	US$20 million	US$20 million (1,030,000 × US$19.4175)
Shares owned	100,000 (10% × 1,000,000)	103,000 (10% × 1,030,000)
Ownership value	US$2,000,000 (100,000 × US$20)	US$2,000,000 (103,000 × US$19.4175)

Note: The exhibit shows intermediate results rounded to four decimal places, but final results are based on carrying intermediate results at full precision.

Companies that regularly pay stock dividends see some advantages to this form of dividend payment. It favors long-term investors, which, in turn, may lower the company's cost of equity financing. The payment of a stock dividend also helps increase the stock's float, which improves the liquidity of the shares and dampens share price volatility.

A traditional belief is that a lower stock price will attract more investors, all else equal. US companies often view the optimal share price range as US$20 to US$80. For a growing company, payment of a regular stock dividend is more likely to help keep the stock in the "optimal" range. In February 2019, for example, Massmart—the second-largest distributor of consumer goods in Africa—changed its established policy of paying interim and final dividends in cash and instead declared a scrip dividend for the 2018 final dividend. When the company pays the same dividend rate on the new shares as it did on the old shares, a shareholder's dividend income increases; however, the company could have accomplished the same result by increasing the cash dividend.

From a company's perspective, the key difference between a stock dividend and a cash dividend is that a cash dividend affects a company's capital structure, whereas a stock dividend has no economic impact on a company. Cash dividends reduce assets (because cash is being paid out) and shareholders' equity (by reducing retained earnings). All else equal, liquidity ratios, such as the cash ratio (cash and short-term marketable securities divided by current liabilities) and current ratio (current assets divided by current liabilities), should decrease, reflecting the reduction in cash. Financial leverage ratios, such as the debt-to-equity ratio (total debt divided by total shareholders' equity) and debt-to-assets ratio (total debt divided by total assets), should also increase. Stock dividends, on the other hand, do not affect assets or shareholders' equity. Although retained earnings are reduced by the value of the stock dividends paid (i.e., by the number of shares issued × price per share), contributed capital increases by the same amount (i.e., the value of the shares issued). As a result, total shareholders' equity does not change. Neither stock dividends nor stock splits (which are discussed in the next section) affect liquidity ratios or financial leverage ratios.

1.2.5 *Stock Splits*

Stock splits are similar to stock dividends in that they have no economic effect on the company, and the shareholders' total cost basis does not change. For example, if a company announces a two-for-one stock split, each shareholder will be issued an additional share for each share currently owned. Thus, a shareholder will have twice as many shares after the split as before the split. Therefore, earnings per share (and all other per share data) will decline by half, leaving the P/E and equity market value unchanged. Assuming the corporation maintains the same dividend payout ratio as before the split, **dividend yield** (annual dividends per share divided by share price) will also be unchanged. Apart from the effect of any information or benefit that investors perceive a stock split to convey, stock splits (like stock dividends) should be neutral in their effect on shareholders' wealth.

Although two-for-one and three-for-one stock splits are the most common, such unusual splits as five-for-four or seven-for-three sometimes occur. It is important for shareholders to recognize that their wealth is not changed by the stock split (just as it was not changed for a stock dividend, all else equal). Exhibit 3 shows an example of a two-for-one split and its impact on stock price, earnings per share, dividends per share, dividend payout ratio, dividend yield, P/E, and market value.

Exhibit 3 Before and After a Two-for-One Stock Split

	Before Split	After Split
Number of shares outstanding	4 million	8 million
Stock price	€40.00	€20.00 (€40/2)
Earnings per share	€1.50	€0.75 (€1.50/2)
Dividends per share	€0.50	€0.25 (€0.50/2)
Dividend payout ratio	1/3	1/3
Dividend yield	1.25%	1.25% (€0.25/€20.00)
P/E	26.7	26.7 (€20.00/€0.75)
Market value of equity	€160 million	€160 million (€20.00 × 8 million)

As can be seen, a two-for-one stock split is basically the same as a 100% stock dividend because all per share data have been reduced by 50%. The only difference is in the accounting treatment: Although both stock dividends and stock splits have no effect on total shareholders' equity, a stock dividend is accounted for as a transfer of retained earnings to contributed capital. A stock split, however, does not affect any of the balances in shareholder equity accounts.

A company may announce a stock split at any time. Typically, a split is announced after a period in which the stock price has risen. Many investors view the announcement of a stock split as a positive sign pointing to future stock price increases. More often, however, announced stock splits merely recognize that the stock has risen enough to justify a stock split to return the stock price to a lower, more marketable price range.

Several of the largest companies in the world (as measured by market value) had stock splits in the last decade. For example, Schneider Electric SA (France) had a two-for-one split in 2011; Whole Foods Market (United States) had a two-for-one split in 2013. In each case, the stock split came after a significant rise in stock price but was not, in and of itself, a meaningful predictor of future price action. However, data show that stock splits have been on the decline in the United States. Although S&P 500 constituent stock splits averaged 45 per year between 1980 and 2017, they reached the maximum of 114 splits in 1986 and have steadily declined since 2015 (e.g., only 5 splits in 2017). This decline in stock splits has been attributed to greater use of funds and exchange-traded funds (ETFs) by individual investors and to changes in market microstructure that have de-linked such transaction costs as commissions paid to number of shares traded. Thus, the concept of a "marketable price range" of a company's stock has become less important.

Much less common than stock splits are reverse stock splits. A **reverse stock split** increases the share price and reduces the number of shares outstanding—again, with no effect on the market value of a company's equity or on shareholders' total cost basis. Just as a high stock price might lead a company to consider a stock split, so too a low stock price may lead a company to consider a reverse stock split. The objective of a reverse stock split is to increase the price of the stock to a higher, more marketable range. As reported in *Barron's*, companies execute reverse splits "to attract institutional investors and mutual funds that often shy from buying stocks trading below US$5." Reverse stock splits are perhaps most common for companies in, or coming out of, financial distress. Kitov Pharma, an Israeli drug developer, announced a 1-for-20 reverse split in December 2018, reducing its issued shares to 16 million, in order to meet minimum share price listing criteria to begin trading on the Tel Aviv Stock Exchange and to begin the trading of its ADRs on the NASDAQ in January 2019.

Reverse splits, historically less common in Asia, are becoming more popular. For example, reverse stock splits were not permitted in Japan under Corporation Law until 2001, but since 2007, they have been actively encouraged by the Tokyo Stock Exchange to meet the Exchange's objective of standardizing trading lot size to 100 shares for listed companies by 1 October 2018. While most companies were compliant by the deadline, on that date 23 companies reduced their trading lot size to 100 shares by carrying out reverse stock splits. As an example, in May 2018 Fuji Electric Co. Ltd announced that it would conduct a 5-for-1 reverse stock split on 1 October 2018 to adjust the unit of investment in the company to a level deemed desirable by the TSE (between ¥50,000 and ¥500,000).

EXAMPLE 2

Globus Maritime Announces a Reverse Split

In May 2018, Globus Maritime Ltd, a Greek dry bulk shipping company providing worldwide maritime transportation services, was warned by NASDAQ that it no longer met the continuing listing requirements once its share price had traded below the US$1 a share minimum price requirement for 30 consecutive business days. Globus was given until the end of October 2018 to regain compliance. Globus announced a 1 for 10 reverse split to occur on 15 October. On 12 October, shares were trading at US$4.25 before the reverse split had taken place.

1 If the reverse split were to take place when the share price was US$4.25, find the expected stock price after a 1-for-10 reverse split, assuming no other factors affect the split.
2 Comment on the following statement: “Shareholder wealth is negatively affected by a reverse stock split.”

Solution to 1:

If the price was US$4.25 before the reverse split, for every 10 shares, a shareholder would have 1 share priced at 10 × US$4.25 = US$42.50.

Solution to 2:

The statement is not generally correct. Considering the reverse split on its own, the market capitalization of the common equity would be unchanged. If the reverse split was interpreted as a good decision (e.g., because the company will be able to retain the advantages of being listed on the NASDAQ), its price and thus market capitalization might increase. But other factors—such as continued limited growth of its operations or continued small share float and turnover—could drive down the stock’s value.

DIVIDEND POLICY AND COMPANY VALUE: THEORY 2

b compare theories of dividend policy and explain implications of each for share value given a description of a corporate dividend action;

Since the early 1960s, financial theorists have debated the extent to which dividend policy (decisions about whether, when, and in what amount to pay dividends) should and does matter to a company’s shareholders. One group of theorists believes that dividend policy is irrelevant to shareholders. This group typically holds that only the decisions of the company that are directly related to investment in working and fixed capital affect shareholders’ wealth. A second group holds that dividend policy does matter to investors, for one or more reasons, and that a company can affect shareholders’ wealth through its dividend policy. Typically, dividend relevance is attributed to either the belief that investors value a unit of dividends more highly than an equal amount of uncertain capital gains or to one or more market imperfections. Such imperfections include taxes (because dividends may be taxed differently than capital gains), asymmetric information (corporate insiders are better informed about their company’s prospects than outside investors), and agency costs (management has a tendency to squander extra cash). We examine these positions and the assumptions that underlie them in the following subsections.

2.1 Dividend Policy Does Not Matter

In a 1961 paper, Miller and Modigliani (“MM”) argued that in a world without taxes, transaction costs, and equal (“symmetric”) information among all investors—that is, under **perfect capital market** assumptions—a company’s dividend policy should have no impact on its cost of capital or on shareholder wealth. Their argument begins by assuming a company has a given capital budget (e.g., it accepts all projects with a positive net present value, or NPV) and that its current capital structure and debt ratio are optimal. Another way of stating this argument is that the dividend decision is independent of a company's investment and financing decisions. For example, suppose that an all-equity financed company decided to pay as a dividend the investment amount it required for its capital budget. To finance capital projects, the company could issue additional common shares in the amount of its capital budget (such financing would leave its capital structure unchanged). The value of the newly issued shares would exactly offset the value of the dividend. Thus, if a company paid out a dividend that represented 5% of equity, its share price would be expected to drop by 5%. If a common stock in Australia is priced at A$20 before an A$1 per share dividend, the implied new price would be A$19. The shareholder has assets worth A$20 if the dividend is not paid or assets worth A$20 if the stock drops to A$19 and an A$1 dividend is paid.

Note that under the MM assumptions, there is no meaningful distinction between dividends and share repurchases (repurchases of outstanding common shares by the issuing company): They are both ways for a company to return cash to shareholders. If a company had few investment opportunities such that its current cash flow was more than that needed for positive NPV projects, it could distribute the excess cash flow via a dividend or a share repurchase. Shareholders selling shares would receive A$20 a share, and shareholders not selling would hold shares whose value continued to be A$20. To see this, suppose the company being discussed has 10,000 shares outstanding, a current free cash flow of A$10,000, and a present value of future cash flows of A$190,000. Thus, the share price is (A$10,000 + A$190,000)/10,000 = A$20. Now if the company uses the free cash flow to repurchase shares, in lieu of paying a dividend of A$1, it will repurchase 500 shares (A$10,000/A$20 = 500). The 9,500 shares left outstanding have a claim on the A$190,000 future cash flow, which results in a share price of A$20 (A$190,000/9,500 = A$20).

An intuitive understanding of MM dividend irrelevance also follows from the concept of a "homemade dividend." In a world with no taxes or transaction costs, if shareholders wanted or needed income, they could construct their own dividend policy by selling sufficient shares to create their desired cash flow stream. Using the example above, assume the company did not pay the A$1 dividend and the stock remained at A$20. A holder of 1,000 shares who desired A$1,000 in cash could sell 50 shares at A$20, thus reducing his or her holdings to 950 shares. Note that by reducing share holdings, second-period dividend income is reduced; higher dividend income in one period is at the expense of exactly offsetting lower dividend income in subsequent periods. The irrelevance argument does not state that dividends per se are irrelevant to share value but that dividend *policy* is irrelevant. By taking the earning power of assets as a given and assuming perfect capital markets, policy alternatives merely involve tradeoffs of different dividend streams of equal present value.

In the real world, market imperfections create some problems for MM's dividend policy irrelevance propositions. First, both companies and individuals incur transaction costs. A company issuing new shares incurs **flotation costs** (i.e., costs in selling shares to the public that include underwriters' fees, legal costs, registration expenses, and possible negative price effects) often estimated to be as much as 4% to 10% of the capital raised, depending on the size of the company and the size of the issue. Shareholders selling shares to create a "homemade" dividend would incur transaction costs and, in some countries, capital gains taxes (of course, cash dividends incur taxes in most countries). Furthermore, selling shares on a periodic basis to create an income stream of dividends can be problematic over time if share prices are volatile. If share prices decline, shareholders have to sell more shares to create the same dividend stream.

2.2 Dividend Policy Matters: The Bird in the Hand Argument

Financial theorists have argued that, even under perfect capital markets assumptions, investors prefer a dollar of dividends to a dollar of potential capital gains from reinvesting earnings because they view dividends as less risky. A related viewpoint is that "the typical dollar of reinvestment has less economic value to the shareholder than a dollar paid in dividends" (Graham, Dodd, Cottle, and Tatham 1962). These arguments are similar and have sometimes been called the "bird in the hand" argument, a reference to the proverb "a bird in the hand is worth two in the bush." By assuming that a given amount of dividends is less risky than the same amount of capital gains, the argument is that a company that pays dividends will have a lower cost of equity capital than an otherwise similar company that does not pay dividends; the lower cost of equity should result in a higher share price. MM contend that this argument is incorrect because, under their assumptions, paying or increasing the dividend today does not affect the risk of future cash flows. Such actions only lower the ex-dividend price of the share.

2.3 Dividend Policy Matters: The Tax Argument

In some countries, dividend income has traditionally been taxed at higher rates than capital gains. In the United States since 2012, for instance, dividends on shares held at least 60 days have been taxed at a maximum rate of 20%, which exceeds the long-term capital gains tax rate of 15%. In mainland China, there is no capital gains tax on shares; however, dividend income is taxed at 20% for shares held less than a month, 10% for shares held between one month and a year, and since 2015 at 0% for shares held longer than a year.

An argument could be made that in a country that taxes dividends at higher rates than capital gains, taxable investors should prefer companies that pay low dividends and reinvest earnings in profitable growth opportunities. Presumably, any growth in earnings in excess of the opportunity cost of funds would translate into a higher share price. If, for any reason, a company lacked growth opportunities sufficient to consume its annual retained earnings, it could distribute such funds through share repurchases (again, the assumption is that capital gains are taxed more lightly than dividends). Taken to its extreme, this argument would advocate a *zero* dividend payout ratio. Real world market considerations may complicate the picture. For example, in some jurisdictions governmental regulation may require companies to distribute excess earnings as dividends or to classify share repurchases as dividends if the repurchases appear to be ongoing in lieu of dividend payments.

OTHER THEORETICAL ISSUES: CLIENTELE EFFECT AND THE INFORMATION CONTENT OF DIVIDEND ACTIONS: SIGNALING

3

c describe types of information (signals) that dividend initiations, increases, decreases, and omissions may convey;

d explain how agency costs may affect a company's payout policy;

In the following section, we present additional perspectives related to the theory of dividend policy.

3.1 The Information Content of Dividend Actions: Signaling

MM assumed that all investors—including outside investors—have the same information about the company: a situation of symmetric information. In reality, corporate managers typically have access to more detailed and extensive information about the company than do outside investors.

A situation of asymmetric information raises the possibility that dividend increases or decreases may affect share price because they may convey new information about the company. A company's board of directors and management, having more information than outside investors, may use dividends to signal to investors about (i.e., convey information on) the company's prospects. A company's decision to initiate, maintain, increase, or cut a dividend may convey more credible information than positive words from management because cash is involved. For a signal to be effective, it must be difficult or costly to mimic by another entity without the same attributes. Dividend increases are costly to mimic because a company that does not expect its cash flows to increase will not be able to maintain the dividend at increasingly high levels in the long run. (In the short run, a company may be able to borrow to fund dividends.)

Empirical studies broadly support the thesis that dividend initiations or increases convey positive information and are associated with future earnings growth, whereas dividend omissions or reductions convey negative information and are associated with future earnings problems. A dividend declaration can help resolve some of the information asymmetry between insiders and outsiders and help close any gap between the market price of shares and their intrinsic value. Evidence in both developed and emerging market equities suggests the presence of an earnings and return effect following dividend initiation announcements. In general, company earnings increase in the year of dividend initiation and in the following several years, and then the announcement of the initiation of a regular cash dividend is accompanied by an excess return. By looking at two historical examples of signaling, Example 3 provides further support for the idea that dividend initiations contain value-relevant information.

EXAMPLE 3

Historical Examples: Information on Dividend Initiations

Following are two examples of the information content of dividend initiations following the 2008 global financial crisis.

A Oracle Corporation, a leading business software maker, initiated a US$0.05 quarterly dividend in May 2009. Oracle's annual US$0.20 dividend amounts to about US$1 billion, a relatively small amount compared with operating cash flow of US$8 billion and another US$9 billion in cash and cash-equivalent assets on its balance sheet at the end of fiscal year 2009. An analyst who follows Oracle for institutional investors saw the Oracle announcement as a signal that the company was well positioned to ride out the downturn and also gain market share.

B In mid-2009, Paris-based Groupe Eurotunnel announced its first ever dividend after it completed a debt restructuring and received insurance proceeds resulting from a fire that had closed the Channel Tunnel. In a 2 June 2009 press release, Eurotunnel's CEO said that this "marked a turning point for the company as its business has returned to the realm of normality"; the company anticipated a return to profitability.

Some researchers have argued that a company's dividend initiation or increase tends to be associated with share price increases because it attracts more attention to the company. Managers have an incentive to increase the company's dividend if they believe the company to be undervalued because the increased scrutiny will lead to a positive price adjustment. In contrast, according to this line of reasoning, managers of overvalued companies have little reason to mimic such a signal because increased scrutiny would presumably result in a downward price adjustment to their shares.

EXAMPLE 4

Signaling with Dividends and the Costs of Mimicking

Suppose that the management of a company with poor future prospects recommends to the board of directors an increase in its dividend. Management explains to the board that investors may then believe that the company has positive future prospects, leading to an increase in share value and shareholder wealth.

1 State whether such imitation is likely to achieve the stated objective over the long term.
2 Justify your answer to Question 1.

Solution to 1:

No, such dividend increases are not likely to achieve the stated objective over the long term for the company described.

Solution to 2:

Dividend increases are costly to mimic because a company that does not expect its cash flows to increase will not be able to maintain the increased dividend. The company will have to either cut the dividend in the future or go to the market to obtain new equity or debt funding to pay the dividend. Both these alternatives are costly for the company because they result in downward revisions, on average, to the stock price.

Many companies take pride in their record of consistently increasing dividends over a long period of time. Standard & Poor's, for example, identifies companies in its US-based S&P 500 Index, Europe 350 Index, Pan Asia Index, and S&P/TSX Canadian Index that have increased their dividend for a number of consecutive years (at least 25 years in the case of the S&P 500, at least 10 years in the case of the Europe 350, at least 7 years in the case of Pan Asia Index, and at least 5 years in the case of the S&P/TSX). These companies are in various industries. When a company's earnings and cash flow outlook has been and continues to be positive, it often views a policy of increasing dividends as an important tool to convey that information to existing and potential shareholders. Companies that consistently increase their dividends seem to share certain characteristics:

- Dominant or niche positions in their industry
- Global operations
- Relatively less volatile earnings
- Relatively high returns on assets
- Relatively low debt ratios (dividend payouts unlikely to be affected by restrictions in debt covenants)

Dividend cuts or omissions, in contrast, present powerful and often negative signals. For companies under financial or operating stress, the dividend declaration date may be viewed with more than usual interest. Will they cut the dividend? Will they omit the dividend altogether? In these instances, merely maintaining the dividend or not cutting it as much as expected is usually viewed as good news (i.e., that current difficulties are transitory and manageable), unless investors view managers as trying to convey erroneous information to the market.

In principle, although difficult in practice, management can attempt to send a positive signal by cutting the dividend. Telstra, a major Australian telecoms company with an enviable record of paying close to 90% of profits as dividends, announced in 2017 a 30% cut in its dividend—its first cut in more than 20 years. Telstra's management explained it intended to use the funds conserved to reinvest in the business. It was planning for the longer term and retaining financial flexibility as a priority because the company faced significant challenges from rising competition and competing technologies. Although management's message was met with an initial 12% share price decline as disappointed yield-focused investors exited the stock, it was, in retrospect, a positive signal. Telstra was viewed by institutional investors as successfully using its cash flow to reorganize to meet business challenges, and it was regarded as one of the few cases in which a large Australian dividend payer was not cutting payouts as a result of extreme financial pressure.

EXAMPLE 5

Dividend Reductions and Price Increases

In November 2018, BT Group Plc, one of the world's largest providers of communication services and solutions operating in over 170 countries, announced it would cut its interim dividend from 4.85 pence a share to 4.62 pence a share. The company also revealed that net cash flow from operating activities had plunged 71% to £754 million and that revenue had fallen 2% to £11.6 billion, with declines across all divisions.

All this despite the fact that in the first six months of the year, the company reported a pretax profit increase to £1.3 billion from £1.1 billion a year prior and a 2% increase in adjusted earnings (EBITDA) to £3.7 billion from £3.6 billion as the telecoms giant cut costs as part of its restructuring. One analyst commented that while the dividend decrease was an "unwelcome surprise," it was also a "prudent move" given the 71% decline in net cash and thus "should not take too much sheen on a dividend yield, which previously stood at an attractive 6.4%." It was also noted that BT Group was replacing its chief executive in February 2019; thus, future dividends would depend on decisions made by the new leadership. As the market digested this information, the telecoms company's share price rose 6.9% to 257 pence per share.

Source: Renae Dyer, "BT Shares Surge Despite Dividend Cut as It Expects Earnings to Hit Top End of Guidance," Proactive Investors (1 November 2018).

Another example of the signaling content of dividends can be found in the actions of eBay, the e-commerce multinational corporation, and its initial dividend declaration in 2019 (24 years after the online retailer was established in 1995 during the dot-com boom). Technology companies have among the lowest dividend yields and below-average dividend payout ratios. This is because most technology companies have high R&D requirements, and some (e.g., integrated circuit manufacturers) are capital intensive. Those that are profitable often achieve returns on assets and owners' equity that are well above average. In addition, business risk is considerable as discoveries and unforeseen advances change the product landscape. All of these considerations would suggest a policy of low (or no) dividend payments so that internally generated funds are directed toward new product development and capital investment that will maintain high growth and returns. Some companies in the technology sector, however, do mature. Legacy tech companies that initiated dividends as their businesses matured and growth slowed include Apple in 2012, Cisco in 2011, Oracle in 2009, and Microsoft in 2003. At the time of eBay's dividend initiation, such non-dividend-paying tech companies as Alibaba, Weibo, Baidu, and JD.com remained the norm in markets where the technology sector was still growing.

In early 2019, eBay declared its first-ever dividend and announced that it would begin paying quarterly dividends of US$0.14 a share, which represented a yield of 1.6% (for comparison, Microsoft's dividend yield at the time was 1.9% and Cisco's was 2.9%). At the same time, eBay announced an increase in its existing share repurchase program to US$4 billion. Investor reaction was mixed. Some believed that eBay was signaling an interest in broadening its investor focus by attracting a new group of shareholders focused on income over growth while refraining from undertaking unprofitable expansion. Others viewed the dividend declaration as an admission that it was becoming a mature company—that it could no longer deliver high returns from reinvesting its earnings. The future growth prospects for the stock, they would argue, had been diminished. In other words, although the dividend initiation showed confidence in eBay's cash flow generation, investors preferred for management's use of internal investments to regenerate eBay's core business. Regardless, few could argue that eBay's dividend initiation declaration in 2019 was not a corporate event of some importance.

3.2 Agency Costs and Dividends as a Mechanism to Control Them

Large, publicly traded corporations typically have a substantial separation between the professional managers who control the corporation's operations and the outside investors who own it. When agents (the managers) and owners (the shareholders) are two separate parties, managers may have an incentive to maximize their own welfare at the company's expense because they own none or relatively small percentages of the company for which they work and thus do not bear all the costs of such actions. This incentive is ultimately also a problem of unequal (asymmetric) information between managers and outside investors because if outside investors could perfectly observe managers, managers would be dissuaded from such actions. One managerial incentive of particular concern is the potential private benefit managers may obtain from investment in negative net present value (NPV) projects. Such projects will generate negative economic returns; but because they may grow the size of the company (measured in sales or assets) and thus enlarge the manager's span of control, the manager may have the incentive to invest in them. This is a particular problem when management's compensation is tied to assets or sales rather than value enhancement, a flaw in the firm's corporate governance. The potential overinvestment agency problem might be alleviated by the payment of dividends. In particular, by paying out all free cash flow to equity in dividends, managers would be constrained in their ability to overinvest by taking on negative NPV projects. This concern or hypothesis that management may create an overinvestment agency cost is known as Jensen's free cash flow hypothesis.

The potential for managers to squander free cash flow by undertaking unprofitable projects is a consideration to be evaluated on a case-by-case basis. Prior to initiating its dividend in 2003, for example, Microsoft accumulated increasingly large cash positions but was not observed to squander monies on unprofitable projects. In some cases, such cash positions may provide financial flexibility to respond quickly to changes in the environment, to grasp unforeseen opportunities, or to survive periods of restricted credit, as in the case of Ford Motor Company's accumulation of cash during profitable years in the 1990s and similarly by Japanese automotive parts manufacturer Denso Corporation in the late 2000s and 2010s. Clearly, there are industry-specific and life-cycle conditions to consider. In general, it makes sense for growing companies in industries characterized by rapid change to hold cash and pay low or no dividends, but it does not make sense for large, mature companies in relatively non-cyclical industries. In general, there is empirical support for the market reaction to dividend change announcements to be stronger for companies with greater potential for overinvestment than for companies with lesser potential for overinvestment.

Another concern when a company is financed by debt as well as equity is that paying dividends can exacerbate the agency conflict between shareholders and bondholders. When a company has debt outstanding, the payment of dividends reduces the cash cushion available to the company for the disbursement of fixed required payments to bondholders. The payment of large dividends, with the intention of transferring wealth from bondholders to shareholders, could lead to underinvestment in profitable projects. All else equal, both dividends and share repurchases increase the default risk of debt. Reflecting bondholders' concern, the bond **indenture** (contract) often includes a covenant restricting distributions to shareholders that might impair the position of bondholders. A typical form of this restriction is to define the maximum allowable amount of distributions to shareholders during the life of the bond. This amount of funds is usually a positive function of the company's current and past earnings and issues of new equity and a negative function of dividends paid since the bonds were issued. Such covenants often do not really restrict the level of dividends as long as those dividends come from new earnings or from new issues of stock. What the covenant attempts to do is prevent the payment of dividends financed by the sale of the company's existing assets or by the issuance of new debt. Covenants that specify minimum levels of EBITDA and/or EBIT coverage of interest charges are frequently used as well. These covenants provide some assurance that operating earnings include a cushion for the payment of fixed charges. Other covenants focus on balance sheet strength—for example, by specifying a maximum value for the ratio of debt to tangible net worth.

EXAMPLE 6

Agency Issues and Dividends

Two dividend-paying companies A and B directly compete with each other. Both companies are all-equity financed and have recent dividend payout ratios averaging 35%. The corporate governance practices at Company B are weaker than at Company A. For example, at B but not A, the chief executive officer is also chair of the board of directors. Recently, profitable investment opportunities for B have become fewer, although operating cash flow for both A and B is strong.

Based only on the information given, investors who own shares in both A and B are *most likely* to press for a dividend increase at:

A Company A, because it has better growth prospects than Company B.

B Company B, because a dividend increase may mitigate potential overinvestment agency problems.

C Company B, because a dividend increase may mitigate potential underinvestment agency problems.

Solution:

B is correct. Company B's strong operating cash flow in an environment of fewer profitable growth opportunities may tempt Company B's management to overinvest. The concern is increased because of Company B's relatively weak corporate governance.

The final example in this section illustrates the complex agency considerations that may affect dividend policy.

EXAMPLE 7

Electric Utilities, Agency Costs, and Dividends

Electric utilities often have above average dividend yields. A distinctive characteristic of many utility companies is that they pay a high percentage of earnings as dividends, while periodically issuing new equity to invest in the many projects necessitated by the capital-intensive nature of their business. This practice of financing dividends with new equity appears unwise because new equity is expensive. Researchers examining a set of US-based electric utilities, however, have demonstrated that there may be a good reason for paying dividends and then issuing equity: the mitigation of the agency problems between managers and shareholders and between utility regulators and utility shareholders.

Because electric utilities are typically monopolies in the sense that they are usually the only providers of electricity in a given area, they are regulated so they are not able to set electricity rates at monopolistically high levels. The regulators are expected to set rates such that the company's operating expenses are met and investors are provided with a fair return. The regulators, however, are usually elected, or are political appointees, and view ratepayers as potential voters. Thus, utility shareholders, in addition to facing potential manager–shareholder agency issues because managers have incentives to consume perquisites or to overinvest, also face a regulator–shareholder conflict in which regulators set rates low to attract the votes of individuals being served by the utility.

In the utility industry, therefore, dividends and the subsequent equity issue are used as mechanisms to monitor managers and regulators. The company pays high dividends and then goes to the capital markets to issue new equity. If the market does not think that shareholders are getting a fair return because regulators are setting rates too low, or because managers are consuming too many perks, the price at which new equity can be sold will fall until the shareholder expectations for returns are met. As a result, the company may not be able to raise sufficient funds to expand its plant to meet increasing electricity demand—the electric utility industry is very capital intensive—and, in the extreme, customer needs may not be met. Faced with this possibility, and potentially angry voters, regulators have incentives to set rates at a fair level. Thus, the equity market serves to monitor and arbitrate conflicts between shareholders and both managers and regulators.

4 OTHER THEORETICAL ISSUES: AGENCY COSTS AND DIVIDENDS AS A MECHANISM TO CONTROL THEM AND DIVIDEND THEORY: SUMMARY

d explain how agency costs may affect a company's payout policy;

What can we conclude about the link between dividends and valuation? In theory, in the absence of market imperfections Miller and Modigliani (1961) find that dividend policy is irrelevant to the wealth of a company's investors. But in reality, the existence of market imperfections makes matters more complicated. In addition, some investors are led, by logic or custom, to prefer dividends.

Unfortunately, in the search for the link between dividend policy and value, the evidence is inconclusive. It is difficult to show an exact relationship between dividends and value because so many variables affect value. We have presented factors that would seem to explain why some companies put emphasis on dividends and others do not. Financial theory predicts that reinvestment opportunities should be the dominant factor. Indeed, no matter where they are located in the world, small, fast-growing companies pay out little or none of their earnings. Regardless of jurisdiction, more mature companies with fewer reinvestment opportunities tend to pay dividends. For these mature companies, taxes, regulations/laws, tradition, signaling, ownership structure, and attempts to reconcile agency conflicts all seem to play a role in determining the dividend payout ratio. At a minimum, in looking at a company an analyst should evaluate whether a given company's dividend policy matches its reinvestment opportunities and legal/financial environment.

5 FACTORS AFFECTING DIVIDEND POLICY IN PRACTICE

e explain factors that affect dividend policy in practice;

f calculate and interpret the effective tax rate on a given currency unit of corporate earnings under double taxation, dividend imputation, and split-rate tax systems;

In Sections 2–4 we discussed theories of dividend policy and value and concluded that the issue is, at best, unresolved. In this section we explore six factors that affect a company's dividend policy, which we defined earlier as decisions about whether, when, and in what amount to pay dividends:

- Investment opportunities
- The expected volatility of future earnings
- Financial flexibility
- Tax considerations
- Flotation costs
- Contractual and legal restrictions

Boards of directors and managers spend considerable time setting dividend policy despite the lack of clear guidance from theory to inform their deliberations. The factors listed are, however, often mentioned by managers themselves as relevant to dividend policy selection in practice. Some of the factors we explore, such as taxation, are not company-specific, whereas other factors, such as possible contractual restrictions on dividend payments and the expected volatility of future earnings, are more company-specific. The factors may be interrelated, and the presence of one may enhance or diminish the effect of another. Importantly, the independence between the investment, financing, and dividend decisions assumed by MM may no longer hold when such market imperfections as information effects, agency problems, and taxes are recognized.

5.1 Investment Opportunities

All else equal, a company with many profitable investment opportunities will tend to pay out less in dividends than a company with fewer opportunities because the former company will have more uses for internally generated cash flows. Internally generated cash flow is generally a cheaper source of equity funding than new equity issuance. Opportunities for new investments, and the speed with which a company needs to respond to them, are influenced by the industry in which the company operates. A company with the ability to delay the initiation of projects without penalty may be willing to pay out more in dividends than a company that needs to act immediately to exploit profitable investment opportunities. Technology companies tend to have much lower average dividend yields than utilities. The chief explanation may be the size and time horizon of profitable investment opportunities in relation to annual operating cash flow generated. For technology companies, the pace of change is rapid, so having internally generated funds available to react to profitable opportunities affords them valuable flexibility. For utility companies, for which there are typically fewer such opportunities and for which change is much slower, higher dividend payouts are indicated.

5.2 The Expected Volatility of Future Earnings

Several important factors in the dividend payout decision have been identified as important to managers. Most managers

- had a target payout ratio based on long-run sustainable earnings;
- focused more on dividend changes (increases or decreases) than on dividend levels; and
- were reluctant to increase the dividend if the increase might soon need to be reversed.

Findings in the United States, United Kingdom, and other countries suggest that managers are reluctant to cut dividends—preferring to smooth them over time. Smoothing takes the form of relating dividend increases to the long-term earnings growth rate, even if short-term earnings are volatile. All else equal, the more volatile earnings are, the greater the risk that a given dividend increase may not be covered by earnings in a future time period. Thus, when earnings are volatile, we expect companies to be more cautious in the size and frequency of dividend increases. These findings also hold for other countries, although variation between countries has been noted in managers' willingness to decrease dividends based on available investment opportunities.

5.3 Financial Flexibility

Companies may not initiate, or may reduce or omit, dividends to obtain the financial flexibility associated with having substantial cash on hand. A company with substantial cash holdings is in a relatively strong position to meet unforeseen operating needs and to exploit investment opportunities with minimum delay. Having a strong cash position can be particularly valuable during economic contractions when the availability of credit may be reduced. Financial flexibility may be viewed as a tactical consideration that is of greater importance when access to liquidity is critical and when the company's dividend payout is relatively large.

A classic example of explaining a dividend decision in terms of the need to preserve financial flexibility occurred with Skanska AB, based in Sweden. On 8 February 2019, Skanska AB, one of the world's biggest construction and development companies, announced its board's suggestion to cut Skanska's dividend going forward by 30% to SKr6.00. This would allow for continued expansion of its project development business while maintaining its financial ability to deliver sustainable shareholder returns. Skanska's Chief Executive Anders Danielsson stated:

> As we enter 2019, there are political and macroeconomic uncertainties which are likely to increase further. In many of our home geographies and sectors, the markets are levelling out and it is difficult to predict how long this relatively favourable environment will last.
>
> *Source*: "Skanska Warns of 'Increasing Uncertainties' and Proposes Dividend Cut," *Financial Times* (8 February 2019): https://www.ft.com/content/9201486e-2b81-11e9-a5ab-ff8ef2b976c7.

The cut was expected to conserve SKr920 million on an annual basis. With approximately SKr19 billion of cash on hand at the time of the statement and with operating cash flows at least covering the previous dividend, the dividend reduction appeared to be accurately characterized as "precautionary." Although the dividend cut announcement was accompanied by a 9% decline in Skanska's share price, the share price quickly recovered. Within two months, it had risen 7% above its pre-dividend cut announcement value, indicating the market's favorable response to Skanska's decision to cut the dividend arising from uncertainty in its operating environment and the desire to maintain financial flexibility.

When increasing financial flexibility is an important consideration, a company may decide to distribute money to shareholders primarily by means of share repurchases (covered in Sections 7–9) rather than regular dividends. A program to repurchase shares in the open market does not involve a formal requirement that any repurchases be executed, and share repurchases in general do not establish the same expectations for continuation in the future as regular dividends.

5.4 Tax Considerations

Taxation is an important factor that affects investment decisions for taxable investors, in particular, because it is the after-tax return that is most relevant to investors. Different jurisdictions tax corporate dividends in a wide variety of ways. Some tax both capital gains and dividend income. Others tax dividends but not capital gains. Even within a given country, taxation can be quite complex. In addition, because taxation is a major fiscal policy tool that is subject to politics, governments have a tendency to "re-address" tax issues, sometimes with great frequency. As with other aspects of taxation, governments use the taxation of dividends to address a variety of goals: to encourage or discourage the retention or distribution of corporate earnings; to redistribute income; or to address other political, social, and/or investment goals.

For the global investor, foreign taxes can be as important as domestic taxes. Foreign tax credits in the investor's home country also may figure importantly into the overall taxation issue. For example, France requires companies domiciled in France to withhold dividends paid to foreign investors at the corporate tax rate (reduced to 25% by 2022), but investors in other countries can usually claim a tax credit on their home country tax return for the amount of that tax, especially where a double tax agreement exists.

5.4.1 *Taxation Methods*

We look at three main systems of taxation that determine dividends: double taxation, imputation, and split-rate. Other tax systems can be a combination of these.

In a **double taxation system**, corporate pretax earnings are taxed at the corporate level and then taxed again at the shareholder level if they are distributed to taxable shareholders as dividends. Exhibit 4 illustrates double taxation, where the individual tax rate on dividends is an assumed maximum of 15%.

Exhibit 4 Double Taxation of Dividends at 15% Personal Tax Rate (per US$100)

	15.0%
Net income before taxes	US$100
Corporate tax rate	35%
Net income after tax	US$65
Dividend assuming 100% payout	US$65
Shareholder tax on dividend	US$9.75
Net dividend to shareholder	US$55.25
Double tax rate on dividend distributions*	44.8%

* Based on pretax income.

Investors will clearly prefer a lower tax rate on dividends, but it is not clear whether they prefer a higher or lower payout. Payout preferences will depend on whether there is a tax on long-term capital gains for shareholders in their country and whether the tax rate on capital gains is higher or lower than the tax rate on dividends. Later, we will discuss a company's decision with respect to the dividend payout ratio.

A second major taxation system is the **dividend imputation tax system**, which effectively ensures that corporate profits distributed as dividends are taxed just once, at the shareholder's tax rate. Australia and New Zealand use a dividend imputation tax system. Under this system, a corporation's earnings are first taxed at the corporate level. When those earnings are distributed to shareholders in the form of dividends, however, shareholders receive a tax credit, known as a **franking credit**, for the taxes that the corporation paid on those distributed earnings (i.e., corporate taxes paid are imputed to the individual shareholder). If the shareholder's marginal tax rate is higher than the company's, the shareholder pays the difference between the two rates. Exhibit 5 shows one variation of a tax imputation system in which a shareholder with a lower marginal tax bracket than the company's actually receives a tax credit for the difference between the corporate rate and his own rate.

Exhibit 5 Taxation of Dividends Based on Tax Imputation System (A$)

	Marginal Shareholder Tax Rate	
	15%	47%
Pretax income	A$100	A$100
Taxes at 30% corporate tax rate	30	30
Net income after tax	70	70
Dividend assuming 100% payout	70	70
Shareholder tax on pretax income	15	47

(continued)

Exhibit 5 (Continued)

	Marginal Shareholder Tax Rate	
	15%	**47%**
Less tax credit for corporate payment	30	30
Tax due from shareholder	(15)	17
Effective tax rate on dividend	15/100 = 15%	47/100 = 47%

A **split-rate tax system** is a third taxation system of greater historical than current importance. Under this system, corporate earnings that are distributed as dividends are taxed at a lower rate at the corporate level than earnings that are retained. At the level of the individual investor, dividends are taxed as ordinary income. Earnings distributed as dividends are still taxed twice, but the relatively low corporate tax rate on earnings mitigates that penalty. Exhibit 6 depicts this split-rate tax system for dividends.

Exhibit 6 Taxation of Dividends Based on Split-Rate System (per €100)

Pretax earnings	€200
Pretax earnings retained	100
35% tax on retained earnings	35
Pretax earnings allocated to dividends	100
20% tax on earnings allocated to dividends	20
Dividends distributed	80
Shareholder tax rate	35%
After tax dividend to shareholder	[(1 − 0.35) × 80] = 52
Effective tax rate on dividend	[20% + (80 × 0.35)%] = 48%

5.4.2 *Shareholder Preference for Current Income versus Capital Gains*

All other things being equal, one could expect that the lower an investor's tax rate on dividends relative to his or her tax rate on capital gains, the stronger the investor's preference for dividends. But other issues also impinge on this preference. The investor may buy high-payout shares for a tax-exempt retirement account. Even if dividends are taxed at a lower rate than capital gains, it is not clear that shareholders will necessarily prefer higher dividends. After all, capital gains taxes do not have to be paid until the shares are sold, whereas taxes on dividends must be paid in the year received even if reinvested. In addition, in some countries, such as the United States and Australia, shares held at the time of death benefit from a step-up valuation or tax exemption as of the death date. Finally, tax-exempt institutions, such as pension funds and endowment funds, are major shareholders in most industrial countries. Such institutions are typically exempt from both taxes on dividends and taxes on capital gains. Hence, all other things being equal, they are indifferent as to whether their return comes in the form of current dividends or capital gains.

5.5 Flotation Costs

Another factor that affects a company's dividend policy is flotation cost. Flotation costs include 1) the fees that the company pays (to investment bankers, attorneys, securities regulators, auditors, and others) to issue shares and 2) the possible adverse market price impact from a rise in the supply of shares outstanding. Aggregate flotation costs are proportionally higher (in terms of percentage of gross proceeds) for smaller companies (which issue fewer shares) than for larger companies. Flotation costs make it more expensive for companies to raise new equity capital than to use their own internally generated funds. As a result, many companies try to avoid establishing a level of dividends that would create the need to raise new equity to finance positive NPV projects.

EXAMPLE 8

A Company That Needs to Reinvest All Internally Generated Funds

Boar's Head Spirits Ltd., based in the United Kingdom, currently does not pay a dividend on its common shares. Boar's Head has an estimated operating cash flow of £500 million. The company's financial analyst has calculated its cost of capital as 12%. The same analyst has evaluated modernization and expansion projects with a positive NPV that would require £800 million. The cost of positive NPV projects exceeds estimated operating cash flow by £300 million (£800 million – £500 million). Having an above average debt ratio for its industry, Boar's Head is reluctant to increase its long-term debt in the next year. Discuss whether you would expect Boar's Head to initiate a dividend based on the above facts.

Solution:

One would expect Boar's Head would not initiate a dividend. As things stand, internally generated funds, as represented by operating cash flow, are not sufficient to fund positive NPV projects. So, payment of a dividend would be at the expense of rejecting positive NPV projects unless the balance of such projects and the dividend were both financed by debt. Given its concern about debt levels, the company would not be expected to pay a dividend that needs to be financed by debt. Because the company has unfunded positive NPV projects, it could consider issuing new shares to fund those projects. The company, however, would not be expected to issue shares solely for the purpose of paying dividends.

5.6 Contractual and Legal Restrictions

The payment of dividends is often affected by legal or contractual restrictions or rules. In some countries, such as Brazil, the distribution of dividends is legally mandated (with certain exceptions). In other countries (e.g., Canada and the United States) the payment of a dividend not specifically indicated to be a liquidating dividend may be restricted by an **impairment of capital rule**. Such a rule requires that the net value of the remaining assets as shown on the balance sheet be at least equal to some specified amount (related to the company's capital).

Contractual restrictions on the amount of dividends that can be paid are often imposed by bondholders in bond indentures. These restrictions require that the company maintain certain ratios (interest coverage ratios, current ratio, etc.) or fulfill certain conditions before dividend payments can be made. Debt covenants in a bond indenture are a response to the agency problems that exist between shareholders and bondholders and are put in place to limit the ability of the shareholders to expropriate wealth from bondholders. As an extreme example, in the absence of covenants or legal restrictions management could liquidate the company's assets and pay the proceeds to the shareholders as a liquidating dividend, leaving the bondholders with nothing to settle their claims.

If a company has issued preference shares, dividends on common shares may not be paid until preference share dividends are paid. In addition, if the preference dividends are cumulative, then preference dividends that are in arrears must be paid before any common dividend can be paid.

5.7 Factors Affecting Dividend Policy: Summary

Several factors of varying degrees of importance can affect a company's dividend policy. In the following example, we explore how these factors affect the dividend policy of a hypothetical company named Makinasi Appliances Company.

EXAMPLE 9

Makinasi Appliances Company Cuts Its Dividend

In September 2018, Makinasi Appliances Company, a hypothetical global home appliances manufacturer, announced it would cut its dividend for the first time in its history. The company, which pays quarterly dividends, said the dividend would be reduced to US$0.70 a share from the US$1.60 paid a year earlier. The 2017 total dividend was US$6.50 a share. The dividend cut ends a 400% cumulative increase in the dividend over 10 years. Faced with plunging global demand for appliances (Makinasi's sales were forecasted to fall 19%) and ongoing competition in the white goods industry, Makinasi was expecting a loss as high as US$32.5 million (operating loss of US$46 million) for fiscal year ending March 2019, compared with the analyst forecasted loss of US$18.3 million for the same period. The company already had a loss of US$28.6 million in fiscal year 2018 (the operating loss was US$30.4 million). Makinasi's plans are to aggressively cut costs: It plans to cut production-related costs by US$18 million and fixed costs by US$21 million. The company has said that the lower dividend is because of the difficulty in maintaining the dividend at its previous level. Board member bonuses have been eliminated, and manager bonuses have been reduced by 40%. Capital spending will be cut by 30% to US$27 million, and R&D spending will be cut by 13.5% to US$24million.

The company announced plans to raise capital via a bond issue for up to US$50 million. The national credit rating agency has cut Makinasi's bond rating from A to A−.

Discuss Makinasi's decision to cut its dividend in light of the factors affecting dividend policy covered in this section.

Solution:

Of the six factors discussed in this section, the *volatility of future earnings* and preservation of *financial flexibility* are the major factors influencing Makinasi's decision to cut its dividend. Paying the full dividend would have lowered Makinasi's liquidity ratios and forced it to raise even more external capital. In addition, paying the full dividend probably would likely have resulted in a more severe downgrade in its bond rating and an increase in the cost of debt financing. Paying the full dividend when faced with huge, larger than expected operating losses also might have sent a signal to investors that Makinasi was not serious about cutting costs and curtailing losses. *Flotation costs* could also play a role in

Makinasi's case. Flotation costs on new equity are typically higher than those on new debt; it is possible that if it paid a dividend of more than US$0.70 a share, it would have to issue new equity in addition to the US$50 million in debt.

PAYOUT POLICIES

6

g compare stable dividend with constant dividend payout ratio, and calculate the dividend under each policy;

l describe broad trends in corporate payout policies;

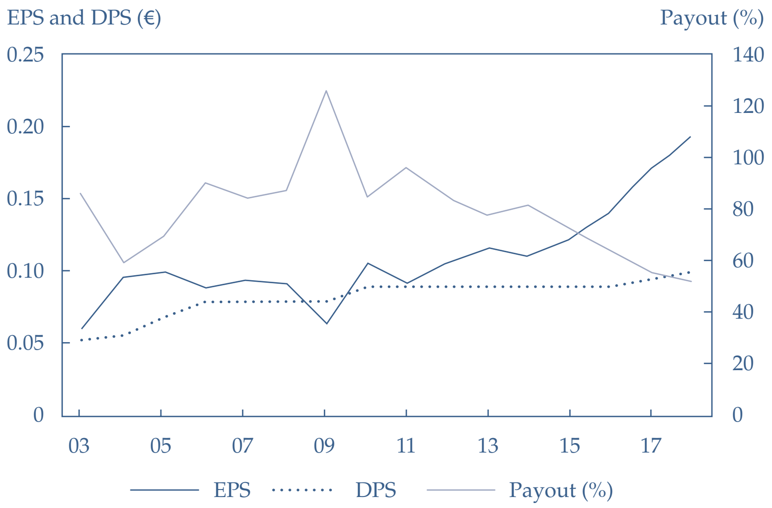
In the following sections we discuss two types of dividend policies: stable dividend and constant dividend payout ratio policies. A **stable dividend policy** is one in which regular dividends are paid that generally do not reflect short-term volatility in earnings. This type of dividend policy is the most common because managers are very reluctant to cut dividends, as discussed earlier. A **constant dividend payout ratio policy** is the policy of paying out a constant percentage of net income in dividends. In Sections 7–9, we discuss share repurchases as an alternative to the payment of cash dividends.

6.1 Stable Dividend Policy

This dividend policy is the most common. Companies that use a stable dividend policy base dividends on a long-term forecast of sustainable earnings and increase dividends when earnings have increased to a sustainably higher level. Thus, if the long-term forecast for sustainable earnings is slow growth, the dividends would be expected to grow slowly over time, more or less independent of cyclical upward or downward spikes in earnings. If sustainable earnings were not expected to grow over time, however, the corresponding dividends would be level (i.e., not growing). Compared with the constant payout ratio policy, a stable dividend policy typically involves less uncertainty for shareholders about the level of future dividends. This is so because the constant payout ratio policy reflects to a higher degree short-term volatility in earnings and/or in investment opportunities.

Many companies pride themselves on a long record of gradually and consistently increasing dividends. Exhibit 7 shows the record of Gruppo Hera (Hera), an Italian multi-utility company that operates in waste management, water, gas, electricity and central heating distribution, and energy trading and electricity generation. Between 2003 and 2018, dividends per share (DPS) show an upward trajectory. Earning declines during this period were accompanied by stable or increasing dividends, underscoring the company's longer-term stated policy of a stable and growing dividend, irrespective of yearly earnings. Consequently, Hera's payout ratio varies widely, between 52% to 125%, over the period shown. For the long term, Hera's management appeared notably optimistic about earnings prospects. In 2019, they committed to a continuing increase in annual dividends per share from €0.10 up to €0.11 by 2022.

Exhibit 7 Gruppo Hera Earnings and Dividends



Source: https://eng.gruppohera.it/group/investor_relations/investor_proposition/hera_share/dividends/

As the example shows, dividends over the period were either stable or rising—even while earnings experienced considerable variability.

A stable dividend policy can be modeled as a process of gradual adjustment toward a target payout ratio based on long-term sustainable earnings. A **target payout ratio** is a goal that represents the proportion of earnings that the company intends to distribute (pay out) to shareholders as dividends over the long term.

A model of gradual adjustment (which may be called a "target payout adjustment model") was developed by John Lintner (1956). The model reflects three basic conclusions from his study of dividend policy: 1) Companies have a target payout ratio based on long-term, sustainable earnings; 2) managers are more concerned with dividend changes than with the level of the dividend; and 3) companies will cut or eliminate a dividend only in extreme circumstances or as a last resort.

A simplified version of Lintner's model can be used to show how a company can adjust its dividend. For example, suppose that the payout ratio is below the target payout ratio and earnings are expected to increase. The expected increase in the dividend can be estimated as a function of four variables: expected earnings next year, the target payout ratio, the previous dividend, and the adjustment factor (one divided by the number of years over which the adjustment in dividends should take place). Suppose that the current dividend is US$0.40, the target payout ratio is 50%, the adjustment factor is 0.2 (i.e., the adjustment is to occur over five years), and expected earnings are US$1.50 for the year ahead (an increase from the US$1 value of last year). The expected increase in dividends is US$0.07, as shown here:

Expected increase in dividends

= (Expected earnings × Target payout ratio − Previous dividend) × Adjustment factor

= (US$1.50 × 0.5 − US$0.40) × 0.2

= US$0.07

Therefore, even though earnings increased 50% from US$1.00 to US$1.50, the dividend would only incrementally increase by about 17.5% from US$0.40 to US$0.47.

By using this model, note that if in the following year earnings temporarily fell from US$1.50 to US$1.34, the dividend might well be increased by up to US$0.04 [(US$1.34 × 0.5 − US$0.47) × 0.2 = US$0.04] a share, because the implied new dividend of US$0.51 would still be moving the company toward its target payout ratio of 50%. Even if earnings were to fall further or even experience a loss, the company would be reluctant to cut or eliminate the dividend (unless its estimate of sustainable earnings or target payout ratio were lowered); instead, it would rather opt to maintain the current dividend until future earnings increases justified an increase in the dividend.

EXAMPLE 10

Determining Dividends by Using a Target Payout Adjustment Model

Last year Luna Inc. had earnings of US$2.00 a share and paid a regular dividend of US$0.40. For the current year, the company anticipates earnings of US$2.80. It has a 30% target payout ratio and uses a 4-year period to adjust the dividend. Compute the expected dividend for the current year.

Solution:

Expected dividend = Previous dividend + [(Expected earnings × Target payout ratio − Previous dividend) × Adjustment factor)]

= US$0.40 + [(US$2.80 × 0.3 − US$0.40) × (1/4)]
= US$0.40 + [(US$0.84 − US$0.40) × (1/4)]
= US$0.51 dividend, an US$0.11 increase

Thus, although earnings are expected to increase by 40%, the increase in the dividend would be 27.5%. Despite the adjustment process, the payout ratio would fall from 20% (US$0.40/US$2.00) to 18.2% (US$0.51/US$2.80). The firm would move toward its target payout ratio if earnings growth were slower and the adjustment time period were shorter (i.e., the adjustment factor higher).

6.2 Constant Dividend Payout Ratio Policy

In this type of policy, a dividend payout ratio decided on by the company is applied to current earnings to calculate the dividend. With this type of dividend policy, dividends fluctuate with earnings in the short term. Constant dividend payout ratio policies are infrequently adopted in practice. Example 11 illustrates this type of policy with Pampas Fertilizer, a hypothetical company.

EXAMPLE 11

Pampas Fertilizer Changes from a Stable to a Constant Dividend Payout Ratio Policy

Pampas Fertilizer, a hypothetical company, is the leading fertilizer producer in Argentina. Its earnings tend to be highly volatile. Demand for fertilizer is seasonal, typically being higher in summer than in winter. On the supply side, costs are primarily driven by ammonia prices that are subject to business cycle influences and are thus very volatile. In consideration of earnings volatility, Pampas might have difficulty sustaining a steadily rising dividend level. In view of such considerations, Pampas changed its dividend policy from a stable dividend policy to a constant dividend payout ratio policy (called a "variable dividend policy" by management) in its fiscal year 2018. The following is the explanation by the company:

> Pampas has paid cash dividends on our common stock since 2003. The annual dividend rate of ARS0.50 per share of common stock, or ARS1.50 per quarter, was paid each fiscal quarter, as shown in the following table, through the second quarter of fiscal year 2018.
>
> Effective 30 November 2017, the company's board of directors approved the use of a variable dividend policy to replace the company's fixed dividend policy. Beginning with the third quarter of fiscal year 2018, Pampas began to pay a dividend to shareholders of its common stock on a quarterly basis for each quarter for which the company reports net income in an amount equal to 25% of such quarterly income.
>
> The board of Pampas implemented the variable dividend policy to more accurately reflect the results of the company's operations while recognizing and allowing for the cyclicality of the fertilizer industry.

Exhibit 8 shows quarterly data for fiscal years 2019 and 2018 in Argentine pesos (ARS).

Exhibit 8 Earnings per Share (EPS) and Dividends per Share (DPS) for Pampas Fertilizer (Fiscal Years Ending 31 March)

Fiscal Period	EPS(ARS)	DPS(ARS)
2019:Q4	9.32	2.350
2019:Q3	4.60	1.152
2019:Q2	15.41	3.852
2019:Q1	10.53	2.636
2018:Q4	7.84	1.961
2018:Q3	18.65	4.660
2018:Q2	26.30	1.500
2018:Q1	21.22	1.500

1. From the table, identify the fiscal quarter when Pampas first applied a constant dividend payout ratio policy.
2. Demonstrate that the dividend for 2019:Q4 reflects the stated current dividend policy.

Solution to 1:

Pampas first used that policy in the third quarter of fiscal year 2018. Until then, a quarterly dividend of ARS1.500 was paid irrespective of quarterly earnings. The payout ratios in all subsequent quarters round to approximately 25%.

Solution to 2:

(EPS ARS9.32)/4 = ARS2.330, which differs only slightly from the reported dividend of ARS2.350 (EPS are rounded to two decimal places, so rounding error is expected).

6.3 Global Trends in Payout Policy

An interesting question is whether corporations are changing their dividend policies in response to changes in the economic environment and in investor preferences. Dividend policy practices have international differences and change through time, even within one market, consistent with the idea that companies adapt their dividend policy over time to changing investor tastes. Typically, fewer companies in a given US stock market index have paid dividends than have companies in a comparable European stock market index. In some Asian markets, companies have significantly increased their dividend payouts, albeit from a lower base, as these companies and markets mature. In addition, the following broad trends in dividend policy have been observed:

- The fraction of companies paying cash dividends has been in long-term decline in most developed markets (e.g., the United States, Canada, the European Union overall, the United Kingdom, and Japan). In Asia-Pacific, however, the value paid out in annual dividends tripled from 2009 to 2019. In the rest of the world, the value of annual dividend payouts only doubled over the same period.
- Since the early 1980s in the United States and the early 1990s in the United Kingdom and continental Europe, the fraction of companies engaging in share repurchases has trended upward. Since the late 2010s, share repurchases by major companies in Asia, particularly in mainland China and Japan, have been substantial (following a history of little to no prior share repurchase activity).

Research on dividend behavior globally shows that aggregate dividend amounts as well as payout ratios have generally increased over time, although the fraction of dividend payers has decreased. For example, studies using data from around the world substantiate the proportion of cash dividend paying firms declining over the long term, with aggregate dividend payments concentrated in a relatively small number of firms. Post-global financial crisis, there has been some reversal in the long-term downward trend in the fraction of dividend payers and payout ratios. The dividend payers are, on average, larger, more profitable, have fewer growth opportunities, and spend less on R&D compared to the non-dividend payers.

Moreover, researchers have documented internationally a negative relationship between dividend initiations/increases and enhanced corporate governance and transparency (such as mandatory adoption of IFRS rules and enforcement of new insider trading laws). This is consistent with the notion of the decreasing information content of dividends and their reduced signaling role as governance and transparency of markets improves. Similarly, findings show less generous dividend payout policies in countries requiring detailed corporate disclosures and having strong investor protection. The reduction in both information asymmetry and agency issues resulting from improved corporate governance, along with the flexibility offered by share repurchases, appear to explain the long-term decline in dividend payers.

7 SHARE REPURCHASES, METHODS AND FINANCIAL STATEMENT EFFECTS

h compare share repurchase methods;

i calculate and compare the effect of a share repurchase on earnings per share when 1) the repurchase is financed with the company's surplus cash and 2) the company uses debt to finance the repurchase;

j calculate the effect of a share repurchase on book value per share;

A **share repurchase** (or **buyback**) is a transaction in which a company buys back its own shares. Unlike stock dividends and stock splits, share repurchases use corporate cash. Hence, share repurchases can be viewed as an alternative to cash dividends. Shares that have been issued and subsequently repurchased are classified as **treasury shares/stock** if they may be reissued or **canceled shares** if they will be retired; in either case, they are not then considered for dividends, voting, or computing earnings per share.

In contrast to the case of cash dividends, usage or growth in usage of share repurchases has historically required enabling regulation. In the United Kingdom, share repurchases became legal in 1981. They were never explicitly illegal in the United States, but usage became substantial only subsequent to US Securities and Exchange Commission rule 10b–18 in 1982. (That rule protected repurchasing companies from charges of share manipulation if repurchases were conducted consistent with the terms of the rule.) Other markets in continental Europe and Asia have also followed with enabling regulation (e.g., 1995 for Japan, 1998 for Germany and Singapore, 1999 for India and Norway, 2000 for Denmark and Sweden). Share repurchases in many markets remain subject to more restrictions than in the United States. Restrictions include requiring shareholder approval of share repurchase programs, limiting the percent of share repurchases to a certain fraction (often 10%) of outstanding shares, allowable repurchase mechanisms, and other restrictions to protect creditors. In many markets, use of share repurchases is becoming increasingly common.

In general, when an amount of share repurchases is authorized, the company is not strictly committed to following through with repurchasing shares. This situation contrasts with the declaration of dividends, where that action does commit the company to pay the dividends. Another contrast with cash dividends is that whereas cash dividends are distributed to shareholders proportionally to their ownership percentage, share repurchases in general do not distribute cash in such a proportionate manner. For example, if repurchases are executed by a company via buy orders in the open market, cash is effectively being received by only those shareholders with concurrent sell orders.

The next section presents the means by which a company may execute a share repurchase program.

7.1 Share Repurchase Methods

Following are the four main ways that companies repurchase shares, listed in order of importance.

1 **Buy in the open market.** This method of share repurchase is the most common, with the company buying its own shares as conditions warrant in the open market. The open market share repurchase method gives the company maximum flexibility. Open market repurchases are the most flexible option for a company because there is no legal obligation to undertake or complete the repurchase program; a company may not follow through with an announced program for various reasons, such as unexpected cash needs for liquidity, acquisitions, or capital expenditures. In the United States, open market transactions do not require shareholder approval, whereas in Europe, shareholder approval is required for buybacks. After studying buybacks in 32 countries, findings by Manconi, Peyer, and Vermaelen (2015) suggest that all companies have shareholder authorization in place to allow management the opportunity to buy back undervalued shares in the future. They conclude that the need for shareholder approval does not compensate for poor corporate governance and instead limits management's flexibility to time buybacks to create long-term shareholder value. Authorizations to repurchase stock can last for years. In many shareholders' minds, the announcement of a repurchase policy provides support for the

share price. If the share repurchases are competently timed to minimize price impact and to exploit perceived undervaluation in the marketplace, this method is also relatively cost effective.

2 **Buy back a fixed number of shares at a fixed price.** Sometimes a company will make a **fixed price tender offer** to repurchase a specific number of shares at a fixed price that is typically at a premium to the current market price. For example, in Australia, if a stock is selling at A$37 a share, a company might offer to buy back 5 million shares from current shareholders at A$40. If shareholders are willing to sell more than 5 million shares, the company will typically buy back a pro rata amount from each shareholder. By setting a fixed date, such as 30 days in the future, a fixed price tender offer can be accomplished quickly.

3 **Dutch auction.** A Dutch auction is also a tender offer to existing shareholders, but instead of specifying a fixed price for a specific number of shares, the company stipulates a range of acceptable prices. A Dutch auction uncovers the minimum price at which the company can buy back the desired number of shares with the company paying that price to all qualifying bids. For example, if the stock price is A$37 a share, the company would offer to buy back 5 million shares in a range of A$38 to A$40 a share. Each shareholder would then indicate the number of shares and the lowest price at which he or she would be willing to sell. The company would then begin to qualify bids beginning with those shareholders who submitted bids at A$38 and continue to qualify bids at higher prices until 5 million shares had been qualified. In our example, that price might be A$39. Shareholders who bid between A$38 and A$39, inclusive, would then be paid A$39 per share for their shares. Like Method 2, Dutch auctions can be accomplished in a short time period.

4 **Repurchase by direct negotiation.** In some markets, a company may negotiate with a major shareholder to buy back its shares, often at a premium to the market price. The company may do this to keep a large block of shares from overhanging the market (and thus acting to dampen the share price). A company may try to prevent an "activist" shareholder from gaining representation on the board of directors. In some of the more infamous cases, unsuccessful takeover attempts have ended with the company buying back the would-be suitor's shares at a premium to the market price, referred to as a **greenmail** transaction, often to the detriment of remaining shareholders. Private repurchases can also be made at discounts to the market price, reflecting the relatively weaker negotiating position of large investors with liquidity needs.

Outside the United States and Canada, almost all share repurchases occur in the open market (Method 1). Note that not all the methods listed may be permissible according to local regulations.

EXAMPLE 12

BCII Considers Alternative Methods of Share Repurchase

The board of directors of British Columbia Industries, Inc. (BCII) is considering a 5 million common share repurchase program. BCII has a sizable cash and marketable securities portfolio. BCII's current stock price is C$37. The company's chief financial officer wants to accomplish the share repurchases in a cost-effective manner. Some board members want repurchases accomplished as quickly as possible, whereas other board members mention the importance of flexibility. Discuss the relative advantages of each of the following methods with respect to cost, flexibility, and speed:

1 Open market share repurchases.
2 A fixed price tender offer.
3 Dutch auction tender offer.

Solution to 1:

Open market share repurchases give the company the most flexibility. BCII can time repurchases, making repurchases when the market prices its stock below its perceived intrinsic value. BCII can also change amounts repurchased or even not execute the repurchase program. Open market repurchases are typically made opportunistically, with cost a more important consideration than speed. Because open market repurchases can be conducted so as to minimize any effects on price and can be timed to exploit prices that are perceived to be below intrinsic value, this method is also relatively cost effective.

Solution to 2:

A fixed price tender offer can be accomplished quickly, but the company usually has to offer a premium. Obviously, this raises the cost of the buyback; however, the premium may provide a positive signal to investors regarding management's view of the value of the stock.

Solution to 3:

Dutch auctions generally enable a company to do the buyback at a lower price than with a fixed price tender offer. For example, a fixed price tender offer for 5 million shares at C$40 would cost BCII C$200 million. If the Dutch auction were successful at C$38, the cost would be C$190 million, a savings of C$10 million. Dutch auctions can be accomplished quickly, though usually not as quickly as fixed price tender offers

7.2 Financial Statement Effects of Repurchases

Share repurchases affect both the balance sheet and income statement. Both assets and shareholders' equity decline if the repurchase is made with surplus cash. As a result, leverage increases. Debt ratios (leverage) will increase even more if the repurchase is financed with debt.

On the income statement, fewer shares outstanding could increase earnings per share (i.e., by reducing the denominator) depending on how and at what cost the repurchase is financed. We discuss the effects on the income statement and balance sheet in the following sections.

7.2.1 *Changes in Earnings per Share*

One rationale for share repurchases often cited by corporate financial officers and some investment analysts is that reducing the number of shares outstanding can increase earnings per share (EPS). Assuming a company's net income does not change, a smaller number of shares after the buyback will produce a higher EPS. If a company's share repurchase is financed by high-cost borrowing, the resulting lower net income can offset the effect of the reduced shares outstanding, producing a lower EPS.

Examples 13 and 14 show changes in EPS resulting from alternative methods of financing a share repurchase.

EXAMPLE 13

Share Repurchase Using Surplus Cash

Takemiya Industries, a Japanese company, has been accumulating cash in recent years with a plan of expanding in emerging Asian markets. Takemiya's management and directors believe that such expansion is no longer practical, and they are considering a share repurchase using surplus cash. Takemiya has 10 million shares outstanding, and its net income is ¥100 million. Takemiya's share price is ¥120. Cash not needed for operations totals ¥240 million and is invested in Japanese government short-term securities that earn close to zero interest. For a share repurchase program of the contemplated size, Takemiya's investment bankers think the stock could be bought in the open market at a ¥20 premium to the current market price, or ¥140 a share. Calculate the impact on EPS if Takemiya uses the surplus cash to repurchase shares at ¥140 per share.

Solution:

First, note that current EPS = (¥100 million net income)/(10 million shares) = ¥10.00. If Takemiya repurchases shares, net income is unchanged at ¥100 million. A share repurchase at ¥140 a share reduces share count by approximately 1.7 million shares (¥240,000,000/¥140) so that 8.3 million shares remain outstanding. Thus, after the share repurchase, EPS should be (¥100 million)/(8.3 million shares) = ¥12.00, approximately. EPS would increase by 20% as a result of the share repurchase. Note that EPS would increase even more if the open market purchases were accomplished at the prevailing market price without the premium.

In the absence of surplus cash and equivalents, companies may fund share repurchases by using long-term debt. Example 14 shows that any increase in EPS is dependent on the company's after-tax borrowing rate on the funds used to repurchase stock.

EXAMPLE 14

Share Repurchases Using Borrowed Funds

Selamat Plantations, Inc., plans to borrow Malaysian ringgit (MYR)12 million, which it will use to repurchase shares. The following information is given:

- Share price at time of share repurchase = MYR60
- Earnings after tax = MYR6.6 million
- EPS before share repurchase = MYR3
- Price/Earnings (P/E) = MYR60/MYR3 = 20
- Earnings yield (E/P) = MYR3/MYR60 = 5%
- Shares outstanding = 2.2 million
- Planned share repurchase = 200,000 shares

1 Calculate the EPS after the share repurchase, assuming the after-tax cost of borrowing is 5%.

2 Calculate the EPS after the share repurchase, assuming the company's borrowing rate increases to 6% because of the increased financial risk of borrowing the MYR12 million.

Solution to 1:

EPS after buyback = (Earnings − After-tax cost of funds)/Shares outstanding after buyback
= [MYR6.6 million − (MYR12 million × 0.05)]/2 million shares
= [MYR6.6 million − (MYR0.6 million)]/2 million shares
= MYR6.0 million/2 million shares
= MYR3.00

With the after-tax cost of borrowing at 5%, the share repurchase has no effect on the company's EPS. Note that the stock's earnings yield, the ratio of earnings per share to share price or E/P, was MYR3/MYR60 = 0.05 or 5%, equal to the after-tax cost of debt.

Solution to 2:

EPS after buyback = (Earnings − After-tax cost of funds)/Shares outstanding after buyback
= [MYR6.6 million − (MYR12 million × 0.06)]/2 million shares
= [MYR6.6 million − (MYR0.72 million)]/2 million shares
= MYR5.88 million/2 million shares
= MYR2.94

Note that in this case, the after-tax cost of debt, 6%, is greater than the 5% earnings yield; thus, a reduction in EPS resulted.

In summary, a share repurchase may increase, decrease, or have no effect on EPS. The effect depends on whether the repurchase is financed internally or externally. In the case of internal financing, a repurchase increases EPS only if the funds used for the repurchase would *not* earn their cost of capital if retained by the company. In the case of external financing, the effect on EPS is positive if the earnings yield exceeds the after-tax cost of financing the repurchase. In Example 14, when the after-tax borrowing rate equaled the earnings yield of 5%, EPS was unchanged as a result of the buyback. Any after-tax borrowing rate above the earnings yield would result in a decline in EPS, whereas an after-tax borrowing rate less than the earnings yield would result in an increase in EPS.

These relationships should be viewed with caution so far as any valuation implications are concerned. Notably, to infer that an increase in EPS indicates an increase in shareholders' wealth would be incorrect. For example, the same surplus cash could also be distributed as a cash dividend. Informally, if one views the total return on a stock as the sum of the dividend yield and a capital gains return, any capital gains as a result of the boost to EPS from the share repurchase may be at the expense of an offsetting loss in dividend yield.

7.2.2 *Changes in Book Value per Share*

Price-to-book value per share is a popular ratio used in equity valuation. The following example shows the impact of a share repurchase on book value per share (BVPS).

EXAMPLE 15

The Effect of a Share Repurchase on Book Value per Share

The market price of both Company A's and Company B's common stock is US$20 a share, and each company has 10 million shares outstanding. Both companies have announced a US$5 million buyback. The only difference is that Company A has a market price per share greater than its book value per share, whereas Company B has a market price per share less than its book value per share:

- Company A has a book value of equity of US$100 million and BVPS of US$100 million/10 million shares = US$10. *The market price per share of US$20 is greater than BVPS of US$10.*
- Company B has a book value of equity of US$300 million and BVPS of US$300 million/10 million shares = US$30. *The market price per share of US$20 is less than BVPS of US$30.*

Both companies:

- buy back 250,000 shares at the market price per share (US$5 million buyback/US$20 per share = 250,000 shares) and
- are left with 9.75 million shares outstanding (10 million pre-buyback shares − 0.25 million repurchased shares = 9.75 million shares).

After the share repurchase:

- Company A's shareholders' equity at book value falls to US$95 million (US$100 million − US$5 million), and its *book value per share decreases* from US$10 to US$9.74 (shareholders' equity/shares outstanding = US$95 million/9.75 million shares = US$9.74).
- Company B's shareholders' equity at book value falls to US$295 million (US$300 million − US$5 million), and its *book value per share increases* from US$30 to US$30.26 (shareholders' equity/shares outstanding = US$295 million/9.75 million = US$30.26).

This example shows that when the market price per share is greater than its book value per share, BVPS will decrease after the share repurchase. When the market price per share is less than BVPS, however, BVPS will increase after a share repurchase.

8 VALUATION EQUIVALENCE OF CASH DIVIDENDS AND SHARE REPURCHASE: THE BASELINE

k explain the choice between paying cash dividends and repurchasing shares;

A share repurchase should be viewed as equivalent to the payment of cash dividends of equal amount in terms of the effect on shareholders' wealth, all other things being equal. "All other things being equal" in this context is shorthand for assumptions that the taxation and information content of cash dividends and share repurchases do not differ. Understanding this baseline equivalence result permits more advanced analysis for when taxation and/or information content do differ between cash dividends and share repurchases. Example 16 demonstrates the claim of equivalence in the "all other things being equal" case.

EXAMPLE 16

The Equivalence of Share Repurchases and Cash Dividends

Rohit Chemical Industries, Inc. (RCII) has 10 million shares outstanding with a current market value of Rs200 per share. WCII's board of directors is considering two ways of distributing RCII's current Rs500 million free cash flow to equity. The first method involves paying an irregular or special cash dividend of Rs500 million/10 million = Rs50 per share. The second method involves repurchasing Rs500 million worth of shares. For simplicity, we make the assumptions that dividends are received when the shares go ex-dividend and that any quantity of shares can be bought at the market price of Rs200 per share. We also assume that the taxation and information content of cash dividends and share repurchases, if any, do not differ. How would the wealth of a shareholder be affected by RCII's choice of method in distributing the Rs500 million?

Solution:

Cash Dividend

After the shares go ex-dividend, a shareholder of a single share would have Rs50 in cash (the dividend) and a share worth Rs200 – Rs50 = Rs150. The ex-dividend value of Rs150 can be demonstrated as the market value of equity after the distribution of Rs500 million divided by the (unchanged) number of shares outstanding after the dividend payment, or [(10 million)(Rs200) – Rs500 million]/10 million = Rs1,500 million/10 million = Rs150. Total wealth from ownership of one share is, therefore, Rs50 + Rs150 = Rs200.

Share Repurchase

With Rs500 million, RCII could repurchase Rs500 million/Rs200 = 2.5 million shares. The post-repurchase share price would be unchanged at Rs200, which can be calculated as the market value of equity after the Rs500 million share repurchase divided by the shares outstanding after the share repurchase, or [(10 million) (Rs200) – Rs500 million]/(10 million – 2.5 million) = Rs1,500 million/7.5 million = Rs200. Total wealth from ownership of one share is, therefore, Rs200—exactly the same as in the case of a cash dividend. Whether the shareholder actually sold the share back to RCII in the share repurchase is irrelevant for a shareholder's wealth: If the share was sold, Rs200 in cash would be realized; if the share was not sold, its market value of Rs200 would count equally toward the shareholder's wealth.

The theme of Example 16 is that a company should not expect to create or destroy shareholder wealth merely by its method of distributing money to shareholders (i.e., by share repurchases as opposed to cash dividends). Example 17 illustrates that if a company repurchases shares from an individual shareholder at a negotiated price representing a premium over the market price, the remaining shareholders' wealth is reduced.

EXAMPLE 17

Direct Negotiation: A Share Repurchase That Transfers Wealth

AfriCitrus (AC) common shares sell at South African rand (ZAR)200, and there are 10 million shares outstanding. Management becomes aware that Kirk Mzazi recently purchased a major position in its outstanding shares with the intention of influencing the business operations of AC in ways the current board does not approve. An adviser to the board has suggested approaching Mzazi privately with an offer to buy back ZAR500 million worth of shares from him at ZAR250 per share, which is a ZAR50 premium over the current market price. The board of AC declines to do so because of the effect of such a repurchase on AC's other shareholders. Determine the effect of the proposed share repurchase on the wealth of shareholders other than Mzazi.

Solution:

With ZAR500 million, AC could repurchase ZAR500 million/ZAR250 = 2 million shares from Mzazi. The post-repurchase share price would be ZAR187.50, which can be calculated as the market value of equity after the ZAR500 million share repurchase divided by the shares outstanding after the share repurchase, or [(10 million)(ZAR200) − ZAR500 million]/(10 million − 2 million) = ZAR1,500 million/8 million = ZAR1875.50. Shareholders other than Mzazi would lose ZAR200 − ZAR187. 50 = ZAR12.50 for each share owned. Although this share repurchase would conserve total wealth (including Mzazi's), it effectively transfers wealth to Mzazi from the other shareholders.

THE DIVIDEND VERSUS SHARE REPURCHASE DECISION

9

k explain the choice between paying cash dividends and repurchasing shares;

The question of the valuation implications of share repurchases and dividends is of great interest to investors. Many investors and corporate managers believe that share repurchases have, on average, a net positive effect on shareholder value Studies have found that share repurchase announcements are accompanied by significant positive excess returns both around the announcement date and for the next two years—and in some studies, five years. An explanation consistent with that finding is that managements tend to buy back their stock when it is undervalued in the marketplace and issue stock when it is overvalued.

Theory concerning the dividend–share repurchase decision generally concludes that share repurchases are equivalent to cash dividends of equal amount in their effect on shareholders' wealth, all other things being equal. Further discussion about the choice revolves around what might not "be equal" and what might cause one distribution mechanism to be preferred over the other. The use of share repurchases also may be legally restricted.

In general, share repurchases can be considered part of a company's broad policy on distributing earnings to shareholders. Also, a company may engage in share repurchases for reasons similar to those mentioned in connection with cash dividends—for example, to distribute free cash flow to equity to common shareholders. A number of additional reasons for share repurchases include the following:

- Potential tax advantages
- Share price support/signaling that the company considers its shares a good investment
- Added managerial flexibility
- Offsetting dilution from employee stock options
- Increasing financial leverage

In jurisdictions that tax shareholder dividends at higher rates than capital gains, share repurchases have a tax advantage over cash dividends. Even if the two tax rates are equal, the option to defer capital gains taxes—by deciding not to participate in the share repurchase—will be valuable to many investors.

Management of a company may view its own shares as undervalued in the marketplace and hence a good investment. Although management's stock market judgment can be just as good or bad as that of any other market participant, corporate management typically does have more information about the company's operation and future prospects than does any outside investor or analyst. Furthermore, share repurchases via open market purchase, the dominant repurchase mechanism, allow management to time share repurchases with respect to market price. The announcement of a share repurchase program is often understood as a positive signal about the company's prospects and attractiveness as an investment. An unexpected announcement of a meaningful share repurchase program can often have the same positive impact on share price as would a better-than-expected earnings report or similar positive event. In the days following the global stock market crash of October 1987, a number of prominent companies announced huge buybacks in an effort to halt the slide in the price of their shares and show confidence in the future. It may have been an important aspect in the stock market recovery that followed. Some investment analysts, however, take issue with the notion that initiation of share repurchases is a positive signal, because a repurchase program could mean that the company has no new profitable investment opportunities and is thus returning cash to shareholders.

Unlike regular cash dividends, share repurchase programs appear not to create the expectation among investors of continuance in the future. Furthermore, in contrast to an announced dividend, the announcement of a share repurchase by open market purchase does not typically create an obligation to follow through with repurchases. Additionally, the timing of share repurchases via open market activity is at managers' discretion. Share repurchases also afford shareholders flexibility because participation is optional, which is not the case with the receipt of cash dividends.

For some companies, share repurchases are used to offset the possible dilution of earnings per share that may result from the exercise of employee stock options. Whether stated or not, many companies try to repurchase at least as many shares as were issued in the exercise of stock options—even though the options are typically exercised at lower prices than the repurchase price.

Another reason for repurchasing shares is to modify the company's capital structure because share repurchases can be used to increase leverage. Share buybacks funded by newly issued debt increase leverage more than those funded by surplus cash.

Among other reasons mentioned for share repurchases by corporate managers is the objective of increasing EPS. This objective, however, is problematic for two reasons. First, even when share repurchases result in an EPS increase, the required rate of return will likely increase, reflecting higher leverage. Second, according to finance theory, changing EPS by changing the number of shares outstanding does not affect shareholder wealth given that total free cash flow is unchanged.

EXAMPLE 18

Share Repurchase to Increase Financial Leverage

Deira Oasis Holdings Inc. (DOHI), with debt and a debt ratio of United Arab Emirates durham (AED)30 million and 30%, respectively, plans a share repurchase program involving AED7 million or 10% of the market value of its common shares.

1 Assuming nothing else changes, what debt ratio would result from financing the repurchases using cash on hand?
2 Assuming nothing else changes, what debt ratio would result from financing the repurchases using new debt?
3 Discuss the effect on value of equity from financing the repurchases using cash on hand, assuming DOHI's net income and P/E remain the same.
4 Discuss the effect on value of equity from financing the repurchases using new debt, assuming DOHI's after-tax cost of debt is greater than its E/P, which remains the same.
5 Discuss the effect on value of debt from financing the repurchases using new debt, assuming the conditions in question 4 and knowing that DOHI is in imminent danger of a credit rating downgrade.

Solution to 1:

Assuming nothing else changes, if DOHI uses cash on hand to make the share repurchase, the debt ratio would increase to 32% (AED30 million/AED93million = 0.3226 or 32.3%).

Solution to 2:

Assuming nothing else changes, if DOHI uses debt to finance the share repurchase, the debt ratio would increase to 37% (AED37 million/AED100 million = 0.3700 or 37.0%).

Solution to 3:

After repurchase, DOHI's equity stands at AED63 million. However, with the same net income and fewer shares outstanding, its EPS would increase. Then, with the same P/E, DOHI's market value of equity would be expected to increase above AED63 million.

Solution to 4:

After repurchase, DOHI's equity stands at AED63 million. However, with the after-tax cost of debt exceeding the E/P, its EPS would decrease. Then, with the same P/E, DOHI's market value of equity would be expected to decrease below AED63 million.

Solution to 5:

After repurchase, DOHI's debt stands at AED37 million. However, with the real threat of a credit rating downgrade, spreads for DOHI's debt versus government treasuries would widen. Then, DOHI's market value of debt would be expected to decrease below AED37 million.

Note that with the assumptions in questions 4 and 5, the post-repurchase market values of both equity and debt would be expected to decrease. Therefore, the proportion of each in DOHI's post-repurchase capital structure is indeterminate based on the information given.

Exhibit 9 shows the results. By either means of financing the share repurchase, financial leverage increases.

Exhibit 9 Estimated Impact on Capital Structure (AED millions)

	Before Buyback		After Buyback			
			All Cash		All Debt	
	AED	%	AED	%	AED	%
Debt	30	30	30	32	37	37
Equity (at market)	70	70	63	68	63	63
Total Cap	100	100	93	100	100	100

Deira Oasis Holdings' beginning debt ratio was 30%. If Deira Oasis Holdings uses borrowed funds to repurchase equity, the debt ratio at market value will increase to 37%, which is significantly more than if it used excess cash (32%).

EXAMPLE 19

ITOCHU Corporation Announces Share Buyback to Improve ROE

In October 2018, ITOCHU Corporation, a leading Japanese *sogo shosha* (general trading company), reported that in order to improve its return on equity (ROE) it would repurchase shares by fiscal year-end March 2019 to achieve a target medium-to-long-term ROE of 13% or higher. Accordingly, ITOCHU said it could repurchase shares in the amount up to ¥30 billion. In February 2019, ITOCHU announced it was increasing its share repurchase target up to ¥100 billion. ITOCHU repurchases in these first two tranches are shown in Exhibit 10.

Exhibit 10 Share Buyback Activities, October 2018 to March 2019

Period	Shares Repurchased	Average Price (¥)	Total Value (¥)
December 2018 – January 2019	15,097,200	1,987	30 billion
February – March 2019	19,024,200	1.997	38 billion
Sum	**34,121,400**	**1,993**	**68 billion**

Source: Annual Report 2019 (online version), ITOCHU Corporation: https://www.itochu.co.jp/en/ir/financial_statements/2020/__icsFiles/afieldfile/2019/08/09/20_1st_03_e.pdf.

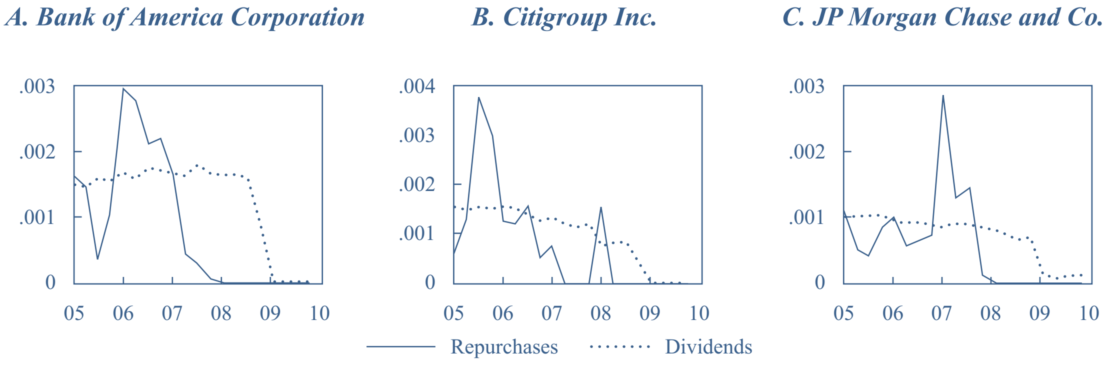
ITOCHU was followed by many other large Japanese companies—including SoftBank, Sony, Haseko, Tokyo Tatemono, and Toppan Printing. Also in February 2019, these companies announced large share buyback programs to improve ROE in response to shareholder activist pressure to improve shareholder returns and governance.

A company can use both special cash dividends and share repurchases as a supplement to regular cash dividends. These means of distributing cash are often used in years when there are large and extraordinary increases in cash flow that are not expected to continue in future years. In making these types of payments, the company essentially communicates that the distribution, like the increase in cash flow, should not be expected to continue in the future. In this context, a share repurchase is effectively an alternative to paying a special cash dividend.

Some companies initiate payouts to shareholders using share repurchases rather than cash dividends. As with the case of a share repurchase substituting for a special cash dividend, the use of share repurchases is again with the expectation that it will not be viewed as creating a fixed commitment.

Although all of the preceding can be the stated or unstated reasons for share repurchases, in general, share repurchases increase when the economy is strong and companies have more cash. During recessions, when cash is often short, share repurchases typically fall. From the fourth quarter of 2004 to the fourth quarter of 2008, the 500 companies in the S&P 500 spent US$1.8 trillion on share repurchases as compared with US$2 trillion on capital expenditures and US$1 trillion on cash dividends. In the market crash of 2008–2009, share repurchases plummeted. Major companies (particularly in the global financial sector) that had made large share repurchases encountered challenges to their financial viability in 2008 and 2009. This caused them to abandon their share repurchases and then to drastically curtail, or even eliminate, their dividends. The predominance of large US banks abandoning their share repurchase programs following the 2008 global financial crisis is shown in Exhibit 11.

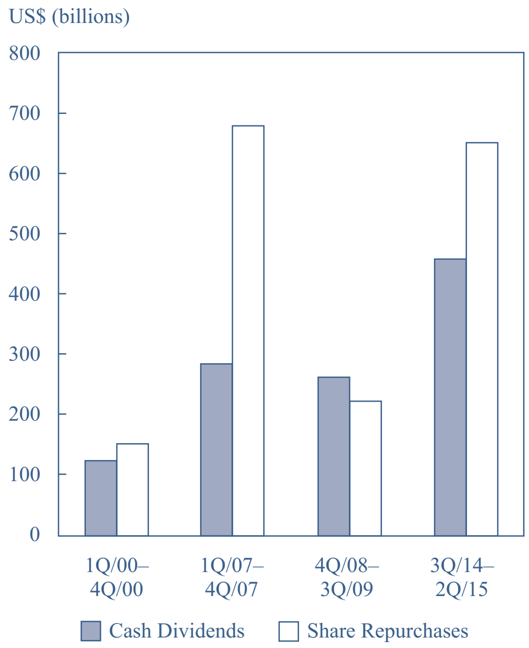
Exhibit 11 Historical Example: Share Repurchases and Dividends for Several Large US Banks



Source: Hirtle (2016).

The curtailing of share repurchases following the 2008 global financial crisis was a general occurrence; it was not restricted to the banking sector. As can be seen in Exhibit 12, data for the companies in the Russell 1000 Index, a broader US stock index than the S&P 500, show that share repurchases grew at almost twice the rate of cash dividends between 2000 and 2007, 25.0% compared to 13.0%. However, during the financial crisis of 2008–2009, companies cut back sharply on their discretionary share repurchases, from US$680 billion to US$223 billion, because many faced shrinking operating cash flows or even financial distress. Although cash dividends were also cut, the decline was much less considerable (US$286 billion to US$262 billion). By 2015, corporate operating cash flows had recovered to the point where total distributions (cash dividends plus share repurchases) reached US$1,102 billion, surpassing their previous peak of US$966 billion in 2007. Share repurchases increased nearly three times from their 2009 levels to reach US$650 billion. However, cash dividends reached US$452 billion, or over 40% of total distributions; this compares to slightly less than 30% of total distributions (US$286 billion/US$966 billion) in 2007. The higher proportion of dividends in total distributions may reflect investors' increased appetite for dividend yield during the extended period of low (or even negative) interest rates on many fixed-income securities that has prevailed in many developed countries since the end of the financial crisis.

Exhibit 12 Historical Example: Share Repurchases and Cash Dividends: Russell 1000 Companies (2000 to 2015)



Time Period	Cash Dividends*	Share Repurchases	CAGR Cash Dividends	CAGR Repurchases
	(US$ billions)		(Base Year is 2000)	
1Q2000–4Q2000	126	152	—	—
1Q2007–4Q2007	286	680	13.0%	25.0%
4Q2008–3Q2009	262	223	9.0%	4.0%
3Q2014–2Q2015	452	650	10.0%	11.0%

* Includes special dividends.
Source: JP Morgan, "2015 Distribution Policy" (September 2015).

Example 20, in which a hypothetical company's board of directors initiates a cash dividend, integrates a number of themes related to cash dividends, stock dividends (in which additional shares are distributed to shareholders instead of cash), and share repurchases.

EXAMPLE 20

Shenzhen Medical Devices' Dividend Policy Decision

Shenzhen Medical Devices Ltd. (SMDL) is a hypothetical company based in Shenzhen, China. SMDL is emerging as a leader in providing medical testing equipment to the pharmaceutical and biotechnology industries. SMDL's primary markets are growing, and the company is spending ¥100 million a year on research and development to enhance its competitive position. SMDL is highly profitable and has substantial positive free cash flow after funding positive NPV projects. During the past three years, SMDL has made significant share repurchases. Subsequent to the removal of tax on cash dividends from shares held more than a year in mainland China, SMDL management is proposing the initiation of a cash dividend. The first dividend is proposed to be an annual dividend of ¥0.40 a share to be paid during the next fiscal year. Based on estimated earnings per share of ¥3.20, this dividend would represent a payout ratio (DPS/EPS) of 0.125 or 12.5%. The proposal that will be brought before the board of directors is the following:

> "Proposed: Shenzhen Medical Devices Ltd. will institute a program of cash dividends. The first dividend will be an annual dividend of ¥0.40 a share, to be paid at a time to be determined during the next fiscal year. Thereafter, an annual dividend will be paid, equal to or above this amount, consistent with the intention of reaching a target payout ratio of 25% in line with management's expectation for long-term sustainable earnings—thereby retaining funds sufficient to finance profitable capital projects."

The company's board of directors will formally consider the dividend proposal at its next meeting in one month's time. Although some directors favor the dividend initiation proposal, other directors, led by Director Z, are skeptical of it. Director Z has stated:

> "The initiation of a cash dividend will suggest to investors that SMDL is no longer a growth company."

As a counterproposal, Director Z has offered his support for the initiation of an annual 2% stock dividend. Director W, a director who is neutral to both the cash dividend and stock dividend ideas, has told Director Z the following:

> "A 2% stock dividend will not affect the wealth of our shareholders."

Exhibit 13 presents selected *pro forma* financials of SMDL, if the directors approve the initiation of a cash dividend.

Exhibit 13 Shenzhen Medical Devices Ltd. Pro Forma Financial Data Assuming Cash Dividend (¥ millions)

Income Statement		Statement of Cash Flows	
Sales	1,200	Cash flow from operations	135
Earnings before taxes	155	Cash flow from investing activities	(84)
Taxes	35	Cash flow from financing activities	
Net income	120	Debt repayment	(4)
		Share repurchase	(32)
		Proposed dividend	(15)
		Estimated change in cash	0

Ratios		Five-Year Forecasts	
Current ratio	2.1	Sales growth	8% annually
Debt/Equity (at market)	0.27	Earnings growth	11% annually
Interest coverage	10.8x	Projected cost of capital	10%
ROA	10.0%		
ROE	19.3%		
P/E	20x		
E/P	5.0%		

Using the information provided, address the following:

1 Critique Director Z's statement.

2 Justify Director W's statement.

3 Identify and explain the dividend policy that the proposed ¥0.40 a share cash dividend reflects.

Solution to 1:

The following points argue against the thesis of Director Z's statement:

- As discussed in the text, dividend initiations and increases are on average associated with higher future earnings growth.
- Forecasted sales and earnings growth rates are relatively high.
- SMDL still has considerable positive NPV projects available to it, as shown by the cash flow from investing activities of negative ¥84 million. This fact is consistent with SMDL being a company with substantial current growth opportunities.
- For the past three years, SMDL has been making share repurchases, so investors are already cognizant that management is distributing cash to shareholders. The initiation of a dividend as a continuation of that policy is less likely to be interpreted as an information signaling event.

Solution to 2:

A stock dividend has no effect on shareholder wealth. A shareholder owns the same percentage of the company and its earnings as it did before the stock dividend. All other things being equal, the price of a stock will decline to reflect the stock dividend, but the decline will be exactly offset by the greater number of shares owned.

Solution to 3:

As shown in the statement of cash flows, the ¥0.40 a share annual dividend reflects a total amount of ¥15 million, fully using SMDL's free cash flow after acceptance of positive NPV projects. However, the proposal brought before the board also states a commitment to maintain the annual dividend at ¥0.40 a share (or greater), as a stable dividend policy would typically imply. Further, the proposal refers to a target payout ratio based on long-term sustainable earnings. These facts taken together are most consistent with a stable dividend policy based on a target payout adjustment model. (The relatively low target payout ratio of 25% of long-term sustainable earnings allows for sufficient funding of profitable capital projects, suitable for maintaining growth as a pharmaceutical company.)

ANALYSIS OF DIVIDEND SAFETY 10

m calculate and interpret dividend coverage ratios based on 1) net income and 2) free cash flow;

n identify characteristics of companies that may not be able to sustain their cash dividend.

The global recession that began in late 2007 gave rise to the largest number of dividend cuts and suspensions since the Great Depression of the 1930s. By mid-2009, S&P 500 dividends for US companies were down by 25% from the prior year, and, as indicated earlier in Exhibit 13, by 3Q 2009 dividends for companies in the broader Russell 1000 index declined by over 8% from 2007 levels. Other markets experienced similar dividend cuts following the global financial crisis; for example, UK companies reduced dividends by 15% and Australian companies by 9% in 2009. In this section, we discuss how an analyst can form a judgment on the likelihood that a company's cash dividend may be cut.

The traditional way of looking at dividend safety is the dividend payout ratio (dividends/net income) and its inverse, the **dividend coverage ratio** (net income/dividends). A higher dividend payout ratio or a lower dividend coverage ratio tends to indicate, all else equal, higher risk of a dividend cut. The logic is that with a relatively high dividend payout ratio, a relatively small percentage decline in earnings could cause the dividend not to be payable out of earnings.

EXAMPLE 21

Traditional Measures of Dividend Safety

Given the following data, calculate the dividend payout and coverage ratios:

Mature European SA	FY2019
Net income available for common stock	€100 million
Dividends paid	€40 million

Solution:

Dividend payout ratio	40/100 = 40%
Dividend coverage ratio	100/40 = 2.5x

In judging these ratios, various generalizations may be stated based on observed practice. In stating these generalizations, we emphasize that they should be confirmed for the particular market and time period being addressed.

Small, young companies generally do not pay dividends, preferring to reinvest internally for growth. However, as such companies grow, they typically initiate dividends and their payout ratios tend to increase over time. Large mature companies often target dividend payout ratios of 40% to 60% so that dividend coverage ratios range from about 1.7x to 2.5x, excluding "extra" payments. Mature companies are expected to be in this range over the course of a 5- to 10-year business cycle. Higher dividend payout ratios (or lower dividend coverage ratios) often constitute a risk factor that a dividend may be cut if earnings decline. High dividend payout ratios in relation to those of peer group companies may also point to dividend safety concerns. When a dividend coverage ratio drops to 1.0, the dividend is considered to be in jeopardy unless non-recurring events, such as an employee strike or a typhoon, are responsible for a temporary decline in earnings. In judging safety, qualitative pluses are awarded for companies that have had stable or increasing dividends, while minuses accrue to companies that have reduced their dividend in the past. Indeed, concerning this issue, Graham et al. (1962) stated that "[t]he absence of rate reduction in the past record is perhaps as important as the presence of numerous rate advances."

Free cash flow to equity represents the cash flow available for distribution as dividends after taking account of working and fixed capital expenditure needs. If those needs are ignored, distribution of dividends may be at cross-purposes with shareholder wealth maximization. Cash flow—specifically, free cash flow to equity (FCFE)—not reported net income, should be viewed as the source of cash dividend payments from that perspective. Thus, analysis of dividend safety can properly include payout and coverage ratios based on FCFE rather than net income. Other cash flow definitions besides FCFE have also been used in such ratios. Examining the correlation of dividends with cash flow measures may also provide insights.

Payouts should be considered in terms of share repurchases as well as dividends because they both represent cash distributions to shareholders. Arguably, a comprehensive measure of dividend safety would relate FCFE to both cash dividends and share repurchases:

FCFE coverage ratio = FCFE/[Dividends + Share repurchases].

If that ratio is 1, the company is returning all available cash to shareholders. If it is significantly greater than 1, the company is improving liquidity by using funds to increase cash and/or marketable securities. A ratio significantly less than 1 is not sustainable because the company is paying out more than it can afford by drawing down existing cash/marketable securities, thereby decreasing liquidity. At some point the company will have to raise new equity or cut back on capital spending.

Fundamental risk factors with regard to dividend safety include above-average financial leverage. Additional issuance of debt, whether to fund projects or to finance the dividend, may be restricted during business downturns.

Example 22 shows an analysis of dividend sustainability for Lygon Resources Ltd. (Lygon), a hypothetical company that is one of the world's largest producers of fertilizer products. The analysis includes the traditional earnings/dividend coverage approach and an alternative FCFE approach that considers total cash payouts to shareholders—dividends and share repurchases.

EXAMPLE 22

Lygon's Coverage Ratios

Lygon Resources Ltd. is a lithium miner and producer with operations in Australia, South America, and South Africa, and export markets worldwide. The company has paid dividends since 1995. Exhibit 14 shows financial information for the company.

Exhibit 14 Lygon Resources

Years Ending 31 December (A$ millions)	2015	2016	2017	2018
Net income (earnings)	540	458	399	341
Cash flow from operations	837	824	679	628
FCInv (capital expenditures)	554	417	296	327
Net borrowing	(120)	(39)	79	(7)
Dividends paid	121	256	277	323
Stock repurchases	0	105	277	0

1 Using the above information, calculate the following for 2015, 2016, 2017, and 2018:
   - A Dividend/earnings payout ratio.
   - B Earnings/dividend coverage ratio.
   - C Free cash flow to equity (FCFE).
   - D FCFE/[Dividend + Stock repurchase] coverage ratio.

2 Discuss the trends in earnings/dividend coverage and in FCFE/[Dividend + Stock repurchase] coverage.

3 Comment on the sustainability of Lygon's dividend and stock repurchase policy after 2017/2018.

Solution to 1:

A Dividend/earnings payout = A\$121/A\$540 = 0.224 or 22.4% in 2015; A\$256/A\$458 = 0.559 or 55.9% in 2016; 0.694 or 69.4% in 2017; and 0.947 or 94.7% in 2018.

B Earnings/dividend coverage = A\$540/A\$121 = 4.46x in 2015; A\$458/A\$256 = 1.79x in 2016; 1.44x in 2017; and 1.06x in 2018.

C FCFE = Cash flow from operations (CFO) − FCInv + Net borrowing = A$837 − A$554 + (A$120) = A$163 in 2015; A$824 − A$417 + (A$39) = A$368 in 2016; A$462 in 2017; and A$294 in 2018.

D FCFE coverage of dividends + Share repurchases = FCFE/[Dividends + Stock repurchases] = A$163/(A$121 + 0) = 1.35x in 2015, and A$368/(A$256 + A$105) = 1.02x in 2016. Similar calculations result in 0.83x in 2017 and 0.91x in 2018.

These results are summarized in Exhibit 15.

Exhibit 15 Lygon Resources Coverage Ratios

Years Ending 31 December	2015	2016	2017	2018
A. Dividend-to-earnings payout ratio	22.4%	55.9%	69.4%	94.7%
B. Earnings-to-dividend coverage ratio (x)	4.46	1.79	1.44	1.06
C. Free cash flow to equity (FCFE) (mil.)	163	368	462	294
D. FCFE/[div. + stock repurch.] cover. (x)	1.35	1.02	0.83	0.91

Solution to 2:

Although earnings/dividend coverage was nearly 4.5x in 2015, it declined steadily over the four years. By 2018, accounting earnings were just sufficient to pay the dividend (1.06x earnings-to-dividend coverage ratio). An analyst who looked at this metric should have suspected problems.

The FCFE coverage ratio was 1.35x in 2015, a year before the stock repurchase program began. In 2016, the FCFE coverage of dividends and stock repurchases declined to 1.02x. Lower capital expenditures were offset by increased dividends and the new stock repurchase program. Despite declining capital expenditures and positive net borrowings, the FCFE coverage ratio continued to fall substantially to 0.83x in 2017 as the company elected to increase distributions to shareholders. Despite completing the stock repurchase program the previous year, by 2018 FCFE had deteriorated so much that FCFE coverage of dividends was still less than 1.0x (0.91x).

Solution to 3:

With the FCFE coverage ratio falling to 0.83x in 2017, management likely realized that it was not prudent to undertake any new discretionary stock repurchases. By 2018, net income was still declining and FCFE coverage of the dividend at less than 1.0x meant that management should probably consider cutting the dividend.

The deterioration over time of Lygon's earnings/dividend coverage and FCFE coverage (of dividends and stock repurchases) was clear. There may be other instances when the earnings-to-dividend coverage ratio declines but still appears healthy. This is why it is important for analysts to closely examine the level and trend of the FCFE coverage ratio and the components of FCFE. Analysts should be particularly alert to companies that support their dividends and stock repurchases by reducing productive capital spending or by adding net debt or by some combination of the two because these neither are sustainable policies.

Whether based on a company's net income or free cash flow, past financial data do not always predict dividend safety. Surprise factors and other unexpected events can confound the most rigorous analysis of past data. Equity and debt markets were shaken in 2008–2009 by the losses taken by almost all US and European banks. These losses led to the cutting and, in some cases, virtual elimination of cash dividends. Not all 21st century investors would agree with Graham et al.'s 1962 assertion that "for the vast majority of common stocks, the dividend record and prospects have always been the most important factor controlling investment quality and value." But most investors would agree that when the market even begins to suspect a decrease or suspension of a company's cash dividend, that expectation is likely to weigh unfavorably on that company's common stock valuation. Therefore, many analysts look for external stock market indicators of market expectations of dividend cuts.

Extremely high dividend yields in comparison with a company's past record and forward-looking earnings is often another warning signal that investors are predicting a dividend cut. For example, the dividend yield on Singapore-listed telecoms company StarHub shares was 9.4% just prior to its fixed-to-variable dividend cut in 2019. After the announced dividend cut to a variable 80% of net profit for 2019 onwards, StarHub shares were still projected to yield about 5.6%, relatively high compared to its yield in recent years prior to the fixed dividend (which were generally about 5%). At the time, shareholder equity value was anticipated to go to zero by 2020 if the fixed dividend continued. In such cases, investors bid down the price of shares such that after the expected cut the expected total return on the shares remains adequate.

The observations of Madden (2008) support an attitude of caution with respect to very high dividend yields. Madden examined yields for the 1,963 stocks in the MSCI World Index. His company classified 865 companies out of the 1,963 companies as a "High Dividend Universe" (HDU). In the early months of the economic decline, Madden found that 78.6% of the companies in the HDU had questionable ability to maintain their dividend payments as compared with 30.7% of all the companies in the MCSI World Index. This point is supported by more recent evidence. Research using data for the S&P 500 Index stocks from 2005 to 2015 shows that the top 5% of dividend-yielding stocks accounted for over 8% of the bottom decile of performance. This over-representation of very high dividend-yielding stocks in the bottom decile of performance is likely attributable to deteriorating corporate fundamentals resulting in non-sustainable dividends. Similarly, in 2016 analysts became concerned that many European companies' dividends were unsustainable because they were paying out the highest proportion of their earnings as dividends in decades (a 60% payout ratio) at a time when their earnings were declining. This caused some companies to change their policies and cut dividends for future reinvestment and balance sheet improvement.

SUMMARY

A company's cash dividend payment and share repurchase policies constitute its payout policy. Both entail the distribution of the company's cash to its shareholders affect the form in which shareholders receive the return on their investment. Among the points this reading has made are the following:

- Dividends can take the form of regular or irregular cash payments, stock dividends, or stock splits. Only cash dividends are payments to shareholders. Stock dividends and splits merely carve equity into smaller pieces and do not create wealth for shareholders. Reverse stock splits usually occur after a stock has dropped to a very low price and do not affect shareholder wealth.

- Regular cash dividends—unlike irregular cash dividends, stock splits, and stock dividends—represent a commitment to pay cash to stockholders on a quarterly, semiannual, or annual basis.
- There are three general theories on investor preference for dividends. The first, MM, argues that given perfect markets dividend policy is irrelevant. The second, "bird in hand" theory, contends that investors value a dollar of dividends today more than uncertain capital gains in the future. The third theory argues that in countries in which dividends are taxed at higher rates than capital gains, taxable investors prefer that companies reinvest earnings in profitable growth opportunities or repurchase shares so they receive more of the return in the form of capital gains.
- An argument for dividend irrelevance given perfect markets is that corporate dividend policy is irrelevant because shareholders can create their preferred cash flow stream by selling the company's shares ("homemade dividends").
- Dividend declarations may provide information to current and prospective shareholders regarding management's confidence in the prospects of the company. Initiating a dividend or increasing a dividend sends a positive signal, whereas cutting a dividend or omitting a dividend typically sends a negative signal. In addition, some institutional and individual shareholders see regular cash dividend payments as a measure of investment quality.
- Payment of dividends can help reduce the agency conflicts between managers and shareholders, but it also can worsen conflicts of interest between shareholders and debtholders.
- Empirically, several factors appear to influence dividend policy, including investment opportunities for the company, the volatility expected in its future earnings, financial flexibility, tax considerations, flotation costs, and contractual and legal restrictions.
- Under double taxation systems, dividends are taxed at both the corporate and shareholder level. Under tax imputation systems, a shareholder receives a tax credit on dividends for the tax paid on corporate profits. Under split-rate taxation systems, corporate profits are taxed at different rates depending on whether the profits are retained or paid out in dividends.
- Companies with outstanding debt often are restricted in the amount of dividends they can pay because of debt covenants and legal restrictions. Some institutions require that a company pay a dividend to be on their "approved" investment list. If a company funds capital expenditures by borrowing while paying earnings out in dividends, it will incur flotation costs on new debt issues.
- Using a stable dividend policy, a company tries to align its dividend growth rate to the company's long-term earnings growth rate. Dividends may increase even in years when earnings decline, and dividends will increase at a lower rate than earnings in boom years.
- A stable dividend policy can be represented by a gradual adjustment process in which the expected dividend is equal to last year's dividend per share plus [(Expected earnings × Target payout ratio − Previous dividend) × Adjustment factor].
- Using a constant dividend payout ratio policy, a company applies a target dividend payout ratio to current earnings; therefore, dividends are more volatile than with a stable dividend policy.
- Share repurchases, or buybacks, most often occur in the open market. Alternatively, tender offers occur at a fixed price or at a price range through a Dutch auction. Shareholders who do not tender increase their relative position

in the company. Direct negotiations with major shareholders to get them to sell their positions are less common because they could destroy value for remaining stockholders.

- Share repurchases made with excess cash have the potential to increase earnings per share, whereas share repurchases made with borrowed funds can increase, decrease, or not affect earnings per share depending on the company's after-tax borrowing rate and earnings yield.
- A share repurchase is equivalent to the payment of a cash dividend of equal amount in its effect on total shareholders' wealth, all other things being equal.
- If the buyback market price per share is greater (less) than the book value per share, then the book value per share will decrease (increase).
- Companies can repurchase shares in lieu of increasing cash dividends. Share repurchases usually offer company management more flexibility than cash dividends by not establishing the expectation that a particular level of cash distribution will be maintained.
- Companies can pay regular cash dividends supplemented by share repurchases. In years of extraordinary increases in earnings, share repurchases can substitute for special cash dividends.
- On the one hand, share repurchases can signal that company officials think their shares are undervalued. On the other hand, share repurchases could send a negative signal that the company has few positive NPV opportunities.
- Analysts are interested in how safe a company's dividend is, specifically whether the company's earnings and, more importantly, its cash flow are sufficient to sustain the payment of the dividend.
- Early warning signs of whether a company can sustain its dividend include the dividend coverage ratio, the level of dividend yield, whether the company borrows to pay the dividend, and the company's past dividend record.

PRACTICE PROBLEMS

1 The payment of a 10% stock dividend by a company will result in an increase in that company's:

A current ratio.

B financial leverage.

C contributed capital.

2 If a company's common shares trade at very low prices, that company would be *most likely* to consider the use of a:

A stock split.

B stock dividend.

C reverse stock split.

3 In a recent presentation, Doug Pearce made two statements about dividends:

Statement 1 "A stock dividend will increase share price on the ex-dividend date, all other things being equal."

Statement 2 "One practical concern with a stock split is that it will reduce the company's price-to-earnings ratio."

Are Pearce's two statements about the effects of the stock dividend and stock split correct?

A No for both statements.

B Yes for Statement 1, and no for Statement 2.

C No for Statement 1, and yes for Statement 2.

4 All other things being equal, the payment of an internally financed cash dividend is *most likely* to result in:

A a lower current ratio.

B a higher current ratio.

C the same current ratio.

5 Match the phrases in Column A with the corresponding dividend theory in Column B. Note that you may use the answers in Column B more than once.

Column A	Column B
1. Bird in the hand	a) Dividend policy matters
2. Homemade dividends	b) Dividend policy is irrelevant
3. High tax rates on dividends	

6 Which of the following assumptions is *not* required for Miller and Modigliani's (MM) dividend theory?

A Shareholders have no transaction costs when buying and selling shares.

B There are no taxes.

C Investors prefer dividends over uncertain capital gains.

7 Sophie Chan owns 100,000 shares of PAT Company. PAT is selling for €40 per share, so Chan's investment is worth €4,000,000. Chan reinvests the gross amount of all dividends received to purchase additional shares. Assume that the

© 2018 CFA Institute. All rights reserved.

clientele for PAT shares consists of tax-exempt investors. If PAT pays a €1.50 dividend, Chan's new share ownership after reinvesting dividends at the ex-dividend price is *most* likely to be closest to:

A 103,600.

B 103,750.

C 103,900.

8 Which of the following is *most* likely to signal negative information concerning a company?

A Share repurchase.

B Decrease in the quarterly dividend rate.

C A two-for-one stock split.

9 WL Corporation is located in a jurisdiction that has a 40% corporate tax rate on pretax income and a 30% personal tax rate on dividends. WL distributes all its after-tax income to shareholders. What is the effective tax rate on WL pretax income distributed in dividends?

A 42%.

B 58%.

C 70%.

10 Which of the following factors is *least likely* to be associated with a company having a low dividend payout ratio?

A High flotation costs on new equity issues.

B High tax rates on dividends.

C Low growth prospects.

11 The dividend policy of Berkshire Gardens Inc. can be represented by a gradual adjustment to a target dividend payout ratio. Last year Berkshire had earnings per share of US$3.00 and paid a dividend of US$0.60 a share. This year it estimates earnings per share will be US$4.00. Find its dividend per share for this year if it has a 25% target payout ratio and uses a five-year period to adjust its dividend.

A US$0.68.

B US$0.80.

C US$0.85.

12 Beta Corporation is a manufacturer of inflatable furniture. Which of the following scenarios best reflects a stable dividend policy for Beta?

A Maintaining a constant dividend payout ratio of 40–50%.

B Maintaining the dividend at US$1.00 a share for several years given no change in Beta's long-term prospects.

C Increasing the dividend 5% a year over several years to reflect the two years in which Beta recognized mark-to-market gains on derivatives positions.

13 A company has 1 million shares outstanding and earnings are £2 million. The company decides to use £10 million in surplus cash to repurchase shares in the open market. The company's shares are trading at £50 per share. If the company uses the entire £10 million of surplus cash to repurchase shares at the market price, the company's earnings per share will be *closest* to:

A £2.00.

B £2.30.

C £2.50.

14 Devon Ltd. common shares sell at US$40 a share, and their estimated price-to-earnings ratio (P/E) is 32. If Devon borrows funds to repurchase shares at its after-tax cost of debt of 5%, its EPS is *most likely* to:

A increase.

B decrease.

C remain the same.

15 A company can borrow funds at an after-tax cost of 4.5%. The company's stock price is US$40 per share, earnings per share is US$2.00, and the company has 15 million shares outstanding. If the company borrows just enough to repurchase 2 million shares of stock at the prevailing market price, that company's earnings per share is *most likely* to:

A increase.

B decrease.

C remain the same.

16 Crozet Corporation plans to borrow just enough money to repurchase 100,000 shares. The following information relates to the share repurchase:

Shares outstanding before buyback	3.1 million
Earnings per share before buyback	US$4.00
Share price at time of buyback	US$50
After-tax cost of borrowing	6%

Crozet's earnings per share after the buyback will be *closest* to:

A US$4.03.

B US$4.10.

C US$4.23.

17 A company with 20 million shares outstanding decides to repurchase 2 million shares at the prevailing market price of €30 per share. At the time of the buyback, the company reports total assets of €850 million and total liabilities of €250 million. As a result of the buyback, that company's book value per share will *most likely*:

A increase.

B decrease.

C remain the same.

18 An analyst gathered the following information about a company:

Number of shares outstanding	10 million
Earnings per share	US$2.00
P/E	20
Book value per share	US$30

If the company repurchases 1 million shares at the prevailing market price, the resulting book value per share will be *closest* to:

A US$26.

B US$27.

C US$29.

19 If a company's objective is to support its stock price in the event of a market downturn, it would be advised to authorize:

A an open market share repurchase plan to be executed over the next five years.

B a tender offer share repurchase at a fixed price effective in 30 days.

C a Dutch auction tender offer effective in 30 days.

20 A company has positive free cash flow and is considering whether to use the entire amount of that free cash flow to pay a special cash dividend or to repurchase shares at the prevailing market price. Shareholders' wealth under the two options will be equivalent unless the:

A company's book value per share is less than the prevailing market price.

B company's book value per share is greater than the prevailing market price.

C tax consequences and/or information content for each alternative is different.

21 Assume that a company is based in a country that has no taxes on dividends or capital gains. The company is considering either paying a special dividend or repurchasing its own shares. Shareholders of the company would have:

A greater wealth if the company paid a special cash dividend.

B greater wealth if the company repurchased its shares.

C the same wealth under either a cash dividend or share repurchase program.

22 Investors may prefer companies that repurchase their shares instead of paying a cash dividend when:

A capital gains are taxed at lower rates than dividends.

B capital gains are taxed at the same rate as dividends.

C the company needs more equity to finance capital expenditures.

The following information relates to Questions 23–24

Janet Wu is treasurer of Wilson Chemical Company, a manufacturer of specialty chemicals used in industrial manufacturing and increasingly in technology applications. Wilson Chemical is selling one of its older divisions for US$70 million cash. Wu is considering whether to recommend a special dividend of US$70 million or a repurchase of 2 million shares of Wilson common stock in the open market. She is reviewing some possible effects of the buyback with the company's financial analyst. Wilson has a long-term record of gradually increasing earnings and dividends.

23 Wilson's share buyback could be a signal that the company:

A is decreasing its financial leverage.

B views its shares as undervalued in the marketplace.

C has more investment opportunities than it could fund internally.

24 The most likely tax environment in which Wilson Chemical's shareholders would prefer that Wilson repurchase its shares (share buybacks) instead of paying dividends is one in which:

A the tax rate on capital gains and dividends is the same.

B capital gains tax rates are higher than dividend income tax rates.

C capital gains tax rates are lower than dividend income tax rates.

The following information relates to questions 25–29

John Ladan is an analyst in the research department of an international securities firm. Ladan is currently analyzing Yeta Products, a publicly traded global consumer goods company located in the United States. Selected data for Yeta are presented in Exhibit 1.

Exhibit 1 Selected Financial Data for Yeta Products

Most Recent Fiscal Year		Current	
Pretax income	US$280 million	Shares outstanding	100 million
Net income after tax	US$182 million	Book value per share	US$25.60
Cash flow from operations	US$235 million	Share price	US$20.00
Capital expenditures	US$175 million		
Earnings per share	US$1.82		

Yeta currently does not pay a dividend, and the company operates with a target capital structure of 40% debt and 60% equity. However, on a recent conference call, Yeta's management indicated that they are considering four payout proposals:

Proposal #1: Issue a 10% stock dividend.

Proposal #2: Repurchase US$40 million in shares using surplus cash.

Proposal #3: Repurchase US$40 million in shares by borrowing US$40 million at an after-tax cost of borrowing of 8.50%.

Proposal #4: Initiate a regular cash dividend.

25 The implementation of Proposal #1 would generally lead to shareholders:

A having to pay tax on the dividend received.

B experiencing a decrease in the total cost basis of their shares.

C having the same proportionate ownership as before implementation.

26 If Yeta's management implemented Proposal #2 at the current share price shown in Exhibit 1, Yeta's book value per share after implementation would be *closest* to:

A US$25.20.

B US$25.71.

C US$26.12.

27 Based on Exhibit 1, if Yeta's management implemented Proposal #3 at the current share price, earnings per share would:

A decrease.

B remain unchanged.

C increase.

28 Based on Yeta's target capital structure, Proposal #4 will *most likely:*

A increase the default risk of Yeta's debt.

B increase the agency conflict between Yeta's shareholders and managers.

C decrease the agency conflict between Yeta's shareholders and bondholders.

29 The implementation of Proposal #4 would *most likely* signal to Ladan and other investors that future earnings growth can be expected to:

A decrease.

B remain unchanged.

C increase.

SOLUTIONS

1 C is correct. A stock dividend is accounted for as a transfer of retained earnings to contributed capital.

2 C is correct. A reverse stock split would increase the price per share of the stock to a higher, more marketable range that could possibly increase the number of investors who would consider buying the stock.

3 A is correct. Both statements are incorrect. A stock dividend will decrease the price per share, all other things being equal. A stock split will reduce the price and earnings per share proportionately, leaving the price-to-earnings ratio the same.

4 A is correct. By reducing corporate cash, a cash dividend reduces the current ratio, whereas a stock dividend (whatever the size) has no effect on the current ratio.

5 The appropriate matches are as follows:

Column A	Column B
1. Bird in the hand	a) Dividend policy matters
2. Homemade dividends	b) Dividend policy is irrelevant
3. High tax rates on dividends	a) Dividend policy matters

6 C is correct. The MM dividend theory assumes no taxes or transaction costs, but it does not assume investors have a preference for dividends over capital gains.

7 C is correct. Because the clientele for PAT investors has the same tax rate (zero) for dividends and capital gains, the ex-dividend stock price of PAT should decline by the amount of the dividend to €40 – €1.50 = €38.50. Chan will purchase €150,000/€38.50 = 3,896 additional shares. This increases her total shares owned to 103,896. Chan's new share ownership is closest to 103,900.

8 B is correct. A decrease in the quarterly dividend rate is likely to signal negative information. A decrease is typically understood as signaling poor future business prospects.

9 B is correct. The effective tax rate can be computed as 1 minus the fraction of 1 unit of earnings that investors retain after all taxes, or 1 – (1 – 0.40)(1 – 0.30) = 0.58 or 58% effective tax rate. Another way to obtain the solution: Corporate taxes = 1.00 × 0.40 = 0.40 and Personal taxes = 0.60 in dividends × 0.30 = 0.18, so Total tax = 0.40 + 0.18 = 0.58, or 58% effective rate.

10 C is correct. With low growth prospects, a company would typically have a high payout ratio, returning funds to its shareholders rather than retaining funds.

11 A is correct. The estimated dividend per share is US$0.68.

Previous DPS = US$0.60

Expected EPS = US$4

Target payout ratio = 0.25

Five-year adjustment factor = 1/5 = 0.2

Expected dividend = Previous dividend + (Expected earnings × Target payout ratio − Previous dividend) × Adjustment factor
= US$0.60 + [(US$4.00 × 0.25 − US$0.60) × 0.2]
= US$0.60 + US$0.08
= US$0.68

12 B is correct. Choice A is consistent with a constant dividend target payout ratio policy. Choice C is not correct because the earnings increases described are not sustainable long term.

13 C is correct. At the current market price, the company can repurchase 200,000 shares (£10 million/£50 = 200,000 shares). The company would have 800,000 shares outstanding after the repurchase (1 million shares − 200,000 shares = 800,000 shares).

EPS before the buyback is £2.00 (£2 million/1 million shares = £2.00). Total earnings after the buyback are the same because the company uses surplus (nonearning) cash to purchase the shares, but the number of shares outstanding is reduced to 800,000. EPS increases to £2.50 (£2 million/ 800,000 shares = £2.50).

14 B is correct. If the P/E is 32, the earnings-to-price ratio (earnings yield or E/P) is 1/32 = 3.125%. When the cost of capital is greater than the earnings yield, earnings dilution will result from the buyback.

15 A is correct. The company's earnings yield (E/P) is US$2/US$40 = 0.05. When the earnings yield is greater than the after-tax cost of borrowed funds, EPS will increase if shares are repurchased using borrowed funds.

16 A is correct.

Total earnings before buyback: US$4.00 × 3,100,000 shares = US$12,400,000

Total amount of borrowing: US$50 × 100,000 shares = US$5,000,000

After-tax cost of borrowing the amount of funds needed: US$5,000,000 × 0.06 = US$300,000

Number of shares outstanding after buyback: 3,100,000 − 100,000 = 3,000,000

EPS after buyback: (US$12,400,000 − US$300,000)/3,000,000 shares = US$4.03

The P/E before the buyback is US$50/US$4 = 12.5; thus, the E/P is 8%. The after-tax cost of debt is 6%; therefore, EPS will increase.

17 C is correct. The company's book value before the buyback is €850 million in assets − €250 million in liabilities = €600 million. Book value per share is €600 million/20 million = €30 per share. The buyback will reduce equity by 2 million shares at the prevailing market price of €30 per share. The book value of equity will be reduced to €600 million − €60 million = €540 million, and the number of shares will be reduced to 18 million; €540 million/18 million = €30 book value per share. If the prevailing market price is equal to the book value per share at the time of the buyback, book value per share is unchanged.

18 C is correct. The prevailing market price is US$2.00(20) = US$40.00 per share; thus, the buyback would reduce equity by US$40 million. Book value of equity before the buyback is US$300 million. Book value of equity after the buyback would be US$300 million − US$40 million = US$260 million. The number of

shares outstanding after the buyback would be 9 million. Thus, book value per share after the buyback would be US$260 million/9 million = US$28.89 ≈ US$29.

19 A is correct. Of the three methods, only an authorized open market share repurchase plan allows the company the flexibility to time share repurchases to coincide with share price declines.

20 C is correct. For the two options to be equivalent with respect to shareholders' wealth, the amount of cash distributed, the taxation, and the information content must be the same for both options.

21 C is correct. When there are no taxes, there are no tax differences between dividends and capital gains. All other things being equal, the effect on shareholder wealth of a dividend and a share repurchase should be the same.

22 A is correct. When capital gains are taxed at lower rates than dividends, investors may prefer companies that return cash to shareholders through share repurchases rather than dividends.

23 B is correct. Management sometimes undertakes share repurchases when it views shares as being undervalued in the marketplace.

24 C is correct. Shareholders would prefer that the company repurchase its shares instead of paying dividends when the tax rate on capital gains is lower than the tax rate on dividends.

25 C is correct. The implementation of Proposal #1, a stock dividend, would not affect a shareholder's proportionate ownership because all shareholders would receive the same proportionate increase in shares. Stock dividends, which are generally not taxable to shareholders, do not impact an investor's total cost basis (they merely reduce the cost basis per share).

A is incorrect because stock dividends are generally not taxable to shareholders. A stock dividend merely divides the "pie" (the market value of shareholders' equity) into smaller pieces.

B is incorrect because an investor's total cost basis will not be affected by a stock dividend; a stock dividend merely reduces the cost basis per share.

26 B is correct. If Yeta implemented Proposal #2, a repurchase of US$40 million in shares, the resulting book value per share (BVPS) would be US$25.71, calculated as follows:

1 Yeta has a current BVPS of US$25.60; therefore, total book value of equity is US$2,560 million (= US$25.60 × 100,000,000 shares).

2 The number of shares Yeta would repurchase is US$40 million/US$20.00 per share = 2 million shares.

3 Yeta shareholders' book value of equity after the buyback would be US$2,520 million (= US$2,560 million – US$40 million).

4 The number of shares after the buyback would be 98 million (= 100 million – 2 million).

5 The BVPS after the buyback would be US$2,520 million/98 million = US$25.71.

A is incorrect because US$25.20 incorrectly uses 100 million shares instead of 98 million shares in calculating BVPS after the buyback: US$2,520 million/100 million = US$25.20.

C is incorrect because US$26.12 incorrectly uses US$2,560 million (current book value) instead of US$2,520 million as the book value of equity in calculating BVPS after the buyback. The BVPS after the buyback is incorrectly calculated as US$2,560 million/98 million = US$26.12.

27 C is correct. In the case of external funding, a company's earnings per share will increase if the stock's earnings yield, which is the ratio of earnings per share to share price, exceeds the after-tax cost of borrowing. Yeta's earnings yield is 9.10% (= US$1.82/US$20.00), which exceeds the after-tax cost of borrowing of 8.50%.

A is incorrect because EPS will increase (not decrease) if the stock's earnings yield (= US$1.82/US$20.00) exceeds the after-tax cost of borrowing. Yeta's earnings yield of 9.10% exceeds the after-tax cost of borrowing of 8.50%.

B is incorrect because EPS will increase (not remain unchanged) if the stock's earnings yield (= US$1.82/US$20.00) exceeds the after-tax cost of borrowing. Yeta's earnings yield of 9.10% exceeds the after-tax cost of borrowing of 8.50%.

28 A is correct. Yeta is financed by both debt and equity; therefore, paying dividends can increase the agency conflict between shareholders and bondholders. The payment of dividends reduces the cash cushion available for the disbursement of fixed required payments to bondholders. All else equal, dividends increase the default risk of debt.

B is incorrect because the agency conflict between shareholders and managers would decrease (not increase) with the payment of dividends. Paying out free cash flow to equity in dividends would constrain managers in their ability to overinvest by taking on negative net present value (NPV) projects.

C is incorrect because paying dividends can increase (not decrease) the agency conflict between shareholders and bondholders. The payment of dividends would reduce the cash cushion available to Yeta for the disbursement of fixed required payments to bondholders. The payment of dividends transfers wealth from bondholders to shareholders and increases the default risk of debt.

29 C is correct. Dividend initiations convey positive information and are associated with future earnings growth, whereas dividend omissions or reductions convey negative information and are associated with future earnings problems.

A is incorrect because dividend initiations convey positive information and are associated with an expected increase (not a decrease) in future earnings growth. Dividend omissions or reductions convey negative information and are associated with future earnings problems.

B is incorrect because dividend initiations convey positive information and are associated with an expectation that future earnings growth will increase (not remain unchanged). In contrast, dividend omissions or reductions convey negative information and are associated with future earnings problems.

CORPORATE ISSUERS

STUDY SESSION 7

Corporate Issuers (2)

This study session presents two major organizational topics of corporate finance. The first topic presented is environmental, social, and governance (ESG) considerations in investment analysis. The process for identifying ESG-related risks and opportunities relevant to security analysis are described. ESG considerations provide analysts with a broader perspective of the risks and investment opportunities of a company's securities. Next, mergers, acquisitions, and corporate restructurings—which create changes in ownership and control—are examined to determine whether 1) value is created from the transaction and 2) acquisition price is justified by the transaction's benefits.

Environmental, Social, and Governance (ESG) Considerations in Investment Analysis

by Deborah S. Kidd, CFA, Young Lee, CFA, JD, and Johan Vanderlugt

Deborah S. Kidd, CFA, is at CFA Institute (USA). Young Lee, CFA, JD, is at MacKay Shields (USA and Europe), MacKay Shields Europe Investment Management Ltd. (Ireland), and MacKay Shields UK LLP (United Kingdom). Johan Vanderlugt is at NN Investment Partners (Netherlands).

LEARNING OUTCOMES

Mastery	*The candidate should be able to:*
☐	**a.** describe global variations in ownership structures and the possible effects of these variations on corporate governance policies and practices;
☐	**b.** evaluate the effectiveness of a company's corporate governance policies and practices;
☐	**c.** describe how ESG-related risk exposures and investment opportunities may be identified and evaluated;
☐	**d.** evaluate ESG risk exposures and investment opportunities related to a company.

INTRODUCTION

1

Environmental, social, and governance (ESG) considerations are increasingly being integrated into investment analysis. Evaluating how ESG factors potentially affect a company may provide analysts with a broader perspective on the risks and investment opportunities of a company's securities. Although corporate governance has long been recognized as having a significant impact on a company's long-term performance, investors have become increasingly concerned with environmental and social factors and how companies manage their resources and risk exposures that relate to such factors. Mismanagement of these resources has led to a number of high-profile corporate events that have negatively affected security prices. Increasingly stringent

CFA Institute would like to thank Hardik Sanjay Shah, CFA, for his contributions to the 2022 update of this reading.

regulatory environments, potentially finite supplies of natural resources, and global trends toward energy conservation and waste reduction have led many investors to place greater emphasis on the management of environmental risks. Similarly, such issues as worker health and safety policies, community impact, and marketing practices have increased the visibility of how a company manages its social capital.

This reading provides an overview of ESG considerations in investment analysis. Section 2 provides an overview of the global variations in corporate ownership structures, as well as how these ownership structures may affect corporate governance outcomes. In Section 3, we discuss company-specific factors that should be considered when evaluating corporate governance in the investment process. Section 4 discusses the identification of ESG-related risks and opportunities that are relevant to security analysis. Section 5 demonstrates the evaluation of ESG-related risks and opportunities through several examples. The reading concludes with a summary of the key points discussed.

2 OWNERSHIP STRUCTURES AND THEIR EFFECTS ON CORPORATE GOVERNANCE

a describe global variations in ownership structures and the possible effects of these variations on corporate governance policies and practices.

The global corporate governance landscape comprises a vast range of ownership structures that reflect unique economic, political, social, legal, and other forces in each country and/or region. Within any of these distinct ownership structures, one may find a variety of complex relationships involving shareholders and other stakeholders who have an interest in the company. Those other stakeholders include creditors, managers (executives), employees, directors, customers, suppliers, governments, and regulators. An understanding of the variation of ownership structures, the conflicts that arise within these structures, types of influential shareholders, and the effects of ownership structure on corporate governance are important considerations for analyzing corporate governance in the investment process.

2.1 Dispersed vs. Concentrated Ownership

Corporate ownership structures are generally classified as *dispersed*, *concentrated*, or a hybrid of the two. **Dispersed ownership** reflects the existence of many shareholders, none of which has the ability to individually exercise control over the corporation. In contrast, **concentrated ownership** reflects an individual shareholder or a group (called *controlling shareholders*) with the ability to exercise control over the corporation. In this context, a group is typically a family, another company (or companies), or a sovereign entity.

On a global basis, concentrated ownership structures are considerably more common than dispersed ownership structures. A global corporate governance report by the Organisation for Economic Co-operation and Development (OECD)[1] noted that 38 out of 47 jurisdictions analyzed have predominantly concentrated ownership structures. Among the other nine jurisdictions, four were characterized as having dispersed ownership structures (Australia, Ireland, the United Kingdom, and the

1 OECD (2017).

United States) and five were characterized as having "hybrid" corporate ownership structures (Canada, Germany, Japan, the Netherlands, and Switzerland). The OECD's classification of corporate ownership structure by jurisdiction is shown in Exhibit 1.

Exhibit 1 Corporate Ownership Classifications

Jurisdictions with Concentrated Ownership	
Austria, Belgium, Brazil, Chile, China, Colombia, Czech Republic, Denmark, Estonia, Finland, France, Greece, Hungary, Iceland, India, Indonesia, Israel, Italy, Latvia, Mexico, New Zealand, Norway, Poland, Portugal, Russia, Singapore, Slovenia, South Africa, South Korea, Spain, Sweden, Turkey, United Arab Emirates	State ownership is characteristic of certain countries, such as China, Norway, and Sweden. In other countries, including Brazil, Mexico, Portugal, and South Korea, families are the predominant shareholders. Company groups are prevalent in a number of additional countries, such as India and Russia.

Jurisdictions with Dispersed Ownership	
Australia, Ireland, United Kingdom, United States	Among the largest companies in Australia, the majority of shares are held (albeit dispersed) by financial institutions. In Ireland, ownership shares tend to be widely dispersed, although there are a few family-controlled companies. Among UK companies, few have major shareholders owning 25% or more of shares. In the United States, ownership of public companies is generally characterized by dispersed shareholdings; listed companies are rarely under the control of a major shareholder.

Hybrid Jurisdictions	
Canada, Germany, Japan, Netherlands, Switzerland	In Canada, among the largest listed firms, a meaningful minority have controlling shareholders. In Germany, a significant number of companies are under "tight control," but in many cases shares are broadly distributed (especially for listed companies). In Japan, a small minority of listed companies have a shareholder that owns a majority of shares. The Netherlands has a more dispersed ownership structure than most continental European countries; however, when accounting for "trust offices," ownership is somewhat more concentrated. In Switzerland, the largest listed companies have more dispersed ownership than medium-sized and smaller companies.

Source: OECD (2017).

The degree of share ownership alone may not necessarily reflect whether the control of a company is dispersed or concentrated. This is true because controlling shareholders may be either **majority shareholders** (i.e., own more than 50% of a corporation's shares) or **minority shareholders** (i.e., own less than 50% of shares). In certain ownership structures, shareholders may have disproportionately high control of a corporation relative to their ownership stakes as a result of horizontal and/or vertical ownership arrangements. **Horizontal ownership** involves companies with mutual business interests (e.g., key customers or suppliers) that have cross-holding share arrangements with each other. This structure can help facilitate strategic alliances and foster long-term relationships among such companies. **Vertical ownership** (or pyramid ownership) involves a company or group that has a controlling interest in two or more holding companies, which in turn have controlling interests in various operating companies.

The existence of *dual-class* (or multiple-class) shares can also serve to disconnect the degree of share ownership from actual control. **Dual-class shares** grant one share class superior or sole voting rights, whereas the other share class has inferior or no voting rights. When used in connection with vertical ownership arrangements, the company or group at the top of the pyramid can issue to itself all or a disproportionately high number of shares with superior voting rights and thus maintain control of the operating companies with relatively fewer total shares of a company owned.

2.2 Conflicts within Different Ownership Structures

The type of corporate ownership structure affects corporate governance policies and practices because of the potentially different set of conflicts that may exist between shareholders and managers, as well as among shareholders themselves.

The combination of *dispersed* ownership and *dispersed* voting power is generally associated with shareholders who lack the power to exercise control over managers. These shareholders are referred to as *weak shareholders*, and such managers are referred to as *strong managers*. Under this combination, conflict between the shareholders and managers of a corporation may be significant. Shareholders are interested in maximizing shareholder value. There is a risk, however, that managers will seek to use a company's resources to pursue their own interests. In corporate governance, this conflict is known as a *principal–agent* problem. This problem can be mitigated if controlling shareholders are present because they may be able to control the board of directors (and, in turn, the appointment of managers) and have the incentive to monitor management.

The combination of *concentrated* ownership and *concentrated* voting power often results in controlling shareholders maintaining a position of power over both managers and minority shareholders; these controlling shareholders are referred to as *strong shareholders*, and such managers are referred to as *weak managers*. In this scenario, controlling shareholders can effectively monitor management because they are able to control the board of directors and, in turn, the appointment of managers. With concentrated ownership and concentrated voting power, however, controlling owners may also be able to allocate company resources to their own benefit at the expense of minority owners. This conflict is known as a *principal–principal* problem.

The combination of *dispersed* ownership and *concentrated* voting power generally leads to the principal–principal problem as well. The one difference, however, is that the strong controlling shareholders do not own a majority of the shares of a company. In this scenario, controlling shareholders with less than majority ownership can exert control over other minority owners through certain mechanisms, such as dual-class share structures and pyramid structures, and can also monitor management owing to their outsized voting power.

Finally, the combination of *concentrated* ownership and *dispersed* voting power arises when there are legal restrictions on the voting rights of large share positions, known as **voting caps**. A number of sovereign governments have imposed voting caps to deter foreign investors from obtaining controlling ownership positions in strategically important local companies.

EXAMPLE 1

Conflicts between Shareholders and Managers

The managers of Company A, a widely held conglomerate, collectively own approximately 30% of the outstanding shares. No other shareholder owns more than a 1% share. Each ownership share has equivalent voting rights. Describe the potential conflict between the shareholders and managers of Company A given its ownership structure and voting rights.

Solution:

Company A has dispersed ownership and dispersed voting power. In this ownership structure, shareholders do not appear to have the ability to control or monitor managers; that is, there are weak shareholders and strong managers. In this case, a risk exists that managers may seek to use company resources to prioritize their own interests rather than to maximize shareholder value. This type of conflict is known as the *principal–agent* problem.

2.3 Types of Influential Shareholders

In different parts of the world, the types of corporate shareholders that have a significant influence on corporate governance vary. Each of these shareholder types possesses its own unique set of motivations, interests, and agendas. By identifying these shareholders, an investment analyst is in a position to further assess corporate governance risks.

2.3.1 *Banks*

In several regions, notably in Europe and Asia, banks often have considerable control over corporations with which they have a lending relationship as well as an equity interest. A conflict of interest could arise if banks have loan exposures to a corporation in addition to their equity investment. For example, if a bank has both a lending relationship with and an equity interest in a corporation, it could seek to influence the corporation to take out large loans, and perhaps on less favorable terms, to the potential detriment of other shareholders. In this situation, appropriate corporate governance controls could ensure that banks that are both creditors and investors appropriately balance their interests as lenders against their interests as shareholders.

2.3.2 *Families*

Family ownership is the predominant form of corporate structure in some parts of the world, notably Latin America and, to a slightly lesser extent, Asia and Europe. In some cases, also commonly in Latin America, individuals serve on the board of directors of multiple corporations. This situation, known as **interlocking directorates**, typically results in the same family or the same member of a corporate group controlling several corporations. A benefit of family control is lower risks associated with principal–agent problems as a result of families having concentrated ownership and management responsibility. Conversely, drawbacks of family ownership may include poor transparency, lack of management accountability, modest consideration for minority shareholder rights, and difficulty in attracting quality talent for management positions.

2.3.3 *State-Owned Enterprises*

State-owned enterprises (SOEs) often exist in corporate sectors that are strategically important to a sovereign government, have minimum initial or ongoing capital requirements that are beyond the private sector's funding ability, or provide certain products or services (e.g., power generation or health services) that the state believes should be provided at a certain price or minimum standard. Listed SOEs are partially owned by sovereign governments but also have shares traded on public stock markets. This structure is called a *mixed-ownership model*. This model tends to have lower market scrutiny of management than that of corporate ownership models, which have implicit or explicit state guarantees to prevent corporate bankruptcy. In some cases, SOEs may pursue policies that enhance social or public policy considerations at the expense of maximizing shareholder value.

2.3.4 *Institutional Investors*

In many countries, institutional investors—typically mutual funds, pension funds, insurance companies, and hedge funds—collectively represent a significant proportion of equity market ownership. Because these investors tend to have considerable resources and market expertise, they can use informed judgment in exercising their shareholder rights. In markets with widely dispersed ownership, institutional investors do not typically control a large enough ownership position to qualify as a controlling shareholder. Institutional investors can promote good corporate governance, however, by holding a company's board and management accountable when the board or management does not appear to be acting in the best interests of shareholders.

2.3.5 *Group Companies*

Some ownership structures, such as the previously mentioned horizontal and vertical ownership structures, may result in shareholders having disproportionately high control relative to their ownership stakes. Cross-holding share arrangements and long-term relationships between these group companies may restrict the potential for a transfer of share ownership—as well as create a potential obstacle for outsiders to purchase a significant portion of shares in companies. Without appropriate corporate governance policies/procedures or regulatory protections, there is a greater risk that corporations controlled by groups engage in related-party transactions at the expense of minority shareholders. Examples of group companies are Samsung (South Korea), Sanwa (Japan), and Grupo Carso (Mexico).

2.3.6 *Private Equity Firms*

Private equity firms, notably those involved in venture capital and leveraged buyouts, are strategic owners that invest in privately owned companies or in public companies with the intent to take them private. Venture capital firms invest in the early stages of a company and provide oversight of portfolio companies. Similarly, leveraged buyout (LBO) firms typically have majority control in mature companies. The involvement of venture capital and LBO firms in the management of corporations may bring important changes to companies' corporate governance, such as the development of corporate codes and implementation of performance-based manager compensation.

2.3.7 *Foreign Investors*

Foreign investors, particularly when investing in emerging market countries, can have a significant influence on local companies when they own more shares than domestic investors own. Foreign investors from countries that have more stringent standards may demand higher levels of transparency and accountability. If a local company chooses to cross-list its shares in another country with greater transparency requirements and investor protections, local minority shareholders may benefit from the arrangement.

2.3.8 *Managers and Board Directors*

When managers and board directors are also shareholders of a company, they are known as **insiders**. As their ownership positions increase, insiders are more likely to dedicate company resources toward long-term profitability because their economic interests in the company have become more aligned with the interests of external shareholders. Large ownership positions, however, may also provide insiders with increased power and an accompanying desire to protect their own interests at the expense of other shareholders.

2.4 Effects of Ownership Structure on Corporate Governance

This subsection highlights the effects of ownership structures on corporate governance policies and practices. Key considerations include board independence; board structure; special voting arrangements; corporate governance codes, laws, and listing requirements; and stewardship codes.

2.4.1 *Director Independence*

Independent board directors (or independent board members) are defined as those with no material relationship with the company with regard to employment, ownership, or remuneration. The percentage of independent board directors tends to be higher in jurisdictions with generally dispersed ownership structures relative to those countries with generally concentrated ownership structures. Independent directors originated in dispersed ownership jurisdictions as a means to strengthen the board's monitoring role over managers. The proportion of independent directors on boards has increased over time amid regulatory responses to corporate scandals (e.g., the Enron Corporation scandal in the early 2000s).

Independent directors generally serve a narrower role in concentrated ownership structures than in dispersed ownership structures. For example, the United States requires that some committees (such as the audit, nomination, and compensation committees) be composed entirely of independent directors. Conversely, in most jurisdictions with concentrated ownership structures, nomination and remuneration committees are not mandatory; when these committees do exist, jurisdictions typically recommend that the committees be wholly or largely composed of independent directors. In short, the principal–agent problem is generally less of a concern in a concentrated ownership structure than in a dispersed ownership structure.

Almost all OECD countries have introduced a requirement or recommendation for the level of independent directors serving on boards. These requirements and recommendations vary by jurisdiction, however. Some countries impose or recommend a minimum number of independent directors (typically ranging from one to three), whereas others impose or recommend a minimum ratio of independent directors (typically ranging from 20% to 50% or greater).

2.4.2 *Board Structures*

A corporation's board of directors is typically structured as either one tier or two tier. A **one-tier board** structure consists of a single board of directors, composed of executive (internal) and non-executive (external) directors. A **two-tier board** structure consists of a supervisory board that oversees a management board. A one-tier board is the most common structure, but a number of jurisdictions mandate a two-tier board structure (e.g., Argentina, Germany, and Russia), whereas other jurisdictions offer the choice of a one-tier or two-tier board (e.g., Brazil and France). The supervisory board of a two-tier board can serve as a control function through activities such as inspecting the corporation's books and records, reviewing the annual report, overseeing the work of external auditors, analyzing information provided by the management board, and setting or influencing management compensation. In certain countries, such as Germany, the supervisory boards comprise representatives from key stakeholders, such as banks and labor or other groups.

2.4.3 *Special Voting Arrangements*

Several jurisdictions have special voting arrangements to improve the position of minority shareholders. For example, Brazil, India, Portugal, Turkey, Italy, Israel, and the United Kingdom have special arrangements that facilitate engagement of minority shareholders in board nomination and election processes. When a UK company has a controlling shareholder, a condition for obtaining a "premium listing" (i.e., meeting the United Kingdom's highest standards of regulation and corporate governance) on the London Stock Exchange is that independent directors must be separately approved by both the entire shareholder base and non-controlling shareholders.

2.4.4 *Corporate Governance Codes, Laws, and Listing Requirements*

Many countries have adopted national corporate governance codes in which companies disclose their adoption of recommended corporate governance practices or explain why they have not done so. In some jurisdictions, companies are required to go beyond this "comply or explain" approach. In Japan, for example, companies with no outside directors must justify why appointing outside directors is not appropriate. Some jurisdictions do not have national corporate governance codes but make use of company law or regulation (e.g., Chile) or stock exchange listing requirements (e.g., India) to achieve similar objectives.

2.4.5 *Stewardship Codes*

Many countries have introduced voluntary codes, known as *stewardship codes*, that encourage investors to exercise their legal rights and increase their level of engagement in corporate governance. In some cases, stewardship codes are not entirely voluntary. As an example, the UK Stewardship Code includes a duty for institutional investors to monitor the companies in which they invest and requires that UK asset managers investing in the shares of UK companies publish a "comply or explain" statement of commitment to the UK Stewardship Code.

3 EVALUATING CORPORATE GOVERNANCE POLICIES AND PROCEDURES

b evaluate the effectiveness of a company's corporate governance policies and practices.

Effective corporate governance is critical for a company's reputation and competitiveness. Benefits of effective corporate governance may include higher profitability, growth in return on equity (or other return metrics), better access to credit, higher and sustainable dividends, favorable long-term share performance, and a lower cost of capital. In contrast, companies with ineffective corporate governance may experience reputational damage, reduced competitiveness, potential share price weakness/volatility, reduced profitability, and a higher cost of capital.

Corporate governance factors are often difficult to quantify. However, an understanding of these factors and their impact on governance policies and procedures can be important for investors to consider. Understanding the disclosed corporate governance policies and procedures is a key starting point for investors. Regular dialogue and engagement efforts with companies can help investors better understand corporate governance policies and procedures. In some situations, shareholder activism can be used to attempt to compel a company to act in a desired manner. **Shareholder activism** refers to strategies used by shareholders to attempt to compel a company to act in a desired manner.

The quality of corporate governance is typically reflected in a company's behavior in the market and toward its stakeholders. To that end, an evaluation of a corporation's board of directors is a starting point for investors. We discuss several of the considerations relating to boards of directors in this section. In addition, a company's policies regarding business ethics, bribery and corruption, whistleblower protection, and related-party transactions can help analysts evaluate a company's corporate governance. In practice, analysts typically adjust the risk premium (cost of capital) or credit spread of a company to reflect their assessment of corporate governance considerations.

3.1 Board Policies and Practices

A starting point for evaluating a board's effectiveness is its policies and practices. An oversight role is one aspect of a board's effectiveness—for example, whether the board is high-performing or dysfunctional. Each capital market is subject to different corporate governance issues, depending on its predominant ownership structure, history, legal environment, culture, and industry diversity. For example, boards of companies with concentrated family ownership structures and concentrated voting power may engage in related-party transactions that benefit family members or affiliates at the expense of outside shareholders.

3.1.1 *Board of Directors Structure*

Generally, when evaluating board structure, investors consider whether the organization and structure of the board—whether it is a one-tier or two-tier structure—provide sufficient oversight, representation, and accountability to shareholders. A related topic is "CEO duality," whereby the chief executive officer (CEO) also serves as chairperson of the board. CEO duality may raise concerns that the monitoring and oversight role of the board may be compromised relative to independent chairperson and CEO roles. When the chairperson is not independent or the role is combined, a company may appoint a lead independent director to help protect investor interests.

3.1.2 *Board Independence*

The independence of the directors, which we discussed previously, is a relevant consideration for investors. The absence or presence of a minority of independent directors is a negative aspect of corporate governance. Without independent directors, the potential exists for management to act in a self-serving manner. Consequently, a lack of independent directors on a board may increase investors' perception of the corporation's risk.

3.1.3 *Board Committees*

The number of board committees and how the committees operate are relevant considerations in an investor's analysis of governance. Committees vary by corporation and industry but generally include audit, governance, remuneration (or compensation), nomination, and risk and compliance committees. When evaluating a company's board committees, investors assess whether there are sufficiently independent committees that focus on key governance concerns, such as audit, compensation, and the selection of directors. The presence of non-independent committee members or executive directors may prompt the consideration of potential conflicts of interest or biases, such as those relating to compensation decisions (remuneration committee), management selection (nomination committee), and the integrity of financial reporting (audit committee).

3.1.4 *Board Skills and Experience*

The underlying skill set and experience of board directors are important investor considerations. A board with concentrated skills and experience may lack sufficient expertise to govern, as may a board with diverse skills and expertise that are not directly related to the company's core operations. In certain sectors/industries that rely on natural resources or face potentially large ESG risks, board members typically have expertise in environmental, climate, or social issues.

An issue related to skills and experience is board tenure. According to many corporate governance codes, a board director's tenure is considered long if it exceeds 10 years. Long tenure of a board member could be viewed positively or negatively. On the positive side, a board member with a long tenure may have a comprehensive understanding of how the corporation's business operates, as well as how effective company management has been during the director's tenure. On the negative side, long tenure may affect the independence of board members (i.e., they could be too closely aligned with management) or may result in directors being less willing to embrace changes in the corporation's business.

3.1.5 *Board Composition*

Board composition primarily reflects the number and diversity of directors, including their professional, cultural, and geographical background, as well as gender, age, and tenure. Boards with too many members or that lack diversity may govern less effectively than boards that are smaller or more diverse. For example, a board with long-tenured board members could become controlling, self-serving, or resistant to the introduction of new practices or policies that may benefit stakeholders.

3.1.6 *Other Considerations in Board Evaluation*

Board evaluation is necessary to maintain a company's competitive position and to meet the expectations of investors, as indicated by the widely recognized Cadbury Report, issued in the United Kingdom in 1992. Dimensions of the board evaluation process may include who evaluates the board, what should be evaluated, to whom the evaluation is targeted, and how the evaluation will be accomplished.

A board evaluation can be performed by the board itself (self-evaluation) or by an outsider on behalf of the board (external review). Some boards may decide to evaluate their performance on an "as needed" basis, whereas others will prefer to conduct a periodic external review. A board evaluation typically covers how the board performs its duties, its leadership, its structure (including the committees), and the interaction between board members and management (including culture). Apart from internal stakeholders, the evaluation may be targeted to the company's shareholders, regulators, or other external stakeholders.

EXAMPLE 2

Evaluating the Board of Directors

A junior analyst is analyzing the board of directors of Style, a fictional global clothing retailer based in Italy. Style was founded by the Donato family and is publicly traded. Style's 11-member board of directors has a chairperson—who is not the CEO—and two independent directors. Among the six non-independent directors, the Donato family accounts for four of them. All these family members have served on the board for at least 20 years. The gender and age characteristics of the board are both diverse, with women representing five of the board's directors—including its chair, Leila Donato—and the directors ranging in age from 35 to 75 years old.

Describe considerations that the junior analyst would use in evaluating the effectiveness of Style's board of directors.

Solution:

The CEO and chairperson roles are separate for Style (no CEO duality), which can be considered a sign of effective corporate governance. In addition, the board appears to be diverse in terms of age and gender, which is typically considered a positive attribute. Conversely, board independence appears to be substandard: Only two board directors are independent, whereas four Donato family members, including the chairperson (Leila Donato), are board members. The tenure of the family board members is also likely to be considered a negative attribute (it far exceeds the typical 10 years).

3.2 Executive Remuneration

Executive remuneration involves such issues as transparency of compensation, performance criteria for incentive plans (both short term and long term), the linkage of remuneration with the company strategy, and the pay differential between the CEO and the average worker. When a corporation has a "say-on-pay" provision, shareholders can vote and/or provide feedback on remuneration issues. A clawback policy allows a company to recover previously paid remuneration if certain events, such as financial restatements, misconduct, breach of the law, or risk management deficiencies, are uncovered.

There is increasing concern among investors regarding "excessive" remuneration, often represented by the ratio of CEO pay to average-worker pay. In evaluating a company's executive remuneration, investors typically consider whether the company's remuneration policies and practices provide appropriate incentives for management to drive the value of a corporation. Company disclosures such as those metrics (also known as key performance indicators, or KPIs) used in executive incentive plans may be useful tools for analysis.

3.3 Shareholder Voting Rights

Shareholder voting rights are important investor considerations. Under **straight voting** share structures, shareholders are granted the right of one vote for each share owned. Dual-class share structures differ from straight voting in that company founders and/or management typically have shares with more voting power than the class of shares available to the general public. That is, dual-class share structures—in contrast to the one share, one vote principle of straight voting—can benefit one group of shareholders over another. Because a potential conflict of interest may exist between minority shareholders and the company's founders and management (some of whom may also serve on the board of directors), it is important for investors to be aware of dual-class share structures when investing.

4 IDENTIFYING ESG-RELATED RISKS AND OPPORTUNITIES

c describe how ESG-related risk exposures and investment opportunities may be identified and evaluated.

A primary challenge when integrating ESG factors into investment analysis is identifying and obtaining information that is relevant and decision-useful. In practice, ESG-related data are generally obtained from publicly available corporate filings, documents, and communications such as corporate sustainability reports that may or may not be assured by a third party. Some of the challenges analysts face are related to inconsistent reporting of ESG information and metrics as well as the fact that the level of disclosure varies because most ESG-related disclosures are voluntary. ESG-related disclosure has generally increased over time, however, because of increased stakeholder and shareholder interest in understanding whether a company effectively manages its ESG risks and opportunities.

4.1 Materiality and Investment Horizon

When considering ESG factors in investment analysis, analysts need to evaluate the *materiality* of the underlying data. In an ESG context, materiality typically refers to ESG-related issues that are expected to affect a company's operations, its financial performance, and the valuation of its securities. In overall financial reporting, information is considered to be material if omission or misstatement of the information could influence users' decisions. Companies' as well as stakeholders' definitions of materiality in an ESG context may differ. Some companies may use the term "material" in emphasizing positive ESG information, although such information may have little impact on the company's operations or financial performance. In contrast, a company may minimize or not report negative ESG information that investors might consider material.

Analysts also consider their investment horizon and holding period when deciding which ESG factors to consider in their analysis, especially credit analysts, because of the different maturities of bonds. Some ESG issues may affect a company's performance in the short term, whereas other issues may be more long term in nature. It is important to note that the time horizon of ESG factors' impact can move from the long term to the short term and vice versa depending on a wide variety of external factors, such as a sudden change in regulation or an ESG-related controversy such as an oil spill. An investor with a short-term investment horizon may find that longer-term ESG issues can have little effect on a security's market value in the near term. Consider a manufacturing company operating in an industry that is expected to face stricter environmental regulations in the future. An investor with a short-term horizon may expect that the company's profitability will not be affected in the short term. An investor with a long-term horizon, however, may anticipate costly upgrades to plants and equipment or significant regulatory fines that are likely to reduce profitability over the longer term.

4.2 Relevant ESG-Related Factors

Corporate governance considerations, such as the structure of the board of directors, are often reasonably consistent across most companies, although best practices vary greatly regionally. In contrast, there is no globally accepted best practice with regard to environmental and social considerations. When identifying a company's specific

ESG risks and opportunities, analysts must determine the relevant factors that affect its industry. For example, energy companies are clearly more affected by environmental factors, whereas banking institutions are typically more affected by social factors (e.g., data security and privacy issues or customer satisfaction) than by environmental factors. Meanwhile, both industries are subject to governance factors. Once an analyst has determined which ESG-related factors are relevant to a company's industry, the analyst can identify applicable qualitative and quantitative data.

Approaches used to identify a company's (or industry's) ESG factors include (1) proprietary methods, (2) ratings and analysis from ESG data providers, and (3) not-for-profit industry initiatives and sustainability reporting frameworks. For example, Access to Nutrition Index evaluates the world's largest food and beverage manufacturers' policies and performance related to the most pressing nutrition challenges: obesity and undernutrition. Each of the above approaches can be used independently, or a combination of approaches can be used.

The first way of identifying company and industry ESG factors is the proprietary method approach. In this approach, analysts use their own judgment or their firm's proprietary tools to identify ESG information by researching companies, news reports, industry associations, environmental groups, financial markets, labor organizations, industry experts, and government organizations. Company-specific ESG data are generally publicly available from such sources as annual reports, corporate citizenship or sustainability reports, proxy reports, and regulatory filings (e.g., the annual 10-K report required by the US Securities and Exchange Commission). Company disclosures can generally be found on company websites.

Exhibit 2 illustrates an example of how management of one key ESG-related issue—climate change—is disclosed by City Developments Limited (CDL) in its sustainability report. Note that other real estate companies may report this information differently. In fact, ESG disclosures in general can range from minimal reporting to comprehensive data and information that span several pages, thus potentially creating comparability issues for analysts. As we discuss later in this section, a number of organizations and initiatives are working toward voluntary or mandatory standardization of various ESG-related metrics.

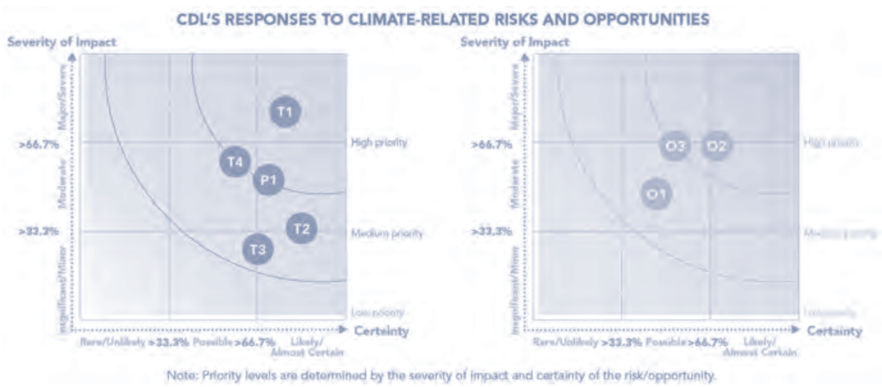
Exhibit 2 Climate Change Scenario Planning for City Developments Limited

Aligned with the recommendations of Task Force on Climate-related Financial Disclosures (TCFD) and Intergovernmental Panel on Climate Change (IPCC), CDL aims to better prepare its business for the potential financial impacts of both physical and transition risks of climate change.

CDL approached the study with two scenarios by 2030: one in which it assumed the world would decarbonize fast enough to meet the Paris Agreement's goal of limiting climate change to a global average surface temperature rise of 2°C; and another scenario that used a more ambitious 1.5°C above pre-industrial level rise. A systematic and cohesive approach was used to holistically assess and quantify all potential impacts on CDL's selected portfolio from material climate-related risks and opportunities.

(continued)

Exhibit 2 (Continued)



Source:

	Transition Risks
T1	Climate-related policy risks (e.g., increased carbon taxes and more-stringent building standards) increase operating and construction costs
T2	Water security risks increase operating costs and disrupt business continuity
T3	Call for companies to take greater responsibility of their waste production, leading to increased operating costs
T4	Climate risks lead to higher insurance premiums, lower coverage, and expose uninsurable assets

	Physical Risks
P1	Increased frequency and severity of climate events such as floods and heatwaves increase the risk of stranded assets

	Opportunities
O1	Consumer activism is on the rise globally
O2	Global shift to low-carbon growth is gaining steam
O3	Pioneering adoption of green finance in Singapore

Source: CDL, "Integrated Sustainability Report 2020."

The second approach in identifying company/industry ESG factors—ESG data providers—involves the use of information supplied by an ESG data provider (vendor), such as MSCI or Sustainalytics. These vendors obtain publicly available corporate ESG disclosures and translate them into individual ESG analyses, scores, and/or rankings for each company in the vendor's universe, often with subjective assessments by ESG analysts. In addition, vendors may score and/or rank companies within their industries and provide detailed industry analyses relating to ESG considerations.

The third approach in identifying ESG factors involves the consideration of not-for-profit initiatives and sustainability reporting frameworks that provide data and insights on ESG issues. These include the International Integrated Reporting Council (IIRC), the Global Reporting Initiative (GRI), the Sustainable Accounting Standards Board (SASB), and the 2° Investing Initiative (2DII), to name a few. The IIRC is a coalition of industry participants that promotes a standardized framework of ESG disclosures in corporate reporting. The GRI has worked with various stakeholder groups to develop sustainability reporting standards. These standards include a list of business activity groups (industries) with relevant sustainability topics that correspond to each group. A GRI report excerpt relating to the consumer durables and household and personal products sector is shown in Exhibit 3. The exhibit indicates the proposed ESG-related topics for this sector as well as additional specifications on these topics, if available. The SASB seeks to promote uniform accounting standards for sustainability reporting. In doing so, it has developed the SASB Materiality Map, which lists relevant ESG-related, sector-specific factors that the organization and industry working groups deem to be material. Exhibit 4 displays a sample SASB Materiality Map that shows the key ESG factors (shaded boxes) for the health care sector.

As well as providing data and analysis, ESG service providers and not-for-profit initiatives provide a variety of tools to help integrate relevant ESG factors.

Exhibit 3 GRI Sustainability Topics—Consumer Durables and Household and Personal Products Sector

Category	Proposed Topic	Topic Specification (where applicable)
Environmental	Materials sourcing	Rare metals; Sourcing standards for raw materials; Sourcing standards on animal testing; Wood-based products from responsibly managed forests
	Product packaging	Not applicable
	Plastic use	Product and packaging
	Chemicals use	International and national chemical safe use regulations; Personal care products; Phthalates and parabens
	Energy efficiency of end products	Consumer electronics
	Life cycle assessment of products	Not applicable
	Product transport efficiency	Not applicable
Social	Migrant workers	Recruitment and employment
	Product safety	Personal care products—human health and the environment
	Transparent product information and labeling	Not applicable
	Access to products, technologies, and services	Consumers with disabilities
	Electronic waste (e-waste) management	Consumer awareness
	Product design	Eco-friendly personal care products
	Product innovation	Energy consumption, GHG emissions and packaging
Other	Corporate governance	Executive board compensation; Gender participation on governance bodies
	Supplier screening	Environmental and social standards in the supply chain

From a risk/reward perspective, the use of **ESG integration**—the implementation of qualitative and quantitative ESG factors in traditional security and industry analysis as well as portfolio construction—typically differs for equity and fixed-income (debt) analysis. In equity analysis, ESG integration is used to both identify potential opportunities and mitigate downside risk, whereas in fixed-income analysis, ESG integration is generally focused on mitigating downside risk as the bond redeems at par on maturity.

The process of identifying and evaluating relevant ESG-related factors is reasonably similar for both equity and corporate credit analysis, because they share the same above-mentioned proprietary methods although material factors may differ based on relevance to credit. ESG integration techniques are also reasonably similar, such as adjustments to forecasted financial metrics and ratios, although the implication differs in practice.

In equity security analysis, ESG-related factors are often analyzed in the context of forecasting financial metrics and ratios, adjusting valuation model variables (e.g., discount rate), or using sensitivity and/or scenario analysis. For example, an analyst might increase her forecast of a hotel company's operating costs because of the impacts of excessive employee turnover—lost productivity, reduced customer satisfaction, and increased expenses for employee searches, temporary workers, and training programs. As another example, an analyst might choose to lower the discount rate for a snack food company that is expected to gain a competitive advantage by transitioning to a sustainable source of a key ingredient in its products.

In credit analysis, ESG factors may be integrated using internal credit assessments, forecasting financial ratios, and relative credit ranking of companies (or governments). In terms of valuation, relative value, spread, duration, and sensitivity/scenario analysis are often used. For example, an analyst may include the effect of lawsuits on the credit ratios, cash flow, or liquidity of a toy company. The same analyst may also estimate the potential for the credit spreads of the toy company's bonds to widen from these lawsuits. Generally speaking, the effect on the credit spreads of an issuer's debt obligations or its credit default swaps (CDSs) may differ depending on maturity. As a different example, consider an analyst who believes that a coal company faces long-term risk from potential **stranded assets**—that is, assets that are obsolete or not economically viable, often owing to changes in regulatory or government policy and/or shifts in demand. In this case, the analyst may believe that valuation of the coal company's 10-year-maturity notes would be considerably more negatively affected than its 1-year-maturity notes.

One particular type of bond an analyst might encounter is a **green bond**. The sidebar "Green Bonds" provides more detail about these securities and how investors typically analyze them. Increasingly, investors use scenario analysis and stress tests to assess the potential impact of key factors, such as physical risks of climate change.

Green Bonds

Green bonds are bonds in which the proceeds are designated by issuers to fund a specific project or portfolio of projects that have environmental or climate benefits. The first green bond, the Climate Awareness Bond, was issued by the European Investment Bank in 2007. Issuers have the primary decision for labeling their bonds "green." This decision is made in close cooperation with the lead underwriter. At a minimum level, issuers provide detail to the investors about the green eligibility criteria for the use of proceeds, in line with the Green Bond Principles (discussed in the next paragraph). Issuers are responsible for providing investors with details on the criteria used to classify the bonds as green and how the bond's proceeds are used. In some cases, issuers may commission independent reviews of the green criteria to provide investors with greater transparency. Issuers of green bonds typically incur additional costs related to the monitoring and reporting of the use of the bond's proceeds. However, these issuers may benefit from a more diversified investor base and potentially a new-issue premium if demand is strong.

The Green Bond Principles, a set of voluntary standards to guide issuers in the determination of labeling a bond as green, were developed in 2014 by a consortium of investment banks. Ongoing monitoring and further development of the Green Bond Principles is the responsibility of the International Capital Market Association, a global securities self-regulatory organization. As the green bond market has evolved, index providers, credit rating agencies, and the not-for-profit Climate Bonds Initiative have developed their own methodologies or standards to assess labeled green bonds. In addition, the European Commission is exploring the feasibility of imposing specific criteria that must be met for a bond to be labeled green.

Green bonds typically resemble an issuer's conventional bonds, with the exception that the bond proceeds are earmarked for green projects. Green bonds normally have the same credit ratings and bondholder recourse as conventional bonds of the same issuer (all else being equal). In addition to conventional or "plain vanilla" corporate bonds, other types of green bonds include project bonds, mortgage-backed and asset-backed securities, and municipal bonds. For example, the state of California's $300 million general obligation 2014 green bond issue is backed by the state's General Fund, just as California's other general obligation bonds are.

Because only the use of proceeds differs, the analysis and valuation of green bonds are essentially the same as those of conventional bonds. Some green bonds, however, may command a premium, or tighter credit spread, versus comparable conventional bonds because of market demand. One unique risk of green bonds is **greenwashing**, which is the risk that the bond's proceeds are not actually used for a beneficial environmental or climate-related project. Greenwashing can result in an investor overpaying for a bond (if the investor paid a premium for the bond's green feature) or holding a bond that does not satisfy a prescribed environmental or climate investment mandate. Liquidity risk may also be a consideration for green bonds, given that they are often purchased by buy-and-hold investors.

5 EVALUATING ESG-RELATED RISKS AND OPPORTUNITIES

d evaluate ESG risk exposures and investment opportunities related to a company.

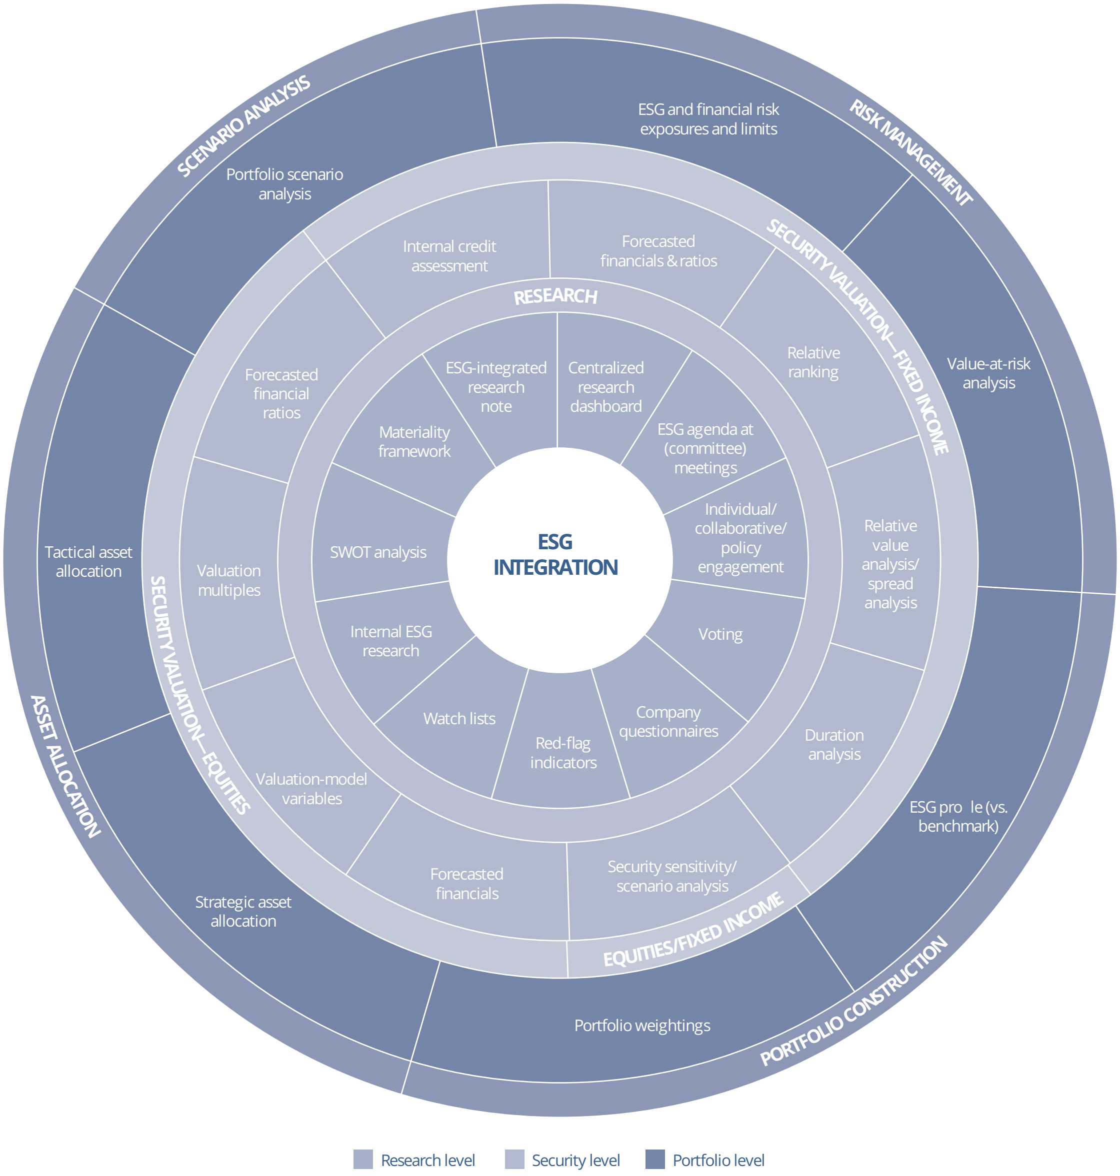
By integrating ESG considerations into the investment process, investors can take a broader perspective of company and industry analysis. In this way, the potential effects of ESG factors on a company's financial statements and valuation can be assessed and, in turn, can help drive investment decisions. In this section, we discuss examples of how ESG considerations can be integrated into financial analysis and valuation, from both an equity and a corporate bond perspective.

5.1 ESG Integration

A typical starting point for ESG integration is the identification of material qualitative and quantitative ESG factors that pertain to a company or its industry. An analyst may evaluate these factors on both a historical and a forecast basis, as well as relative to a company's peers, and then make relevant adjustments to a company's financial statements or valuation. ESG-related adjustments to a company's income statement and cash flow statement typically relate to projected revenues, operating/non-operating costs, operating margins, earnings, capital expenditures, or other items. ESG-related adjustments to a company's balance sheet often reflect an analyst's estimate of impaired assets. For equities, valuation adjustments often include adjusting a company's cost of capital using the discount rate or a multiple of price or terminal value. For bonds, an analyst may adjust an issuer's credit spread or CDS to reflect anticipated effects from ESG considerations.

The use of qualitative and quantitative research, as well as securities valuation of equities and fixed income, are key elements of the "ESG Integration Framework" (see Exhibit 5). Portfolio construction, asset allocation, scenario analysis, and risk management form the remainder of this framework.

Exhibit 5 The ESG Integration Framework



Source: Guidance and Case Studies for ESG Integration: Equities and Fixed Income, 2018

5.2 Examples of ESG Integration

This section provides examples of ESG integration for three fictitious companies in different industries: beverages, pharmaceuticals, and banks. For simplicity, each integration example focuses on either environmental, social, or governance factors—largely depending on which is most relevant for that company or its industry. Note that although specific industries are used in the examples, the underlying concepts can be applied to other industries as well. Finally, given the scope of this reading, we focus on the *effects* of ESG integration on financial analysis and valuation rather than the computations involved.

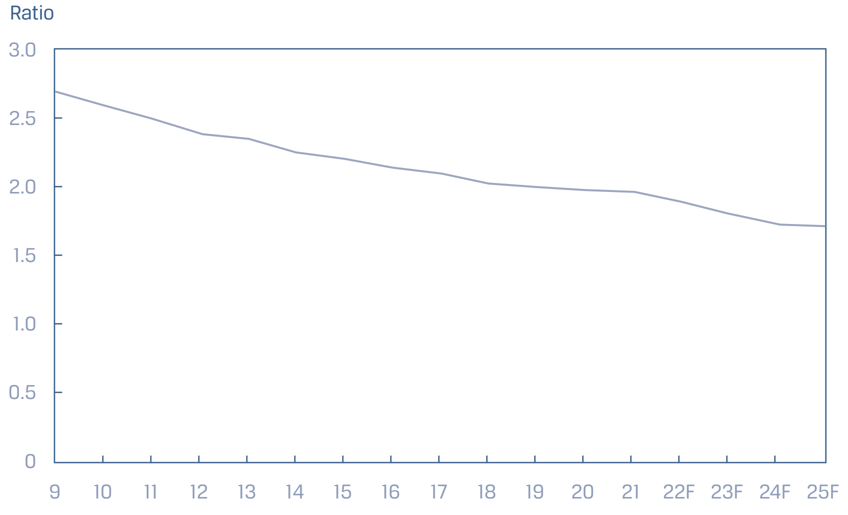
EXAMPLE 3

ESG Integration—Environmental Factors (Beverage Company)

Based in the United States, Frizzle Drinks (Frizzle) is a fictitious non-alcoholic beverage company that ranks among the largest in the world. Frizzle operates in both developed and emerging markets, including countries where water is scarce. Frizzle is a significant user of water in its operations. Given that water is a key ingredient in Frizzle's beverages, the continued availability of water is critical to the company's manufacturing process. Because of its extensive use of water, Frizzle faces ongoing regulatory scrutiny for pollution and effects on climate change. Ultimately, how Frizzle conserves and manages its water usage has implications for product pricing and company/brand reputation.

Sam Smith, CFA, is analyzing the effects of environmental factors on Frizzle's financial statements. Based on his research, Smith considers "water intensity" to be a key ESG metric for the beverage industry. Water intensity is defined as the ratio of total liters of water used per one liter of a beverage product. Exhibit 6 illustrates the trend of Frizzle's water intensity ratio from 2009 to 2021, as well as the consensus forecast ratio for the subsequent four years. Frizzle has steadily decreased its water usage over the past several years. From 2009 to 2021, its water intensity ratio declined by 27%. By the end of 2025(F), the company aims to reduce its water intensity by another 13%.

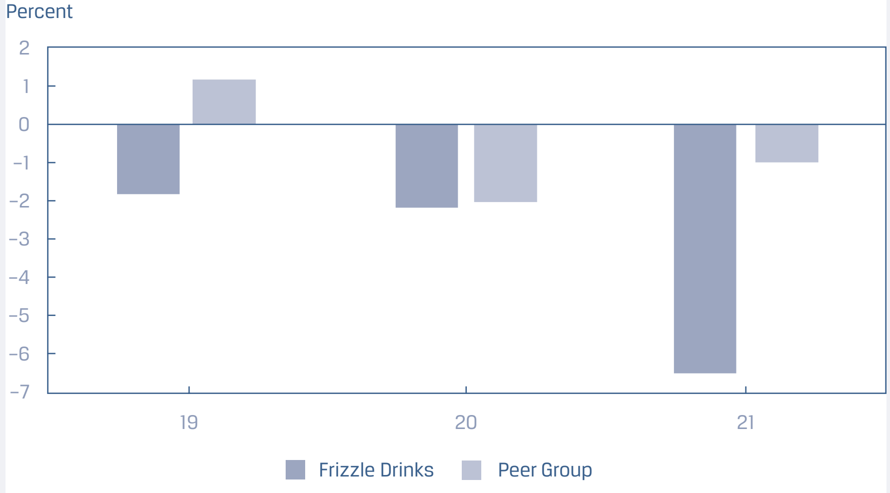
Exhibit 6 Water Intensity Ratio (in liters)



Note: (F) indicates forecast year.

Exhibit 7 compares the year-over-year change in Frizzle's water intensity ratio with that of its peer group over the past three years. To facilitate comparison among companies of varying sizes, Smith normalized the reported water intensity ratios by calculating the water intensity ratio per $1 million of revenue. Exhibit 7 illustrates that Frizzle's water intensity has decreased considerably relative to its peers over the past few years, particularly in the last reported year, 2021.

Exhibit 7 Water Intensity Ratio Change per $1 Million of Revenue



Next, Smith analyzes the effects of Frizzle's water intensity on its overall financial performance and compares it with the adjusted financial performance of its peers. As one example, Smith adjusts Frizzle's operating costs to account for the improved effects of water intensity (i.e., reduced usage). For the first projected year, 2022, Smith expects that Frizzle's cost of goods sold as a percentage of revenues (before any ESG adjustment) will be 40% and its peer group average will be 42%. For the same forecast period, Smith assumes that Frizzle's reduction in water intensity will result in a 1% reduction in its cost of goods sold/revenues, whereas the peer group average will remain the same. Exhibit 8 demonstrates this improvement in cost of goods sold/revenues on both an absolute and a relative basis. By extension, Exhibit 9 shows the absolute and relative improvement in Frizzle's gross margin (sales minus cost of goods sold) percentage.

Exhibit 8 Cost of Goods Sold as a Percentage of Revenue

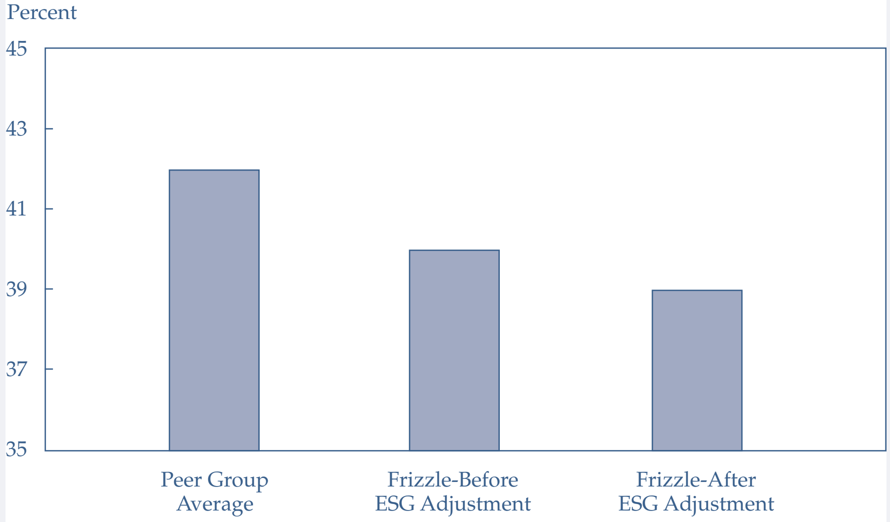


Exhibit 9 Gross Margin

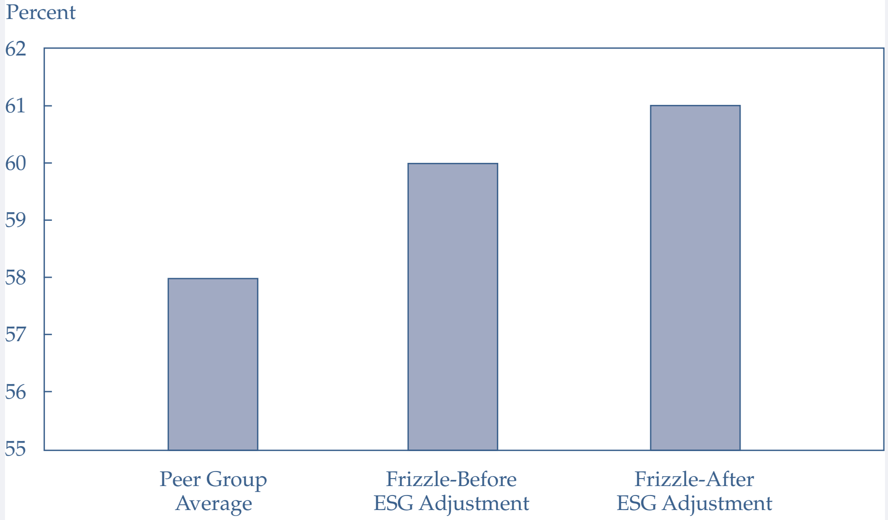

In the last step of the integration analysis, Smith incorporates Frizzle's adjusted financial performance in valuing Frizzle's stock, bonds, and, if applicable, CDSs. In this example, Smith judges that Frizzle's lower cost of goods sold from the adjustment would result in higher forecast earnings and, all else being equal, a theoretically higher fair value for Frizzle's stock. With respect to Frizzle's bonds and CDSs, Frizzle's operating cash flow would improve through a lower cost of goods sold. When assessing the credit spreads of Frizzle's bonds and/or CDSs, Smith will analyze whether the lower relative ESG risk is already reflected in current spread levels and adjust accordingly.

EXAMPLE 4

ESG Integration—Social Factors (Pharmaceutical Company)

Well Pharma (Well) is a fictitious European pharmaceutical company that manufactures drug products for autoimmune diseases and immune disorders. Over the last five years, Well has had the weakest track record among its peers in terms of product recalls and regulatory warning letters for manufacturing and marketing-related violations. Specifically, the company has been subject to four major drug quality and safety scandals arising from adverse side effects. These scandals have resulted in lost sales, multiple lawsuits, and significant fines. Business disruptions, lawsuits, and fines have reduced revenues and increased costs for the company.

As Well's experience shows, product quality is a material social factor for pharmaceutical companies in general. Smith assumes that a drug company's product quality is a combination of the factors shown in Exhibit 10.

Exhibit 10 Social Factors—Pharmaceuticals

Factor	Description
Product Quality Controversies	Have there been any controversies linked to the company's product or service quality and responsibility?
Regulatory Warning Letters	Number of regulatory warning letters received by the company
Product Recalls	Number and severity of product recalls (voluntary and involuntary)
Regulatory Fines	Level of fines imposed by regulator linked to poor product quality and/or irresponsible behavior
Product Quality Certifications Percentage	Percentage of plants certified according to a widely accepted product safety/quality standard (e.g., ISO 9001 or equivalent)

Exhibit 11 shows the number of regulatory warning letters received, as well as product and marketing controversies faced, by Well and several peers. As the graph shows, Well has received significantly more of these letters than its peers have.

Exhibit 11 Regulatory Warning Letters and Product Quality Controversies

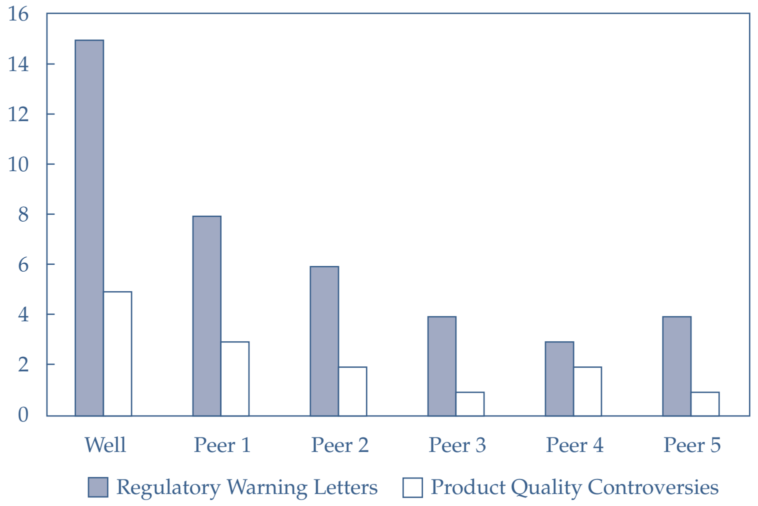

Exhibit 12 demonstrates how the factors listed in Exhibit 10 may affect the financial statements of Well and other pharmaceutical companies.

Exhibit 12 Social Factor Effects on Financial Performance

Factor	Financial Impact
Product Quality Controversies	Damage to brand value resulting in potential decrease in sales
Regulatory Warning Letters	Increased costs to comply with regulatory requirements
Product Recalls	Losses in sales revenue; increased costs of implementing product recalls
Regulatory Fines	Provisions for pharmaceutical sales returns and product-related litigation
Product Quality Certifications Percentage	Lower percentage increases risks of product quality issues, leading to product recalls and related costs

Based on these financial effects, Smith adjusts Well's projected revenues, operating expenses, and non-operating expenses. The nature of these financial statement adjustments will likely differ depending on whether Smith expects these product quality issues to be recurring or non-recurring in nature. Smith assumes that revenues will decrease by 2% over the next year because of existing product quality controversies. For operating expenses, Smith assumes that Well's cost of goods sold relative to revenues will increase by 1.3% to reflect product quality and additional investments in its manufacturing process. Exhibit 13 shows that Well's cost of goods sold as a percentage of revenues is in line with that of its peers, but the additional costs will increase this ratio well above that of the peer group. In addition to operating expenses, Smith forecasts that Well's non-operating expenses, such as restructuring charges, and other non-recurring costs will be an additional 4.5% of operating income. Exhibit 14 shows the current non-operating expense ratio for Well versus its peer group average, as well as the forecast amount.

Exhibit 13 Cost of Goods Sold as a Percentage of Revenue

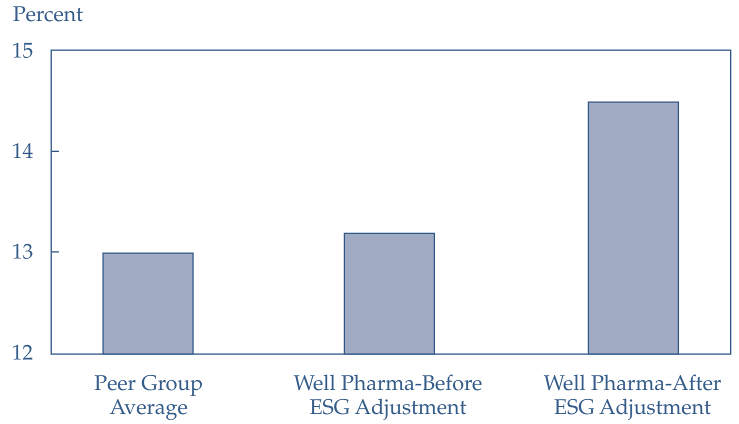

Exhibit 14 Non-Operating Expenses as a Percentage of Operating Income

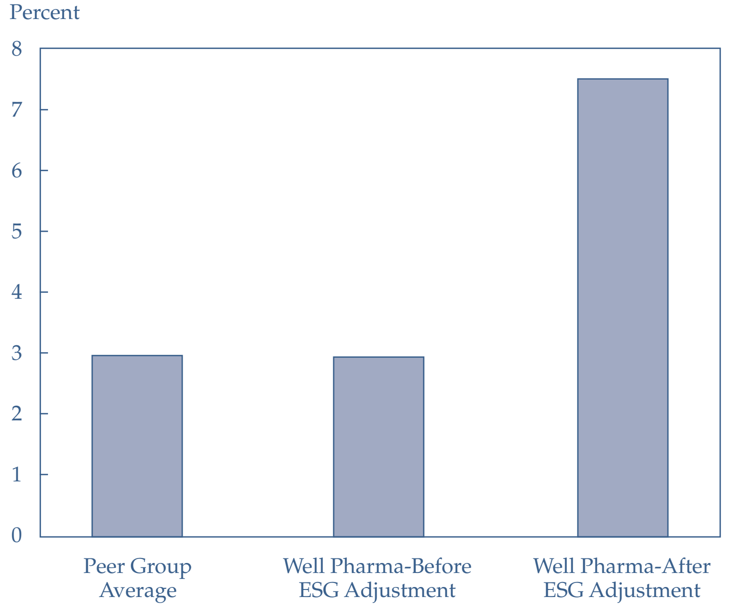

Smith believes that the valuation implications for Well's stock and bonds could be significant based on its poor product quality and safety track record. Expectations of future poor performance could have a direct impact on earnings and cash flow to the detriment of both shareholders and bondholders. In addition, Smith believes there could be adverse valuation implications if investors view Well's brand value and reputation as impaired.

EXAMPLE 5

ESG Integration—Governance Factors (Bank Holding Company)

Sumiyoshi Banking Group (Sumiyoshi) is a fictitious Japanese bank holding company, with operations in Japan (80% of revenues), the United States, and Southeast Asia. Sumiyoshi's core businesses are commercial banking, leasing, securities, and consumer finance. As with most global banks, corporate governance reforms have become increasingly prominent for Sumiyoshi.

Smith has prepared Exhibit 15 to show how Sumiyoshi's board of directors compares with the majority of its domestic peer group, on the basis of governance factors discussed in Section 2 of this reading.

Exhibit 15 Corporate Governance Factors—Banks

	Domestic peer group	Sumiyoshi Bank
Board type	Two tier	Two tier
Board size, no. of directors	13	14
Total assets/director	JPY14.9 million	JPY13.3 million

(continued)

Exhibit 15 (Continued)

	Domestic peer group	Sumiyoshi Bank
CEO duality	Yes	Yes
Independent chairperson	Yes	No
Board independence %	47%	36%
Board gender diversity	17% female; 83% male	7% female; 93% male
Directors with long tenure (>10 years)	0%	14%
Number of board committees	5	4
Audit, nomination, remuneration, and risk committees in place?	Yes	Yes
Additional board committees?	Yes, governance committee	No
Non-executive directors with industry executive experience/total independent directors	67%	20%
Short-term and long-term incentive plan metrics disclosed?	No	No
Concentrated ownership	No single large shareholder	No single large shareholder
Say-on-pay provision	Yes	No
Straight voting	Yes	Yes
Dual-class shares	No	No

Smith notes that Sumiyoshi lags its peers in in several elements of board composition, such as the lack of an independent chairperson, a lower level of board independence and diversity, fewer board members with industry executive experience, and a number of board directors with long tenures. In addition to board composition, Smith uses credit risk as a proxy for a bank's corporate governance risk. In particular, Smith reviews one key banking credit measure—non-performing loans (NPLs). NPLs are loans that are not current in paying the contractual amounts that are due (i.e., interest or principal payments).

Smith analyzes Sumiyoshi's credit risk by dividing its NPLs by the amount of its total loans outstanding. Smith estimates that Sumiyoshi's ratio of NPLs to total loans is 50 bps higher than its peer group average, reflecting Sumiyoshi's comparatively weaker credit/governance risk. To account for the effect of higher credit risk than that of its peers, Smith may increase the risk premium embedded in his valuation of Sumiyoshi's stock. When valuing Sumiyoshi's corporate bonds, Smith might increase the credit spread relative to peers embedded in the company's outstanding issues.

SUMMARY

- Shareholder ownership structures are commonly classified as dispersed, concentrated, or a hybrid of the two.

- Dispersed ownership reflects the existence of many shareholders, none of which, either individually or collectively, has the ability to exercise control over the corporation. Concentrated corporate ownership reflects an individual shareholder or a group (controlling shareholders) with the ability to exercise control over the corporation.
- Controlling shareholders may be either majority shareholders or minority shareholders.
- Horizontal ownership involves companies with mutual business interests that have cross-holding share arrangements with each other. Vertical (or pyramid) ownership involves a company or group that has a controlling interest in two or more holding companies, which in turn have controlling interests in various operating companies.
- Dual-class (or multiple-class) shares grant one or more share classes superior or even sole voting rights while other share classes have inferior or no voting rights.
- Types of influential owners include banks, families, sovereign governments, institutional investors, group companies, private equity firms, foreign investors, managers, and board directors.
- A corporation's board of directors is typically structured as either one tier or two tier. A one-tier board consists of a single board of directors, composed of executive (internal) and non-executive (external) directors. A two-tier board consists of a supervisory board that oversees a management board.
- CEO duality exists when the chief executive officer also serves as chairperson of the board.
- A primary challenge of integrating ESG factors into investment analysis is identifying and obtaining information that is relevant, comparable, and decision-useful.
- ESG information and metrics are inconsistently reported by companies, and such disclosure is voluntary, which provides additional challenges for analysts.
- In an ESG context, materiality typically refers to ESG-related issues that are expected to affect a company's operations or financial performance and the valuation of its securities.
- Corporate governance considerations, such as the structure of the board of directors, tend to be reasonably consistent across most companies. In contrast, environmental and social considerations often differ greatly.
- Analysts typically use three main sources of information to identify a company's (or industry's) ESG factors: (1) proprietary research, (2) ratings and analysis from ESG data providers, or (3) research from not-for-profit industry organizations and initiatives.
- In equity analysis, ESG integration is used to both identify potential opportunities and mitigate downside risk, whereas in fixed-income analysis, ESG integration is generally focused on mitigating downside risk.
- A typical starting point for ESG integration is the identification of material qualitative and quantitative ESG factors that pertain to a company or its industry.

PRACTICE PROBLEMS

The following information relates to Questions 1 and 2

Liz Kite is a research analyst for a global equity investment firm. She is conducting research on two publicly traded companies, Company A and Company B.

Company A has a large number of shareholders, with no single investor owning more than 5% of the outstanding shares. Company B is managed by a family who owns 60% of the outstanding shares. Both companies offer a single share class with equivalent voting rights.

1 **Determine** the relative level of risk (high or low) of principal–agent problems being present at each company. **Justify** your response.

2 **Discuss** drawbacks *most likely* associated with the ownership structure of Company B.

---

3 Clayton Streett is a consultant specializing in corporate governance issues. His current assignment is to evaluate the effectiveness of the board of Jess-Kait Worldwide. Streett seeks to determine if aspects of the company's corporate governance warrant a higher than average risk premium for the company's shares.

Jess-Kait Worldwide has a one-tier board structure, with the CEO serving as the chair of the board. Of the 20 board members, 8 are executive and 12 are non-executive (i.e., independent). The executive members primarily serve on the compliance and investment committees, while the non-executive members primarily serve on the audit, compensation, and board selection committees. The executive board members have all served on the board for more than 20 years, while the non-executive members' average tenure is only 5 years.

Determine which board considerations would *most likely* warrant a higher than average risk premium for the shares of Jess-Kait Worldwide. **Justify** each response.

i. Structure

ii. Independence

iii. Committees

iv. Composition

Determine which board considerations would *most likely* warrant a higher than average risk premium for the shares of Jess-Kait Worldwide. Justify each response.

Board Consideration	Higher Risk Premium?	Justification
i) Structure	Yes No

Determine which board considerations would *most likely* warrant a higher than average risk premium for the shares of Jess-Kait Worldwide. Justify each response.

Board Consideration	Higher Risk Premium?	Justification
ii) Independence	Yes No	
iii) Committees	Yes No	
iv) Composition	Yes No	

The following information relates to Questions 4 and 5

Chambers Carlisle was recently hired as an analyst for a fixed-income fund with a short-term investment horizon. Carlisle focuses on bonds in the materials sector and incorporates environmental, social, and governance (ESG) factors into his analysis. His previous employer was a buy-and-hold equity fund, where Carlisle included ESG factors in his analysis of equities in the materials sector.

4 **Discuss** how Carlisle's ESG analysis in his new position *most likely* differs from that in his previous position.

Carlisle identifies the ESG risk factors that are relevant to companies in the materials sector. He conducts his research by reviewing public documents, such as company annual reports, regulatory filings, and proxy reports.

5 **Discuss** the challenges *most likely* associated with Carlisle's research approach.

The following information relates to Questions 6 and 7

Dalanta Transportation operates a rail transportation business in the Southwest United States. Competition in the region for rail transport has intensified in the last few years, resulting in decreasing profit margins. Dalanta has received multiple warnings from state and federal regulators and faces potential fines for violating clean air regulations due to excessive greenhouse gas emissions (GHG) by the company's aging fleet of trains. As a result, the company has been the target of highly publicized criticism from environmental activist groups.

6 **Discuss** the potential effects of environmental, social, and governance (ESG) factors on Dalanta's financial performance.

Dalanta's CEO hires a consultant to help the company address the ESG issues. The CEO had planned to issue a conventional bond to finance the replacement of the oldest half of the fleet of trains, but the consultant recommends that Dalanta issue a green bond to finance the purchase of new trains.

7 **Discuss** *one* advantage and *one* disadvantage to Dalanta if the company follows the consultant's financing recommendation.

The following scenario applies to Questions 8–15

Karen Maghami is a portfolio manager for a mutual fund. Maghami, working with analyst Marcel Lynbrock, is researching two companies: Syvie Electric and EnileGEN. Located in the same country, both companies produce electricity from conventional and renewable sources. Maghami wants to integrate environmental, social, and governance (ESG) factors into the analysis of each company's financial statements.

Syvie Electric is a stock exchange-listed, state-owned enterprise (SOE). The sovereign government holds 58% of shares; remaining shares are publicly traded. EnileGEN is a public company owned primarily by institutional investors.

Lynbrock starts with an analysis of corporate governance factors. Relevant information about the two companies is summarized in Exhibit 1.

Exhibit 1 Select Corporate Governance Information: Syvie Electric and EnileGEN

	Syvie Electric	EnileGEN
Ownership Information and Voting Policies		
Percentage of shares owned by the largest shareholder	58%	9%
Straight voting	Yes	Yes
Board Information		
Board structure	One-tier	Two-tier
CEO duality	No	Yes
Number of directors	8	11
Percentage of directors with experience in industry	27%	88%
Remuneration Policies		
Clawback policy	No	Yes
Say-on-pay provision	Yes	No

After reviewing the corporate governance information, Maghami and Lynbrock focus on factors related to environmental and social considerations. Lynbrock asks Maghami, "What resource would you recommend using to find a list of ESG factors material to the electricity generation sector?"

Next, Maghami and Lynbrock discuss the effect of expected regulatory changes on stock and bond values for both companies. The government recently announced that it intends to authorize a new environmental regulation requiring that a minimum of 35% of electricity be produced from renewable sources. The exact timing of the new regulation is unknown, but EnileGEN already exceeds the minimum level by a significant margin. Maghami notes that the new regulation should give EnileGEN a competitive edge in the industry, and for scenario analysis purposes, she asks Lynbrock to assume that the regulation will take effect in two years. Lynbrock uses a discounted cash flow model to value EnileGEN stock under the assumption requested by Maghami.

Lynbrock believes that the new regulation will make three of Syvie Electric's coal-fired power stations no longer financially viable within 10 years following implementation. Maghami asks Lynbrock to estimate the potential effect on Syvie Electric's balance sheet and the potential impact on the value of Syvie Electric bonds.

Maghami reads in Syvie Electric's most recent financial statements that the company plans to issue green bonds. Maghami asks Lynbrock to evaluate any possible valuation risks or opportunities associated with green bonds. Lynbrock tells Maghami the following:

Statement 1	Green bonds offer higher protection for an investor because they typically are backed by the income derived from the environmental project they are used to fund.
Statement 2	Issuing green bonds ensures a lower cost of capital because the green feature typically results in a tighter credit spread compared with conventional bonds.
Statement 3	A unique risk related to green bonds is greenwashing, which is the risk that the bond's proceeds are not actually used for a beneficial environmental or climate-related project.

8 Based on Exhibit 1 and their ownership structures, market scrutiny of Syvie Electric's management is *most likely:*

A lower than EnileGEN.

B the same as EnileGEN.

C higher than EnileGEN.

9 Based on the ownership structures of Syvie Electric and EnileGEN, a principal–principal problem is *most likely* to occur in the case of:

A only EnileGEN.

B only Syvie Electric.

C both Syvie Electric and EnileGEN.

10 Based on Exhibit 1, which of the following statements is correct?

A Due to also being on the board, the EnileGEN CEO has two votes for each share owned.

B In the case of managerial misconduct, EnileGEN may be able to recover previously paid remuneration.

C Syvie Electric's corporate structure can be described as having concentrated ownership and dispersed voting power.

11 In response to Maghami's ESG question, Lynbrock should *most likely* recommend using:

A the SASB Materiality Map.

B the Green Bond Principles.

C each company's sustainability report.

12 To reflect the effect of the regulatory scenario requested by Maghami on EnileGEN's stock value, Lynbrock should:

A increase the credit spread.

B decrease the discount rate.

C increase projected operating costs.

13 To reflect the effect of the new regulation on Syvie Electric's balance sheet, Lynbrock should:

A increase terminal value.

B increase impaired assets.

C decrease capital expenditures.

14 Under the regulatory scenario requested by Maghami, Lynbrock should increase the credit spread of a Syvie Electric 10-year bond:

A less than the spread of a 2-year bond.

B by the same amount as the spread of a 2-year bond.

C more than the spread of a 2-year bond.

15 Which of Lynbrock's statements about green bonds is correct?

A Statement 1

B Statement 2

C Statement 3

SOLUTIONS

1 Risk of principal–agent problems:

- Company A has dispersed ownership and dispersed voting power. This results in weak shareholders and strong managers, which suggests a high risk of principal–agent problems.
- Company B has concentrated ownership and concentrated voting power. This results in strong shareholders and weak managers, which suggests a low risk of principal–agent problems.

Company A has a large number of shareholders, with no single shareholder owning more than 5% of the outstanding shares. The combination of dispersed ownership and dispersed voting power is generally associated with shareholders who lack the power to exercise control over managers. These shareholders are referred to as weak shareholders, and such managers are referred to as strong managers. Under this combination, there is a high risk that managers will seek to utilize a company's resources to pursue their own interests rather than those of the shareholders. This conflict is known as a principal–agent problem.

Company B is managed by a family who owns a majority of the outstanding voting shares. One of the benefits of family control through concentrated ownership and management is a low risk of principal–agent problems. Family control can, however, lead to principal–principal problems as the rights of minority shareholders may receive only modest consideration.

2 Drawbacks of Company B's ownership structure include the following:

- Poor transparency
- Lack of management accountability
- Modest consideration for minority shareholder rights
- Difficulty in attracting quality talent for management positions

Company B is managed by a family who owns a majority of the outstanding voting shares. Drawbacks to family ownership may include poor transparency, lack of management accountability, modest consideration for minority shareholder rights, and difficulty in attracting quality talent for management positions.

3

Determine which board considerations would *most likely* warrant a higher than average risk premium for the shares of Jess-Kait Worldwide. Justify each response.

Board Consideration	Higher Risk Premium?	Justification
i) Structure	Yes No	The structure of Jess-Kait's board is one-tier, with the CEO also serving as chair of the board. This CEO duality may raise concerns that the monitoring and oversight role of the board may be compromised. This negative attribute would likely warrant a higher than average risk premium.

Determine which board considerations would *most likely* warrant a higher than average risk premium for the shares of Jess-Kait Worldwide. Justify each response.

Board Consideration	Higher Risk Premium?	Justification
ii) Independence	Yes / **No**	Jess-Kait's board is comprised of 20 members, 12 of whom are independent. Having a majority of the board members be independent is a positive attribute and likely would not warrant a higher than average risk premium.
iii) Committees	Yes / **No**	When evaluating a board's committees, Streett should assess whether the key governance committees, such as the audit, compensation, and board selection committees, are sufficiently independent. With the non-executive board members primarily serving on these three important committees, there appears to be sufficient independence. This positive attribute likely would not warrant a higher than average risk premium.
iv) Composition	**Yes** / No	The executive board members have all served on the board for at least 20 years, which is a long tenure for board members. Long-tenured board members could become controlling, self-serving, or resistant to the introduction of new practices or policies that may be beneficial to stakeholders. This situation is especially troubling due to the fact that the non-executive board members' average tenure is only 5 years. This negative attribute would likely warrant a higher than average risk premium.

4 The investment horizon for the fixed-income securities in his new position is short term in nature, while his prior position had a long-term investment horizon.

ESG integration in fixed-income analysis generally focuses on mitigating downside risks, while ESG integration in equity analysis also includes identifying potential opportunities.

When deciding what ESG factors to consider in their analysis, analysts must consider the investment horizon. Some ESG issues may affect a company's performance in the short term, while other issues may affect it more in the long term. An investor with a short-term investment horizon may find that longer-term issues have little impact on a security's valuation in the near term. Since Carlisle's new job focuses on short-term fixed income, he is likely more concerned with short-term ESG issues than long-term ESG issues. In his previous position, the buy-and-hold nature of the equity fund implies a long-term investment horizon, so Carlisle would likely have considered both short-term and long-term ESG issues.

Carlisle's current position is in fixed-income analysis, while his previous position was in equity analysis. From a risk/reward perspective, the use of ESG integration typically differs for equity and fixed-income analysis. In equity analysis, ESG integration is used to both identify potential opportunities and mitigate downside risk, whereas in fixed-income analysis, ESG integration is generally focused only on mitigating downside risk.

5 Challenges:

- ESG information and metrics may be reported inconsistently by companies.
- ESG-related disclosures are voluntary for many companies, and the level of voluntary disclosure varies.

A primary challenge when integrating ESG factors into investment analysis is identifying and obtaining information that is relevant and useful. Carlisle's research approach involves reviewing public documents, such as company annual reports, regulatory filings, and proxy reports. A challenge he will face is that ESG information and metrics may be reported inconsistently by companies. Another challenge is that a number of ESG-related disclosures are voluntary for many companies, and the level of voluntary disclosure varies.

6 Potential effects:

- Increased costs to comply with regulatory requirements
- Potential fines for violating clean air regulations
- Damage to corporate reputation that could potentially decrease sales

Dalanta must address the clean air regulations. The costs to comply with these regulations could be significant, but the potential fines for failing to comply with these regulations could also be significant. These expenses would have a negative effect on Dalanta's financial performance. Finally, the company received highly publicized criticism from environmental activist groups. Such criticism could damage Dalanta's reputation and have a negative effect on sales, especially considering the increasingly competitive landscape for rail transport in the region.

7 Advantages and disadvantages:

Advantages:

- Green bonds can command a premium over comparable conventional bonds
- Lower cost of capital due to green bond premium

Disadvantages:

- Additional costs related to the monitoring and reporting of the use of the bond's proceeds
- Lack of liquidity of green bonds when purchased and held by buy-and-hold investors

Dalanta's financing of the new trains using green bonds may provide advantages compared to conventional bonds. Some green bonds can command a premium, or tighter credit spread, versus comparable conventional bonds due to market demand. This tighter credit spread could have a positive effect on Dalanta's cost of capital and valuation. However, issuing green bonds could result in Dalanta incurring additional costs related to the monitoring and reporting of the use of the bond's proceeds. In addition, liquidity risk is associated with green bonds that are purchased and held by buy-and-hold investors.

8 A is correct. Syvie Electric is a listed SOE with a mixed-ownership model in which 58% of the shares are owned by a sovereign government. The remaining shares trade on a public stock market. A mixed-ownership model tends to have lower market scrutiny of management than that of corporate ownership models. Additionally, Syvie Electric has a lower percentage of directors with industry experience compared to EnileGEN. A board with experience that is not directly related to the company's core operations may lack sufficient expertise to govern. EnileGEN's shares are owned primarily by institutional investors. Even though EnileGEN has dispersed ownership, institutional investors can promote good corporate governance by holding a company's board and management accountable when the board or management does not appear to be acting in the best interests of shareholders. Consequently, market scrutiny of Syvie Electric's management is most likely lower compared with EnileGEN.

9 B is correct. Syvie Electric's largest shareholder owns 58% of the shares; therefore, the company can be described as having concentrated ownership and concentrated voting power. The combination of concentrated ownership and concentrated voting power is generally associated with controlling shareholders maintaining a position of power over both managers and minority shareholders, known as a principal–principal problem. EnileGEN's largest stockholder owns 9% of shares; hence, the company can be classified as having dispersed ownership. EnileGEN also has a straight voting policy, which results in each of the shareholders having one vote per share; thus, EnileGEN also has dispersed voting power. The combination of dispersed ownership and dispersed voting power is generally associated with shareholders who lack the power to exercise control over managers. This conflict is known as a principal–agent problem. Consequently, the principal–principal problem is most likely to occur in Syvie Electric, not in EnileGEN.

10 B is correct. EnileGEN has a clawback policy, which allows a company to recover previously paid remuneration if certain events—such as financial restatements, misconduct, breach of the law, or risk management deficiencies—are uncovered. Consequently, EnileGEN may be able to recover previously paid remuneration from management in case of misconduct.

A is incorrect because even though EnileGEN's CEO also serves as chair of the board (CEO duality), the CEO does not hold dual-class shares because the company has a straight voting policy (i.e., one share, one vote). Consequently, the CEO of EnileGEN does not have two votes for each share.

C is incorrect because Syvie Electric has concentrated ownership and concentrated voting power (58% of shares are owned by a single shareholder). Consequently, Syvie Electric's ownership structure cannot be described as concentrated ownership with dispersed voting power.

11 A is correct. Maghami wants to find a resource that lists ESG factors material to the electricity generation sector. In an ESG context, materiality typically refers to ESG-related issues that are expected to affect a company's operations, its financial performance, and the valuation of its securities. The Sustainability Accounting Standards Board (the SASB) seeks to promote uniform accounting standards for sustainability reporting. For this purpose, the SASB developed the SASB Materiality Map, which lists relevant ESG-related, sector-specific factors that the organization deems to be material.

B is incorrect because the Green Bond Principles are voluntary standards to guide issuers in the determination of labeling a bond green. The Green Bond Principles do not provide a list of ESG-related factors that are material to a specific sector.

C is incorrect because companies' definitions of materiality in an ESG context may differ in usefulness. For example, some companies may use the term "material" in emphasizing positive ESG information even though such information may have little impact on the company's operations or financial performance. Other companies may minimize or not report negative ESG information that investors might consider material. Consequently, a company's sustainability report is not as likely as a SASB Materiality Map to provide a list of ESG-related factors that are material to a specific sector.

12 B is correct. For scenario analysis purposes, Maghami asks Lynbrock to assume that the new environmental regulation will take effect in two years. In equity security analysis, ESG-related factors are often analyzed in the context of forecasting financial metrics and ratios, by adjusting valuation model variables (e.g., discount rate), or using sensitivity and/or scenario analysis. Lynbrock should decrease the discount rate given that EnileGEN should have a competitive edge over its competitors due to the new environmental regulation.

A is incorrect because Lynbrock is estimating the expected effect of the new environmental regulation on EnileGEN's stock, not bond, value. Additionally, to justify a credit spread increase, the risk for a company would have to increase. Instead, the anticipated environmental regulation should give EnileGEN a competitive edge, thereby reducing risk.

C is incorrect because the new environmental regulation should not impact EnileGEN's operating costs. The company already exceeds the minimum percentage of renewably-sourced electric production expected to be required by the new regulation.

13 B is correct. Syvie Electric is facing risk from stranded assets—that is, assets that are obsolete or not economically viable owing to changes in regulatory or government policy. ESG-related adjustments to a company's balance sheet often reflect an analyst's estimate of impaired assets.

A is incorrect because adjusting terminal value applies to equity valuation; it is not an adjustment to a company's balance sheet.

C is incorrect because decreasing capital expenditures would be reflected in the income and cash flow statements, not the balance sheet.

14 C is correct. Syvie Electric is facing risk from stranded assets—that is, assets that are obsolete or not economically viable owing to changes in regulatory or government policy. The new environmental regulation is expected to be in effect in 2 years, so a 10-year bond will be more negatively impacted than a current 2-year bond. To reflect this, Lynbrock should increase the credit spread of the 10-year bond more than the spread of the 2-year bond.

15 C is correct. Statement 3 is correct because one unique risk of green bonds is greenwashing, which is the risk that the bond's proceeds are not actually used for a beneficial environmental or climate-related project. Greenwashing can result in an investor overpaying for a bond (if the investor paid a premium for the bond's green feature) or holding a bond that does not satisfy a prescribed environmental or climate investment mandate.

A is incorrect because Statement 1 is incorrect. Green bonds are typically similar to an issuer's conventional bonds, with the exception that the bond proceeds are earmarked for green projects. Green bonds normally have the same credit ratings and bondholder recourse as conventional bonds of the same issuer (all else being equal).

B is incorrect because Statement 2 is incorrect. It is true that some green bonds command a premium, or tighter credit spread, versus comparable conventional bonds because of high market demand. This would reduce a company's cost of capital. However, issuing green bonds does not always ensure a lower cost of capital for a company because green bonds are typically similar to an issuer's conventional bonds. Green bonds normally have the same credit ratings and bondholder recourse as conventional bonds of the same issuer. Furthermore, green bonds may be less liquid than conventional bonds, such that they don't command a premium from investors. Green bonds also have higher reporting and monitoring costs than conventional bonds, thus potentially resulting in higher costs for the issuer.

Mergers and Acquisitions

by Rosita P. Chang, PhD, CFA, and Keith M. Moore, PhD, CFA

Rosita P. Chang, PhD, CFA, is at Shidler College of Business, University of Hawaii at Manoa (USA). Keith M. Moore, PhD, CFA (USA).

LEARNING OUTCOMES

Mastery	*The candidate should be able to:*
☐	**a.** classify merger and acquisition (M&A) activities based on forms of integration and relatedness of business activities;
☐	**b.** explain common motivations behind M&A activity;
☐	**c.** explain bootstrapping of EPS and calculate a company's post-merger EPS;
☐	**d.** explain, based on industry life cycles, the relation between merger motivations and types of mergers;
☐	**e.** contrast merger transaction characteristics by form of acquisition, method of payment, and attitude of target management;
☐	**f.** distinguish among pre-offer and post-offer takeover defense mechanisms;
☐	**g.** compare the discounted cash flow, comparable company, and comparable transaction analyses for valuing a target company, including the advantages and disadvantages of each;
☐	**h.** evaluate a takeover bid and its effects on the target shareholders versus the acquirer shareholders;
☐	**i.** explain how price and payment method affect the distribution of risks and benefits in M&A transactions;
☐	**j.** describe characteristics of M&A transactions that create value;
☐	**k.** distinguish among equity carve-outs, spin-offs, split-offs, and liquidation;
☐	**l.** explain common reasons for restructuring.

1 INTRODUCTION

Companies enter into corporate restructuring activities such as mergers and acquisitions for a variety of reasons. Many companies use mergers as a means to achieve growth or gain operational efficiencies. Others seek to acquire unique capabilities or resources, increase market power, or diversify their businesses. In all cases, it is important for both equity and fixed income analysts to understand the motives for mergers and their financial and operational consequences.

Merger and acquisition (M&A) activities involve a variety of complexities and risks. Analysts should assess these factors, including the expected value arising from a proposed business combination relative to deal price, in addition to the likelihood that the combination will take place and the intended results will be achieved. They should also consider actions taken by other shareholders, regulators, market participants, and competitors, in addition to transaction specifics, given the potential impact of all these factors on deal completion and valuation.

Analysts should be able to answer questions such as: Does the proposed transaction make economic sense and align with management's stated business strategy? How is the transaction being financed, and how will this financing approach affect company financials? How likely is the deal to take place, and what are associated risks? In the case of a hostile bid, does the target company have options to successfully fend off the unwanted bid? What is the anticipated impact for shareholders? Bondholders?

EXAMPLE 1

Takeda–Shire Acquisition

On 5 December 2018, shareholders of Takeda Pharmaceutical, a 237-year-old company and Japan's largest pharmaceutical firm, approved the acquisition of Shire, a UK-listed, Irish-headquartered drug maker of similar size with an operational base in the United States. Announced in May 2018, the US$62 billion deal was aimed at transforming Takeda into a top 10 global pharmaceutical company with a sizable US footprint. It was the largest deal announced worldwide for 2018.

The deal was also the largest international acquisition ever attempted by a Japanese company. Takeda's offer consisted of shares and cash. It also involved a US$30 billion increase in balance sheet debt. Takeda's CEO undertook a nine-month-long campaign to secure the deal. The deal was confirmed in December 2018 with 88% Takeda shareholder approval, despite significant resistance from some Takeda shareholders, including the original Takeda family, who were concerned about the additional risk created by the acquisition.

Takeda–Shire Deal Timeline

Strategy	
September 2016	Takeda's "Vision 2025" business plan envisions sustaining growth year over year.
Rumor	
28 March 2018	Takeda says "considering making an approach to Shire."
6 April	Takeda, Pfizer, and Amgen viewed as likely bidders for Shire.

(Continued)

Courtship	
29 March 2018	Takeda initial offer: £44/share, with £16 in cash.
11 April	Takeda second offer: £45.5/share, £16.75 cash.
13 April	Takeda third offer: £46.5/share, £17.75 cash.
14 April	Shire's board announces it unanimously rejects third offer.
20 April	Takeda fourth offer: £47/share, £21 cash.
24 April	Takeda fifth offer: £49/share, £21.75 cash.
Acquisition	
8 May 2018	Shire accepts fifth offer of £49/share, £21.75 cash, valuing deal at US$62 billion.
14 May	Takeda announces asset disposals to help fund the acquisition.
10 July	US Federal Trade Commission grants regulatory approval for Shire deal.
14 September	Chinese regulator approves Shire deal.
18 October	Japanese regulator approves Shire deal.
20 November	EU regulator approves Shire deal.
20 November	Proxy advisors Glass, Lewis & Co. and Institutional Shareholder Services recommend deal.
May–November 2018	Takeda minority shareholders (including Takeda family) lobby against proposed deal, citing increased risk and loss of Japanese "roots."
Integration	
5 December 2018	Takeda shareholders vote to approve deal.
7 January 2019	Takeda CEO announces integration "well underway."
8 January 2019	Deal closes.
Value creation	
14 May 2019	CEO announces 43% increase in original cost synergies anticipated from acquisition.
December 2019	Takeda's core earnings margin expected to reach 25%, with long-term earnings margin forecast for 35%, up from an earnings margin of 22% in 2018.
March 2020	Takeda sales expected to rise 57% year over year.
Projection for 2023	Divestments of US$10 billion expected to stabilize balance sheet, with the expansion of five key businesses including in neuroscience and in treatments for cancer and rare diseases.

Takeda's motivations for the deal included the potential for sustainable earnings growth believed to be available through Shire's products and markets. Takeda was at that time projecting declining profitability from existing products and limited growth in the Japanese market. Additionally, synergies through new product development, earnings diversification, and cost savings were anticipated from the deal. Despite positive expectations, in the nine months between Takeda's announcement in March 2018 and the time the deal closed, Takeda's share price dropped 26% while Shire's rose 33%.

Following increasing offers in value by Takeda, a series of regulatory approvals post–Shire acceptance, and announcements of a divestments program to help fund the acquisition, the deal finally closed in January 2019. By May 2019, Takeda's management was reporting significant cost savings and projecting major improvements to core earnings margins in the years ahead.

This reading will discuss many of the issues involved in M&A deals, such as form of payment in a merger, legal and contractual issues, and the necessity for regulatory approval. Most importantly, this reading aims to equip you with basic tools and a framework for analyzing such deals. In subsequent sections, we will discuss basic types of M&A, underlying motives, transaction characteristics, governing regulations, and how to evaluate a target company and a proposed merger.

2 MERGERS AND ACQUISITIONS: DEFINITIONS AND CLASSIFICATIONS

a identify merger and acquisition (M&A) activities based on forms of integration and relatedness of business activities;

Business combinations come in different forms. A distinction can be made between acquisitions and mergers. In the context of M&A, an **acquisition** is the purchase of some portion of one company by another. An acquisition might refer to the purchase of assets from another company, the purchase of a definable segment of another entity, such as a subsidiary, or the purchase of an entire company, in which case the acquisition would be known as a merger. A **merger** represents the absorption of one company by another. That is, one of the companies remains and the other ceases to exist as a separate entity. Typically, the smaller of the two entities is merged into the larger, but that is not always the case.

Mergers can be classified by the form of integration. In a **statutory merger**, one of the companies ceases to exist as an identifiable entity and all its assets and liabilities become part of the purchasing company. In a **subsidiary merger**, the company being purchased becomes a subsidiary of the purchaser, which is often done in cases where the company being purchased has a strong brand or good image among consumers that the acquiring company wants to retain. A **consolidation** is similar to a statutory merger except that in a consolidation, *both* companies terminate their previous legal existence and become part of a newly formed company. A consolidation is common in mergers where both companies are approximately the same size.

The parties to a merger are often identified as the target company and the acquiring company. The company being acquired is the **target company**, or simply the **target**. The company acquiring the target is called the **acquiring company**, or the **acquirer**. We will use this terminology throughout the reading.

In practice, many of the terms used to describe various types of transactions are used loosely such that the distinctions between them are blurred. For example, the term "consolidation" is often applied to transactions in which the entities are about the same size, even if the transaction is technically a statutory merger. Similarly, mergers are often described more generally as **takeovers**, although that term is often reserved to describe **hostile transactions**, which are attempts to acquire a company against the wishes of its managers and board of directors. A **friendly transaction**, in contrast, describes a potential business combination that is endorsed by the managers of both companies, although that is certainly no guarantee that the merger will ultimately occur.

An additional way that mergers are classified is based on the relatedness of the merging companies' business activities. Considered this way, there are three basic types of mergers: horizontal, vertical, and conglomerate.

A **horizontal merger** is one in which the merging companies are in the same kind of business, usually as competitors. The 2017 merger between leading chemical companies Dow Chemical (full name: Dow Chemical Company) and DuPont (full name: E.I. du Pont de Nemours and Company) is one example of a horizontal merger. Another example is Disney's acquisition of 21st Century Fox, also in 2017. One of the great motivators behind horizontal mergers is the pursuit of **economies of scale**, which are savings achieved through the consolidation of operations and elimination of duplicate resources. Another common reason for horizontal mergers is to increase market power, because the merger results in a reduction of the number of industry competitors and an increase in the size of the acquiring company.

In a **vertical merger**, the acquirer buys another company in the same production chain, such as a supplier or a distributor. In addition to cost savings, a vertical merger may provide greater control over the production process in terms of quality or procurement of resources or greater control over the distribution of the acquirer's finished goods. If the acquirer purchases a target that is ahead of it in the value chain (a supplier), it is called **backward integration**. An example of backward integration is if a steel manufacturer purchases an iron ore mining company. When an acquirer purchases a company that is further down the value chain (a distributor), it is called **forward integration**. An example of forward integration is the 2018 acquisition of palliative care provider Aspire Health by Anthem, the health insurance provider operating Blue Cross and Blue Shield insurance plans in the United States. By bringing palliative care and support services to the insurer's enrollees and their families, the merger brought the provision of medical insurance and community-based medical care services into one integrated company.

When an acquirer purchases another company that is unrelated to its core business, it may be called a **conglomerate merger**. Amazon's acquisition of Whole Foods in 2017 is an example of a conglomerate merger, in which the leading online retailer acquired a "bricks and mortar" grocery store chain. The concept of company-level diversification has been used as a rationale for inter-industry mergers; by investing in companies from a variety of industries, an organization may reduce its total cash flow volatility. Since the 1990s, however, conglomerates have been viewed as inefficient managers of capital. As a result, many conglomerates have been broken up and fewer conglomerate mergers take place. As we will discuss in the section on merger motivations, company-level diversification is not necessarily in the shareholders' best interests.

MOTIVES FOR MERGERS

3

b explain common motivations behind M&A activity;

c explain bootstrapping of EPS and calculate a company's post-merger EPS;

d explain, based on industry life cycles, the relation between merger motivations and types of mergers;

In the previous section, we mentioned some of the basic motives behind mergers, such as the search for economies of scale (in a horizontal merger) or cost savings through integration (in a vertical merger). In this section, we will expand on this topic and survey some of the reasons companies merge—the motives or rationales for merger.

Most often, mergers are pursued because of perceived economic benefits that will result, although in some cases, management may have other reasons for undertaking a merger.

The topic is important because in assessing a proposed combination, investors and analysts need to carefully evaluate the rationale behind the merger. Does the underlying business strategy and management's stated rationale make sense? Is the merger likely to create value? What is the probability that each of the stated goals for the merger will be attained? Keep in mind that many motives are interrelated and that there are typically several motives, both acknowledged and tacit, behind any given merger.

3.1 Synergy

Among the most common motivations for a merger is the creation of synergy, in which the whole of the combined company will be worth more than the sum of its parts. Generally speaking, synergies created through a merger will either reduce costs or enhance revenues. Cost synergies are typically achieved through economies of scale in research and development, procurement, manufacturing, sales and marketing, distribution, and administration. Revenue synergies are created through the cross-selling of products, expanded market share, or higher prices arising from reduced competition. For example, a bank that acquires its competitors can both increase its market share and realize operating efficiencies by closing duplicate branches and integrating back-office operations.

3.2 Growth

Corporate managers are under constant pressure to grow their companies' revenues, and they often turn to M&A activity to achieve that growth. Companies can grow either by making investments internally (i.e., **organic growth**) or by buying the necessary resources externally (i.e., **external growth**). It is typically faster for companies to grow externally. Growth through M&A activity is common when a company is in a mature industry. For example, the global oil industry is a mature industry, and BP, ExxonMobil, and Chevron Corporation have increased their reserves and output by acquiring smaller competitors.

External growth can also mitigate risk. It is considered less risky to merge with an existing company than to enter an unfamiliar market and establish the resources internally. In the months leading up to 2017, a surge in outbound cross-border M&A transactions (amounting to US$1 trillion in total) occurred in China, many motivated by the desire of Chinese companies to establish footholds in international markets.

3.3 Increasing Market Power

In industries with few competitors or in which market share is sufficiently concentrated, horizontal integration may be a means to increase market power. When a company increases its market power through horizontal mergers, it may develop greater ability to influence market prices. Taken to an extreme, horizontal integration results in a monopoly.

Vertical integration may also result in increased market power. Vertical mergers can lock in a company's sources of critical supplies or create captive markets for its products. Imagine, for example, an industry in which one company supplies raw materials to two separate manufacturing companies. If one of the manufacturers were to acquire the raw materials provider, the acquirer would be in a position to influence industry output and ultimately prices. As we will discuss further in the section on competition law (also referred to as antitrust law in the United States), government regulators routinely block both horizontal and vertical mergers that sufficiently reduce competition in an industry and concentrate market power in the hands of too few companies.

3.4 Acquiring Unique Capabilities and Resources

Many companies undertake a merger or an acquisition either to pursue competitive advantages or to shore up lacking resources. When a company cannot cost-effectively create internally the capabilities needed to sustain its future success, it may seek to acquire them elsewhere. For example, a company may engage in M&A activity in order to acquire specific competencies or resources it lacks, such as a strong research department, nimble sales force, intellectual capital, or creative talent.

3.5 Unlocking Hidden Value

A potential target company may be uncompetitive over a sustained period for a host of reasons, such as poor management, lack of resources, high legacy costs, or poor organizational structure. When a potential target is underperforming, an acquirer may believe it can acquire the company cheaply and then unlock hidden value through reorganization, better management, or synergy. If the target has been underperforming significantly, the acquirer may even believe it can obtain the company for less than its breakup value. A company's **breakup value** is the value that can be achieved if a company's assets are divided and sold separately.

Sometimes mergers are conducted because the acquirer believes that it is purchasing assets for less than their replacement cost. For example, a pharmaceutical company may believe it can acquire another company's research more cheaply than through undergoing a lengthy development process of its own. Or, an oil company may believe it will be less expensive to acquire another oil company's assets than to find and develop its own additional reserves.

3.6 Tax Considerations

It is possible for a profitable acquirer to benefit from merging with a target that has accumulated a large amount of tax losses. Instead of carrying the tax losses forward, the merged company would use the tax losses to immediately lower its tax liability. In many countries, the taxing authority disallows an offset when the primary reason for the merger is tax avoidance. Mergers are typically conducted for a variety of reasons, however, and it is difficult for regulatory authorities to prove that tax considerations are a primary motivator.

3.7 Cross-Border Motivations

The growth of cross-border deals was high during the 1990s, as international M&A became a popular strategy for developed country–based multinational companies seeking to extend their market reach, acquire new manufacturing facilities, develop new sources of raw materials, and tap into the capital markets. Subsequently, significant international M&A activity took place in the other direction, as companies in countries whose economies had grown significantly as a result of this globalization sought to extend their own market reach for the same reasons. In addition to the various factors that drive domestic mergers, cross-border mergers can provide an efficient way of achieving other international business goals.

3.7.1 *Exploiting Market Imperfections*

Cross-border transactions can enable companies to more fully exploit market imperfections. For example, to take advantage of differences in the relative cost of labor, a manufacturer may purchase a company in a country with comparatively lower labor costs.

3.7.2 *Overcoming Adverse Government Policy*

Cross-border mergers can also offer a means by which to overcome disadvantageous government policy—for example, to circumvent protective tariffs, quotas, or other barriers to free trade.

3.7.3 *Technology Transfer*

Companies that possess a new or superior technology may make acquisitions abroad in order to open new markets or otherwise more fully exploit their business advantage. Conversely, it is common for a company to purchase a non-domestic company that possesses a new or superior technology in order to enhance the acquirer's competitive position both at home and abroad.

3.7.4 *Product Differentiation*

Companies often purchase companies in other nations in order to exploit the advantages of having a highly differentiated line of products. Similarly, buying certain intangibles, such as a good reputation, helps to ensure success in the global market.

3.7.5 *Following Clients*

Companies may engage in a cross-border merger to follow and support domestic clients more effectively. For example, since 2005, many Chinese banks have established a presence outside Greater China to provide services abroad to their domestic clients as Chinese companies increased their activity in international markets.

EXAMPLE 2

Takeda–Shire Acquisition Motives

The Takeda–Shire acquisition involved a number of motivations described so far in this section.

Synergy. Takeda expected significant synergies from the deal. On a long-term basis, core earnings margins were anticipated to reach 35%, up from 22% in 2018. Synergies and margin improvements also arose from post-merger disposals of low-revenue-generating products.

New product growth. Traditionally, companies in the pharmaceutical sector have a robust new product pipeline. Takeda had only two new major drugs, in late-stage clinical trials, in its pipeline. The Shire acquisition allowed cash flow from existing Shire products to bolster revenues, allowing time and investment in new product development for the next five years.

Market power. Takeda's strategy was to become a top 10 global pharmaceutical company by acquiring Shire, a company of equivalent size. By doing this, Takeda believed it could gain market power, enabling it to compete longer term in the global pharmaceutical market.

Unique capabilities and resources. With its extremely limited new product pipeline, and sales of existing drugs slowing substantially in response to increasing competition from generic drugs, revenue expectations for Takeda were expected to show significant decline without the deal. The Shire acquisition brought in a portfolio of lucrative rare disease pharmaceuticals, bolstering the combined group's revenue forecasts.

Cross-border motivations. An established company in Japan for more than two centuries, Takeda was also Japan's largest company in the industry. Nevertheless, its CEO believed that to be a successful pharmaceutical company, Takeda needed to be successful outside Japan because Japan accounted for only a small fraction of the global pharmaceutical market. With downward pressure on Japanese drug prices in response to health ministry policies, the Shire acquisition resulted in more than half of Takeda's revenues coming from the US market, where significant growth in drug markets and margins was expected.

3.8 Diversification

Companies sometimes cite diversification as one of the motives behind a merger. The idea behind company-level diversification is to treat the company as a portfolio of investments in other companies. If a conglomerate invests in companies from a variety of industries, then the variability of the conglomerate's total cash flows should decrease, at least to the extent that the industries are uncorrelated.

Although this motive may seem rational, typically it is not in the best interests of the conglomerate's shareholders. In a well-functioning capital market, investors can diversify their own portfolios more easily and at less expense than a company can. Additionally, the desire to diversify has led some companies to lose sight of their major competitive strengths and to expand into businesses in which they lack comparative advantages.

3.9 Managers' Personal Incentives

Various managerial-related theories for mergers have been developed over the years based on evidence of agency problems. **Managerialism theories** posit that because executive compensation is highly correlated with company size, corporate executives are motivated to engage in mergers to maximize the size of their company rather than shareholder value. Additionally, corporate executives may be motivated by self-aggrandizement. For example, being the senior executive of a large company conveys great power and prestige.

3.10 Bootstrapping Earnings

Even when there are no reasons to believe that synergies or growth would result from a merger, it is possible to create the illusion of such synergies or growth. When a company's earnings increase as a consequence of the merger transaction itself rather than because of resulting economic benefits of the combination, it is referred to as the "bootstrap effect" or "bootstrapping earnings." The bootstrap effect occurs when the acquiring company's shares trade at a higher P/E than those of the target and the acquirer's P/E does not decline following the merger.

EXAMPLE 3

Bootstrapping Earnings

Assume two companies are planning a merger. Company A is the acquirer, Company T is the target, and Company A* is the post-merger combination of the two companies. The companies' stock prices and earnings per share are as shown in the following table. Note that the acquirer has a P/E of 25.0 and the target has a P/E of 20.0:

	A	T	A*
Stock price	\$100.00	\$50.00	
EPS	\$4.00	\$2.50	\$4.20
P/E	25.0	20.0	
Total shares outstanding	100,000	50,000	125,000
Total earnings	\$400,000	\$125,000	\$525,000
Market value of equity	\$10,000,000	\$2,500,000	

Given its stock price, the acquirer can issue 25,000 of its own shares and use the proceeds to buy the target company. This amount is determined by dividing the target's market value by the acquirer's stock price (\$2,500,000/\$100 = 25,000). The total shares outstanding of the merged company will be 125,000—the acquirer's initial 100,000 shares plus the 25,000 shares that the acquirer issued to purchase the target. After the merger, the company's combined earnings are divided by the number of shares outstanding to determine the new EPS (\$525,000/125,000 = \$4.20), which is \$0.20 per share higher than the acquirer would have reported without the merger.

If the acquirer's pre-merger stock price had been \$80 instead of \$100, then A's pre-merger P/E would have been 20.0 (\$80/\$4.00). Under that scenario, the acquirer would have issued 31,250 shares to purchase the target. The EPS of the merged company would then have been \$525,000/131,250 = \$4.00, thus illustrating that for bootstrapping to work, the acquirer's P/E must be higher than the target's P/E.

If the market is efficient, the post-merger P/E should adjust to the weighted average of the two companies' contributions to the merged company's earnings. In the previous example, the merged company's P/E would be about 23.8, which implies that the acquirer's stock price would remain at \$100. If, however, the acquiring company's P/E is higher than the target's and management can convince investors to value the merged company using the acquirer's pre-merger P/E, then the stock price of the new company should rise. If the acquirer bootstraps earnings to \$4.20 per share as shown in the preceding example, then the share price should increase to \$105 if investors apply the pre-merger P/E of 25.0 times earnings (\$4.20 × 25.0 = \$105). When there are no expected gains from synergy or other factors, such share price increases are not expected. The market usually recognizes the bootstrapping effect, and post-merger P/Es adjust accordingly.

3.11 Mergers and the Industry Life Cycle

The types of mergers (e.g., horizontal, vertical, or conglomerate) occurring in an industry, as well as the motivations behind those mergers, will vary over time as an industry proceeds through its life cycle. The stages in an industry life cycle are normally categorized by their rates of growth in sales with five growth stages that vary in length. These stages are as follows:

1 Embryonic
2 Growth
3 Shakeout
4 Mature
5 Decline

In the embryonic stage, the industry exhibits substantial development costs and has low, but slowly increasing, sales growth. In this phase, younger, smaller companies may sell themselves to larger companies in mature or declining industries that are looking for ways to enter into a new growth industry. Alternatively, young companies may look to merge with companies that provide them with opportunities to pool management and capital resources. Types of mergers commonly occurring in this stage are conglomerate and horizontal.

When growth is rapidly accelerating, the industry exhibits high profit margins caused by a few market participants. Explosive growth in sales may necessitate large capital requirements to expand existing capacity. Conglomerate and horizontal mergers commonly occur in the rapid growth stage.

In the shakeout stage, the industry experiences a drop in the entry of new competitors, but growth potential remains. Horizontal and vertical mergers may be undertaken to achieve economies of scale, savings, and operational efficiencies.

Upon market maturity, the industry faces increasing competition and capacity constraints. Mergers may be undertaken to achieve economies of scale in research, production, and marketing to match the low costs and price performance of other companies (both domestic and international). Large companies may acquire smaller ones in order to improve management and provide a broader financial base. Horizontal mergers are characteristic of this stage.

In the decline stage, the industry faces overcapacity and eroding profit margins. Horizontal mergers may be undertaken to ensure survival, and vertical mergers may be carried out to increase efficiency and profit margins. Companies in related industries may merge to exploit synergy. Companies in this industry may acquire companies in young industries. Horizontal, vertical, and conglomerate mergers are most common to this stage.

MERGER TRANSACTION CHARACTERISTICS 4

e contrast merger transaction characteristics by form of acquisition, method of payment, and attitude of target management;

The specifics of M&A transactions can vary along many dimensions, including the form of acquisition, financing, timing, control and governance, accounting choices, and numerous details ranging from the post-merger board composition to the location of the new headquarters. In this section, we will focus on the form of acquisition, method of payment, and mindset of target management. These three characteristics play a large role in determining how the transaction will occur, which regulatory rules might apply, how the transaction will be valued, and how it may be taxed.

4.1 Form of Acquisition

There are two basic forms of acquisition: An acquirer can purchase either the target's stock or its assets. The decision will have several consequences, as summarized in Exhibit 1.

Stock purchases are the most common form of acquisition. A **stock purchase** occurs when the acquirer gives the target company's shareholders some combination of cash and securities in exchange for shares of the target company's stock. For a stock purchase to proceed, it must be approved by at least 50% of the target company's shareholders and sometimes more, depending on the legal jurisdiction. Although it can be difficult and time consuming to win shareholder approval, it also stands as an opportunity to circumvent the target company's management in cases where management opposes the merger.

In an **asset purchase**, the acquirer purchases the target company's assets and payment is made directly to the target company. One advantage of this type of transaction is that it can be conducted more quickly and easily than a stock purchase because shareholder approval is not normally required unless a substantial proportion of the assets is being sold, usually more than 50%. Another advantage is that an acquirer can focus on buying the parts of a company of particular interest, such as a specific division, rather than the entire company.

Exhibit 1 Major Differences of Stock versus Asset Purchases

	Stock Purchase	Asset Purchase
Payment	Target shareholders receive compensation in exchange for their shares.	Payment is made to the selling company rather than directly to shareholders.
Shareholder approval	Shareholder approval required.	Shareholder approval might not be required.
Liabilities	Acquirer assumes the target's liabilities.	Acquirer generally avoids the assumption of liabilities.
Complexity	Simpler; less likely to require complex amendment of asset-related legal documents.	More complex; more likely to require reassignment, novation, or renegotiation of contracts, etc.
Regulatory approval	More likely to be subject to regulatory scrutiny and approval.	Less likely to involve regulatory approval.

Another key difference relates to the assumption of liabilities. In stock purchases, the acquiring company assumes the target company's liabilities. Acquiring companies must thus be on guard to avoid assuming unexpected or undisclosed liabilities. With asset purchases, acquiring companies generally avoid assuming the target's liabilities. Purchasing substantially all of a company's assets instead of conducting a stock purchase so as to specifically avoid assuming liabilities is fraught with legal risk, however, because courts have tended to hold acquirers responsible for the liabilities in these cases.

Some of the more dramatic consequences of the decision to pursue one form of acquisition versus another concern taxation. In some countries, in a stock purchase, the target company's shareholders exchange their shares for compensation and must pay tax on their gains, but there are no tax consequences at the corporate level. In some countries, for an asset purchase, there are no direct tax consequences for the target company's shareholders, but the target company itself may be subject to corporate taxes. The complexity of M&A deals, coupled with the complexity and variability of tax laws in different jurisdictions, means tax treatment varies widely.

In addition to shifting the basic tax burden, the form-of-acquisition decision plays a role in determining how tax rules are applied in accounting for the merger. For example, use of a target's accumulated tax losses is allowable in many countries (such as Argentina, Australia, France, Singapore, South Africa, and the United States) for stock purchases but not for asset purchases.

4.2 Method of Payment

The acquirer can pay for the merger with cash, securities, or some combination of the two in what is called a **mixed offering**. In a **cash offering**, the cash might come from the acquiring company's existing assets or from a debt issue. In the most general case of a **securities offering**, the target shareholders receive shares of the acquirer's common stock as compensation. In a consolidation, the target company's shareholders may receive new shares in the surviving entity. Instead of common stock, however, the acquirer might offer other securities, such as preferred shares or even debt securities.

In a stock offering, the **exchange ratio** determines the number of shares that stockholders in the target company receive in exchange for each of their shares in the target company. Because share prices are constantly fluctuating, exchange ratios are typically negotiated in advance for a range of stock prices. The acquirer's cost is the product of the exchange ratio, the number of outstanding shares of the target company, and the value of the stock given to target shareholders. Each shareholder of the target company receives new shares based on the number of target shares he owns multiplied by the exchange ratio.

EXAMPLE 4

Stock Offering

TAJ Education Group, an Indian online education provider, has announced its intended acquisition of Acchaa Prep Company Ltd, a small tutoring company specializing in after-school prep courses. In a press release, TAJ Education outlines the terms of the merger, which specify that Acchaa Prep's shareholders will each receive 0.90 shares of TAJ Education for every share of Acchaa Prep owned. Acchaa Prep has 1 million shares outstanding. On the day of the merger announcement, TAJ Education's stock closed at Rs200.00 and Acchaa Prep's stock closed at Rs150.00. Sunita Jugnauth is an individual investor who owns 500 shares of Acchaa Prep, currently worth Rs75,000 (500 × Rs150.00).

1 Based on the current share prices, what is the cost of the acquisition for TAJ Education?

2 How many shares of TAJ Education will Jugnauth receive, and what is the value of those shares (based on current share prices)?

Solution to 1:

Because there are 1 million shares of Acchaa Prep outstanding and the exchange ratio is 0.90 shares, TAJ Education will need to issue 0.90 × 1 million = 900,000 shares of TAJ Education stock to complete the transaction. Because the cost per share of TAJ Education stock is currently Rs200.00, the cost of the transaction to TAJ Education will be Rs200.00 × 900,000 = Rs180 million.

Solution to 2:

Jugnauth will turn over her 500 shares of Acchaa Prep stock. As compensation, she will receive 0.90 × 500 = 450 shares of stock in TAJ Education. With each share of TAJ Education being worth Rs200.00, the value of those shares to Jugnauth is Rs90,000.

Note that the value of Jugnauth's Acchaa Prep shares was Rs75,000. The Rs15,000 difference in value is a premium paid by TAJ Education for control of Acchaa Prep. The pre-merger value of Acchaa Prep was Rs150 million, but TAJ Education's total cost to purchase the company was Rs180 million. The 20% or Rs30 million difference is the total-control premium paid by TAJ Education.

A variety of factors influence a company's decision to negotiate for one method of payment versus another. As we shall explore in more detail later, the form of payment affects the distribution of risk and reward between acquirer and target shareholders. In a stock offering, target company shareholders assume a portion of the reward as well as a portion of the risk related to the estimated synergies and the target company's value. Consequently, when an acquiring company's management is highly confident both in their ability to complete the merger and in the value to be created by the merger, they are more inclined to negotiate for a cash offering rather than a stock offering.

Another factor in the decision relates to the relative valuations of the companies involved in the transaction. When an acquirer's shares are considered overvalued by the market relative to the target company's shares, stock financing is more appropriate. In effect, the shares are more valuable as a currency. In fact, investors sometimes interpret an acquirer's stock offering as a signal that the company's shares may be overvalued. This effect is similar to the negative market reaction observed in seasoned equity offerings. During the stock market bubble in the late 1990s, stock financing of mergers was popular, accounting for well over half of all deals in the United States. In the early 2000s after merger accounting rules changed, making all-share deals less attractive, stock financing dropped significantly to a low of 10% in 2017. This shift marked a period during which companies had substantial cash on their balance sheets and broad-based investor concerns about equity valuation levels.

Another important consideration when deciding on the payment method is the accompanying change in capital structure. The costs and benefits of different payment structures reflect how the offer will affect the acquirer's capital structure. For instance, on the one hand, borrowing to raise funds for a cash offering increases the acquirer's financial leverage and risk. On the other hand, issuing a significant number of new common shares for a stock offering can dilute the ownership interests of existing shareholders.

4.3 Mindset of Target Management

Mergers are referred to as either friendly or hostile depending on how the target company's senior managers and board of directors view the offer. The distinction is not trivial because an enormous amount of time and resources can be expended by both acquirer and target when the takeover is hostile. Whether a merger is friendly or hostile affects how it is completed, what regulations must be followed, how long the transaction takes, and possibly how much value is created (or destroyed) as a result of the combination.

4.3.1 *Friendly Mergers*

Unless there is cause to think the target will be hostile to a merger, the acquirer will generally start the process by approaching target management directly. The target could approach the acquirer, although this method is much less common. If both management teams are amenable to a potential deal, then the two companies enter into merger discussions. The negotiations revolve around the consideration to be received by the target company's shareholders and the terms of the transaction as well as other aspects, such as the post-merger management structure.

Before negotiations can culminate in a formal deal, each of the parties examines the others' books and records in a process called due diligence. The purpose of due diligence is to protect the companies' respective shareholders by attempting to confirm the accuracy of representations made during negotiations. For example, an acquirer would want to ensure that the target's assets exist and are worth approximately what was claimed by the target. Likewise, a target might want to examine an acquirer's financial records to gauge the likelihood that the acquirer has the capacity to pay for the acquisition as outlined in negotiations. Any deficiencies or problems uncovered during the due diligence process could affect negotiations, resulting in adjustments to the terms or price of the deal. If the issue is large enough, the business combination might be called off entirely.

Once due diligence and negotiations have been completed, the companies enter into a **definitive merger agreement**, a contract written by both companies' attorneys and ultimately signed by each party to the transaction. The agreement contains the details of the transaction, including the terms, warranties, conditions, termination details, and the rights of all parties.

Common industry practice has evolved such that companies typically discuss potential transactions in private and maintain secrecy until the definitive merger agreement is reached. This trend may have been influenced by shifts in securities laws toward more stringent rules related to the disclosure of material developments to the public. Additionally, news of a merger can cause dramatic stock price changes for the parties to the transaction. Premature announcement of a deal can cause volatile swings in the stock prices of the companies as they proceed through negotiations.

After the definitive merger agreement has been signed, the transaction is generally announced to the public through a joint press release by the companies. In a friendly merger, the target company's management endorses the merger and recommends that its stockholders approve the transaction. In cases where a shareholder vote is needed, whether it is the target shareholders approving the stock purchase or the acquirer shareholders approving the issuance of a significant number of new shares, the material facts are provided to the appropriate shareholders in a public document called a **proxy statement**, which is given to shareholders in anticipation of their vote.

After all the necessary approvals have been obtained—from shareholders as well as any other parties, such as regulatory bodies—the attorneys file the required documentation with securities regulators and the merger is officially completed. Target shareholders receive the consideration agreed upon under the terms of the transaction, and the companies are officially and legally combined.

4.3.2 *Hostile Mergers*

In a hostile merger, which is a merger that is opposed by the target company's management, the acquirer may decide to circumvent the target management's objections by submitting a merger proposal directly to the target company's board of directors and bypassing the CEO. This tactic is known as a **bear hug**.

Because bear hugs are not formal offers and have not been mutually agreed upon, there are no standard procedures in these cases. If the offer is high enough to warrant serious consideration, then the board may appoint a special committee to negotiate a sale of the target.

Although unlikely in practice, it is possible that target management will capitulate after a bear hug and enter into negotiations, which may ultimately lead to a friendly merger. If the bear hug is unsuccessful, then the hopeful acquirer may attempt to appeal more directly to the target company's shareholders.

One method for taking a merger appeal directly to shareholders is through a **tender offer**, whereby the acquirer invites target shareholders to submit ("tender") their shares in return for the proposed payment. Although tender offers are often associated with hostile mergers, in which the offer is opposed by the target company's management and board of directors, they can also occur in a friendly context. It is up to the individual shareholders to physically tender shares to the acquiring company's agent in order to receive payment. A tender offer can be made with cash, shares of the acquirer's own stock, other securities, or some combination of securities and cash. Because a cash tender offer can be completed in less time than a cash merger, some acquiring companies use this type of transaction to gain control of a target company quickly.

Another method of taking over a target company involves the use of a proxy fight. In a **proxy fight**, a company or individual seeks to take control of a company through a shareholder vote. Proxy solicitation is approved by regulators and then mailed directly to target company shareholders. The shareholders are asked to vote for the acquirer's proposed slate of directors. If the acquirer's slate is elected to the target's board, then it is able to replace the target company's management. At this point, the transaction may evolve into a friendly merger.

Regardless of how an acquirer seeks to establish control, target managers have a variety of alternatives available for defending the company against unwanted overtures. In these cases, the target usually retains the services of law firms and investment bankers to design a defense against the unwanted takeover attempt. As we will discuss in the next section, target company managers may use a variety of legal and financial defensive maneuvers to ward off a takeover attempt.

5 TAKEOVERS AND THEIR DEFENSE MECHANISMS

f identify and explain pre-offer and post-offer takeover defense mechanisms;

When a target company is faced with a hostile tender offer (takeover) attempt, the target managers and board of directors face a basic choice. They can decide to negotiate and sell the company, either to the hostile bidder or a third party, or they can attempt to remain independent. Aside from the strength of the company's defenses and target management's resolve to stay independent, the premium over the market price offered by the acquirer for the target company's shares is the major driving factor in the decision to support or resist any given takeover.

If the target management decides to resist the unwanted overture, they have a variety of takeover defense mechanisms at their disposal. Once the decision has been reached, the target company generally seeks the counsel of investment bankers and lawyers to explore the fairness of the hostile offer and to advise the board of the alternatives.

A target might use defensive measures to delay, negotiate a better deal for shareholders, or attempt to keep the company independent. Defensive measures can be implemented either before or after a takeover attempt has begun. Most law firms specializing in takeovers recommend that defenses be set up before a company receives or expects any takeover activity.

5.1 Pre-Offer Takeover Defense Mechanisms

In the United States, most hostile takeover attempts result in litigation. The courts generally bless legal pre-offer defense mechanisms but tend to scrutinize post-offer defenses very closely. The target usually assumes the burden of proof in showing that the recently enacted defenses are not simply intended to perpetuate management's tenure at the target company. It is for this reason that most attorneys recommend that target companies put defenses in place prior to any takeover action. Following this policy gives the target more flexibility when defending against a takeover bid.

Takeover regulation in most jurisdictions outside the United States, however, is more likely to emphasize shareholder choice with director-neutrality in hostile takeover situations, thereby involving reduced opportunity for parties to resort to litigation and consequently a lower influence from the courts.

With different twists in takeover strategy come new innovations and variations in takeover defenses. Given the many possible variations, the following is not an exhaustive list but an overview of the more well-known anti-takeover strategies. The two broad varieties of pre-offer defenses are rights-based defenses, such as poison pills and poison puts, and a variety of changes to the corporate charter (e.g., staggered boards of directors and supermajority provisions) that are sometimes collectively referred to as **shark repellents**.

5.1.1 *Poison Pills*

A **poison pill** is a legal device that makes it prohibitively costly for an acquirer to take control of a target without the prior approval of the target's board of directors. Most poison pills make the target company less attractive by creating rights that allow for the issuance of shares of the target company's stock at a substantial discount to market value.

There are two basic types of poison pills: the **flip-in pill** and the **flip-over pill**. When the common shareholder of the target company has the right to buy its shares at a discount, the pill is known as a flip-in. The pill is triggered when a specific level of ownership is exceeded. Because the acquiring company is generally prohibited from participating in the purchase through the pill, the acquirer is subject to a significant level of dilution. Most plans give the target's board of directors the right to redeem the pill prior to any triggering event. If the takeover becomes friendly, the board generally exercises this waiver.

In the case of a flip-over pill, the target company's common shareholders receive the right to purchase shares of the acquiring company at a significant discount from the market price, which causes dilution to all existing acquiring company shareholders. Again, the board of the target generally retains the right to redeem the pill should the transaction become friendly.

Another possible aspect of the poison pill is the **"dead-hand" provision**. This provision allows the board of the target to redeem or cancel the poison pill only by a vote of the continuing directors. Because continuing directors are generally defined as directors who were on the target company's board prior to the takeover attempt, this provision has the effect of making it much more difficult to take over a target without prior board approval.

5.1.2 *Poison Puts*

Whereas poison pills grant common shareholders certain rights in a hostile takeover attempt, **poison puts** give rights to the target company's bondholders. In the event of a takeover, poison puts allow bondholders to put the bonds to the company. In other words, if the provision is triggered by a hostile takeover attempt, then bondholders have the right to sell their bonds back to the target at a redemption price that is pre-specified in the bond indenture, typically at or above par value. The effect of a poison put defense is to require that an acquirer be prepared to refinance the target's debt immediately after the takeover. This defense increases the need for cash and raises the cost of the acquisition.

5.1.3 *Staggered Board of Directors*

Instead of electing the entire board of directors each year at the company's annual meeting, a company may arrange to stagger the terms for board members so that only a portion of the board seats are due for election each year. For example, if the company has a board consisting of nine directors, members could be elected for three-year terms with only three directors coming up for election each year. The effect of this staggered board is that it would take at least two years to elect enough directors to take control of the board.

5.1.4 *Restricted Voting Rights*

Some target companies adopt a mechanism that restricts stockholders who have recently acquired large blocks of stock from voting their shares. Usually, there is a trigger stockholding level, such as 15% or 20%. Shareholders who meet or exceed this trigger point are no longer able to exercise their voting rights without the target company's board releasing the shareholder from the constraint. The possibility of owning a controlling position in the target without being able to vote the shares serves as a deterrent.

5.1.5 *Supermajority Voting Provisions*

Many target companies change their charter and bylaws to provide for a higher percentage approval by shareholders for mergers than normally is required. A typical provision might require a vote of 80% of the outstanding shares of the target company (as opposed to a simple 51% majority). This supermajority requirement is triggered by a hostile takeover attempt and is frequently accompanied by a provision that prevents the hostile acquirer from voting its shares. Thus, even if an acquirer is able to accumulate a substantial portion of the target's shares, it may have great difficulty accumulating enough votes to approve a merger.

5.1.6 *Fair Price Amendments*

Fair price amendments are changes to the corporate charter and bylaws that disallow mergers for which the offer is below some threshold. For example, a fair price amendment might require an acquirer to pay at least as much as the highest stock price at which the target has traded in the public market over a specified period. Fair price amendments protect targets against temporary declines in their share prices by setting a floor value bid. Additionally, fair price amendments protect against two-tiered tender offers, in which the acquirer offers a higher bid in a first step tender offer with the threat of a lower bid in a second step tender offer for those who do not tender right away.

5.1.7 *Golden Parachutes*

Golden parachutes are compensation agreements between the target company and its senior managers. These employment contracts allow the executives to receive lucrative payouts, usually several years' worth of salary, if they leave the target company following a change in corporate control. In practice, golden parachutes do not offer much deterrent, especially for large deals in which the managers' compensation is small relative to the overall takeover price. One reason they persist is that they help alleviate target management's concerns about job loss. Golden parachutes may encourage key executives to stay with the target as the takeover progresses and the target explores all options to generate shareholder value. Some contend that without golden parachutes, target company executives might be quicker to seek employment offers from other companies to secure their financial future. Whether this is actually the case and whether golden parachutes are fair and in shareholders' best interest is the subject of considerable debate among shareholder rights activists and senior managers.

Generally, rights-based defenses (poison pills and puts) are pre-offer defenses that are available in the United States but not in many other jurisdictions, where such "frustrating" actions are often banned. In contrast, charter-based (staggered boards, supermajority, restricted voting rights, and fair price amendments) and contract-based (golden parachute) defenses are pre-offer defenses available in many countries and jurisdictions (in line with the emphasis on shareholder choice), including the United States.

5.2 Post-Offer Takeover Defense Mechanisms

A target also has several defensive mechanisms that can be used once a takeover has already been initiated. Because they may be less successful when used in isolation and because they have historically been subject to greater scrutiny by the courts, post-offer defenses are typically used in conjunction with pre-offer defenses.

5.2.1 *"Just Say No" Defense*

Probably the simplest place for a target company to start when confronted with a hostile takeover bid is to rely on pre-takeover defenses and to decline the offer. If the acquirer attempts a bear hug or tender offer, then target management typically lobbies the board of directors and shareholders to decline and build a case for why the offering price is inadequate or why the offer is otherwise not in the shareholders' best interests. This strategy forces the hopeful acquirer to adjust its bid or further reveal its own strategy in order to advance the takeover attempt.

The Takeda–Shire acquisition provides a good illustration of the "just say no" defense. In the four-week period following Takeda's initial offer, the Shire board was able to extract four more offers from Takeda with increasingly higher prices and cash components. Under the UK takeover code "put up or shut up" rule, Takeda had up to 28 days after public announcement to make its final offer or else walk away from the deal for six months. The Shire board was able to use this rule to best effect by declining early offers on the basis that they substantially undervalued the company and its growth prospects, without having to first refer to shareholders. Just before the 28-day deadline, the Shire board obtained an offer from Takeda that Shire shareholders were satisfied to accept within two weeks. The final outcome was an accepted price almost 10% higher than the initial offer, as well as an increase in the cash component from 36% to 44% of the total offer price.

5.2.2 *Litigation*

A popular technique used by many target companies is to file a lawsuit against the acquiring company based on alleged violations of securities or competition laws. **Competition laws** are laws which promote or maintain market competition by regulating anti-competitive conduct. Unless there is a serious competition law violation, these suits rarely stop a takeover bid. Instead, they often serve as a delaying tactic to create additional time for target management to develop other responses to the unwanted offer. Generally, any securities law violations, even if upheld, can be corrected with additional public disclosures. In many countries, generally most competition law claims that eventually prevent takeover attempts are initiated by either competition, foreign investment, or securities regulators rather than by the target company.

5.2.3 *Greenmail*

This technique involves an agreement allowing the target to repurchase its own shares from the acquiring company, usually at a premium to the market price. Greenmail is usually accompanied by an agreement that the acquirer will not pursue another hostile takeover attempt of the target for a set period. In effect, greenmail is the termination of a hostile takeover through a payoff to the acquirer. The shareholders of the target company do not receive any compensation for their shares.

Greenmail was popular in the United States during the early 1980s, but its use became extremely restricted by the late 1980s after the US Internal Revenue Code was amended to add a 50% tax on profits realized by acquirers through greenmail. Since the mid-2010s, a resurgence in the use of greenmail in the United States has occurred, prompted by activist investors acquiring stakes to drive corporate change. Activist investor strategies in general do not trigger the hostile takeover 50% tax provisions.

In many other countries, such as the United Kingdom and China, greenmail is not permitted as a takeover defense under takeover codes or company law, in line with shareholder-friendly, director-neutral takeover regulatory systems.

5.2.4 *Share Repurchase*

Rather than repurchasing only the shares held by the acquiring company, as in greenmail, a target might use a share repurchase to acquire shares from any shareholder. For example, a target may initiate a cash tender offer for its own outstanding shares. An effective repurchase can increase the potential cost for an acquirer by either increasing the stock's price outright or by causing the acquirer to increase its bid to remain competitive with the target company's tender offer for its own shares. Additionally, a share repurchase often has the effect of increasing the target company's use of leverage because borrowing is typically required to purchase the shares. This additional debt makes the target less attractive as a takeover candidate.

In some cases, a target company buys all of its shares and converts to a privately held company in a transaction called a leveraged buyout. In a **leveraged buyout** (LBO), the management team generally partners with a private equity firm that specializes in buyouts. The new entity borrows a high proportion of the overall purchase price; the financial firm contributes a certain amount of capital; and the management team provides the management expertise to run the business. In exchange for their expertise, management generally receives a payout percentage based on the profitability and success of the company after the LBO is completed. This strategy may allow the target to defend against a hostile bid provided that the LBO provides target shareholders with a level of value that exceeds the would-be acquirer's offer.

5.2.5 *Leveraged Recapitalization*

A technique somewhat related to the leveraged buyout is the leveraged recapitalization. A **leveraged recapitalization** involves the assumption of a large amount of debt that is then used to finance share repurchases (but in contrast to a leveraged buyout, in a recapitalization, some shares remain in public hands). The effect is to dramatically change the company's capital structure while attempting to deliver a value to target shareholders in excess of the hostile bid.

5.2.6 *"Crown Jewel" Defense*

After a hostile takeover is announced, a target may decide to sell off a subsidiary or asset to a third party. If the acquisition of this subsidiary or asset was one of the acquirer's major motivations for the proposed merger, then this strategy could cause the acquirer to abandon its takeover effort. When a target initiates such a sale after a hostile takeover bid is announced, there is a good chance that the courts will declare this strategy illegal.

5.2.7 *Pac-Man® Defense*

The target can defend itself by making a counteroffer to acquire the hostile bidder. This technique is rarely used because, in most cases, it means that a smaller company (the target) is making a bid for a larger entity. Additionally, once a target uses a Pac-Man® defense, it forgoes the ability to use a number of other defensive strategies. For instance, after making a counteroffer, a target cannot very well take the acquirer to court claiming a competition law violation. Further, in many jurisdictions other than the United States, such as the United Kingdom, a counteroffer would require shareholder approval to be obtained first, decreasing the likelihood of this defense being used.

5.2.8 *White Knight Defense*

Often the best outcome for target shareholders is for the target company's board to seek a third party to purchase the company in lieu of the hostile bidder. This third party is called a **white knight** because it is coming to the aid of the target. A target usually initiates this technique by seeking out another company that has a strategic fit with the target. Based on a good strategic fit, the third party can often justify a higher price for the target than what the hostile bidder is offering.

Once a white knight bid is made public, it may elicit an additional higher bid from the hostile bidder. This dynamic can kick off a competitive bidding situation. In some cases, because of the competitive nature of the bidders, the winner's curse can prevail and the target company shareholders may receive a very good deal. **Winner's curse** is the tendency for the winner in certain competitive bidding situations to overpay, whether because of overestimation of intrinsic value, emotion, or information asymmetries. The winner's curse is most likely to occur when the target company has roughly the same value to all bidders but the target's true value is hard to ascertain. The average bid in such cases may represent the best estimate of the target's intrinsic value, whereas the high (winning) bid overestimates its intrinsic value.

5.2.9 *White Squire Defense*

In the **white squire** defense, the target seeks a friendly party to buy a substantial minority stake in the target—enough to block the hostile takeover without selling the entire company. Although the white squire may pay a significant premium for a substantial number of the target's shares, these shares may be purchased directly from the target company and the target shareholders may not receive any of the proceeds. For example, the white squire could purchase shares of convertible preferred stock instead of common stock.

The use of the white squire defense may carry a high litigation risk depending on the details of the transaction and local regulations. Additionally, stock exchange listing requirements sometimes require that target shareholders vote to approve these types of transactions, and shareholders may not endorse any transaction that does not provide an adequate premium to them directly.

REGULATION AND COMPETITION LAW 6

Even when a merger has been accepted by the target company's senior managers, the board of directors, and shareholders, the combination must still be approved by regulatory authorities. Additionally, there are a variety of rules that companies must follow when initiating and completing the merger transaction. This section provides an overview of the key rules and issues that arise from M&A activity.

The two major bodies of jurisprudence relating to mergers are competition law and securities law. Competition laws are intended to ensure that markets remain competitive; securities laws are concerned largely with maintaining both fairness in merger activities and confidence in the financial markets.

Most countries have competition laws, which prohibit mergers and acquisitions that impede competition, generally focusing on restricting monopolies and attempts at restraint of trade. At least 135 jurisdictions have competition laws in place, and these jurisdictions produce roughly 95% of world GDP, which illustrates the significance of competition policy in regulating financial markets. Early competition laws generally focused on horizontal mergers. In subsequent years, however, the laws were updated to address vertical and conglomerate mergers in addition to the acquisition of assets.

To ensure that the laws can be effectively enforced, most jurisdictions have established regulatory agencies with the resources to oversee and enforce competition laws. For example, in the United States, the Federal Trade Commission (FTC) is the regulatory agency that works with the US Department of Justice (DoJ) to enforce antitrust law. China's equivalent is the Anti-Monopoly Enforcement Agency (AEA), which is responsible for enforcing China's Anti-Monopoly Law and where its enforcement powers for merger control are carried out by the Ministry of Commerce (MOFCOM). Most regulators have the opportunity to review and approve mergers in advance, providing an opportunity to halt a merger prior to its completion rather than having to disassemble a company after a merger is later deemed to be anticompetitive.

In Europe, the European Commission (EC) has the authority to review the competition law implications of transactions among companies that generate significant revenues within the European Union. Although the EC member states have jurisdiction on mergers within their respective national borders and their own competition regulators, such as the French Competition Authority (FCA) in France, mergers with significant cross-border effects are subject to EC review. Similar to the requirements in the United States and many other countries, pre-merger notification is required.

In addition to regulatory watchdogs, such as the FTC and the EC, approval may be needed from other regulatory agencies. For example, in most countries, a merger involving banks would require approval from that country's banking regulator, whereas one involving insurance companies would usually require approval from insurance industry regulators. In some cases, if one of the company's businesses is deemed to be of strategic national interest, additional government approvals may be necessary. Each merger must be analyzed by legal experts to determine the specific regulatory approvals required to comply with the relevant rules and laws. This is a very specialized area and can cause significant delays in the closing of some transactions.

The situation can become further complicated when the merging companies have a global presence that falls within multiple jurisdictions of regulatory control. For example, a large trans-Atlantic merger would require approval of both the US regulatory bodies and the EC. Global companies often face dozens of regulatory agencies with different standards and filing requirements. For example, the Dow Chemical–DuPont merger announced in late 2015 involved sales and production in more than 160 countries, requiring competition law approval in more than 40 jurisdictions around the world. The merger was regarded as approved and proceeding once approval had been obtained from the major market regulators of the United States, European Union, China, India, Brazil, and South Africa. The merger was completed in 2017. Regulators typically examine market share data when determining potential competition law and related regulatory guidelines violations. Although there was competition regulation in response to Microsoft's dominant market position, the subsequent emergence of a number of dominant technology companies has largely occurred with little attention from competition regulators. In 2018, however, this sector started to receive greater attention, and in June 2019 the US House of Representatives began looking into possible anti-competitive behavior by these companies, often referred to as "tech giants."

At the same time, the US competition regulators announced they would divide up their investigation, with the DoJ handling potential antitrust investigations of Apple and Google and the FTC taking on Facebook and Amazon.

EXAMPLE 5

Evolving Regulation: Competition Concerns and the Tech Giants

Competition laws continue to evolve in response to global economic and commercial trends, as well as technological developments. Although not subject to a high degree of regulatory intervention to date, the digital sector has become a key area of focus for regulators.

Concerns with respect to competition regulation of the largest technology companies, often referred to as "tech giants" because of their undisputed dominance and market influence in their respective categories, include the following:

Under-regulation. The digital industry represents a significant proportion of economic activity in many countries. This development has occurred without the level of competition regulation and oversight to which other more developed or mature traditional industries have been subject in their activities. There is concern among major regulators as to whether the traditional competition regulation toolkit is "fit for purpose" and appropriate for regulatory oversight of this developing sector.

"Killer" acquisitions. Although the sector has developed based on technological innovation and the related disruption of traditional businesses, it is widely thought that dominant companies in the digital sector may acquire start-ups solely with the intention of closing them down to limit innovation and competition. Competition regulators are considering if and how these "killer" acquisitions should be better policed.

Data aggregation. Regulators are increasingly concerned that the aggregation of data by large private-sector digital companies will provide the basis for inefficient barriers to entry and anti-competitive conduct. In September 2018, the EC said that it will "carefully review transactions which lead to the acquisition of important sets of data."

When reviewing quantitative and qualitative data, one should note that merger guidelines are just that—guidelines. It is possible that under unusual circumstances, the regulator may not challenge one merger that does violate the guidelines and may challenge another merger that does not.

Each transaction must be analyzed carefully to fully explore all potential competition law issues. Recent examples of this level of scrutiny are the different approaches taken by the DoJ regarding the AT&T–Time Warner and Disney–21st Century Fox mergers, both vertical mergers in the same industry. The AT&T–Time Warner merger, valued at US$85 billion, was announced in 2016. In late 2017, the DoJ challenged the merger in the courts, which found in favor of the merger by mid 2018, and the deal moved ahead. The DoJ appealed this decision, but in February 2019, an appeal court decision refused to block the merger. In contrast, the Disney–21st Century Fox merger, announced in early 2018 and valued at US$71 billion, was approved by all entities within six months and closed by March 2019. This transaction was uncharacteristically fast—deals of that size generally take at least a year or more to obtain approvals.

When conflicts between companies and regulators arise, it is often because of disagreements about how the markets are defined. Regulators must consider the market in terms of both geography and product. When considering the industry's geography, regulators must decide whether the relevant competitors are global, national, regional, or local. When considering product offerings, there may be one or multiple relevant product market overlaps. In some cases, the overlap may be clear, and in other transactions it may not be obvious.

Parties to the transaction are usually counseled by attorneys who have relevant experience in competition law. Most companies try to complete their analyses prior to signing a merger agreement in order to avoid entering into a long period of uncertainty while the government decides whether to challenge the transaction. Not only do delays increase costs, they may also cause the companies to lose other important strategic opportunities.

Most regulatory interventions involve horizontal mergers—for example, 88% of competition regulatory interventions in 2017 involved horizontal mergers. Nevertheless, regulatory intervention in vertical and conglomerate mergers, which are often less likely to have adverse competition effects than horizontal mergers, does occur and is increasing. Examples include the EC's prohibition of the Deutsche Börse–London Stock Exchange merger in 2017 (resulting, in part, from the merged entity's ability and incentive to hamper rivals' access to its own securities depository), as well as the DoJ's challenge to the AT&T–Time Warner merger.

7 TARGET COMPANY VALUATION: DISCOUNTED CASH FLOW ANALYSIS

g compare the discounted cash flow, comparable company, and comparable transaction analyses for valuing a target company, including the advantages and disadvantages of each;

In this section, we examine the analysis of merger activity from two perspectives. First, we discuss valuation of the target company, something of key importance for analysts on both sides of the deal as well as for shareholders as they all grapple to determine the fairness and adequacy of an offer. Then, we discuss the analysis of the bid. Analysts can estimate the distribution of benefits in a merger based on expected synergies relative to the premium paid for the target in excess of its intrinsic value.

7.1 Target Company Valuation

The three basic valuation techniques that companies and their advisers use to value companies in an M&A context are discounted cash flow analysis, comparable company analysis, and comparable transaction analysis. An analyst is likely to use some combination of these primary techniques, and possibly others, when gauging a company's fair value.

7.1.1 *Discounted Cash Flow Analysis*

Discounted cash flow (DCF) analysis, as it is generally applied in this context, discounts the company's expected future free cash flows to the present in order to derive an estimate for the company's value. **Free cash flow** (FCF) is the relevant measure in this context because it represents the actual cash that would be available to the company's investors after making all investments necessary to maintain the company as an ongoing enterprise. Free cash flows are the internally generated funds that can be distributed to the company's investors (e.g., shareholders and bondholders) without impairing the value of the company.

There are several variations to the models an analyst might use to estimate and discount free cash flows. Estimating a company's free cash flows begins with the creation of pro forma financial statements. The first step is to select an appropriate time horizon for the first stage. The first stage should include only those years over which the analyst feels capable of generating reasonably accurate estimates of the company's free cash flows. These free cash flow estimates are then discounted to their present value.

To incorporate value deriving from years beyond the first stage, the analyst estimates the value of expected second-stage free cash flows as of the end of the first stage. The result is the so-called terminal value (or continuing value) of the company. The analyst then discounts the terminal value back to the present. The sum of the two pieces (the present value of first-stage expected free cash flows plus the present value of the company's terminal value) is the estimated value of the company.

There is no standard approach for creating pro forma financial statements. The art of financial analysis involves an ability to use the appropriate tools and to exercise good judgment in order to produce the best possible estimates for each financial statement item. In the process, analysts make adjustments to their prior projections based on proposed synergies and the announced plans for the merged company. For example, duplicated resources might result in the sale of one of the target's divisions. Or, the operating costs might be adjusted downward in anticipation of economies of scale. These adjustments are easier to estimate in friendly mergers where the analyst has access to detailed financial data about the target than in hostile mergers. But even in a hostile merger scenario, an analyst with experience in the appropriate industry can still make reasonably good estimates.

Once pro forma financial statements have been generated, the analyst can begin the conversion from pro forma net income to pro forma free cash flow for each year of the first stage. The free cash flows are discounted back to present at the company's weighted average cost of capital (WACC). When evaluating the target from a non-control perspective, we would use the target's WACC, which reflects that company's existing business risk and operating environment. In anticipation of a merger, however, we would adjust that WACC to reflect any anticipated changes in the target's risk from such actions as a redeployment of assets or change in capital structure.

There are two standard methods for calculating a terminal value. The first makes use of the constant growth formula. To apply the constant growth formula, an analyst must select a terminal growth rate, which is the long-term equilibrium growth rate that the company can expect to achieve in perpetuity, accounting for both inflation and real growth. The terminal growth rate is often lower than the growth rate applied during the first stage because any advantages from synergies, new opportunities, or cost reductions are transitory as competitors adjust and the industry evolves over time. The constant growth formula can be applied whenever the terminal growth rate is less than the WACC.

A second method for estimating the terminal value involves applying a multiple at which the analyst expects the average company to sell at the end of the first stage. The analyst might use a free cash flow or other multiple that reflects the expected risk, growth, and economic conditions in the terminal year. Market multiples are rules of thumb applied by analysts, investment bankers, and venture capitalists to produce rough estimates of a company's value. Multiples tend to vary by industry. They can be based on anything applicable to the industry and correlated with market prices. Some service industries tend to be priced as multiples of EBITDA (earnings before interest, taxes, depreciation, and amortization). In contrast, retail stores in some industries might be priced based on multiples applied to floor space. In these cases, the respective multiples can be used directly to produce a terminal value, or they can be incorporated into a pro forma analysis to convert the multiple into a consistent value for free cash flow.

For example, if a company is in an industry where the typical company sells for about 20 times FCF and its free cash flow for the year is $1,799,000, then the company's terminal value estimate would be:

Terminal value = 20 × $1,799,000 = $35,980,000 = $36.0 million

Having established an estimate for the terminal value, the analyst must discount it back from the end of the estimate horizon to the present. The discount rate used is the same WACC estimate applied to discount the free cash flows.

The assumed terminal growth rate and WACC estimate can have a dramatic impact on the terminal value calculation: The final estimate of the company's value will only be as accurate as the estimates used in the model.

Advantages of Using Discounted Cash Flow Analysis

- Expected changes in the target company's cash flows (e.g., from operating synergies and cost structure changes) can be readily modeled.
- An estimate of intrinsic value based on forecast fundamentals is provided by the model.
- Changes in assumptions and estimates can be incorporated by customizing and modifying the model.

Disadvantages of Using Discounted Cash Flow Analysis

- It is difficult to apply when free cash flows do not align with profitability within the first stage. For example, a rapidly expanding company may be profitable but have negative free cash flows because of heavy capital expenditures to the horizon that can be forecast with confidence. The company's free cash flow value will then derive from a later and harder-to-estimate period when free cash flow turns positive.
- Estimating cash flows and earnings far into the future is not an exact science. There is a great deal of uncertainty in estimates for the following year, and even greater uncertainty in perpetuity.
- Estimates of discount rates can change over time because of capital market developments or changes that specifically affect the companies in question. These changes can also significantly affect acquisition estimates.
- Terminal value estimates often subject the acquisition value calculations to a disproportionate degree of estimate error. The estimate of terminal value can differ depending on the specific technique used. Additionally, the range of estimates can be affected dramatically by small changes in the assumed growth and WACC estimates.

8 TARGET COMPANY VALUATION: COMPARABLE COMPANY AND COMPARABLE TRANSACTION ANALYSIS

g compare the discounted cash flow, comparable company, and comparable transaction analyses for valuing a target company, including the advantages and disadvantages of each;

A second approach that investment bankers use to estimate acquisition values is called "comparable company analysis." In this approach, the analyst first defines a set of other companies that are similar to the target company under review. This set may include companies within the target's primary industry as well as companies in similar industries. The sample should be formed to include as many companies as possible that have similar size and capital structure to the target.

Once a set of comparable companies is defined, the next step is to calculate various relative value measures based on the current market prices of the comparable companies in the sample. Such valuation is often based on enterprise multiples. A company's enterprise value is the market value of its debt and equity minus the value of its cash and investments. Examples include enterprise value to free cash flow, enterprise value to EBITDA, enterprise value to EBIT, and enterprise value to sales. Because the denominator in such ratios is pre-interest, they may be preferred when the companies being compared have differences in leverage. The equity can also be valued directly using equity multiples, such as P/E, price to cash flow per share (P/CF), price to sales per share (P/S), and price to book value per share (P/BV).

The specific ratios that the analyst selects are determined by the industry under observation. Often, in addition to common market multiples, analysts will include industry-specific multiples. For instance, in the oil and gas industry, in addition to looking at price paid to earnings and cash flow ratios, many analysts evaluate the price paid per barrel of oil or per thousand cubic feet of natural gas reserves.

Analysts typically review the mean, median, and range for whichever metrics are chosen, and then they apply those values to corresponding estimates for the target to develop an estimated company value. This approach is quite similar to the one we discussed earlier for using multiples to produce a terminal value estimate. In this case, however, we are calculating various relative value metrics rather than using an industry rule of thumb.

Each metric (P/E, P/CF, etc.) is likely to produce a different estimate for the target's value. Analysts hope that these values converge because that increases confidence in the overall estimate. To the extent that they diverge, analysts must apply judgment and experience to decide which estimates are producing the most accurate market values.

It should be noted that the value determined up to this point in the process yields an estimate of where the target company should trade as a stock in the marketplace relative to the companies in the sample. To calculate an acquisition value, the analyst must also estimate a takeover premium. The **takeover premium** is the amount by which the takeover price for each share of stock must exceed the current stock price in order to entice shareholders to relinquish control of the company to an acquirer. This premium is usually expressed as a percentage of the stock price and is calculated as follows:

$$\mathrm{PRM} = \frac{(\mathrm{DP} - \mathrm{SP})}{\mathrm{SP}} \tag{1}$$

where

PRM = takeover premium (as a percentage of stock price)
DP = deal price per share of the target company
SP = stock price of the target company

The analyst must be careful to note any pre-deal jump in the price that may have occurred because of takeover speculation in the market. In these cases, the analyst should apply the takeover premium to a selected representative price from before any speculative influences on the stock price. To calculate the relevant takeover premium for a transaction, analysts usually compile a list of the takeover premiums paid for companies similar to the target. Preferably, the calculations will be from the recent past because acquisition values and premiums tend to vary over time and economic cycles.

Advantages of Using Comparable Company Analysis

- This method provides a reasonable approximation of a target company's value relative to similar companies in the market. It assumes that "like" assets should be valued on a similar basis in the market.
- With this method, most of the required data are readily available.
- The estimates of value are derived directly from the market. This approach is unlike the discounted cash flow method, in which the takeover value is determined based on many assumptions and estimates.

Disadvantages of Using Comparable Company Analysis

- The method is sensitive to market mispricing. To illustrate the issue, suppose that the comparable companies are overvalued. A valuation relative to those companies may suggest a value that is too high in the sense that values would be revised downward when the market corrects.
- Using this approach yields a market-estimated fair *stock* price for the target company. To estimate a fair *takeover* price, analysts must additionally estimate a fair takeover premium and use that information to adjust the estimated stock price.
- The analysis may be inaccurate because it is difficult for the analyst to incorporate any specific plans for the target (e.g., changing capital structure or eliminating duplicate resources) in the analysis.
- The data available for past premiums may not be timely or accurate for the particular target company under consideration.

8.1 Comparable Transaction Analysis

A third common approach to value target companies is known as "comparable transaction analysis." This approach is closely related to comparable company analysis except that the analyst uses details from recent takeover transactions for comparable companies to make direct estimates of the target company's takeover value.

The first step in comparable transaction analysis is to collect a relevant sample of recent takeover transactions. The sample should be as broad as possible but limited to companies in the same industry as the target, or at least closely related. Once the transactions are identified, the analyst can look at the same types of relative value multiples that were used in comparable company analysis (P/E, P/CF, other industry-specific multiples, etc.). In this case, however, we are not comparing the target against market multiples. For this approach we compare the multiples actually paid for similar companies in other M&A deals. As before, analysts typically look at **descriptive statistics**, such as the mean, median, and range for the multiples, and use judgment and experience when applying that information to estimate the target's value.

EXAMPLE 6

Comparable Transaction Analysis

Joel Hofer, an analyst with an investment banking firm, has been asked to estimate a fair price for the General Health Company's proposed acquisition of Medical Services, Inc. He has already taken the initial step and assembled a sample containing companies involved in acquisitions within the same industry in which

Medical Services operates. These companies have all been acquired in the past two years. Details on the acquisition prices and relevant pricing variables are shown in the following table.

Valuation Variables	Acquired Company 1	Acquired Company 2	Acquired Company 3
Acquisition share price ($)	35.00	16.50	87.00
Earnings per share ($)	2.12	0.89	4.37
Cash flow per share ($)	3.06	1.98	7.95
Book value per share ($)	9.62	4.90	21.62
Sales per share ($)	15.26	7.61	32.66

The next step in the process is for Hofer to calculate the multiples at which each company was acquired:

Relative Valuation Ratio	Comparable Company 1	Comparable Company 2	Comparable Company 3	Mean
P/E	16.5	18.5	19.9	18.3
P/CF	11.4	8.3	10.9	10.2
P/BV	3.6	3.4	4.0	3.7
P/S	2.3	2.2	2.7	2.4

After reviewing the distribution of the various values around their respective means, Hofer is confident about using the mean value for each ratio because the range in values above and below the mean is reasonably small. Based on his experience with this particular industry, Hofer believes that cash flows are a particularly important predictor of value for these types of companies. Consequently, instead of finding an equally weighted average, Hofer has decided to apply the following weights for calculating a weighted average estimated price.

Target Company Valuation Variables

	Target Company (a)	Comparable Companies' Valuation Multiples	Mean Multiple Paid for Comparable Companies (b)	Estimated Takeover Value Based on Comparables (c = a × b)	Weight (d)	Weighted Estimates (e = c × d)
Earnings per share	$ 2.62	P/E	18.3	$47.95	20%	$ 9.59
Cash flow per share	$ 4.33	P/CF	10.2	$44.17	40%	$17.67
Book value per share	$12.65	P/BV	3.7	$46.81	20%	$ 9.36
Sales per share	$22.98	P/S	2.4	$55.15	20%	$11.03
Weighted average estimate						**$47.65**

In sum, Hofer multiplied each valuation multiple by the corresponding variable for the target company to produce an estimated takeover value based on each comparable. He then decided to overweight cash flow per share and calculated a weighted average to determine an overall takeover value estimate of

$47.65 per share for Medical Services, Inc. The same procedure could be repeated using the median, high, and low valuations for each of the valuation variables. This process would generate a range of takeover values for Medical Services, Inc.

Advantages of Comparable Transaction Approach

- It is not necessary to separately estimate a takeover premium. The takeover premium is derived directly from the comparable transactions.
- The takeover value estimates come directly from values that were recently established in the market. This approach is unlike the discounted cash flow method, in which the takeover value is determined based on many assumptions and estimates.
- The use of prices established through other recent transactions reduces litigation risk for both companies' board of directors and managers regarding the merger transaction's pricing.

Disadvantages of Comparable Transaction Approach

- Because the value estimates assume that the M&A market has properly determined the intrinsic value of the target companies, there is a risk that the real takeover values in past transactions were not accurate. If true, these inaccurate takeover values are imputed in the estimates based on them.
- There may be no, or an inadequate number of, comparable transactions to use for calculating the takeover value. In these cases, analysts may try to use data from related industries. These derived values may not be accurate for the specific industry under study.
- The analysis may be inaccurate because it is difficult for the analyst to incorporate any specific plans for the target (e.g., changing capital structure or eliminating duplicate resources) into the analysis.

9 MERGER BID ANALYSIS

h evaluate a takeover bid and its effects on the target shareholders versus the acquirer shareholders;

i explain how price and payment method affect the distribution of risks and benefits in M&A transactions;

Assessing the target's value is important, but it is insufficient for an assessment of the deal. Even if both the acquirer and the target separately agree on the target company's underlying value, the acquirer will obviously want to pay the lowest price possible while the target will negotiate for the highest price possible. Both the price and form of payment in a merger will determine the distribution of risks and benefits between the counterparties to the deal.

Acquirers must typically pay a premium to induce the owners of the target company to relinquish control. In an M&A transaction, the premium is the portion of the compensation received by the target company's shareholders that is in excess of the pre-merger market value of their shares. The target company's managers will attempt to negotiate the highest possible premium relative to the value of the target company.

A burst of speculative stock activity typically accompanies merger negotiations. This activity usually results in a higher share price for the target company in anticipation of a takeover premium. When conducting a bid evaluation, the analyst should use some combination of an assessment of the company's intrinsic value and a representative stock price from before any merger speculation.

$$\text{Target shareholders' gain} = \text{Premium} = P_T - V_T \quad (2)$$

where

P_T = price paid for the target company
V_T = pre-merger value of the target company

The acquirer is willing to pay in excess of the target company's value in anticipation of reaping its own gains. The acquirer's gains are derived from the synergies generated by the transaction—usually from some combination of cost reductions and revenue enhancements. All else constant, synergies increase the value of the acquiring company by the value of the synergies minus the premium paid to target shareholders:

$$\text{Acquirer's gain} = \text{Synergies} - \text{Premium} = S - (P_T - V_T) \quad (3)$$

where

S = synergies created by the business combination

The post-merger value of the combined company is a function of the two companies' pre-merger values, the synergies created by the merger, and any cash paid to the target shareholders as part of the transaction:

$$V_{A^*} = V_A + V_T + S - C \quad (4)$$

where

V_{A^*} = post-merger value of the combined companies
V_A = pre-merger value of the acquirer
C = cash paid to target shareholders

When evaluating a bid, the pre-merger value of the target company is the absolute minimum bid that target shareholders should accept. Individual shareholders could sell their shares in the open market for that much instead of tendering their shares for a lower bid. At the other extreme, unless there are mitigating circumstances or other economic justifications, the acquirer's shareholders would not want to pay more than the pre-merger value of the target company plus the value of any expected synergies. If the acquirer were to pay more than that, then the acquirer's post-merger value would be lower than its pre-merger value—therefore, a reduction in shareholder value.

Bidding should thus generally be confined to a range dictated by the synergies expected from the transaction, with each side of the transaction negotiating to capture as much of the synergies as possible. Consequently, analysis of a merger depends not only on an assessment of the target company's value but also on estimates of the value of any synergies that the merged company is expected to attain.

Confidence in synergy estimates will have implications not only for the bid price but also for the method of payment. The reason for this is that different methods of payment for the merger—cash offer, stock offer, or mixed offer—inherently provide varying degrees of risk shifting with respect to misestimating the value of merger synergies. To see why this is the case, we will first walk through the evaluation of an offer for each method of payment.

EXAMPLE 7

Adagio Software Offer

Adagio Software, Inc., and Tantalus Software Solutions, Inc., are negotiating a friendly acquisition of Tantalus by Adagio. The management teams at both companies have informally agreed upon a transaction value of about €12.00 per share of Tantalus Software Solutions stock but are presently negotiating alternative forms of payment. Sunil Agrawal, CFA, works for Tantalus Software Solutions' investment banking team and is evaluating three alternative offers presented by Adagio Software:

1 Cash Offer: Adagio will pay €12.00 per share of Tantalus stock.
2 Stock Offer: Adagio will give Tantalus shareholders 0.80 shares of Adagio stock per share of Tantalus stock.
3 Mixed offer: Adagio will pay €6.00 plus 0.40 shares of Adagio stock per share of Tantalus stock.

Agrawal estimates that the merger of the two companies will result in economies of scale with a net present value of €90 million. To aid in the analysis, Agrawal has also compiled the following data:

	Adagio	Tantalus
Pre-merger stock price	€15.00	€10.00
Number of shares outstanding (millions)	75	30
Pre-merger market value (millions)	€1,125	€300

Based only on the information given, which of the three offers should Agrawal recommend to the Tantalus Software Solutions management team?

Solution:

Alternative 1:

Cash offer of €12.00 per share of Tantalus stock. A cash offer is the most straightforward and easiest to evaluate. The price paid for the target company, P_T, is equal to the cash price per share times the number of target shares: €12.00 × 30 million = €360 million. Because Tantalus' value, V_T, is €300 million, the premium is the difference between the two: €360 million – €300 million = €60 million.

Adagio's gain in this transaction is €30 million, which equals the value of the synergies minus the premium paid to Tantalus shareholders. A longer way to get to the same conclusion is to remember that the value of the post-merger combined company equals the pre-merger values of both companies plus the value of created synergies less the cash paid to target shareholders: $V_{A^*} = V_A + V_T + S - C$ = €1,125 + 300 + 90 – 360 = €1,155 million. Adagio's pre-merger market value was €1,125 million, and Adagio's gain from the transaction is thus €1,155 – 1,125 = €30 million. Agrawal can divide the post-merger market value of €1,155 by the number of shares outstanding to determine Adagio's post-merger stock price. Under a cash offer, Adagio will not issue additional shares of stock, so Agrawal divides €1,155 by 75 million shares to see that, all else constant, Adagio's stock price after the merger should rise to €15.40.

In an all-cash offer, Tantalus shareholders receive €60 million—the premium. Adagio's gain from the transaction equals the expected synergies (€90 million) less the premium paid to Tantalus shareholders (€60 million), which equals €30 million.

Alternative 2:

Stock offer of 0.80 shares of Adagio stock per share of Tantalus stock. A stock offer of 0.80 shares might seem at first glance to be equivalent to a cash offer of €12.00, because Adagio's share price is €15.00 (0.80 × €15 = €12). The results are actually slightly different, however, because Agrawal must account for the dilution that occurs when Adagio issues new shares to Tantalus stockholders. Because there are 30 million shares of the target outstanding, Adagio must issue 30 million × 0.80 = 24 million shares.

To calculate the price paid for Tantalus, Agrawal starts by ascertaining the post-merger value of the combined company. Agrawal uses the same formula as before while using a value of zero for C because this is a stock offer and no cash is changing hands: $V_{A^*} = V_A + V_T + S - C$ = €1,125 + 300 + 90 − 0 = €1,515 million. Next, Agrawal divides Adagio's post-merger value by the post-merger number of shares outstanding. Because Adagio issued 24 million shares to complete the transaction, Agrawal adds 24 million to the original 75 million shares outstanding and arrives at 99 million. Dividing the post-merger market value by the post-merger number of shares outstanding, Agrawal determines that the value of each share given to Tantalus shareholders is actually worth €1,515 million/99 million = €15.30 and that the total value paid to Tantalus shareholders is €15.30 × 24 million = €367 million.

The premium is thus €367 − 300 = €67 million, which is €7 million higher than it was for the cash offer. Because the target shareholders receive €7 million more than in the cash offer, the acquirer's gain is correspondingly less. Because the synergies are valued at €90 million and the premium is €67 million, the acquirer's gain under a stock transaction with these terms is €23 million.

Alternative 3:

Mixed offer of €6.00 plus 0.40 shares of Adagio stock per share of Tantalus stock. A mixed offer will still result in some dilution, although not as much as a pure stock offer. Agrawal begins by calculating Adagio's post-merger value. Agrawal inserts €180 million for C because the company is paying €6 per share for 30 million shares: $V_{A^*} = V_A + V_T + S - C$ = €1,125 + 300 + 90 − 180 = €1,335 million.

Next, Agrawal determines that Adagio must issue 12 million shares to complete the transaction: 0.40 × 30 million = 12 million. Combined with the original 75 million shares outstanding, Adagio's post-merger number of shares outstanding will be 87 million. Agrawal divides €1,335 million by 87 million and finds that each share given to the Tantalus shareholders is worth €15.35.

The total value paid to Tantalus shareholders includes a cash component, €6.00 × 30 million = €180 million, and a stock component, 12 million shares issued with a value of €15.35 each equaling €184 million. Added together, the total value is €180 + €184 = €364 million, and the premium is therefore €364 million − €300 million = €64 million. The acquirer's gain is €26 million.

Conclusion:

Agrawal should recommend that the Tantalus Software Solutions management team opt for the all-stock offer because that alternative provides Tantalus shareholders the most value (the highest premium).

In Example 7, Adagio's gain ranged from €30 million in the pure cash offer to €26 million in the mixed offer and €23 million in the pure stock offer. If the dilution of a stock offer reduces the acquirer's gains from the transaction, why would an acquirer ever pay stock in a merger? The answer brings us back to the beginning of the section, where we pointed out that the price and form of payment in a merger determine the distribution of risks and benefits. The choice of payment method is influenced by both parties' confidence in the estimated synergies and the relative value of the acquirer's shares.

The more confident the managers are that the estimated synergies will be realized, the more the acquiring managers will prefer to pay with cash and the more the target managers will prefer to receive stock. And the more the merger is paid for with the acquirer's stock, the more that the risks and benefits of realizing synergies will be passed on to the target shareholders. For example, in the cash offer we analyzed in Example 7, if the synergies later turned out to be worth €60 million rather than the originally estimated €90 million, then the Tantalus shareholders' premium would be unaffected but Adagio's gain would completely evaporate. In contrast, if the synergies were greater than estimated, then Tantalus shareholders' premium would still be unchanged but Adagio's gain would increase.

When stock is used as payment, the target shareholders become part owners of the acquiring company. In the Adagio stock offer, Tantalus shareholders would receive 24 million shares and thus own 24/99 (24.2%) of the post-merger acquirer. Thus, Tantalus shareholders would participate by that proportion in any deviation of synergies from pre-merger estimates. If synergies were worth only €60 million, Adagio would lose its €23 million gain and Tantalus shareholders' gain from the transaction would fall by €7 million.

The other factor affecting the method of payment decision relates to the counterparties' confidence in the companies' relative values. The more confident managers are in estimates of the target company's value, the more the acquirer will prefer cash and the more the target will prefer stock. For example, what if Adagio estimates that Tantalus is worth more than €10 per share and consequently offers €12.50 per share in cash instead of €12.00? In that case, Tantalus shareholders would receive a premium that is €15 million higher and Adagio's gain from the transaction would be reduced by €15 million to €15 million.

10 BENEFITS FROM MERGERS

j describe characteristics of M&A transactions that create value;

What does the empirical evidence say about who actually gains in business combinations? Studies on the performance of mergers fall into two categories: short-term performance studies, which examine stock returns surrounding merger announcement dates, and long-term performance studies of post-merger companies. The empirical evidence suggests that merger transactions create value for target company shareholders in the short run. On average, target shareholders reap 30% premiums over the stock's pre-announcement market price, and the acquirer's stock price falls, on average, between 1% and 3%. Moreover, on average, both the acquirer and target tend to see higher stock returns surrounding cash acquisition offers than around share offers.

The high average premiums paid to target shareholders may be attributed, at least partly, to the winner's curse—the tendency for competitive bidding to result in overpayment. Even if the average bidding company accurately estimates the target company's value, some bidders will overestimate the target's value and other potential buyers will underestimate its value. Unless the winner can exploit some strong synergies that are unavailable to other bidders, the winning bidder is likely to be the one who most overestimates the value.

Roll argues that high takeover bids may stem from hubris, from "the overbearing presumption of bidders that their valuations are correct." Implied in this behavior is that these executives are somehow smarter than everyone else and can see value where others cannot. Even if there were no synergies from a merger, managerial hubris would still lead to higher-than-market bids and a transfer of wealth from the acquiring company's shareholders to the target's shareholders. The empirical evidence is consistent with Roll's hubris hypothesis.

When examining a longer period, empirical evidence shows that acquirers outperformed comparable non-acquirer companies over a five-year period from 2011–2016. This outperformance has been attributed to the reinvestment of capital via M&A into the business and growth, whereas the non-acquirers allocated a large portion of their capital to share buybacks and dividends, which ultimately shortchanged shareholders through poor growth. Total shareholder returns to acquiring companies over 2011–16 were about 16%, compared with 8% for non-acquirers.

Nevertheless, it is important that analysts thoroughly scrutinize estimates of synergy and post-merger value creation by deal. Analysts must attempt to distinguish those deals that create value and those that do not. Even though investment in quality growth via M&As produces outperformance for shareholders, companies with surplus cash but few new investment opportunities are prone to make acquisitions rather than distribute excess cash to shareholders. When distinguishing value-creating deals, analysts must examine the operational strengths possessed by the acquirer and the target to discern the likelihood that post-merger synergies will be achieved.

Based on past empirical results, the following are characteristics of M&A deals that create value:

- **The buyer is strong**. Acquirers whose earnings and share prices grow at a rate above the industry average for three years before the acquisition earn statistically significant positive returns on announcement.
- **The transaction premiums are relatively low**. Acquirers earn negative returns on announcement when paying a high premium.
- **The number of bidders is low**. Acquirer stock returns are negatively related to the number of bidders.
- **The initial market reaction is favorable**. Initial market reaction is an important barometer for the value investors place on the gains from merging as well as an indication of future returns. If the acquiring company's stock price falls when the deal is announced, investors are sending a message that the merger benefits are doubtful or that the acquirer is paying too much.

CORPORATE RESTRUCTURING 11

k compare and contrast equity carve-outs, spin-offs, split-offs, and liquidation;

l explain common reasons for restructuring.

Just as mergers and acquisitions are a means by which companies grow bigger, a corporate restructuring is usually used in reference to ways that companies get smaller—by selling, splitting off, or otherwise shedding operating assets. When a company decides to sell, liquidate, or spin off a division or a subsidiary, it is referred to as a **divestiture**.

Given that, as we have discussed, many companies have great difficulty actually achieving the planned synergies of a business combination, it is unsurprising that many companies seek to undo previous mergers. Indeed, periods of intense merger activity are often followed by periods of heightened restructuring activity. Of course, previous mergers that did not work out as planned are not the only reason companies may choose to divest assets. Some of the common reasons for restructuring follow:

- **Change in strategic focus.** Either through acquisitions or other investments over time, companies often become engaged in multiple markets. Management may hope to improve performance by eliminating divisions or subsidiaries that are outside the company's core strategic focus.
- **Poor fit.** Sometimes a company will decide that a particular division is a poor fit within the overall company. For example, the company may lack the expertise or resources to fully exploit opportunities pursued by the division and may decide to sell the segment to another company that does have the necessary resources. Or, the division might simply not be profitable enough to justify continued investment based on the company's cost of capital.
- **Reverse synergy.** Managers may feel that a segment of the company is undervalued by the market, sometimes because of poor performance of the overall company or because the division is not a good strategic fit. In these cases, it is possible that the division and the company will be worth more separately than combined.
- **Financial or cash flow needs.** If times are tough, managers may decide to sell off portions of the company as a means by which to raise cash or cut expenses.

Restructuring can take many forms, but the three basic ways that a company divests assets are a sale to another company, a spin-off to shareholders, or liquidation. As part of a sale to another company, a company might offer to sell the assets of a division or may offer an equity carve-out. An **equity carve-out** involves the creation of a new legal entity and sales of equity in it to outsiders.

In a **spin-off**, shareholders of the parent company receive a proportional number of shares in a new, separate entity. Whereas the sale of a division results in an inflow of cash to the parent company, a spin-off does not. A spin-off simply results in shareholders owning stock in two different companies where there used to be one. A similar type of transaction is called a **split-off**, whereby some of the parent company's shareholders are given shares in a newly created entity in exchange for their shares of the parent company. **Liquidation** involves breaking up a company, division, or subsidiary and selling off its assets piecemeal. For a company, liquidation is typically associated with bankruptcy.

SUMMARY

Mergers and acquisitions are complex transactions. The process often involves not only the acquiring and target companies but also a variety of other stakeholders, including competition law regulatory agencies. To fully evaluate a merger, analysts must ask two fundamental questions: First, will the transaction create value; and second, does the acquisition price outweigh the potential benefit? This reading has made the following important points.

- An acquisition is the purchase of some portion of one company by another. A merger represents the absorption of one company by another such that only one entity survives following the transaction.

- Mergers can be categorized by the form of integration. In a statutory merger, one company is merged into another; in a subsidiary merger, the target becomes a subsidiary of the acquirer; and in a consolidation, both the acquirer and target become part of a newly formed company.
- Horizontal mergers occur among peer companies engaged in the same kind of business. Vertical mergers occur among companies along a given value chain. Conglomerates are formed by companies in unrelated businesses.
- Merger activity tends to be concentrated in industries undergoing changes, such as deregulation or technological advancement.
- The motives for M&A activity include synergy, growth, market power, the acquisition of unique capabilities and resources, diversification, increased earnings, management's personal incentives, tax considerations, and the possibilities of uncovering hidden value. Cross-border motivations may involve technology transfer, product differentiation, government policy, and the opportunities to serve existing clients abroad.
- A merger transaction may take the form of a stock purchase (when the acquirer gives the target company's shareholders some combination of cash or securities in exchange for shares of the target company's stock) or an asset purchase (when the acquirer purchases the target company's assets and payment is made directly to the target company). The decision of which approach to take will affect other aspects of the transaction, such as how approval is obtained, which laws apply, how the liabilities are treated, and how the shareholders and the company are taxed.
- The method of payment for a merger can be cash, securities, or a mixed offering with some of both. The exchange ratio in a stock or mixed offering determines the number of shares that stockholders in the target company will receive in exchange for each of their shares in the target company.
- Hostile transactions are those opposed by target managers, whereas friendly transactions are endorsed by the target company's managers. There are a variety of both pre- and post-offer defenses a target can use to ward off an unwanted takeover bid.
- Examples of pre-offer defense mechanisms include poison pills and puts, incorporation in a jurisdiction with restrictive takeover laws, staggered boards of directors, restricted voting rights, supermajority voting provisions, fair price amendments, and golden parachutes.
- Examples of post-offer defenses include the "just say no" defense, litigation, greenmail, share repurchases, leveraged recapitalization, "crown jewel" defense, Pac-Man® defense, or finding a white knight or a white squire.
- Competition law prohibits mergers and acquisitions that impede competition.
- Three major tools for valuing a target company are discounted cash flow analysis (which involves discounting free cash flows estimated with pro forma financial statements), comparable company analysis (which estimates a company's intrinsic value based on relative valuation metrics for similar companies), and comparable transaction analysis (which derives valuation from details of recent takeover transactions for comparable companies).
- In a merger bid, the gain to target shareholders is measured as the control premium, which equals the price paid for the target company in excess of its value. The acquirer gains equal the value of any synergies created by the merger minus the premium paid to target shareholders. Together, the bid and the method of

payment determine the distribution of risks and returns among acquirer and target shareholders with regard to realization of synergies as well as correct estimation of the target company's value.

- The empirical evidence suggests that merger transactions create value for target company shareholders. Acquirers, in contrast, tend to accrue value in the years following a merger. This finding suggests that synergies are often overestimated or difficult to achieve.
- When a company decides to sell, liquidate, or spin off a division or a subsidiary, it is referred to as a divestiture. Companies may divest assets for a variety of reasons, including a change in strategic focus, poor fit of the asset within the corporation, reverse synergy, or cash flow needs.
- The three basic ways that a company divests assets are a sale to another company, a spin-off to shareholders, and liquidation.

PRACTICE PROBLEMS

The following information relates to Questions 1–5

Modern Auto, an automobile parts supplier, has made an offer to acquire Sky Systems, creator of software for the airline industry. The offer is to pay Sky Systems' shareholders the current market value of their stock in Modern Auto's stock. The relevant information used in those calculations is as follows:

	Modern Auto	Sky Systems
Share price	$40	$25
Number of outstanding shares (millions)	40	15
Earnings (millions)	$100	$30

Although the combined company's total earnings will not increase and are estimated to be $130 million, Charles Wilhelm (treasurer of Modern Auto) argues that there are two attractive reasons to merge. First, Wilhelm says, "The merger of Modern Auto and Sky Systems will result in lower risk for our shareholders because of the diversification effect." Second, Wilhelm also says, "If our EPS increases, our stock price will increase in line with the EPS increase because our P/E will stay the same."

Sky Systems managers are not interested in the offer by Modern Auto. The managers, instead, approach HiFly, Inc., which is in the same industry as Sky Systems, to see if it would be interested in acquiring Sky Systems. HiFly is interested, and both companies believe there will be synergies from this acquisition. If HiFly were to acquire Sky Systems, it would do so by paying $400 million in cash.

1 The acquisition of Sky Systems by Modern Auto and the acquisition of Sky Systems by HiFly, respectively, would be examples of a:

A vertical merger and a horizontal merger.

B conglomerate merger and a vertical merger.

C conglomerate merger and a horizontal merger.

2 If Sky Systems were to be acquired by Modern Auto under the terms of the original offer, the post-merger EPS of the new company would be *closest* to:

A $2.00.

B $2.32.

C $2.63.

3 Are Wilhelm's two statements about his shareholders benefiting from the diversification effect of the merger and about the increase in the stock price, respectively, correct?

	The Merger Will Result in Lower Risk for Shareholders	Stock Price Will Increase in Line with the EPS Increase
A	No	No
B	No	Yes
C	Yes	No

© 2013 CFA Institute. All rights reserved.

4 Which of the following defenses *best* describes the role of HiFly in the acquisition scenario?

A Crown jewel

B Pac-Man®

C White knight

5 Suppose HiFly acquires Sky Systems for the stated terms. The gain to Sky Systems shareholders resulting from the merger transaction would be *closest* to:

A $25 million.

B $160 million.

C $375 million.

The following information relates to Question 6

Kinetic Corporation is considering acquiring High Tech Systems. Jim Smith, vice president of finance at Kinetic, is conducting the analysis of High Tech. Smith is aware of several approaches that could be used for this purpose. He plans to consider each of these approaches in his analysis and has collected or estimated the necessary financial data.

While discussing his analysis with a colleague, Smith makes two comments. His first comment is: "If there were a pre-announcement run-up in Quadrant's price because of speculation, the takeover premium should be computed based on the price prior to the run-up." Smith's second comment is: "Because the comparable transaction approach is based on the acquisition price, the takeover premium is implicitly recognized in this approach."

6 Are Smith's two comments about his analysis correct?

A Both of his comments are correct.

B Both of his comments are incorrect.

C His first comment is correct, and his second comment is incorrect.

The following information relates to Questions 7–12 and is based on "Corporate Governance" and this reading

Mark Zin and Stella Lee are CEO and CFO, respectively, of Moonbase Corporation. They are concerned that Moonbase is undervalued and subject to a hostile takeover bid. To assess the value of their own firm, they are reviewing current financial data for Jupiter PLC, Saturn Corporation, and Voyager Corporation, three firms they believe are comparable to Moonbase.

Relative Valuation Ratio	Jupiter	Saturn	Voyager
P/E	23.00	19.50	21.50
P/B	4.24	5.25	4.91
P/CF	12.60	11.40	13.30

Zin believes Moonbase should trade at similar multiples to these firms and that each valuation ratio measure is equally valid. Moonbase has a current stock price of \$34.00 per share, earnings of \$1.75 per share, book value of \$8.50 per share, and cash flow of \$3.20 per share. Using the average of each of the three multiples for the three comparable firms, Zin finds that Moonbase is undervalued.

Lee states that the low valuation reflects current poor performance of a subsidiary of Moonbase. She recommends that the board of directors consider divesting the subsidiary in a manner that would provide cash inflow to Moonbase.

Zin proposes that some action should be taken before a hostile takeover bid is made. He asks Lee if changes can be made to the corporate governance structure in order to make it more difficult for an unwanted suitor to succeed.

In response, Lee makes two comments of actions that would make a hostile takeover more difficult. Lee's first comment is, "Moonbase can institute a poison pill that allows our shareholders, other than the hostile bidder, to purchase shares at a substantial discount to current market value." Lee's second comment is, "Moonbase can instead institute a poison put. The put allows shareholders the opportunity to redeem their shares at a substantial premium to current market value."

Zin is also concerned about the general attitude of outside investors with the governance of Moonbase. He has read brokerage reports indicating that the Moonbase governance ratings are generally low. Zin believes the following statements describe characteristics that should provide Moonbase with a strong governance rating.

Statement 1 Moonbase's directors obtain advice from the corporate counsel to aid them in assessing the firm's compliance with regulatory requirements.

Statement 2 Five of the 10 members of the board of directors are not employed by Moonbase and are considered independent. Although not employed by the company, two of the independent directors are former executives of the company and thus can contribute useful expertise relevant for the business.

Statement 3 The board's audit committee is organized so as to have sufficient resources to carry out its task, with an internal staff that reports routinely and directly to the audit committee.

Zin is particularly proud of the fact that Moonbase has begun drafting a "Statement of Corporate Governance" (SCG) that will be available on the company website for viewing by shareholders, investment analysts, and any interested stakeholders. In particular, the SCG pays special attention to policies that ensure effective contributions from the board of directors. These policies include the following:

Policy 1 Training is provided to directors prior to joining the board and periodically thereafter.

Policy 2 Statements are provided of management's assessment of the board's performance of its fiduciary responsibilities.

Policy 3 Statements are provided of directors' responsibilities regarding oversight and monitoring of the firm's risk management and compliance functions.

Zin concludes the discussion by announcing that Johann Steris, a highly regarded ex-CFO of a major corporation, is under consideration as a member of an expanded board of directors. Zin states that Steris meets all the requirements as an independent director, including the fact that he will not violate the interlocking directorship requirement. Steris also will bring experience as a member of the compensation committee of the board of another firm. He also comments that Steris desires to serve on either the audit or compensation committee of the Moonbase board and that good governance practice suggests that Steris would not be prohibited from serving on either committee.

7 The value the CEO estimated based on comparable company analysis is *closest* to:
   A $37.33.
   B $39.30.
   C $40.80.
8 The divestiture technique that Lee is recommending is *most likely*:
   A a spin-off.
   B a split-off.
   C an equity carve-out.
9 With regard to poison pills and puts, Lee's comments are:
   A correct.
   B incorrect with regard to the poison put.
   C incorrect with regard to the poison pill.
10 Which statement by Zin provides the *most* support for a strong governance rating?
   A Statement 1
   B Statement 2
   C Statement 3
11 Which policy of the Statement of Corporate Governance is *least likely* to ensure effective contributions from the board of directors?
   A Policy 1
   B Policy 2
   C Policy 3
12 Is Zin's comment that good governance practice does not preclude Steris from serving on either of the two committees of the Moonbase board correct?
   A Yes.
   B No, good governance practice precludes Steris from serving on the audit committee.
   C No, good governance practice precludes Steris from serving on the compensation committee.

The following information relates to Questions 13–15

Josh Logan is a buy-side equity analyst who follows Durtech. Logan's supervisor believes that Durtech is a likely takeover candidate and has asked Logan to estimate the company's value per share in the event of an all-stock takeover bid. Logan plans to estimate Durtech's value per share using three approaches: discounted cash flow, comparable company analysis, and comparable transaction analysis.

Durtech has 1.2 million common shares outstanding and no outstanding long-term debt or preferred stock. Logan estimates that Durtech's free cash flows at the end of the next three years will be $5.0 million, $6.0 million, and $7.0 million, respectively. After Year 3, he projects that free cash flow will grow at 5% per year. He determines the appropriate discount rate for this free cash flow stream is 15% per year.

Applying discounted cash flow analysis to the preceding information, Logan determines that Durtech's fair enterprise value is $61.8 million. In a separate analysis based on ratios, Logan estimates that at the end of the third year, Durtech will be worth 10 times its Year 3 free cash flow.

Logan gathers data on two companies comparable to Durtech: Alphatech and Betatech. He believes that price-to-earnings, price-to-sales, and price-to-book-value per share of these companies should be used to value Durtech. The relevant data for the three companies are given in Exhibit 1.

Exhibit 1 Valuation Variables for Durtech and Comparable Companies

Valuation Variables	Alphatech	Betatech	Durtech
Current stock price ($)	72.00	45.00	24.00
Earnings per share ($)	2.00	1.50	1.00
Sales per share ($)	32.00	22.50	16.00
Book value per share ($)	18.00	10.00	8.00

Logan also identifies one recent takeover transaction and analyzes its takeover premium (the amount by which its takeover price per share exceeds its current stock price). Omegatech is comparable to the possible transaction on Durtech. Omegatech had a stock price of $44.40 per share prior to a newspaper report of a takeover rumor. After the takeover rumor was reported, the price rose immediately to $60.30 per share. Eventually, the takeover offer was accepted by Omegatech's shareholders for $55.00 per share. One-year trailing earnings per share for Omegatech immediately prior to the takeover were $1.25 per share.

13 Based on Exhibit 1 and the mean of each of the valuation ratios, Logan's estimate of Durtech's value per share should be *closest* to:

A $30.44.

B $33.67.

C $34.67.

14 Based on the premium on a recent comparable transaction, Logan's best estimate of the takeover premium for Durtech is *closest* to:

A 19.9%.

B 23.9%.

C 35.8%.

15 Using comparable transaction analysis, Logan's estimate of the fair acquisition value per share for Durtech is *closest* to:

A $35.52.

B $42.59.

C $44.00.

SOLUTIONS

1 C is correct. These are conglomerate and horizontal mergers, respectively.

2 C is correct. EPS is \$2.63.

Because Modern Auto's stock price is \$40 and Sky Systems' stock price is \$25, Modern Auto will acquire Sky Systems by exchanging 1 of its shares for 40/25 = 1.60 shares of Sky Systems. There are 15 million shares of Sky Systems. Their acquisition will take 15/1.60 = 9.375 million shares of Modern Auto. The total number of shares after the merger = 49.375 million. The EPS after the merger = 130/49.375 = \$2.63.

3 A is correct. Both of the statements by Wilhelm are wrong.

The first statement is wrong because diversification by itself does not lower risk for shareholders. Investors can diversify very cheaply on their own by purchasing stocks of different companies (for example, a Modern Auto shareholder could purchase stocks of Sky Systems).

The second statement is also wrong. The P/E will not necessarily remain the same following the merger and is more likely to decline. The pre-merger P/E for Modern Auto is 40/2.50 = 16. After the merger, the EPS would be \$130 million/49.375 million shares, or 2.6329. The post-merger P/E will probably fall to 40/2.6329 = 15.19.

4 C is correct. HiFly is a white knight.

5 A is correct.

$$\text{Target shareholders' gain} = \text{Premium} = P_T - V_T$$

P_T = Price paid for the target company = \$400 million as provided in the vignette

V_T = Pre-merger value of the target = \$25 share price × 15 million shares = \$375 million

\$400 million – \$375 million = \$25 million

6 A is correct. Both of Smith's statements are correct.

If there was a pre-announcement run-up in Quadrant's price because of speculation, the takeover premium should be computed based on the price prior to the run-up. Because the comparable transaction approach is based on the acquisition price, the takeover premium is implicitly recognized in this approach.

7 B is correct. Value is \$39.30.

Average P/E is 21.33 = (23.00 + 19.50 + 21.50)/3

Value based on P/E = 21.33 (1.75) = 37.33

Average P/B is 4.80 = (4.24 + 5.25 + 4.91)/3

Value based on P/B = 4.80 (8.50) = 40.80

Average P/CF is 12.43 = (12.60 + 11.40 + 13.30)/3

Value based on P/CF = 12.43 (3.20) = 39.79

Because Zin believes each valuation ratio is equally valid, value is a simple average of the three values.

Value = (37.33 + 40.80 + 39.79)/3 = 39.30

8 C is correct. An equity carve-out involves sale of equity in a new legal entity to outsiders and would thus result in a cash inflow for Moonbase. A spin-off or a split-off does not generate a cash flow to the firm.

9 B is correct. The first comment about the poison pill is correct, but the second comment is incorrect. Shareholders do not “put” their shares to the company; rather bondholders can exercise the put in the event of a hostile takeover. Bondholders have the right to sell their bonds back to the target at a redemption price that is pre-specified in the bond indenture, typically at or above par value.

10 C is correct. Statement 3 provides the most support for a strong governance rating. The statement describes the manner in which the audit committee should work. The other two statements do not support a strong governance rating as each casts doubt about the independence of the board from management’s control.

11 B is correct. The second policy is least likely to ensure effective contributions from the board. The board through self-assessment, and not management, should assess the board’s performance.

12 A is correct. As an independent director, without an interlocking relationship and with the expertise required, Steris would be eligible to serve on either of the two committees.

13 B is correct.

Step 1. Compute Valuation Ratios

Valuation Ratio	Alphatech	Betatech	Mean
P/E	36.00	30.00	33.00
P/S	2.25	2.00	2.125
P/BV	4.00	4.50	4.25

Step 2. Apply to Durtech’s Variables

Valuation Ratio	Durtech	Mean Multiple	Estimated Stock Price
Earnings per share	1.00	33.00	33.00
Sales per share	16.00	2.125	34.00
Book value per share	8.00	4.25	34.00

Step 3. Determine Mean Value: $(33 + 34 + 34)/3 = \$33.67$ per share

14 B is correct. A comparable transaction sells for premium of $55/44.4 - 1 = 23.9\%$.

15 C is correct. Omegatech’s transaction P/E: $55/1.25 = 44$. So estimated fair acquisition value per share is $44 \times 1 = \$44.00$.

Capital Budgeting

by John D. Stowe, PhD, CFA, and Jacques R. Gagné, FSA, CFA, CIPM

John D. Stowe, PhD, CFA, is at Ohio University (USA). Jacques R. Gagné, FSA, CFA, CIPM, is at ENAP (Canada).

LEARNING OUTCOMES

Mastery	*The candidate should be able to:*
☐	**a.** calculate the yearly cash flows of expansion and replacement capital projects and evaluate how the choice of depreciation method affects those cash flows;
☐	**b.** explain how inflation affects capital budgeting analysis;
☐	**c.** evaluate capital projects and determine the optimal capital project in situations of 1) mutually exclusive projects with unequal lives, using either the least common multiple of lives approach or the equivalent annual annuity approach, and 2) capital rationing;
☐	**d.** explain how sensitivity analysis, scenario analysis, and Monte Carlo simulation can be used to assess the standalone risk of a capital project;
☐	**e.** describe types of real options relevant to a capital project;
☐	**f.** describe common capital budgeting pitfalls.

INTRODUCTION

1

Capital budgeting is the process that companies use for investing in capital projects—those projects with a life of a year or more. The Level I curriculum presented the basic principles of this process and the major discounted cash flow (DCF) investment criteria: net present value (NPV) and internal rate of return (IRR). The payback period and the accounting rate of return also are commonly used, although they have drawbacks compared with DCF methods. This reading expands on the basic principles by projecting the cash flows needed in these models and applying the models to a variety of more complicated situations.

This reading is organized as follows: Section 2 presents a crucial element of the capital budgeting process: organizing the cash flow information that is the raw material of the analysis. Sections 2.4 and 3 look further at cash flow analysis, considering

© 2020 CFA Institute. All rights reserved.

alternative depreciation methods, replacement projects (in contract to expansion projects), and the effects of inflation. Sections 4–7 demonstrate methods to extend the basic investment criteria to address economic alternatives and risk. These methods include mutually exclusive projects with differing lives, sensitivity analysis, scenario analysis, simulation models, and real options analysis. These sections also discuss several common pitfalls in capital budgeting analysis. Finally, Section 8 summarizes the reading.

2 CASH FLOW PROJECTIONS

a calculate the yearly cash flows of expansion and replacement capital projects and evaluate how the choice of depreciation method affects those cash flows;

In this section, we detail how cash flows are found for an "expansion" project. An expansion project is an independent investment that does not affect the cash flows for the rest of the company. In Section 2.4, we will deal with a "replacement" project, in which the cash flow analysis is more complicated. A replacement project must deal with the differences between the cash flows that occur with the new investment and the cash flows that would have occurred for the investment being replaced.

2.1 Table Format with Cash Flows Collected by Year

The cash flows for a conventional expansion project can be grouped into 1) the investment outlays, 2) after-tax operating cash flows over the project's life, and 3) terminal year after-tax non-operating cash flows. Exhibit 1 gives an example of the cash flows for a capital project in which all of the cash flows are collected by year.

Exhibit 1 Capital Budgeting Cash Flows Example (Cash Flows Collected by Year)

Year	0	1	2	3	4	5
Investment outlays						
Fixed capital	–200,000					
Net working capital	–30,000					
Total	–230,000					
Annual after-tax operating cash flows						
Sales		220,000	220,000	220,000	220,000	220,000
Cash operating expenses		90,000	90,000	90,000	90,000	90,000
Depreciation		35,000	35,000	35,000	35,000	35,000
Operating income before taxes		95,000	95,000	95,000	95,000	95,000
Taxes on operating income		38,000	38,000	38,000	38,000	38,000
Operating income after taxes		57,000	57,000	57,000	57,000	57,000
Add back: Depreciation		35,000	35,000	35,000	35,000	35,000
After-tax operating cash flow		92,000	92,000	92,000	92,000	92,000
Terminal year after-tax non-operating cash flows						
After-tax salvage value						40,000
Return of net working capital						30,000
Total						70,000

Exhibit 1 (Continued)

Year	0	1	2	3	4	5
Total after-tax cash flow	−230,000	92,000	92,000	92,000	92,000	162,000
Net present value at 10% required rate of return	162,217					
Internal rate of return	32.70%					

The investment outlays include a $200,000 outlay for fixed capital items. This outlay includes $25,000 for non-depreciable land, plus $175,000 for equipment that will be depreciated straight-line to zero over five years. The investment in net working capital is the net investment in short-term assets required for the investment. This amount is the investment in receivables and inventory needed, less the short-term payables generated by the project. In this case, the project requires $50,000 of current assets but generates $20,000 in current liabilities, resulting in a total investment in net working capital of $30,000. The total investment outlay at time zero is $230,000.

Each year, sales will be $220,000 and cash operating expenses will be $90,000. Annual depreciation for the $175,000 depreciable equipment is $35,000 (one-fifth of the cost). The result is an operating income before taxes of $95,000. Income taxes at a 40% rate are 0.40 × $95,000 = $38,000, which leaves operating income after taxes of $57,000. Adding back the depreciation charge of $35,000 gives the annual after-tax operating cash flow of $92,000.

At the end of Year 5, the company will sell off the fixed capital assets. In this case, the fixed capital assets (including the land) are sold for $50,000, which represents a gain of $25,000 over the remaining book value of $25,000. The gain of $25,000 is taxed at 40%, resulting in a tax of $10,000. This leaves $40,000 for the fixed capital assets after taxes. Additionally, the net working capital investment of $30,000 is recovered because the short-term assets (such as inventory and receivables) and short-term liabilities (such as payables) are no longer needed for the project. Total terminal year non-operating cash flows are then $70,000.

The investment project has a required rate of return of 10%. Discounting the future cash flows at 10% and subtracting the investment outlay gives an NPV of $162,217. The internal rate of return is 32.70%. Because the investment has a positive NPV, this project should be accepted. The project should also be accepted based on the IRR criterion because the IRR is greater than the required rate of return.

2.2 Table Format with Cash Flows Collected by Type

In the layout in Exhibit 1, we essentially collected the cash flows in the columns, by *year*, and then found the NPV by summing the present values of the annual cash flows (at the bottom of each column). There is another way of organizing the same information. We could also find the NPV by finding the present values of the cash flows in Exhibit 1 by rows, which are the *types* of cash flows. Exhibit 2 illustrates this approach:

Exhibit 2 Capital Budgeting Cash Flows Example (Cash Flows Collected by Type)

Time	Type of Cash Flow	Before-Tax Cash Flow	After-Tax Cash Flow	PV at 10%
0	Fixed capital	−200,000	−200,000	−200,000
0	Net working capital	−30,000	−30,000	−30,000

(continued)

Exhibit 2 (Continued)

Time	Type of Cash Flow	Before-Tax Cash Flow	After-Tax Cash Flow	PV at 10%
1–5	Sales minus cash expenses	220,000 – 90,000 = 130,000	130,000(1 – 0.40) = 78,000	295,681
1–5	Depreciation tax savings	None	0.40(35,000) = 14,000	53,071
5	After-tax salvage value	50,000	50,000 – 0.40(50,000 – 25,000) = 40,000	24,837
5	Return of net working capital	30,000	30,000	18,628
			NPV =	162,217

As Exhibit 2 shows, the outlays in fixed capital and in net working capital at time zero total \$230,000. For Years 1 through 5, the company realizes an after-tax cash flow for sales minus cash expenses of \$78,000, which has a present value of \$295,681. The depreciation charge results in a tax savings of \$14,000 per year, which has a present value of \$53,071. The present values of the after-tax salvage and of the return of net working capital are also shown in the Exhibit. The present value of all cash flows is an NPV of \$162,217. Obviously, collecting the after-tax cash flows by year, as in Exhibit 1, or by type, as in Exhibit 2, results in the same NPV.

2.3 Equation Format for Organizing Cash Flows

The capital budgeting cash flows in the foregoing example project were laid out in one of two alternative tabular formats. Analysts also may wish to take another approach. Instead of producing a table, you can also look at the cash flows using equations such as the following:

1 Initial outlay: For a new investment:

$$\text{Outlay} = \text{FCInv} + \text{NWCInv},$$

where

FCInv = investment in new fixed capital

NWCInv = investment in net working capital

This equation can be generalized for a replacement project (covered in Section 2.4.2), in which existing fixed capital is sold and provides some of the funding for the new fixed capital purchased. The outlay is then

$$\text{Outlay} = \text{FCInv} + \text{NWCInv} - \text{Sal}_0 + t(\text{Sal}_0 - B_0), \tag{1}$$

where

Sal_0 = cash proceeds (salvage value) from sale of old fixed capital

t = tax rate

B_0 = book value of old fixed capital

2 Annual after-tax operating cash flow:

$$CF = (S - C - D)(1 - t) + D, \text{ or} \tag{2}$$

$$CF = (S - C)(1 - t) + tD \tag{3}$$

where

S = sales
C = cash operating expenses
D = depreciation charge

3 Terminal year after-tax non-operating cash flow:

$$\text{TNOCF} = \text{Sal}_T + \text{NWCInv} - t(\text{Sal}_T - B_T) \tag{4}$$

where

Sal_T = cash proceeds (salvage value) from sale of fixed capital on termination date
B_T = book value of fixed capital on termination date

The outlay in the example is found with Equation 1:

Outlay = 200,000 + 30,000 – 0 + 0 = $230,000

For a replacement project, the old fixed capital would be sold for cash (Sal_0) and then there would be either taxes paid on the gain (if $\text{Sal}_0 - B_0$ were positive) or a tax saving (if $\text{Sal}_0 - B_0$ were negative). In this example, Sal_0 and $t(\text{Sal}_0 - B_0)$ are zero because no existing fixed capital is sold at time zero.

Using Equation 2, we find that the annual after-tax operating cash flow is

$$\begin{aligned}\text{CF} &= (S - C - D)(1 - t) + D\\ &= (220{,}000 - 90{,}000 - 35{,}000)(1 - 0.40) + 35{,}000\\ &= 95{,}000 \times (0.60) + 35{,}000\\ &= 57{,}000 + 35{,}000 = \$92{,}000\end{aligned}$$

Equation 2 is the project's net income plus depreciation. An identical cash flow results if we use Equation 3:

$$\begin{aligned}\text{CF} &= (S - C)(1 - t) + tD\\ &= (220{,}000 - 90{,}000)(1 - 0.40) + 0.40(35{,}000)\\ &= 130{,}000(0.60) + 0.40(35{,}000) = 78{,}000 + 14{,}000 = \$92{,}000\end{aligned}$$

Equation 3 is the after-tax sales and cash expenses plus the depreciation tax savings. The analyst can use either equation.

Equation 4 provides the terminal year non-operating cash flow:

$$\begin{aligned}\text{TNOCF} &= \text{Sal}_T + \text{NWCInv} - t(\text{Sal}_T - B_T)\\ &= 50{,}000 + 30{,}000 - 0.40(50{,}000 - 25{,}000)\\ &= 50{,}000 + 30{,}000 - 10{,}000 = \$70{,}000\end{aligned}$$

The old fixed capital (including land) is sold for $50,000, but $10,000 of taxes must be paid on the gain. Including the $30,000 return of net working capital gives a terminal year non-operating cash flow of $70,000.

The NPV of the project is the present value of the cash flows—an outlay of $230,000 at time zero, an annuity of $92,000 for five years, plus a single payment of $70,000 in five years:

$$\begin{aligned}\text{NPV} &= -230{,}000 + \sum_{t=1}^{5}\frac{92{,}000}{(1.10)^t} + \frac{70{,}000}{(1.10)^5}\\ &= -230{,}000 + 348{,}752 + 43{,}465 = \$162{,}217\end{aligned}$$

We obtain an identical NPV of $162,217 whether we use a tabular format collecting cash flows by year, a tabular format collecting cash flows by type, or an equation format using Equations 1 through 4. The analyst usually has some flexibility in choosing how to solve a problem. Furthermore, the analysis that an analyst receives from someone else could be in varying formats. The analyst must interpret this information correctly regardless of format. An analyst may need to present information in alternative formats, depending on what the client or user of the information wishes to see. All that is important is that the cash flows are complete (with no cash flows omitted and none double-counted), that their timing is recognized, and that the discounting is done correctly.

2.4 More on Cash Flow Projections

Cash flow analysis can become fairly complicated. Section 2.4 extends the analysis of the previous section to include more details on depreciation methods, replacement projects (as opposed to simple expansion projects), and the effects of inflation.

2.4.1 *Straight-Line and Accelerated Depreciation Methods*

Before going on to more-complicated investment decisions, we should mention the variety of depreciation methods that are in use. The example in Section 2.1 assumed straight-line depreciation down to a zero salvage value. The CFA accounting curriculum and most accounting texts give good descriptions of the straight-line method, the sum-of-years digits method, the double-declining balance method (and the 150% declining balance method), and the units-of-production and service hours method.

All countries specify the depreciation methods that are acceptable for tax purposes in their jurisdictions. The country specifies an asset class for each type of capital investment and a special depreciation schedule for each class. A few of the many examples of depreciation rate schedules appear in Exhibit 3.

Exhibit 3 Examples of Depreciation Rate Schedules

Year	5-Year SL	3-Year DDB	5-Year DDB	10-Year DDB	15-Year 150%DB
1	20.00%	33.33%	20.00%	10.00%	5.00%
2	20.00	44.45	32.00	18.00	9.50
3	20.00	14.81	19.20	14.40	8.55
4	20.00	7.41	11.52*	11.52	7.70
5	20.00		11.52	9.22	6.93
6			5.76	7.37	6.23
7				6.55*	5.90*
8				6.55	5.90
9				6.55	5.90
10				6.55	5.90
11				3.29	5.90
12					5.90
13					5.90
14					5.90

Exhibit 3 (Continued)

Year	5-Year SL	3-Year DDB	5-Year DDB	10-Year DDB	15-Year 150%DB
15					5.90
16					2.99

Notes: SL is straight-line depreciation. DDB is double-declining balance with a half-year convention. 150%DB is 150% declining balance with a half-year convention.
* Denotes a switch to the straight-line method of depreciation when optimal.

Take the five-year DDB property in Exhibit 3 as an example. With double-declining balance, the depreciation each year is 2/5 = 40% of the beginning-of-year book value. With a half-year convention, however, the asset is assumed to be in service for only six months during the first year, and only one-half of the depreciation, or 20%, is allowed the first year. After the first year, the depreciation rate is 40% of the beginning balance until Year 4, when straight-line depreciation would be at least as large, so we switch to straight-line. Yearly depreciation amounts and book values are shown in the following table.

Year	Depreciation (%)	Ending Book Value (%)
1	20.00	80.00
2	32.00 (= 40 × 80)	48.00
3	19.20 (= 40 × 48)	28.80
4	11.52* (= 40 × 28.8)	17.28
5	11.52 (= 40 × 28.8)	5.76
6	5.76 (= 20 × 28.8)	0.00

* Denotes a switch to the straight-line method of depreciation when optimal.

In Year 4, the beginning book value is 28.80% (100% minus the first three years' depreciation), and there are 2.5 years of remaining life. So with straight-line depreciation, 40% of the 28.80% (11.52%) is allocated to Year 4, 40% to Year 5 (11.52%), and 20% (5.76%) to Year 6. In Year 6, we have one-half of a year of the straight-line depreciation remaining because we assumed the asset was placed in service halfway through the first year.

Accelerated depreciation generally improves the NPV of a capital project compared with straight-line depreciation. For an example of this effect, we will assume the same capital project as in Exhibit 1, except that the depreciation is for the three-year property with double-declining balance with a half-year convention (3-Year DDB in Exhibit 3). When using straight-line, the depreciation was 20% per year ($35,000). Using the DDB depreciation percentages for the property shown in Exhibit 3, the first-year depreciation is 0.3333 × 175,000 = $58,327.50, second-year depreciation is 0.4445 × 175,000 = $77,787.50, third-year depreciation is 0.1481 × 175,000 = $25,917.50, fourth-year depreciation is 0.0741 × 175,000 = $12,967.50, and fifth-year depreciation is zero. The impact on the project's NPV and IRR is shown in Exhibit 4.

Exhibit 4 Capital Budgeting Example with Accelerated Depreciation

Year	0	1	2	3	4	5
Investment outlays:						
Fixed capital	–200,000					
Net working capital	–30,000					
Total	–230,000					
Annual after-tax operating cash flows:						
Sales		220,000	220,000	220,000	220,000	220,000
Cash operating expenses		90,000	90,000	90,000	90,000	90,000
Depreciation		58,328	77,788	25,918	12,968	0
Operating income before taxes		71,673	52,213	104,083	117,033	130,000
Taxes on operating income (40%)		28,669	20,885	41,633	46,813	52,000
Operating income after taxes		43,004	31,328	62,450	70,220	78,000
Add back: Depreciation		58,328	77,788	25,918	12,968	0
After-tax operating cash flow		101,331	109,115	88,367	83,187	78,000
Terminal year after-tax non-operating cash flows:						
After-tax salvage value						40,000
Return of net working capital						30,000
Total						70,000
Total after-tax cash flows	–230,000	101,331	109,115	88,367	83,187	148,000
Net present value at 10% required rate of return	$167,403					
Internal rate of return		34.74%				

As Exhibit 4 shows, the depreciation charges still sum to $175,000 (except for $2 of rounding), but they are larger in Years 1 and 2 and smaller in Years 3, 4, and 5. Although this method reduces operating income after taxes in Years 1 and 2 (and increases it in Years 3, 4, and 5), it reduces tax outflows in Years 1 and 2 and increases them later. Consequently, the after-tax operating cash flows (which were $92,000 per year) increase in the early years and decrease in later years. This dynamic increases the NPV from $162,217 to $167,403, a difference of $5,186. The IRR also increases from 32.70% to 34.74%.

The impact of accelerated depreciation can be seen without going through the complete analysis in Exhibit 4. We previously showed in Exhibit 2 that the present value of the depreciation tax savings (which was an annuity of 0.40 × $35,000 = $14,000 a year for five years) was $53,071. The present value of the tax savings from accelerated depreciation is shown in Exhibit 5.

Exhibit 5 Present Value of Tax Savings from Accelerated Depreciation

Year	Depreciation ($)	Tax Savings	PV at 10% ($)
1	58,327.50	0.40 × $58,327.5 = $23,331	21,210
2	77,787.50	0.40 × $77,787.5 = $31,115	25,715
3	25,917.50	0.40 × $25,917.5 = $10,367	7,789
4	12,967.50	0.40 × $12,967.5 = $5,187	3,543

Exhibit 5 (Continued)

Year	Depreciation ($)	Tax Savings	PV at 10% ($)
5	0	0.40 × $0 = $0	0
Total present value			58,257

By using the accelerated depreciation schedule, we increase the present value of the tax savings from $53,071 (from Exhibit 2) to $58,257, an increase of $5,186. The tax deferral associated with the accelerated depreciation (compared with straight-line) adds $5,186 to the NPV of the project.

There are a myriad of tax and depreciation schedules that apply to investment projects around the world. These tax and depreciation schedules are also subject to change from year to year. To accurately assess the profitability of a particular capital project, it is vital to identify and apply the schedules that are relevant to the capital budgeting decision at hand.

2.4.2 *Cash Flows for a Replacement Project*

In Section 2.1, we evaluated the cash flows for an expansion project, basing our after-tax cash flows on the outlays, annual operating cash flows after tax, and salvage value for the project by itself. In many cases, however, investing in a project will be more complicated. Investing could affect many of the company's cash flows. In principle, the cash flows relevant to an investing decision are the incremental cash flows: the cash flows the company realizes *with* the investment compared with the cash flows the company would realize *without* the investment. For example, suppose we are investing in a new project with an outlay of $100,000, and we sell off existing assets that the project replaces for $30,000. The incremental outlay is $70,000.

A very common investment decision is a replacement decision, in which old equipment is replaced with new equipment. This decision requires very careful analysis of the cash flows. The skills required to detail the replacement decision cash flows are also useful for other decisions in which an investment affects other cash flows in the company. We use the term "replacement" loosely, primarily to indicate that the cash flow analysis is more complicated than it was for the simpler expansion decision.

Assume we are considering the replacement of old equipment with new equipment that has more capacity and is less costly to operate. The characteristics of the old and new equipment are given in the following table:

Old Equipment		New Equipment	
Current book value	$400,000		
Current market value	$600,000	Acquisition cost	$1,000,000
Remaining life	10 years	Life	10 years
Annual sales	$300,000	Annual sales	$450,000
Cash operating expenses	$120,000	Cash operating expenses	$150,000
Annual depreciation	$40,000	Annual depreciation	$100,000
Accounting salvage value	$0	Accounting salvage value	$0
Expected salvage value	$100,000	Expected salvage value	$200,000

If the new equipment replaces the old equipment, an additional investment of $80,000 in net working capital will be required. The tax rate is 30%, and the required rate of return is 8%.

The cash flows can be found by carefully constructing tables like Exhibit 1 or by using Equations 1 through 4. The initial outlay is the investment in the new equipment plus the additional investment in net working capital less the after-tax proceeds from selling the old equipment:

$$\text{Outlay} = \text{FCInv} + \text{NWCInv} - \text{Sal}_0 + t(\text{Sal}_0 - B_0)$$
$$\text{Outlay} = 1{,}000{,}000 + 80{,}000 - 600{,}000 + 0.3(600{,}000 - 400{,}000) = \$540{,}000$$

In this case, the outlay of \$540,000 is \$1,080,000 for new equipment and net working capital minus the after-tax proceeds of \$540,000 the company receives from selling the old equipment. The incremental operating cash flows are

$$\begin{aligned} \text{CF} &= (S - C - D)(1 - t) + D \\ &= [(450{,}000 - 300{,}000) - (150{,}000 - 120{,}000) - (100{,}000 - 40{,}000)](1 - 0.30) \\ &\quad + (100{,}000 - 40{,}000) \\ &= (150{,}000 - 30{,}000 - 60{,}000)(1 - 0.30) + 60{,}000 = \$102{,}000. \end{aligned}$$

The incremental sales are \$150,000, incremental cash operating expenses are \$30,000, and incremental depreciation is \$60,000. The incremental after-tax operating cash flow is \$102,000 per year.

At the project termination, the new equipment is expected to be sold for \$200,000, which constitutes an incremental cash flow of \$100,000 over the \$100,000 expected salvage price of the old equipment. Because the accounting salvage values for both the new and old equipment were zero, this gain is taxable at 30%. The company also recaptures its investment in net working capital. The terminal year incremental after-tax non-operating cash flow is

$$\begin{aligned} \text{TNOCF} &= \text{Sal}_T + \text{NWCInv} - t(\text{Sal}_T - B_T) \\ &= (200{,}000 - 100{,}000) + 80{,}000 - 0.30[(200{,}000 - 100{,}000) - (0 - 0)] \\ &= \$150{,}000. \end{aligned}$$

Once the cash flows are identified, the NPV and IRR are readily found. The NPV, found by discounting the cash flows at the 8% required rate of return, is

$$\text{NPV} = -540{,}000 + \sum_{t=1}^{10} \frac{102{,}000}{1.08^t} + \frac{150{,}000}{1.08^{10}} = \$213{,}907$$

The IRR, found with a financial calculator, is 15.40%. Because the NPV is positive, this equipment replacement decision is attractive. The fact that the IRR exceeds the 8% required rate of return leads to the same conclusion.

The key to estimating the incremental cash flows for the replacement is to compare the cash flows that occur with the new investment to the cash flows that would have occurred without the new investment. The analyst is comparing the cash flows with a particular course of action to the cash flows with an alternative course of action.

3 EFFECTS OF INFLATION ON CAPITAL BUDGETING ANALYSIS

b explain how inflation affects capital budgeting analysis;

Inflation affects capital budgeting analysis in several ways. The first decision the analyst must make is whether to do the analysis in "nominal" terms or in "real" terms. Nominal cash flows include the effects of inflation, while real cash flows are adjusted downward to remove the effects of inflation. It is perfectly acceptable to do the analysis in either nominal or real terms, and sound decisions can be made either way. Inflation creates some issues, however, regardless of the approach.

The cash flows and discount rate used should both be nominal or both be real. In other words, nominal cash flows should be discounted at a nominal discount rate, and real cash flows should be discounted at a real rate. The real rate, just like real cash flows, has had the effect of inflation taken out. In general, the relationship between real and nominal rates is

$$(1 + \text{Nominal rate}) = (1 + \text{Real rate})(1 + \text{Inflation rate}).$$

Inflation reduces the value of depreciation tax savings (unless the tax system adjusts depreciation for inflation). The effect of expected inflation is captured in the discounted cash flow analysis. If inflation is higher than expected, the profitability of the investment is correspondingly lower than expected. Inflation essentially shifts wealth from the taxpayer to the government. Higher-than-expected inflation increases the corporation's real taxes because it reduces the value of the depreciation tax shelter. Conversely, lower-than-expected inflation reduces real taxes (the depreciation tax shelters are more valuable than expected).

Inflation also reduces the value of fixed payments to bondholders. When bonds are originally issued, bondholders pay a price for the bonds reflecting their inflationary expectations. If inflation is higher than expected, the real payments to bondholders are lower than expected. Higher-than-expected inflation shifts wealth from bondholders to the issuing corporations. Conversely, if inflation is lower than expected, the real interest expenses of the corporation increase, shifting wealth from the issuing corporation to its bondholders.

Finally, inflation does not affect all revenues and costs uniformly. The company's after-tax cash flows will be better or worse than expected depending on how particular sales outputs or cost inputs are affected. Furthermore, contracting with customers, suppliers, employees, and sources of capital can be complicated as inflation rises.

The capital budgeting model accommodates the effects of inflation, although inflation complicates the capital budgeting process (and the operations of a business, in general).

PROJECT ANALYSIS AND EVALUATION

4

c evaluate capital projects and determine the optimal capital project in situations of 1) mutually exclusive projects with unequal lives, using either the least common multiple of lives approach or the equivalent annual annuity approach, and 2) capital rationing;

Assessing the opportunity costs and analyzing the risks of capital investments becomes more complex and sophisticated as you examine real cases. The first project interaction we examine in this section is that of comparing **mutually exclusive projects** with unequal lives. We will briefly describe other project interactions but will not examine them in detail. We also examine the process of capital budgeting under capital rationing.

4.1 Mutually Exclusive Projects with Unequal Lives

We have previously looked at mutually exclusive projects and decided that the best project is the one with the greatest NPV. However, if the mutually exclusive projects have differing lives and the projects will be replaced (or replicated) repeatedly when they wear out, the analysis is more complicated. The analysis of a one-shot (one time only) investment differs from that of an investment chain (in which the asset is replaced regularly in the future).

For example, assume we have two projects with unequal lives of two and three years, with the following after-tax cash flows:

Project S

CF_t	–100	60	90	
t (time)	0	1	2	3

Project L

CF_t	–140	80	70	60
t (time)	0	1	2	3

Both projects have a 10% required rate of return. The NPV of Project S is \$28.93 and the NPV of Project L is \$35.66. Given that the two projects are mutually exclusive, Project L, with the greater NPV, should be chosen.

Let us now assume, however, that these are not one-shot investments but rather investments in assets that the company will need to replace when they wear out. Project S would be replaced every two years and Project L every three years. This situation is often referred to as a replacement chain. In this type of problem, one should examine the entire chain and not just the first link in the chain. If the projects are part of a replacement chain, examining the cash flows for only the initial investment for Projects S and L is improper because Project L provides cash flows during Year 3, when Project S provides none.

There are two logically equivalent ways of comparing mutually exclusive projects in a replacement chain. They are the "least common multiple of lives" approach and the "equivalent annual annuity" approach.

4.1.1 *Least Common Multiple of Lives Approach*

For the least common multiple of lives approach, the analyst extends the time horizon of analysis so that the lives of both projects will divide exactly into the horizon. For Projects S and L, the least common multiple of 2 and 3 is 6: The two-year project would be replicated three times over the six-year horizon and the three-year project would be replicated two times over the six-year horizon. The cash flows for replicating Projects S and L over a six-year horizon are shown on the following timelines:

Project S

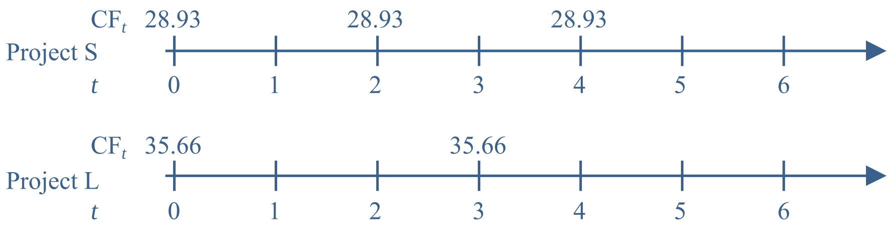
CF_t	–100	60	(–100+90)	60	(–100+90)	60	90
t	0	1	2	3	4	5	6

Project L

CF_t	–140	80	70	(–140+60)	80	70	60
t	0	1	2	3	4	5	6

Discounting the cash flows for the six-year horizon results in an NPV for Project S of \$72.59 and an NPV for Project L of \$62.45. Apparently, investing in Project S and replicating the investment over time has a greater NPV than choosing Project L and replicating it. This decision is the reverse of the one we made when looking solely at the NPVs of the initial investments!

Because the NPV of a single investment represents the present values of its cash flows, you can also visualize the NPV of a replacement chain as the present value of the NPVs of each investment (or link) in the chain. For Projects S and L, the NPVs of each investment are shown on the following timelines:



Investing in Project S is equivalent to receiving values of \$28.93 at times 0, 2, and 4, whereas investing in Project L is equivalent to receiving values of \$35.66 at times 0 and 3. The present values of these cash flow patterns are \$72.59 for Project S and \$62.45 for Project L. Discounting the NPVs of each investment in the chain is equivalent to discounting all of the individual cash flows in the chain.

4.1.2 *Equivalent Annual Annuity Approach*

The other method for properly evaluating a replacement chain is called the equivalent annual annuity (EAA) approach. The name for this approach is very descriptive. For an investment project with an outlay and variable cash flows in the future, the project NPV summarizes the equivalent value at time zero. For this same project, the EAA is the annuity payment (series of equal annual payments over the project's life) that is equivalent in value to the NPV.

Analysts can use a simple two-step procedure to find the EAA. The first step is to find the present value of all of the cash flows for an investment—the investment's NPV. The second step is to calculate an annuity payment that has a value equivalent to the NPV. For Project S above, we already calculated the NPV of the project over its two-year life to be \$28.93. The second step is to find an annuity payment for the two-year life that is equivalent. For a two-year life and a 10% discount rate, a payment of \$16.66 is the equivalent annuity.

The EAA for Project L is found by annuitizing its \$35.66 NPV over three years, so the EAA for Project L is \$14.34.

The decision rule for the EAA approach is to choose the investment chain that has the highest EAA, which in this case is Project S.

Given these two approaches to comparing replacement chains, which one should the analyst use? As a practical matter, the two approaches are logically equivalent and will result in the same decision. More specifically, the NPVs of a replacement chain over the least common multiple of lives (six years) were \$72.59 for Project S and \$62.45 for Project L. If we discount the EAA for Project S (\$16.66) and the EAA for Project L (\$14.34) for six years (treating each as a six-year annuity), we find the same NPVs. Hence, the least common multiple of lives and EAA approaches are consistent with each other. Consequently, the analyst can choose one approach over the other based on personal preference. Or, if the audience for the analyst's work prefers to see the analysis using one approach, the analyst can simply produce the analysis in that format.

4.2 Capital Rationing

When a company's capital budget has a size constraint, a **capital rationing** approach is needed. For example, the capital budget is a fixed money amount. A fixed capital budget can place the company in several interesting situations. To illustrate these, we will assume that the company has a fixed \$1,000 capital budget and has the opportunity to invest in four projects. The projects are of variable profitability.

In the first situation, the budget is adequate to invest in all profitable projects. Consider the four projects in Exhibit 6.

Exhibit 6 First Capital Rationing Example

	Investment Outlay	NPV	PI	IRR (%)
Project 1	600	220	1.37	15
Project 2	200	70	1.35	16
Project 3	200	−60	0.70	10
Project 4	400	−100	0.75	8

In this case, the company has two positive-NPV projects, Projects 1 and 2, which involve a total outlay of $800. Their total NPV is $290. The Profitability Index (PI) for each project – or ratio of the present value of future cash flows to initial investment – is 1.37 and 1.35 respectively. The company should choose these projects, and it will have $200 in its capital budget left over. These excess funds can be used elsewhere in the company (moved to someone else's budget, used to pay dividends or repurchase shares, or used to pay down debt). If a manager is afraid to return the excess funds and chooses to invest in Project 3, the manager will consume the whole capital budget but reduce the total NPV to $230, essentially destroying $60 of wealth for the company.

A second case exists in which the company has more profitable projects than it can choose, but it is able to invest in the most profitable ones available. Continuing with the $1,000 capital budget, this second case is illustrated in Exhibit 7.

Exhibit 7 Second Capital Rationing Example

	Investment Outlay	NPV	PI	IRR (%)
Project 5	600	300	1.50	16
Project 6	200	80	1.40	18
Project 7	200	60	1.30	12
Project 8	200	40	1.20	14

When the analyst has a fixed budget, the PI is especially useful because it shows the profitability of each investment per currency unit invested. If we rank these projects by their PIs, Projects 5, 6, and 7 are the best projects, and we are able to select them. This selection results in a total NPV of $440. The IRRs, shown in the last column, are not a reliable guide to choosing projects under capital rationing because a high-IRR project may have a low NPV. Wealth maximization is best guided by the NPV criterion.

A third case exists in which the company has more profitable projects than it can choose, but it is not able to invest in the most profitable ones available. Assume the company cannot invest in fractional projects: It must take all or none of each project it chooses. Continuing with the $1,000 capital budget, this case is illustrated in Exhibit 8.

Exhibit 8 Third Capital Rationing Example

	Investment Outlay	NPV	PI	IRR (%)
Project 9	600	300	1.50	15
Project 10	600	270	1.45	16

Exhibit 8 (Continued)

	Investment Outlay	NPV	PI	IRR (%)
Project 11	200	80	1.40	12
Project 12	400	100	1.25	11

In this example, an unlimited budget of $1,800 would generate a total NPV of $750. When the budget constraint is imposed, however, the highest NPV results from choosing Projects 9 and 12. The company is forced to choose its best project and its fourth-best project, as indicated by their relative PIs. Any other combination of projects either violates the budget constraint or has a lower total NPV.

Capital rationing has the potential to misallocate resources. Capital markets are supposed to allocate funds to their highest and best uses, with the opportunity cost of funds (used as the discount rate for NPVs or the hurdle rate for IRRs) guiding this allocation process. Capital rationing violates market efficiency if society's resources are not allocated where they will generate the best returns. Companies that use capital rationing may be doing either "hard" or "soft" capital rationing. Under hard capital rationing, the budget is fixed and managers cannot go beyond it. Under soft capital rationing, managers may be allowed to overspend their budgets if they argue effectively that the additional funds will be deployed profitably.

In the case of hard rationing, choosing the optimal projects that fit within the budget and maximize the company's NPV can be computationally intensive. Sometimes, managers use estimates and trial and error to find the optimal set of projects. The PI can be used as a guide in this trial and error process. Other times, the number of possibilities is so daunting that mathematical programming algorithms are used.

5 RISK ANALYSIS OF CAPITAL INVESTMENTS - STAND ALONE METHODS

d explain how sensitivity analysis, scenario analysis, and Monte Carlo simulation can be used to assess the standalone risk of a capital project;

So far, we have evaluated projects by calculating a single NPV to decide whether a project is profitable. We took a single value, or point estimate, of each input into the model and combined the values to calculate the NPV.

Risk is usually measured as a dispersion of outcomes. In the case of standalone risk, we typically measure the riskiness of a project by the dispersion of its NPVs or the dispersion of its IRRs. Sensitivity analysis, scenario analysis, and simulation analysis are very popular standalone risk analysis methods. These risk measures depend on the variation of the project's cash flows.

To illustrate the standalone risk tools, we will use the following "base case" capital project:

Unit price	$5.00
Annual unit sales	40,000
Variable cost per unit	$1.50
Investment in fixed capital	$300,000
Investment in working capital	$50,000

(continued)

Project life	6 years
Depreciation (straight-line)	$50,000
Expected salvage value	$60,000
Tax rate	40%
Required rate of return	12%

The outlay, from Equation 1, is $300,000 plus $50,000, or $350,000. The annual after-tax operating cash flow, from Equation 2, is

$$\begin{aligned} CF &= (S - C - D)(1 - t) + D \\ &= [(5 \times 40{,}000) - (1.50 \times 40{,}000) - (50{,}000)](1 - 0.40) + 50{,}000 \\ &= \$104{,}000 \end{aligned}$$

The terminal year after-tax non-operating cash flow, from Equation 4, is

$$\begin{aligned} TNOCF &= Sal_6 + NWCInv - t(Sal_6 - B_6) \\ &= 60{,}000 + 50{,}000 - 0.40(60{,}000 - 0) = \$86{,}000 \end{aligned}$$

The project NPV is

$$NPV = -350{,}000 + \sum_{t=1}^{6} \frac{104{,}000}{1.12^t} + \frac{86{,}000}{1.12^6} = -350{,}000 + 471{,}157 = \$121{,}157$$

5.1 Sensitivity Analysis

Sensitivity analysis calculates the effect on the NPV of changes in one input variable at a time. The foregoing base case has several input variables. If we wish to do a sensitivity analysis of several of them, we must specify the changes in each that we wish to evaluate. Suppose we want to consider the following:

	Base Value	Low Value	High Value
Unit price	$5.00	$4.50	$5.50
Annual unit sales	40,000	35,000	45,000
Variable cost per unit	$1.50	$1.40	$1.60
Expected salvage value	$60,000	$30,000	$80,000
Tax rate	40%	38%	42%
Required rate of return	12%	10%	14%

We have changed each of six input variables. Exhibit 9 shows the NPV calculated for the base case. Then the NPV is recalculated by changing one variable from its base case value to its high or low value.

Exhibit 9 Sensitivity of Project NPV to Changes in a Variable

	Project NPV			
Variable	Base Case ($)	With Low Estimate ($)	With High Estimate ($)	Range of Estimates ($)
Unit price	121,157	71,820	170,494	98,674
Annual unit sales	121,157	77,987	164,326	86,339
Cost per unit	121,157	131,024	111,289	19,735
Salvage value	121,157	112,037	127,236	15,199

Exhibit 9 (Continued)

Variable	Project NPV Base Case ($)	With Low Estimate ($)	With High Estimate ($)	Range of Estimates ($)
Tax rate	121,157	129,165	113,148	16,017
Required return	121,157	151,492	93,602	57,890

As Exhibit 9 shows, the project's NPV is most sensitive to changes in the unit price variable and least sensitive to changes in the salvage value. Roughly speaking, the project's NPV is most sensitive to changes in unit price and in unit sales. It is least affected by changes in cost per unit, salvage value, and the tax rate. Changes in the required rate of return also have a substantial effect but not as much as changes in price or unit sales.

In a sensitivity analysis, the manager can choose which variables to change and by how much. Many companies have access to software that can be instructed to change a particular variable by a certain amount—for example, to increase or decrease unit price, unit sales, and cost per unit by 10%. The software then produces the changes in NPV for each of these changes. Sensitivity analysis can be used to establish which variables are most influential on a project's success or failure.

5.2 Scenario Analysis

Sensitivity analysis calculates the effect on the NPV of changes in one variable at a time. In contrast, scenario analysis creates scenarios that consist of changes in several of the input variables and calculates the NPV for each scenario. Although corporations could construct a large number of scenarios, in practice they usually use only three. They can be labeled variously, but we will present an example with "pessimistic," "most likely," and "optimistic" scenarios. Continuing with the basic example from the previous section, the values of the input variables for the three scenarios appear in the following table.

Exhibit 10 Input Variables and NPV for Scenario Analysis

Variable	Scenario Pessimistic	Most Likely	Optimistic
Unit price	$4.50	$5.00	$5.50
Annual unit sales	35,000	40,000	45,000
Variable cost per unit	$1.60	$1.50	$1.40
Investment in fixed capital	$320,000	$300,000	$280,000
Investment in working capital	$50,000	$50,000	$50,000
Project life	6 years	6 years	6 years
Depreciation (straight-line)	$53,333	$50,000	$46,667
Salvage value	$40,000	$60,000	$80,000
Tax rate	40%	40%	40%
Required rate of return	13%	12%	11%

(continued)

Exhibit 10 (Continued)

	Scenario		
Variable	**Pessimistic**	**Most Likely**	**Optimistic**
NPV	−$5,725	$121,157	$269,685
IRR	12.49%	22.60%	34.24%

The most likely scenario is the same as the base case we used previously for sensitivity analysis, and the NPV for the most likely scenario is $121,157. To form the pessimistic and optimistic scenarios, managers change several of the assumptions for each scenario. For the pessimistic scenario, several of the input variables are changed to reflect higher costs, lower revenues, and a higher required rate of return. As the table shows, the result is a negative NPV for the pessimistic scenario and an IRR that is less than the pessimistic scenario's 13% required rate of return. For the optimistic scenario, the more favorable revenues, costs, and required rate of return result in very good NPV and IRR.

For this example, the scenario analysis reveals the possibility of an unprofitable investment, with a negative NPV and with an IRR less than the cost of capital. The range for the NPV is fairly large compared with the size of the initial investment, which indicates that the investment is fairly risky. This example included three scenarios for which management wants to know the investment's profitability for each set of assumptions. Other scenarios can be investigated if management chooses to do so.

5.3 Simulation (Monte Carlo) Analysis

Simulation analysis is a procedure for estimating a probability distribution of outcomes, such as for the NPV or IRR for a capital investment project. Instead of assuming a single value (a point estimate) for the input variables in a capital budgeting spreadsheet, the analyst can assume several variables to be stochastic, following their own probability distributions. By simulating the results hundreds or thousands of times, the analyst can build a good estimate of the distributions for the NPV or IRR. Because of the volume of computations, analysts and corporate managers rely heavily on their personal computers and specialized simulation software. Example 1 presents a simple simulation analysis.

EXAMPLE 1

Capital Budgeting Simulation

Gouhua Zhang has made the following assumptions for a capital budgeting project:

- Fixed capital investment is 20,000; no investment in net working capital is required.
- The project has an expected five-year life.
- The fixed capital is depreciated straight-line to zero over a five-year life. The salvage value is normally distributed with an expected value of 2,000 and a standard deviation of 500.
- Unit sales in Year 1 are normally distributed with a mean of 2,000 and a standard deviation of 200.

- Unit sales growth after Year 1 is normally distributed with a mean of 6% and standard deviation of 4%. Assume the same sales growth rate for Years 2–5.
- The sales price is 5.00 per unit, normally distributed with a standard deviation of 0.25 per unit. The same price holds for all five years.
- Cash operating expenses as a percentage of total revenue are normally distributed with a mean and standard deviation of 30% and 3%, respectively.
- The discount rate is 12% and the tax rate is 40%.

1 What are the NPV and IRR, using the expected values of all input variables?

2 Perform a simulation analysis and provide probability distributions for the NPV and IRR.

Solution to 1:

Exhibit 11 Expected Cash Flows for Simulation Example

Time	0	1	2	3	4	5
Fixed capital	−20,000					
After-tax salvage value						1,200
Price		5.00	5.00	5.00	5.00	5.00
Output		2,000	2,120	2,247	2,382	2,525
Revenue		10,000	10,600	11,236	11,910	12,625
Cash operating expenses		3,000	3,180	3,371	3,573	3,787
Depreciation		4,000	4,000	4,000	4,000	4,000
Operating income before taxes		3,000	3,420	3,865	4,337	4,837
Taxes on operating income		1,200	1,368	1,546	1,735	1,935
Operating income after taxes		1,800	2,052	2,319	2,602	2,902
Depreciation		4,000	4,000	4,000	4,000	4,000
Total after-tax cash flow	−20,000	5,800	6,052	6,319	6,602	8,102
NPV (at r = 12%)	3,294					
IRR	18.11%					

Based on the point estimates for each variable (the mean values for each), shown in Exhibit 11, Zhang should find the NPV to be 3,294 and the IRR to be 18.11%.

Solution to 2:

Zhang performs a simulation with 10,000 iterations. For each iteration, values for the five stochastic variables (price, output, output growth rate, cash expense percentage, and salvage value) are selected from their assumed distributions, and the NPV and IRR are calculated. After the 10,000 iterations, the resulting information about the probability distributions for the NPV and IRR is shown in Exhibit 12 and Exhibit 13.

Exhibit 12A Distribution for NPV

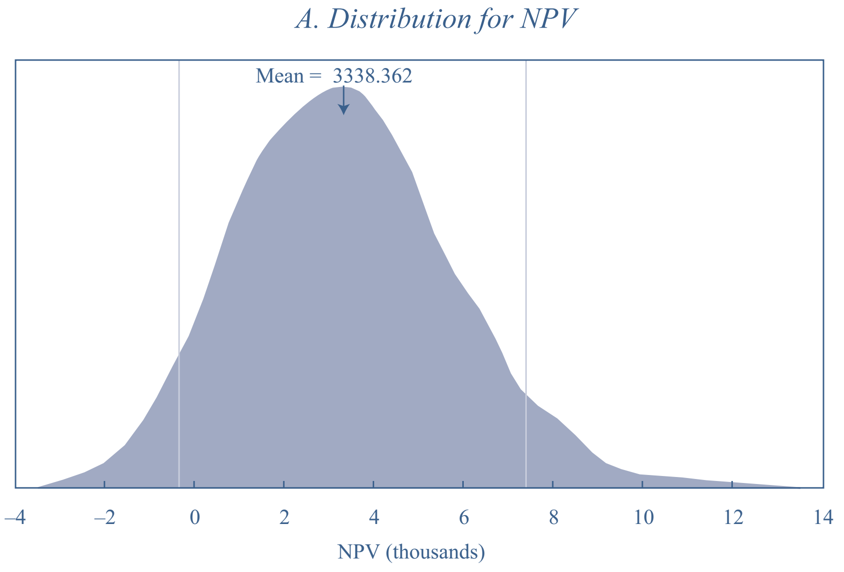


Exhibit 12B Distribution for IRR

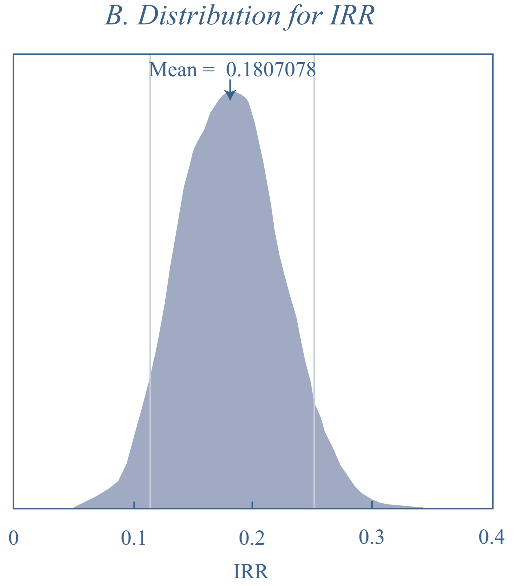

Exhibit 13 Summary Statistics for NPV and IRR

Statistic	NPV	IRR
Mean	3,338	18.07%
Standard deviation	2,364	4.18%
Skewness	0.2909	0.1130
Kurtosis	3.146	2.996

Exhibit 13 (Continued)

Statistic	NPV	IRR
Median	3,236	18.01%
90% confidence interval	−379 to 7,413	11.38% to 25.13%

Correlations between Input Variables and NPV and IRR

Input Variable	NPV	IRR
Output	0.71	0.72
Output growth rate	0.49	0.47
Price	0.34	0.34
Cash expense proportion	−0.28	−0.29
Salvage value	0.06	0.05

As the figure shows, the distributions for the NPV and IRR are somewhat normal looking. The means and standard deviations for each are given in Exhibit 13. Both distributions have a slight positive skewness, which means the distributions are skewed to the right. The two kurtosis values are fairly close to 3.0, which means that the distributions are not peaked or fat-tailed compared with the standard normal distribution. The median is the value at which 50% of the 10,000 outcomes fall on either side. The 90% confidence intervals show that 90% of the observations fall between −379 and 7,413 for the NPV and between 11.38% and 25.13% for the IRR. Although not shown in the table, 7.04% of the observations had a negative NPV and an IRR less than the 12% discount rate.

The means of the NPV and IRR from the simulation (in Exhibit 13) are fairly close to their values calculated using point estimates for all of the input variables (in Exhibit 11). This is not always the case, but it is here. The additional information from a simulation is the dispersions of the NPV and IRR. Given his assumptions and model, the simulation results show Zhang the distributions of NPV and IRR outcomes that should be expected. Managers and analysts often prefer to know these total distributions rather than just their mean values.

The correlations in Exhibit 13 can be interpreted as sensitivity measures. Changes in the "output" variable have the highest correlation with NPV and IRR outcomes. The salvage value has the lowest (absolute value) correlation.

This capital budgeting simulation example was not very complex, with only five stochastic variables. The example's five input variables were assumed to be normally distributed—in reality, many other distributions can be used. Finally, the randomly chosen values for each variable were assumed to be independent. They can be selected jointly instead of independently. Simulation techniques have proved to be a boon for addressing capital budgeting problems.

Sensitivity analysis, scenario analysis, and simulation analysis are well-developed standalone risk analysis methods. These risk measures depend on the variation of the project's cash flows.

6 REAL OPTIONS

e describe types of real options relevant to a capital project;

Real options are capital budgeting options that allow managers to make decisions in the future that alter the value of capital budgeting investment decisions made today. Instead of making all capital budgeting decisions now, at time zero, managers can wait and make additional decisions at future dates when these future decisions are contingent upon future economic events or information. These sequential decisions, in which future decisions depend on the decisions made today as well as on future economic events, are very realistic capital budgeting applications.

Real options are like financial options—they just deal with real assets instead of financial assets. A simple financial option could be a call option on a share of stock. Suppose the stock is selling for \$50, the exercise (strike) price is \$50, and the option expires in one year. If the stock goes up to \$60, you exercise the option and have a gain of \$10 in one year. If the stock goes down to \$40, you do not exercise, and you have no gain. However, zero gain is better than the \$10 loss you would have had if you had purchased the stock at the beginning of the year. Real options, like financial options, entail the right to make a decision but not the obligation. The corporation should exercise a real option only if it is value-enhancing.

Just as financial options are contingent on an underlying asset, real options are contingent on future events. The flexibility that real options give to managers can greatly enhance the NPV of the company's capital investments. The following are several types of these real options:

- *Timing Options.* Instead of investing now, the company can delay investing. Delaying an investment and basing the decision on hopefully improved information that you might have in, say, a year could help improve the NPV of the projects selected. **Project sequencing** options allow the firm to defer the decision to invest in a future project until the outcome of some or all of a current project is known. Projects are sequenced through time, so that investing in a project creates the option to invest in future projects.
- *Sizing Options.* If after investing, the company can abandon the project when the financial results are disappointing, it has an **abandonment option**. At some future date, if the cash flow from abandoning a project exceeds the present value of the cash flows from continuing the project, managers should exercise the abandonment option. Conversely, if the company can make additional investments when future financial results are strong, the company has a **growth option** or an expansion option. When estimating the cash flows from an expansion, the analyst must be wary of **cannibalization**, which occurs when an investment takes customers and sales away from another part of the company.
- *Flexibility Options.* Once an investment is made, other operational flexibilities may be available besides abandonment or expansion. For example, suppose demand exceeds capacity. Management may be able to exercise a **price-setting option**. By increasing prices, the company could benefit from the excess demand, which it cannot do by increasing production. There are also **production-flexibility options**, which offer the operational flexibility to alter production when demand varies from what is forecast. Even though it is expensive, the company can profit from working overtime or from adding additional shifts. The company can also work with customers and suppliers for

their mutual benefit whenever a demand–supply mismatch occurs. This type of option also includes the possibility of using different inputs or producing different outputs.

- *Fundamental Options*. In cases like the aforementioned, there are options embedded in a project that can raise its value. In other cases, the whole investment is essentially an option. The payoffs from the investment are contingent on an underlying asset, just like most financial options. For example, the value of an oil well or refinery investment is contingent on the price of oil. The value of a gold mine is contingent on the price of gold. If oil prices are low, you likely would not choose to drill a well. If oil prices are high, you go ahead and drill. Many R&D (research and development) projects also look like options.

There are several approaches to evaluating capital budgeting projects with real options. One of the difficulties with real options is that the analysis can be very complicated. Although some of the problems are simple and can be readily solved, many of them are so complex that they are expensive to evaluate or you may not have much confidence in the analysis. Four common sense approaches to real options analysis follow.

1 **Use DCF analysis without considering options.** If the NPV is positive without considering real options, and the project has real options that would simply add more value, it is unnecessary to evaluate the options. Just go ahead and make the investment.

2 **Consider the Project NPV = NPV (based on DCF alone) − Cost of options + Value of options.** Calculate the NPV based on expected cash flows. Then simply add the value associated with real options. For example, if a project has a negative NPV based on DCF alone of $50 million, will the options add at least that much to its value?

3 **Use decision trees.** Although they are not as conceptually sound as option pricing models, decision trees can capture the essence of many sequential-decision-making problems.

4 **Use option pricing models.** Except for simple options, the technical requirements for solving these models may require you to hire special consultants or "quants." Some large companies have their own specialists.

The analyst is confronted with 1) a variety of real options that investment projects may possess and 2) a decision about how to reasonably value these options. Example 2 deals with production flexibility; in this case, an additional investment outlay gives the company an option to use alternative fuel sources.

EXAMPLE 2

Production-Flexibility Option

Auvergne AquaFarms estimated the NPV of the expected cash flows from a new processing plant to be −€0.40 million. Auvergne is evaluating an incremental investment of €0.30 million that would give management the flexibility to switch among coal, natural gas, and oil as energy sources. The original plant relied only on coal. The option to switch to cheaper sources of energy when they are available has an estimated value of €1.20 million. What is the value of the new processing plant including this real option to use alternative energy sources?

Solution:

The NPV, including the real option, should be

$$\begin{aligned}\text{Project NPV} &= \text{NPV (based on DCF alone)} - \text{Cost of options} + \\ &\quad \text{Value of options}\\ \text{Project NPV} &= -0.40 \text{ million} - 0.30 \text{ million} + 1.20 \text{ million}\\ &= €0.50 \text{ million}\end{aligned}$$

Without the flexibility offered by the real option, the plant is unprofitable. The real option to adapt to cheaper energy sources adds enough to the value of this investment to give it a positive NPV.

7 COMMON CAPITAL BUDGETING PITFALLS

f describe common capital budgeting pitfalls.

Although the principles of capital budgeting may be easy to learn, applying the principles to real world investment opportunities can be challenging. Some of the common capital budgeting mistakes that managers make are listed here.

Not incorporating economic responses into the investment analysis. Economic responses to an investment often affect its profitability, and these responses have to be correctly anticipated. For example, in response to a successful investment, competitors can enter and reduce the investment's profitability. Similarly, vendors, suppliers, and employees may want to gain from a profitable enterprise. Companies that make highly profitable investments often find that a competitive marketplace eventually causes profitability to revert to normal levels.

Misusing capital budgeting templates. Because hundreds or even thousands of projects need to be analyzed over time, corporations provide standardized capital budgeting templates for managers to use in evaluating projects. This situation creates risks if the template model does not match the project or if employees input inappropriate information.

Pushing pet projects. Projects that influential managers want the corporation to invest in are known as **pet projects**. Ideally, such projects will receive the normal scrutiny that other investments receive and will be selected on the strength of their own merits. Often, unfortunately, pet projects are selected without undergoing normal capital budgeting analysis. Or, the pet project receives the analysis, but overly optimistic projections are used to inflate the project's profitability.

Basing investment decisions on EPS, net income, or return on equity. Managers sometimes have incentives to boost EPS, net income, or ROE. Many investments, even those with strong NPVs, do not boost these accounting numbers in the short run and may even reduce them. Paying attention to short-run accounting numbers can result in choosing projects that are not in the long-run economic interests of the business.

Using IRR to make investment decisions. The NPV criterion is economically sound. The IRR criterion is also sound for independent projects (with conventional cash flow patterns). If projects are mutually exclusive or competitive with each other, investing in projects based on the IRR will tend to result in choosing smaller, short-term projects with high IRRs at the expense of larger, longer-term, high-NPV projects. Basing decisions on paybacks or accounting rates of return is even more dangerous. These measures can be economically unsound.

Incorrectly accounting for cash flows. In analyzing a complicated project, it is easy to omit relevant cash flows, double-count cash flows, and mishandle taxes.

Over- or underestimating overhead costs. In large companies, the cost of a project must include the overhead it generates for such things as management time, information technology support, financial systems, and other support. Although these items are hard to estimate, over- or underestimating these overhead costs can lead to poor investment decisions.

Not using the appropriate risk-adjusted discount rate. The required rate of return for a project should be based on its risk. If a project is being financed with debt (or with equity), you should still use the project's required rate of return and not the cost of debt (or the cost of equity). Similarly, a high-risk project should not be discounted at the company's overall cost of capital, but at the project's required rate of return. Discount rate errors have a huge impact on the computed NPVs of long-lived projects.

Overspending and underspending the capital budget. Spending all of the investment budget just because it is available is another common mistake. Politically, many managers will spend all of their budget and argue that their budget is too small. In a well-run company, managers will return excess funds whenever their profitable projects cost less than their budget, and managers will make a sound case for extra funds if their budget is too small.

Failing to consider investment alternatives. Generating good investment ideas is the most basic step in the capital budgeting process, and many good alternatives are never even considered.

Incorrectly handling sunk costs and opportunity costs. Ignoring sunk costs is difficult for managers to do. Furthermore, not identifying the economic alternatives (real and financial) that are the opportunity costs is probably the biggest failure in much analysis. Only costs that change with the decision are relevant.

SUMMARY

Capital budgeting is the process that companies use for decision making on capital projects—those projects with a life of a year or more. This reading developed the principles behind the basic capital budgeting model, the cash flows that go into the model, and several extensions of the basic model.

- Analysts often organize the cash flows for capital budgeting in tables, summing all of the cash flows occurring at each point in time. These totals are then used to find an NPV or IRR. Alternatively, tables collecting cash flows by type can be used. Equations for the capital budgeting cash flows are as follows:

  Initial outlay:

  $$\text{Outlay} = \text{FCInv} + \text{NWCInv} - \text{Sal}_0 + \text{t}(\text{Sal}_0 - \text{B}_0)$$

  Annual after-tax operating cash flow:

  $$\text{CF} = (\text{S} - \text{C} - \text{D})(1 - t) + \text{D, or}$$

  $$\text{CF} = (\text{S} - \text{C})(1 - t) + t\text{D}$$

  Terminal year after-tax non-operating cash flow:

  $$\text{TNOCF} = \text{Sal}_\text{T} + \text{NWCInv} - t(\text{Sal}_\text{T} - \text{B}_\text{T})$$

- Depreciation schedules affect taxable income, taxes paid, and after-tax cash flows, and therefore capital budgeting valuations.
- When inflation exists, the analyst should perform capital budgeting analysis in "nominal" terms if cash flows are nominal and in "real" terms if cash flows are real.

- Inflation reduces the value of depreciation tax savings (unless the tax system adjusts depreciation for inflation). Inflation reduces the value of fixed payments to bondholders. Inflation usually does not affect all revenues and costs uniformly. Contracting with customers, suppliers, employees, and sources of capital can be complicated as inflation rises.
- Two ways of comparing mutually exclusive projects in a replacement chain are the "least common multiple of lives" approach and the "equivalent annual annuity" approach.
- For the least common multiple of lives approach, the analyst extends the time horizon of analysis so that the lives of both projects will divide exactly into the horizon. The projects are replicated over this horizon, and the NPV for the total cash flows over the least common multiple of lives is used to evaluate the investments.
- The equivalent annual annuity is the annuity payment (series of equal annual payments over the project's life) that is equivalent in value to the project's actual cash flows. Analysts find the present value of all of the cash flows for an investment (the NPV) and then calculate an annuity payment that has a value equivalent to the NPV.
- With capital rationing, the company's capital budget has a size constraint. Under "hard" capital rationing, the budget is fixed. In the case of hard rationing, managers use trial and error and sometimes mathematical programming to find the optimal set of projects. In that situation, it is best to use the NPV or PI valuation methods.
- Sensitivity analysis calculates the effect on the NPV of changes in one input variable at a time.
- Scenario analysis creates scenarios that consist of changes in several of the input variables and calculates the NPV for each scenario.
- Simulation (Monte Carlo) analysis is used to estimate probability distributions for the NPV or IRR of a capital project. Simulations randomly select values for stochastic input variables and then repeatedly calculate the project NPV and IRR to find their distributions.
- Real options can be classified as 1) timing options; 2) sizing options, which can be abandonment options or growth (expansion) options; 3) flexibility options, which can be price-setting options or production-flexibility options; and 4) fundamental options.

PRACTICE PROBLEMS

1 FITCO is considering the purchase of new equipment. The equipment costs \$350,000, and an additional \$110,000 is needed to install it. The equipment will be depreciated straight-line to zero over a five-year life. The equipment will generate additional annual revenues of \$265,000, and it will have annual cash operating expenses of \$83,000. The equipment will be sold for \$85,000 after five years. An inventory investment of \$73,000 is required during the life of the investment. FITCO is in the 40% tax bracket, and its cost of capital is 10%. What is the project NPV?

A \$52,122

B \$64,090

C \$97,449

2 After estimating a project's NPV, the analyst is advised that the fixed capital outlay will be revised upward by \$100,000. The fixed capital outlay is depreciated straight-line over an eight-year life. The tax rate is 40%, and the required rate of return is 10%. No changes in cash operating revenues, cash operating expenses, or salvage value are expected. What is the effect on the project NPV?

A \$100,000 decrease

B \$73,325 decrease

C \$59,988 decrease

3 When assembling the cash flows to calculate an NPV or IRR, the project's after-tax interest expenses should be subtracted from the cash flows for:

A the IRR calculation but not the NPV calculation.

B both the NPV calculation and the IRR calculation.

C neither the NPV calculation nor the IRR calculation.

4 Standard Corporation is investing \$400,000 of fixed capital in a project that will be depreciated straight-line to zero over its 10-year life. Annual sales are expected to be \$240,000, and annual cash operating expenses are expected to be \$110,000. An investment of \$40,000 in net working capital is required over the project's life. The corporate income tax rate is 30%. What is the after-tax operating cash flow expected in Year 1?

A \$63,000

B \$92,000

C \$103,000

5 Five years ago, Frater Zahn's Company invested £38 million—£30 million in fixed capital and another £8 million in working capital—in a bakery. Today, Frater Zahn's is selling the fixed assets for £21 million and liquidating the investment in working capital. The book value of the fixed assets is £15 million, and the marginal tax rate is 40%. The fifth year's after-tax non-operating cash flow to Frater Zahn's is *closest* to:

A £20.6 million.

B £23.0 million.

C £26.6 million.

The following information relates to Questions 6–8

Nanjing Techno Group is considering the purchase of a new 60-ton stamping press. The press costs CNY360,000, and an additional CNY40,000 is needed to install it. The press will be depreciated straight-line to zero over a five-year life. The press will generate no additional revenues, but it will reduce cash operating expenses by CNY140,000 annually. The press will be sold for CNY120,000 after five years. An inventory investment of CNY60,000 is required during the life of the investment. Nanjing Techno is in the 40% tax bracket.

6 What is the Nanjing Techno net investment outlay?

A CNY400,000

B CNY420,000

C CNY460,000

7 Nanjing Techno's incremental annual after-tax operating cash flow is *closest* to:

A CNY116,000.

B CNY124,000.

C CNY140,000.

8 What is the terminal year after-tax non-operating cash flow at the end of Year 5?

A CNY108,000.

B CNY132,000.

C CNY180,000.

The following information relates to Questions 9–12

Mei Yang is head of analyst recruiting for PPA Securities. She has been very frustrated by the number of job applicants who, in spite of their stellar pedigrees, seem to have little understanding of basic financial concepts. Yang has written a set of conceptual questions and simple problems for the human resources department to use to screen for the better candidates in the applicant pool. A few of her corporate finance questions and problems follow.

Concept 1 "A company invests in depreciable assets, financed partly by issuing fixed-rate bonds. If inflation is lower than expected, the value of the real tax savings from depreciation and the value of the real after-tax interest expense are both reduced."

Concept 2 "Sensitivity analysis and scenario analysis are useful tools for estimating the impact on a project's NPV of changing the value of one capital budgeting input variable at a time."

Concept 3 "When comparing two mutually exclusive projects with unequal lives, the IRR is a good approach for choosing the better project because it does not require equal lives."

Concept 4 "Project-specific betas should be used instead of company betas whenever the risk of the project differs from that of the company."

Problem	"Bo Gansu Electronics Co., Ltd. is investing CNY100 in a project that is being depreciated straight-line to zero over a two-year life with no salvage value. The project will generate earnings before interest and taxes of CNY50 each year for two years. Bo Gansu Company's weighted average cost of capital and required rate of return for the project are both 12%, and its tax rate is 30%."

9 For Concept 1, the statement is correct regarding the effects on:

A the real tax savings from depreciation but incorrect regarding the real after-tax interest expense.

B both the real tax savings from depreciation and the real after-tax interest expense.

C neither the real tax savings from depreciation nor the real after-tax interest expense.

10 For Concept 2, the statement is correct regarding:

A sensitivity analysis but incorrect regarding scenario analysis.

B scenario analysis but incorrect regarding sensitivity analysis.

C both sensitivity analysis and scenario analysis.

11 Are the statements identified as Concept 3 and Concept 4 correct?

A No for Concepts 3 and 4

B No for Concept 3 but yes for Concept 4

C Yes for Concept 3 but no for Concept 4

12 The after-tax operating cash flows for the Bo Gansu Company are:

A CNY50 in both years.

B CNY70 in both years.

C CNY85 in both years.

The following information relates to Questions 13–18

The capital budgeting committee for Laroache Industries is meeting. Laroache is a North American conglomerate that has several divisions. One of these divisions, Laroache Livery, operates a large fleet of vans. Laroache's management is evaluating whether it is optimal to operate new vans for two, three, or four years before replacing them. The managers have estimated the investment outlay, annual after-tax operating expenses, and after-tax salvage cash flows for each of the service lives. Because revenues and some operating costs are unaffected by the choice of service life, they were ignored in the analysis. Laroache Livery's opportunity cost of funds is 10%. The following table gives the cash flows in thousands of Canadian dollars (C$).

Service Life	Investment	Year 1	Year 2	Year 3	Year 4	Salvage
2 years	−40,000	−12,000	−15,000			20,000
3 years	−40,000	−12,000	−15,000	−20,000		17,000
4 years	−40,000	−12,000	−15,000	−20,000	−25,000	12,000

Schoeman Products, another division of Laroache, has evaluated several investment projects and now must choose the subset of them that fits within its C$40 million capital budget. The outlays and NPVs for the six projects are given below. Schoeman cannot buy fractional projects and must buy all or none of a project. The currency amounts are in millions of Canadian dollars.

Project	Outlay	PV of Future Cash Flows	NPV
1	31	44	13
2	15	21	6
3	12	16.5	4.5
4	10	13	3
5	8	11	3
6	6	8	2

Schoeman wants to determine which subset of the six projects is optimal.

A final proposal comes from the division Society Services, which has an investment opportunity with a real option to invest further if conditions warrant. The crucial details are as follows:

- The original project:
  - An outlay of C$190 million at time zero.
  - Cash flows of C$40 million per year for Years 1–10 if demand is "high."
  - Cash flows of C$20 million per year for Years 1–10 if demand is "low."
- Additional cash flows with the optional expansion project:
  - An outlay of C$190 million at time one.
  - Cash flows of C$40 million per year for Years 2–10 if demand is "high."
  - Cash flows of C$20 million per year for Years 2–10 if demand is "low."
- Whether demand is "high" or "low" in Years 1–10 will be revealed during the first year. The probability of "high" demand is 0.50, and the probability of "low" demand is 0.50.
- The option to make the expansion investment depends on making the initial investment. If the initial investment is not made, the option to expand does not exist.
- The required rate of return is 10%.

Society Services wants to evaluate its investment alternatives.

The internal auditor for Laroache Industries has made several suggestions for improving capital budgeting processes at the company. The internal auditor's suggestions are as follows:

Suggestion 1 "In order to put all capital budgeting proposals on an equal footing, the projects should all use the risk-free rate for the required rate of return."

Suggestion 2 "Because you cannot exercise both of them, you should not permit a given project to have both an abandonment option and an expansion/growth option."

Suggestion 3 "When rationing capital, it is better to choose the portfolio of investments that maximizes the company NPV than the portfolio that maximizes the company IRR."

Suggestion 4 "Project betas should be used for establishing the required rate of return whenever the project's beta is different from the company's beta."

13 What is the optimal service life for Laroache Livery's fleet of vans?

A Two years

B Three years

C Four years

14 The optimal subset of the six projects that Schoeman is considering consists of Projects:

A 1 and 5

B 2, 3, and 4

C 2, 4, 5, and 6

15 What is the NPV (C$ millions) of the original project for Society Services without considering the expansion option?

A −6.11

B −5.66

C 2.33

16 What is the NPV (C$ millions) of the optimal set of investment decisions for Society Services including the expansion option?

A 6.34

B 12.68

C 31.03

17 Should the capital budgeting committee accept the internal auditor's first and second suggestions, respectively?

A No for Suggestions 1 and 2

B No for Suggestion 1 and yes for Suggestion 2

C Yes for Suggestion 1 and no for Suggestion 2

18 Should the capital budgeting committee accept the internal auditor's third and fourth suggestions, respectively?

A No for Suggestions 3 and 4

B Yes for Suggestions 3 and 4

C No for Suggestion 3 and yes for Suggestion 4

The following information relates to Questions 19–24

Maximilian Böhm is reviewing several capital budgeting proposals from subsidiaries of his company. Although his reviews deal with several details that may seem like minutiae, the company places a premium on the care it exercises in making its investment decisions.

The first proposal is a project for Richie Express, which is investing $500,000, all in fixed capital, in a project that will have operating income after taxes of $20,000 and depreciation of $40,000 each year for the next three years. Richie Express will sell the asset in three years, paying 30% taxes on any excess of the selling price over book value. The proposal indicates that a $647,500 terminal selling price will enable the company to earn a 15% internal rate of return on the investment. Böhm doubts that this terminal value estimate is correct.

Another proposal concerns Gasup Company, which does natural gas exploration. A new investment has been identified by the Gasup finance department with the following projected cash flows:

- Investment outlays are $6 million immediately and $1 million at the end of the first year.
- After-tax operating cash flows are $0.5 million at the end of the first year and $4 million at the end of each of the second, third, fourth, and fifth years. In addition, an after-tax outflow occurs at the end of the five-year project that has not been included in the operating cash flows: $5 million required for environmental cleanup.
- The required rate of return on natural gas exploration is 18%.

The Gasup analyst is unsure about the calculation of the NPV and the IRR because the outlay is staged over two years.

Finally, Dominion Company is evaluating two mutually exclusive projects: The Pinto grinder involves an outlay of $100,000, annual after-tax operating cash flows of $45,000, an after-tax salvage value of $25,000, and a three-year life. The Bolten grinder has an outlay of $125,000, annual after-tax operating cash flows of $47,000, an after-tax salvage value of $20,000, and a four-year life. The required rate of return is 10%. The NPV and EAA of the Pinto grinder are $30,691 and $12,341, respectively. Whichever grinder is chosen, it will have to be replaced at the end of its service life. The analyst is unsure about which grinder should be chosen.

Böhm and his colleague Beth Goldberg have an extended conversation about capital budgeting issues, which includes the following comments. Goldberg makes two comments about real options:

Comment 1 "The abandonment option is valuable, but it should be exercised only when the abandonment value is above the amount of the original investment."

Comment 2 "If the cost of a real option is less than its value, this will increase the NPV of the investment project in which the real option is embedded."

Böhm also makes several comments about specific projects under consideration:

Comment A The land and building were purchased five years ago for $10 million. This is the amount that should now be included in the fixed capital investment."

Comment B "We can improve the project's NPV by using the after-tax cost of debt as the discount rate. If we finance the project with 100% debt, this discount rate would be appropriate."

Comment C "It is generally safer to use the NPV than the IRR in making capital budgeting decisions. When evaluating mutually exclusive projects, however, if the projects have conventional cash flow patterns and have the same investment outlays, it is acceptable to use either the NPV or IRR."

Comment D "You should not base a capital budgeting decision on its immediate impact on EPS."

19 What terminal selling price is required for a 15% internal rate of return on the Richie project?

A $588,028

B $593,771

C $625,839

20 The NPV and IRR, respectively, of the Gasup Company investment are *closest* to:

A $509,600 and 21.4%.

B $509,600 and 31.3%.

C $946,700 and 31.3%.

21 Of the two grinders that the Dominion Company is evaluating, Böhm should recommend the:

A Bolten grinder because its NPV is higher than the Pinto grinder NPV.

B Bolten grinder because its EAA is higher than the Pinto grinder EAA.

C Pinto grinder because its EAA is higher than the Bolten grinder EAA.

22 Are Goldberg's comments about real options correct?

A No for Comment 1 and Comment 2

B No for Comment 1 and yes for Comment 2

C Yes for Comment 1 and no for Comment 2

23 Is Böhm most likely correct regarding Comment A about the $10 million investment and Comment B about using the after-tax cost of debt?

A No for both comments

B Yes for both comments

C No for Comment A and yes for Comment B

24 Is Böhm most likely correct regarding Comment C that it is acceptable to use either NPV or IRR and Comment D about the immediate impact on EPS?

A No for both comments

B Yes for both comments

C No for Comment C and yes for Comment D

The following information relates to Questions 25–30

Geet Patel is a sell-side analyst who covers the pharmaceutical industry. One of the companies she follows, PRT-Assam Pharma, is evaluating a regional distribution center. The financial predictions for the capital project are as follows:

- Fixed capital outlay is INR1.50 billion.
- Investment in net working capital is INR0.40 billion.
- Straight-line depreciation is over a six-year period with zero salvage value.
- Project life is 12 years.
- Additional annual revenues are INR0.10 billion.

- Annual cash operating expenses are reduced by INR0.25 billion.
- The capital equipment is sold for INR0.50 billion in 12 years.
- Tax rate is 40%.
- Required rate of return is 12%.

Patel is evaluating this investment to see whether it has the potential to affect PRT-Assam Pharma's stock price. Patel estimates the NPV of the project to be INR0.41 billion, which should increase the company's value.

Patel is evaluating the effects of other changes to her capital budgeting assumptions. She wants to know the effect of a switch from straight-line to accelerated depreciation on the company's operating income and the project's NPV. She also believes that the initial outlay might be much smaller than initially assumed. Specifically, she thinks the outlay for fixed capital might be INR0.24 billion lower, with no change in salvage value.

When reviewing her work, Patel's supervisor provides the following comments. "I note that you are relying heavily on the NPV approach to valuing the investment decision. I don't think you should use an IRR because of the multiple IRR problem that is likely to arise with the PRT-Assam Pharma project. The equivalent annual annuity, however, would be a more appropriate measure to use for the project than the NPV. I suggest that you compute an EAA."

25 Patel should estimate the after-tax operating cash flow for Years 1–6 and 7–12, respectively, to be *closest* to:

A INR0.31 billion and INR0.21 billion.

B INR0.31 billion and INR0.25 billion.

C INR0.35 billion and INR0.25 billion.

26 Patel should estimate the initial outlay and the terminal year non-operating cash flow, respectively, to be *closest* to:

A INR1.50 billion and INR0.70 billion.

B INR1.90 billion and INR0.70 billion.

C INR1.90 billion and INR0.90 billion.

27 Is Patel's estimate of the NPV of the project correct?

A Yes

B No, the NPV is –INR0.01 billion

C No, the NPV is INR0.34 billion

28 A switch from straight-line to accelerated depreciation would:

A increase the NPV and decrease the first-year operating income after taxes.

B increase the first-year operating income after taxes and decrease the NPV.

C increase both the NPV and first-year operating income after taxes.

29 If the outlay is lower by the amount that Patel suggests, the project NPV should increase by an amount *closest* to:

A INR0.09 billion.

B INR0.14 billion.

C INR0.17 billion.

30 How should you evaluate the comments by Patel's supervisor about not using the IRR and about using the EAA? The supervisor is:

A incorrect about both.

B correct about IRR and incorrect about EAA.

C incorrect about IRR and correct about EAA.

The following information relates to Questions 31–36

Carlos Velasquez, CFA, is a financial analyst with Embelesado, S.A., a Spanish manufacturer of sailboats and sailing equipment. Velasquez is evaluating a proposal for Embelesado to build sailboats for a foreign competitor that lacks production capacity and sells in a different market. The sailboat project is perceived to have the same risk as Embelesado's other projects.

The proposal covers a limited time horizon—three years—after which the competitor expects to be situated in a new, larger production facility. The limited time horizon appeals to Embelesado, which currently has excess capacity but expects to begin its own product expansion in slightly more than three years.

Velasquez has collected much of the information necessary to evaluate this proposal in Exhibits 1 and 2.

Exhibit 1 Selected Data for Sailboat Proposal (currency amounts in € millions)

Initial fixed capital outlay	60
Annual contracted revenues	60
Annual operating costs	25
Initial working capital outlay (recovered at end of the project)	10
Annual depreciation expense (both book and tax accounting)	20
Economic life of facility (years)	3
Salvage (book) value of facility at end of project	0
Expected market value of facility at end of project	5

Exhibit 2 Selected Data for Embelesado, S.A.

Book value of long-term debt/total assets	28.6%
Book value of equity/total assets	71.4%
Market value of long-term debt/market value of company	23.1%
Market value of equity/market value of company	76.9%
Coupon rate on existing long-term debt	8.5%
Interest rate on new long-term debt	8.0%
Cost of equity	13.0%
Marginal tax rate	35.0%
Maximum acceptable payback period	2 years

Velasquez recognizes that Embelesado is currently financed at its target capital structure and expects that the capital structure will be maintained if the sailboat project is undertaken. Embelesado's managers disagree, however, about the method that should be used to evaluate capital budgeting proposals.

One of Embelesado's vice presidents asks Velasquez the following questions:

Question 1	Will projects that meet a corporation's payback criterion for acceptance necessarily have a positive NPV?
Question 2	For mutually exclusive projects, will the NPV and IRR methods necessarily agree on project ranking?
Question 3	For the sailboat project, what will be the effects of using accelerated depreciation (for both book and tax accounting) instead of straight-line depreciation on a) the NPV and b) the total net cash flow in the terminal year?
Question 4	Assuming a 13% discount rate, what will be the increase in the sailboat project's NPV if the expected market value of the facility at end of project is €15 million rather than €5 million?

31 The weighted average cost of capital for Embelesado is *closest* to:

A 10.78%.

B 11.20%.

C 11.85%.

32 The total net cash flow (in € millions) for the sailboat project in its terminal year is *closest* to:

A 33.00.

B 39.75.

C 43.00.

33 The IRR for the sailboat project is *closest* to:

A 18.5%.

B 19.7%.

C 20.3%.

34 The best responses that Velasquez can make to Question 1 and Question 2 are:

	Question 1	Question 2
A	No	No
B	No	Yes
C	Yes	No

35 In response to Question 3, what are the *most likely* effects on the NPV and the total net cash flow in the terminal year, respectively?

	NPV	Total Net Cash Flow in Terminal Year
A	Increase	Increase
B	Increase	Decrease
C	Decrease	Increase

36 In response to Question 4, the increase in the sailboat project's NPV (in € millions) is *closest* to:

A 4.50.

B 6.50.

C 6.76.

The following information relates to Questions 37–42

María Hernández is a sell-side analyst covering the electronics industry in Spain. One of the companies she follows, SG Electronics, S.A., has recently announced plans to begin producing and selling a new series of video cameras. Hernández estimates that this project will increase the value of the company, and consequently, she plans to change her research opinion on the company from a "hold" to a "buy." Her initial financial predictions for the project are as follows:

- Fixed capital equipment outlay is €2,750,000.
- At the beginning of the project, a required increase in current assets of €200,000 and a required increase in current liabilities of €125,000.
- Straight-line depreciation to zero over a five-year life.
- Project life of five years.
- Incremental annual unit sales of 3,000 at a unit price of €600.
- Annual fixed cash expenses of €125,000; variable cash expenses of €125 per unit.
- The capital equipment is expected to be sold for €450,000 at the end of Year 5. At the end of the project, the net working capital investment will be recovered.
- Tax rate of 40%.
- Based on the capital asset pricing model, the required rate of return is 12%.

Hernández estimates the project's expected NPV to be €975,538 and the IRR to be 24.6%. She also performs a sensitivity analysis by changing the input variable assumptions used in her initial analysis.

When reviewing Hernández's work, her supervisor, Arturo Costa, notes that she did not include changes in the depreciation method, initial fixed capital outlay, or inflation assumptions in her sensitivity analysis. As a result, Costa asks the following questions:

Question 1 "What would be the effect on the project's NPV if the initial fixed capital equipment outlay increased from €2,750,000 to €3,000,000, with everything else held constant?"

Question 2 "How would a higher-than-expected inflation rate affect the value of the real tax savings from depreciation and the value of the real after-tax interest expense, with everything else held constant?"

Question 3 "You are using a required rate of return of 12% when the company's weighted average cost of capital (WACC) is 10%. Why are you using a required rate of return for the project greater than the company's WACC?"

Before ending the meeting, Costa tells Hernández: “Last year the company produced a prototype at a cost of €500,000. Now management is having doubts about the market appeal of the product in its current design, and so they are considering delaying the start of the project for a year, until the prototype can be shown to industry experts.”

37 Using Hernández’s initial financial predictions, the estimated annual after-tax operating cash flow is *closest* to:

A €780,000.

B €1,000,000.

C €1,075,000.

38 Using Hernández’s initial financial predictions, the estimated terminal year after-tax non-operating cash flow is *closest* to:

A €195,000.

B €270,000.

C €345,000.

39 Hernández’s best response to Costa’s first question is that the project’s NPV would decrease by an amount *closest* to:

A €142,000.

B €178,000.

C €250,000.

40 Hernández’s *best* response to Costa’s second question is that:

A real tax savings from depreciation and real interest expense would be lower.

B real tax savings from depreciation would be higher and real interest expense would be lower.

C real tax savings from depreciation would be lower and real interest expense would be higher.

41 Hernández’s *best* response to Costa’s third question is: “Because:

A the project will plot above the security market line.”

B the project’s beta is greater than the company’s beta.”

C the project’s IRR is greater than the required rate of return.”

42 Should Costa’s end-of-meeting comments result in changes to Hernández’s capital budgeting analysis?

A No

B Yes, but only to incorporate the possible delay

C Yes, to incorporate both the possible delay and the cost of producing the prototype

SOLUTIONS

1 C is correct.

Outlay = FCInv + NWCInv − Sal_0 + t(Sal_0 − B_0)

= (350,000 + 110,000) + 73,000 − 0 + 0

= $533,000

The installed cost is $350,000 + $110,000 = $460,000, so the annual depreciation is $460,000/5 = $92,000. The annual after-tax operating cash flow for Years 1–5 is

$$\begin{aligned} CF &= (S - C - D)(1 - t) + D \\ &= (265{,}000 - 83{,}000 - 92{,}000)(1 - 0.40) + 92{,}000 \\ &= \$146{,}000. \end{aligned}$$

The terminal year after-tax non-operating cash flow in Year 5 is

$$\begin{aligned} TNOCF &= Sal_5 + NWCInv - t(Sal_5 - B_5) \\ &= 85{,}000 + 73{,}000 - 0.40(85{,}000 - 0) \\ &= \$124{,}000. \end{aligned}$$

The NPV is

$$NPV = -533{,}000 + \sum_{t=1}^{5} \frac{146{,}000}{1.10^t} + \frac{124{,}000}{1.10^5} = \$97{,}449$$

2 B is correct. The additional annual depreciation is $100,000/8 = $12,500. The depreciation tax savings is 0.40 ($12,500) = $5,000. The change in project NPV is

$$-100{,}000 + \sum_{t=1}^{8} \frac{5{,}000}{(1.10)^t} = -100{,}000 + 26{,}675 = -\$73{,}325$$

3 C is correct. Financing costs are not subtracted from the cash flows for either the NPV or the IRR. The effects of financing costs are captured in the discount rate used.

4 C is correct. The annual depreciation charge is $400,000/10 = $40,000. The after-tax operating cash flow in Year 1 should be

$$\begin{aligned} CF &= (S - C - D)(1 - t) + D \\ &= (240{,}000 - 110{,}000 - 40{,}000)(1 - 0.30) + 40{,}000 \\ &= 63{,}000 + 40{,}000 \\ &= \$103{,}000. \end{aligned}$$

5 C is correct. The terminal year after-tax non-operating cash flow is

$$\begin{aligned} TNOCF &= Sal_5 + NWCInv - t(Sal_5 - B_5) \\ &= 21 + 8 - 0.40(21 - 15) \\ &= £26.6.\ \text{million}. \end{aligned}$$

6 C is correct. The investment outlay is

$$\begin{aligned} Outlay &= FCInv + NWCInv - Sal_0 + t(Sal_0 - B_0) \\ &= (360{,}000 + 40{,}000) + 60{,}000 - 0 + 0 \\ &= CNY460{,}000. \end{aligned}$$

7 A is correct. Depreciation will be CNY400,000/5 = CNY80,000 per year. The annual after-tax operating cash flow is

$$\begin{aligned} CF &= (S - C - D)(1 - t) + D \\ &= [0 - (-140{,}000) - 80{,}000](1 - 0.40) + 80{,}000 \\ &= \text{CNY}116{,}000. \end{aligned}$$

8 B is correct. The terminal year non-operating cash flow is

$$\begin{aligned} TNOCF &= Sal_5 + NWCInv - t(Sal_5 - B_5) \\ &= 120{,}000 + 60{,}000 - 0.40(120{,}000 - 0) \\ &= \text{CNY}132{,}000. \end{aligned}$$

9 C is correct. The value of the depreciation tax savings is increased, and the value of the real after-tax interest expense is also increased. Because of the lower inflation, the value has increased (essentially discounting at a lower rate).

10 A is correct. The statement is correct for sensitivity analysis but not for scenario analysis (in which several input variables are changed for each scenario).

11 B is correct. Either the least-common multiple of lives or the equivalent annual annuity approach should be used (both use the NPV, not the IRR). Concept 4 is correct as given.

12 C is correct. The problem gives EBIT, not EBITDA.

$$CF = (S - C - D)(1 - t) + D$$

$$= 50(1 - 0.3) + 50$$

$$= \text{CNY}85 \text{ each year}$$

13 B is correct. The way to solve the problem is to calculate the equivalent annual annuity and choose the service life with the lowest annual cost. For a two-year service life, the NPV is

$$NPV = -40{,}000 + \frac{-12{,}000}{1.10^1} + \frac{-15{,}000}{1.10^2} + \frac{20{,}000}{1.10^2} = -46{,}776.86$$

The EAA (PV = −46,776.86, N = 2, and i = 10%) is −26,952.38.

For a three-year service life, the NPV is

$$\begin{aligned} NPV &= -40{,}000 + \frac{-12{,}000}{1.10^1} + \frac{-15{,}000}{1.10^2} + \frac{-20{,}000}{1.10^3} + \frac{17{,}000}{1.10^3} \\ &= -65{,}559.73 \end{aligned}$$

The EAA (PV = −65,559.73, N = 3, and i = 10%) is −26,362.54.

For a four-year service life, the NPV is

$$\begin{aligned} NPV &= -40{,}000 + \frac{-12{,}000}{1.10^1} + \frac{-15{,}000}{1.10^2} + \frac{-20{,}000}{1.10^3} + \frac{-25{,}000}{1.10^4} \\ &\quad + \frac{12{,}000}{1.10^4} = -87{,}211.26 \end{aligned}$$

The EAA (PV = −87,211.26, N = 4, and i = 10%) is −27,512.61.

The three-year service life has the lowest annual cost. Laroache should replace the vans every three years.

14 A is correct. To help the selection process, use the profitability index for each project, which shows the total present value per dollar invested.

Project	Outlay	PV of Future Cash Flows	NPV	PI	PI Rank
1	31	44	13	1.419	1
2	15	21	6	1.400	2
3	12	16.5	4.5	1.375	(tie) 3
4	10	13	3	1.300	6
5	8	11	3	1.375	(tie) 3
6	6	8	2	1.333	5

Try to incorporate the high-PI projects into the budget using trial and error. These trials include the following:

Set of Projects	Total Outlay	Total NPV
1 and 5	39	16
2, 3, and 4	37	13.5
2, 3, and 5	35	13.5
2, 4, 5, and 6	39	14

Among the sets of projects suggested, the optimal set is the one with the highest NPV, provided its total outlay does not exceed C$40 million. The set consisting of Projects 1 and 5 produces the highest NPV.

15 B is correct.

If demand is "high," the NPV is

$$\text{NPV} = -190 + \sum_{t=1}^{10} \frac{40}{1.10^t} = \text{C\$55.783 million}$$

If demand is "low," the NPV is

$$\text{NPV} = -190 + \sum_{t=1}^{10} \frac{20}{1.10^t} = -\text{C\$67.109 million}$$

The expected NPV is 0.50(55.783) + 0.50(–67.109) = –C$5.663 million.

16 B is correct. Assume we are at Time 1. The NPV of the expansion (at Time 1) if demand is "high" is

$$\text{NPV} = -190 + \sum_{t=1}^{9} \frac{40}{1.10^t} = \text{C\$40.361 million}$$

The NPV of the expansion (at Time 1) if demand is "low" is

$$\text{NPV} = -190 + \sum_{t=1}^{9} \frac{20}{1.10^t} = -\text{C\$74.820 million}$$

The optimal decision is to expand if demand is "high" and not expand if "low."

Because the expansion option is exercised only when its value is positive, which happens 50% of the time, the expected value of the expansion project, at Time 0, is

$$\text{NPV} = \frac{1}{1.10} 0.50(40.361) = \text{C\$18.346 million}$$

The total NPV of the initial project and the expansion project is

NPV = −C$5.663 million + C$18.346 million = C$12.683 million.

The optional expansion project, handled optimally, adds sufficient value to make this a positive NPV project.

17 A is correct. Both suggestions are bad. In valuing projects, expected cash flows should be discounted at required rates of return that reflect their risk, not at a risk-free rate that ignores risk. Even though both options cannot be simultaneously exercised, they can both add value. If demand is high, you can exercise the growth option, and if demand is low, you can exercise the abandonment option.

18 B is correct. Both suggestions are good. Choosing projects with high IRRs might cause the company to concentrate on short-term projects that reduce the company's NPV. Whenever the project risk differs from the company risk, a project-specific required rate of return should be used.

19 C is correct. The after-tax operating cash flow for each of the next three years is \$20,000 + \$40,000 = \$60,000. The book value in three years will be \$380,000 (the original cost less three years' depreciation). So the terminal year after-tax non-operating cash flow will be Sal_3 − 0.30(Sal_3 −\$380,000), where Sal_3 is the selling price. For a 15% return, the PV of future cash flows must equal the investment:

$$500{,}000 = \frac{60{,}000}{1.15} + \frac{60{,}000}{1.15^2} + \frac{60{,}000}{1.15^3} + \frac{\mathrm{Sal}_3 - 0.30\left(\mathrm{Sal}_3 - 380{,}000\right)}{1.15^3}$$

There are several paths to follow to solve for Sal_3.

$$363{,}006.5 = \frac{\mathrm{Sal}_3 - 0.30\left(\mathrm{Sal}_3 - 380{,}000\right)}{1.15^3}$$

$$\mathrm{Sal}_3 - 0.30\left(\mathrm{Sal}_3 - 380{,}000\right) = 552{,}087.5$$

$$0.70\ \mathrm{Sal}_3 = 438{,}087.5$$

$$\mathrm{Sal}_3 = \$625{,}839$$

20 A is correct. The cash flows (in \$ millions) for the five-year gas project are as follows:

Time	Outlays	After-Tax Operating Cash Flows	Total After-Tax Cash Flows
0	6.0	0.0	−6.0
1	1.0	0.5	−0.5
2	0.0	4.0	4.0
3	0.0	4.0	4.0
4	0.0	4.0	4.0
5	5.0	4.0	−1.0

Given the required rate of return of 18%, the NPV can be calculated with the following equation or with a financial calculator:

$$\mathrm{NPV} = -6.0 + \frac{-0.5}{1.18} + \frac{4.0}{1.18^2} + \frac{4.0}{1.18^3} + \frac{4.0}{1.18^4} + \frac{-1.0}{1.18^5}$$

$$\mathrm{NPV} = \$509{,}579$$

Similarly, the IRR can be calculated from the following equation:

$$-6.0 + \frac{-0.5}{1+r} + \frac{4.0}{(1+r)^2} + \frac{4.0}{(1+r)^3} + \frac{4.0}{(1+r)^4} + \frac{-1.0}{(1+r)^5} = 0$$

Solving for r with a financial calculator or spreadsheet software will yield 21.4% for the internal rate of return. Note that in spite of the fact that we are dealing with a non-conventional cash flow pattern, the IRR has a unique solution. The NPV profile declines as the required rate of return increases, and the NPV value crosses the x-axis (required rate of return) only one time, at 21.4%.

21 C is correct. Because the mutually exclusive projects have unequal lives, the EAA should be used instead of the NPV. The NPV and EAA for the Pinto grinder are correct. For the Bolten grinder, the NPV is

$$\text{NPV} = -125{,}000 + \sum_{t=1}^{4} \frac{47{,}000}{1.10^t} + \frac{20{,}000}{1.10^4} = 37{,}644$$

To find the Bolten EAA, take the NPV for Bolten and annualize it for four years (N = 4, PV = 37,644, and i = 10%). The Bolten EAA is \$11,876. Consequently, the Pinto grinder has the better EAA of \$12,341.

22 B is correct. Goldberg's first comment is wrong. A project should be abandoned in the future only when its abandonment value is more than the discounted value of the remaining cash flows. Goldberg's second comment is correct.

23 A is correct. The \$10 million original cost is a sunk cost and not relevant. The correct investment is today's opportunity cost, the market value today. The correct discount rate is the project required rate of return.

24 C is correct. Even if they are the same size, a short-term project with a high IRR can have a lower NPV than a longer-term project. The immediate impact on EPS does not capture the full effect of the cash flows over the project's entire life.

25 A is correct. The annual depreciation charge for Years 1–6 is 1.5/6 = 0.25. Annual after-tax operating cash flows for Years 1–6 are as follows:

$$\text{CF} = (\text{S} - \text{C} - \text{D})(1 - \text{t}) + \text{D}$$

$$= [0.10 - (-0.25) - 0.25](1 - 0.40) + 0.25$$

$$= 0.06 + 0.25 = \text{INR}0.31 \text{ billion}$$

Annual after-tax operating cash flows for Years 7–12 are as follows:

$$\text{CF} = (\text{S} - \text{C} - \text{D})(1 - \text{t}) + \text{D}$$

$$= [0.10 - (-0.25) - 0](1 - 0.40) + 0$$

$$= \text{INR}0.21 \text{ billion}$$

26 B is correct.

Outlay at time zero is as follows:

$$\text{Outlay} = \text{FCInv} + \text{NWCInv} - \text{Sal}_0 + \text{t}(\text{Sal}_0 - \text{B}_0)$$

$$= 1.50 + 0.40 - 0 + 0$$

$$= \text{INR}1.90 \text{ billion}$$

Terminal year after-tax non-operating cash flow is

$$\text{TNOCF} = \text{Sal}_{12} + \text{NWCInv} - \text{t}(\text{Sal}_{12} - \text{B}_{12})$$

$= 0.50 + 0.40 - 0.40(0.50 - 0)$

$= \text{INR}0.70$ billion

27 B is correct. The cash flows, computed in the first two questions, are as follows:

Time 0	–INR1.90 billion
Time 1–6	INR0.31 billion
Time 7–12	INR0.21 billion
Time 12	INR0.70 billion

The NPV is

$$\begin{aligned} \text{NPV} &= -1.90 + \sum_{t=1}^{6}\frac{0.31}{1.12^t} + \sum_{t=7}^{12}\frac{0.21}{1.12^t} + \frac{0.70}{1.12^{12}} \\ &= -1.90 + 1.2745 + 0.4374 + 0.1797 \\ &= -\text{INR}0.0084 \text{ billion} \approx -\text{INR}0.01 \text{ billion} \end{aligned}$$

28 A is correct. Accelerated depreciation shifts depreciation expense toward the earlier years so that first-year operating income after taxes will be lower. Because depreciation is a non-cash expense, however, it must be added back to operating income after taxes in order to obtain after-tax operating cash flow. This process shifts cash flows from later years to earlier years, increasing the NPV.

29 C is correct. The outlay is lower by INR0.24, which will decrease the annual depreciation by INR0.04 for the first six years. The annual additional taxes from the loss of the depreciation tax shelter are INR0.04(0.40) = INR0.016. The after-tax cash flows are higher by €0.24 at time zero (because of the smaller investment) and lower by €0.016 for the first six years. The NPV increases by

$$\text{NPV} = +0.24 - \sum_{t=1}^{6}\frac{0.016}{1.12^t} = 0.24 - 0.0658 = 0.1742 = \text{INR}0.17 \text{ billion}$$

30 A is correct. Both of the supervisor's comments are incorrect. Because the PRT-Assam Pharma project is a conventional project (an outflow followed by inflows), the multiple IRR problem cannot occur. The EAA is preferred over the NPV when dealing with mutually exclusive projects with differing lives, a scenario that is not relevant for this decision. The PRT-Assam Pharma project is freestanding, so the NPV approach is appropriate.

31 B is correct. The weighted average cost of capital for Embelesado is calculated as follows:

$$\begin{aligned} \text{WACC} &= (\text{Market weight of debt} \times \text{After-tax cost of debt}) + \\ &\quad\ (\text{Market weight of equity} \times \text{Cost of equity}) \\ &= w_d k_d(1 - \text{t}) + w_{cs}k_{cs} = 0.231(8.0\%)(1 - 0.35) + 0.769(13.0\%) \\ &= 1.201\% + 9.997\% \\ &= 11.198\%, \text{ rounded to } 11.20\% \end{aligned}$$

32 C is correct. The terminal year cash flow (in millions) is as follows:

Revenues	€60.00
Less operating costs	25.00
Less depreciation expenses	20.00
= Taxable income	15.00
Less taxes @ 35%	(5.25)

= Net income	9.75
Plus depreciation expenses	20.00
= After-tax operating CF	29.75
+ Recover WC	10.00
+ Ending market value	5.00
Less taxes on sale proceeds @ 35%	(1.75)*
= Terminal Year CF	€43.00

* The tax on the sale proceeds is 35% multiplied by the gain of €5.00 = €1.75.

33 C is correct. This is the IRR for a project with the following cash flows: (€70,000) in Year 0, €29,750 at Years 1 and 2, and €43,000 at Year 3.

	Years 1 & 2	Year 3
Revenues	€60,000	€60,000
Less operating costs	25,000	25,000
Less depreciation expense	20,000	20,000
= Taxable income	15,000	15,000
Less taxes @ 35%	5,250	5,250
= Net income	9,750	9,750
Plus depreciation expense	20,000	20,000
= After-tax operating CF	€29,750	29,750
+ Recover WC		10,000
+ Salvage value		5,000
– Less taxes on salvage value @ 35%		1,750
= Terminal year CF		€43,000

The IRR of 20.29% is readily found with a financial calculator:

$$70{,}000 = \frac{29{,}750}{(1 + IRR)^1} + \frac{29{,}750}{(1 + IRR)^2} + \frac{43{,}000}{(1 + IRR)^3}$$

You can also "reverse-engineer" the answer using the choices given in the question.

34 A is correct. Projects with shorter paybacks do not necessarily have a positive NPV. For mutually exclusive projects, the NPV and IRR criteria will not necessarily provide the same project ranking.

35 B is correct. Additional depreciation in earlier periods will shield Embelesado from additional taxes, thus increasing the net cash flows in earlier years of the project and increasing the project's NPV. This also means that there will be less depreciation expense in the terminal year of the project, however, thus shielding less income and increasing taxes. Terminal-year net cash flow will likely decrease.

36 A is correct. The entire €10 million will be subject to taxes, resulting in an additional €6.5 million after taxes. As indicated in the following calculation, when discounted at 13% for three years, this has a present value of €4.5048 (rounded to €4.50 million):

$$PV = \frac{10.0(1 - 0.35)}{(1.13)^3} = \frac{6.50}{(1.13)^3} = 4.50$$

37 B is correct. Using the equation CF = (S − C) × (1 − t) + tD, the numbers are as follows:

$$\begin{aligned}
\text{Sales} &= \text{P} \times \text{Q} = €600 \times 3{,}000 = €1{,}800{,}000 \\
\text{Costs} &= \text{Variable cost} \times \text{Q} + \text{Fixed costs} = (125 \times 3{,}000) + \\
&\quad €125{,}000 \\
&= 500{,}000 \\
\text{Depreciation expense} &= €2{,}750{,}000 \div 5 = €550{,}000 \\
\text{CF} &= (1{,}800{,}000 - 500{,}000) \times (1 - 0.40) + (550{,}000 \times \\
&\quad 0.40) \\
&= 780{,}000 + 220{,}000 \\
&= €1{,}000{,}000
\end{aligned}$$

38 C is correct. The terminal year non-operating cash flow includes the after-tax salvage value and the recovery of net working capital = €450,000 × (1 − 0.40) + €75,000 = €345,000.

(Note: Terminal year recovery of net working capital investment = Decrease in current assets − Decrease in current liabilities = €200,000 − €125,000 = €75,000.)

39 B is correct. Calculations: The outlay is higher by €250,000, which will increase annual depreciation by €50,000 over the five-year period. The annual additional tax savings from the higher depreciation expense is 50,000 × (0.40) = 20,000. Therefore NPV should decrease by

$$\text{NPV} = -250{,}000 + \sum_{t=1}^{5} \frac{20{,}000}{1.12^t} = -250{,}000 + 72{,}095.524 = -177{,}904$$

40 A is correct. Higher-than-expected inflation increases the corporation's real taxes because it reduces the value of the depreciation tax shelter; it also decreases the real interest expense because payments to bondholders in real terms are lower than expected.

41 B is correct. When a project is more or less risky than the company, project beta and not WACC should be used to establish the required rate of return for the capital project. In this case, the required rate of return is greater than the WACC, which means the project beta (risk) is greater than the company's beta.

42 B is correct. Timing options (e.g., delay investing) should be included in the NPV analysis, but sunk costs should not.

Equity Valuation

STUDY SESSIONS

Study Session 8	Equity Valuation (1)
Study Session 9	Equity Valuation (2)

TOPIC LEVEL LEARNING OUTCOME

The candidate should be able to analyze and evaluate equity securities using appropriate valuation concepts and techniques. The candidate should also be able to estimate risk and expected return of equities in global contexts.

Companies across the world differ widely in their operating and reporting models and risk–return considerations. A privately held, early stage financial technology startup with few physical assets or cash flows will look and operate differently than a mature auto manufacturer with complex operations across the globe. Fortunately, equity valuation methods exist that, based on the fundamental inputs available, can be applied to value the business, investment, or transaction in question. In each case, determining the most appropriate method to apply requires a sound understanding of the company and its industry.

EQUITY VALUATION

STUDY SESSION 8

Equity Valuation (1)

This study session introduces essential equity valuation concepts. The various definitions of value and the application of equity valuation techniques to solve everyday problems are first discussed. A five-step equity valuation process is then described with the three main categories of equity valuation models (absolute, relative, total entity) presented in step three. Key return measures including the equity risk premium and derivation of the equity required return using various models (CAPM, multifactor, build up) conclude the session.

Equity Valuation: Applications and Processes

by Jerald E. Pinto, PhD, CFA, Elaine Henry, PhD, CFA, Thomas R. Robinson, PhD, CFA, CAIA, and John D. Stowe, PhD, CFA

Jerald E. Pinto, PhD, CFA, is at CFA Institute (USA). Elaine Henry, PhD, CFA, is at Stevens Institute of Technology (USA). Thomas R. Robinson, PhD, CFA, CAIA, is at Robinson Global Investment Management LLC, (USA). John D. Stowe, PhD, CFA, is at Ohio University (USA).

LEARNING OUTCOMES

Mastery	*The candidate should be able to:*
☐	**a.** define valuation and intrinsic value and explain sources of perceived mispricing;
☐	**b.** explain the going concern assumption and contrast a going concern value to a liquidation value;
☐	**c.** describe definitions of value and justify which definition of value is most relevant to public company valuation;
☐	**d.** describe applications of equity valuation;
☐	**e.** describe questions that should be addressed in conducting an industry and competitive analysis;
☐	**f.** contrast absolute and relative valuation models and describe examples of each type of model;
☐	**g.** describe sum-of-the-parts valuation and conglomerate discounts;
☐	**h.** explain broad criteria for choosing an appropriate approach for valuing a given company.

INTRODUCTION AND VALUE DEFINITIONS 1

a define valuation and intrinsic value and explain sources of perceived mispricing;

© 2020 CFA Institute. All rights reserved.

b explain the going concern assumption and contrast a going concern value to a liquidation value;

c describe definitions of value and justify which definition of value is most relevant to public company valuation;

Every day, thousands of participants in the investment profession—investors, portfolio managers, regulators, researchers—face a common and often perplexing question: What is the value of a particular asset? The answers to this question usually influence success or failure in achieving investment objectives. For one group of those participants—equity analysts—the question and its potential answers are particularly critical because determining the value of an ownership stake is at the heart of their professional activities and decisions. **Valuation** is the estimation of an asset's value based on variables perceived to be related to future investment returns, on comparisons with similar assets, or, when relevant, on estimates of immediate liquidation proceeds. Skill in valuation is a very important element of success in investing.

We address some basic questions: What is value? Who uses equity valuations? What is the importance of industry knowledge? How can the analyst effectively communicate his analysis? We answer these and other questions and lay a foundation for the topics that follow.

The following section defines value and describes the various uses of equity valuation. The subsequent sections examine the steps in the valuation process, including the analyst's role and responsibilities, and discuss how valuation results are communicated. They also provide some guidance on the content and format of an effective research report.

1.1 Value Definitions and Valuation Applications

Before summarizing the various applications of equity valuation tools, it is helpful to define what is meant by "value" and to understand that the meaning can vary in different contexts. The context of a valuation, including its objective, generally determines the appropriate definition of value and thus affects the analyst's selection of a valuation approach.

1.1.1 *What Is Value?*

Several perspectives on value serve as the foundation for the variety of valuation models available to the equity analyst. Intrinsic value is the necessary starting point, but other concepts of value—going-concern value, liquidation value, and fair value—are also important.

1.1.1.1 Intrinsic Value A critical assumption in equity valuation, as applied to publicly traded securities, is that the market *price* of a security can differ from its intrinsic *value*. The **intrinsic value** of any asset is the value of the asset given a hypothetically complete understanding of the asset's investment characteristics. For any particular investor, an estimate of intrinsic value reflects his or her view of the "true" or "real" value of an asset. If one assumed that the market price of an equity security perfectly reflected its intrinsic value, "valuation" would simply require looking at the market price. Roughly, it is just such an assumption that underpins traditional efficient market theory, which suggests that an asset's market price is the best available estimate of its intrinsic value.

An important theoretical counter to the notion that market price and intrinsic value are identical can be found in the Grossman–Stiglitz paradox. If market prices, which are essentially freely obtainable, perfectly reflect a security's intrinsic value, then a rational investor would not incur the costs of obtaining and analyzing information to obtain a second estimate of the security's value. If no investor obtains and analyzes information about a security, however, then how can the market price reflect the security's intrinsic value? The **rational efficient markets formulation** (Grossman and Stiglitz 1980) recognizes that investors will not rationally incur the expenses of gathering information unless they expect to be rewarded by higher gross returns compared with the free alternative of accepting the market price. Furthermore, modern theorists recognize that when intrinsic value is difficult to determine, as is the case for common stock, and when trading costs exist, even further room exists for price to diverge from value (Lee, Myers, and Swaminathan 1999).

Thus, analysts often view market prices both with respect and with skepticism. They seek to identify mispricing, and at the same time, they often rely on price eventually converging to intrinsic value. They also recognize distinctions among the levels of **market efficiency** in different markets or tiers of markets (for example, stocks heavily followed by analysts and stocks neglected by analysts). Overall, equity valuation, when applied to market-traded securities, admits the possibility of mispricing. Throughout the discussion, then, we distinguish between the market price, P, and the intrinsic value ("value" for short), V.

For an active investment manager, valuation is an inherent part of the attempt to produce investment returns that exceed the returns commensurate with the investment's risk—that is, positive excess risk-adjusted returns. An excess risk-adjusted return is also called an **abnormal return** or **alpha**. (Return concepts will be more fully discussed later.) The active investment manager hopes to capture a positive alpha as a result of his or her efforts to estimate intrinsic value. Any departure of market price from the manager's estimate of intrinsic value is a perceived **mispricing** (i.e., a difference between the estimated intrinsic value and the market price of an asset).

These ideas can be illuminated through the following expression that identifies two possible sources of perceived mispricing:

$$V_E - P = (V - P) + (V_E - V),$$

where

V_E = estimated value
P = market price
V = intrinsic value

[Note: One can derive the above expression as $V_E - P = V_E - P + V - V = (V - P) + (V_E - V)$.]

This expression states that the difference between a valuation estimate and the prevailing market price is, by definition, equal to the sum of two components. The first component is the true mispricing—that is, the difference between the true but unobservable intrinsic value V and the observed market price P (this difference contributes to the abnormal return). The second component is the difference between the valuation estimate and the true but unobservable intrinsic value—that is, the error in the estimate of the intrinsic value.

To obtain a useful estimate of intrinsic value, an analyst must combine accurate forecasts with an appropriate valuation model. The quality of the analyst's forecasts, in particular the expectational inputs used in valuation models, is a key element in determining investment success. For active security selection to be consistently successful, the manager's expectations must differ from consensus expectations and be, on average, correct as well.

Uncertainty is constantly present in equity valuation. Confidence in one's expectations is always realistically partial. In applying any valuation approach, analysts can never be sure that they have accounted for all the sources of risk reflected in an asset's price. Because competing equity risk models will always exist, there is no obvious final resolution to this dilemma. Even if an analyst makes adequate risk adjustments, develops accurate forecasts, and employs appropriate valuation models, success is not assured. Temporal market conditions may prevent the investor from capturing the benefits of any perceived mispricing. Convergence of the market price to perceived intrinsic value may not happen within the investor's investment horizon, if at all. So, besides evidence of mispricing, some active investors look for the presence of a particular market or corporate event (**catalyst**) that will cause the marketplace to re-evaluate a company's prospects.

1.1.1.2 Going-Concern Value and Liquidation Value A company generally has one value if it is to be immediately dissolved and another value if it will continue in operation. In estimating value, a **going-concern assumption** is the assumption that the company will continue its business activities into the foreseeable future. In other words, the company will continue to produce and sell its goods and services, use its assets in a value-maximizing way for a relevant economic time frame, and access its optimal sources of financing. The **going-concern value** of a company is its value under a going-concern assumption. Models of going-concern value are our focus.

Nevertheless, a going-concern assumption may not be appropriate for a company in financial distress. An alternative to a company's going-concern value is its value if it were dissolved and its assets sold individually, known as its **liquidation value**. For many companies, the value added by assets working together and by human capital applied to managing those assets makes estimated going-concern value greater than liquidation value (although, a persistently unprofitable business may be worth more "dead" than "alive"). Beyond the value added by assets working together or by applying managerial skill to those assets, the value of a company's assets would likely differ depending on the time frame available for liquidating them. For example, the value of nonperishable inventory that had to be immediately liquidated would typically be lower than the value of inventory that could be sold during a longer period of time (i.e., in an "orderly" fashion). Thus, such concepts as **orderly liquidation value** are sometimes distinguished.

1.1.1.3 Fair Market Value and Investment Value For an analyst valuing public equities, intrinsic value is typically the relevant concept of value. In other contexts, however, other definitions of value are relevant. For example, a buy–sell agreement among the owners of a private business—specifying how and when the owners (e.g., shareholders or partners) can sell their ownership interest and at what price—might be primarily concerned with equitable treatment of both sellers and buyers. In that context, the relevant definition of value would likely be fair market value. **Fair market value** is the price at which an asset (or liability) would change hands between a willing buyer and a willing seller when the former is not under any compulsion to buy and the latter is not under any compulsion to sell. Furthermore, the concept of fair market value generally includes an assumption that both buyer and seller are informed of all material aspects of the underlying investment. Fair market value has often been used in valuation related to assessing taxes. In a financial reporting context—for example, in valuing an asset for the purpose of impairment testing—financial reporting standards reference **fair value**, a related (but not identical) concept and provide a specific definition: "Fair value is the amount for which an asset could be exchanged, a liability settled, or an equity instrument granted could be exchanged between knowledgeable, willing parties in an arm's length transaction."

Assuming the marketplace has confidence that the company's management is acting in the owners' best interests, market prices should tend, in the long run, to reflect fair market value. In some situations, however, an asset is worth more to a particular buyer (e.g., because of potential operating synergies). The concept of value to a specific buyer taking account of potential synergies and based on the investor's requirements and expectations is called **investment value**.

1.1.1.4 Definitions of Value: Summary Analysts valuing an asset need to be aware of the definition or definitions of value relevant to the assignment. For the valuation of public equities, an intrinsic value definition of values is generally relevant. Intrinsic value, estimated under a going-concern assumption, is the focus of these equity valuation sections.

APPLICATIONS OF EQUITY VALUATION

2

d describe applications of equity valuation;

Investment analysts work in a wide variety of organizations and positions. As a result, they apply the tools of equity valuation to address a range of practical problems. In particular, analysts use valuation concepts and models to accomplish the following:

- *Selecting stocks*. Stock selection is the primary use of the tools presented here. Equity analysts continually address the same question for every common stock that is either a current or prospective portfolio holding or for every stock that he or she is responsible for covering: Is this security fairly priced, overpriced, or underpriced relative to its current estimated intrinsic value and relative to the prices of comparable securities?
- *Inferring* (*extracting*) *market expectations*. Market prices reflect the expectations of investors about the future performance of companies. Analysts may ask: What expectations about a company's future performance are consistent with the current market price for that company's stock? What assumptions about the company's fundamentals would justify the current price? (**Fundamentals** are characteristics of a company related to profitability, financial strength, or risk.) These questions may be relevant to the analyst for several reasons:
  - The analyst can evaluate the reasonableness of the expectations implied by the market price by comparing the market's implied expectations to his own expectations.
  - The market's expectations for a fundamental characteristic of one company may be useful as a benchmark or comparison value of the same characteristic for another company.

  To extract or reverse-engineer a market expectation, the analyst selects a valuation model that relates value to expectations about fundamentals and is appropriate given the characteristics of the stock. Next, the analyst estimates values for all fundamentals in the model except the fundamental of interest. The analyst then solves for that value of the fundamental of interest that results in a model value equal to the current market price.
- *Evaluating corporate events*. Investment bankers, corporate analysts, and investment analysts use valuation tools to assess the impact of such corporate events as mergers, acquisitions, divestitures, spin-offs, and going-private transactions. Each of these events affects a company's future cash flows and thus the value of its equity. Furthermore, in mergers and acquisitions, the acquiring company's own common stock is often used as currency for the purchase. Investors then want to know whether the stock is fairly valued.
- *Rendering fairness opinions*. The parties to a merger may be required to seek a fairness opinion on the terms of the merger from a third party, such as an investment bank. Valuation is central to such opinions.
- *Evaluating business strategies and models*. Companies concerned with maximizing shareholder value evaluate the effect of alternative strategies on share value.

- *Communicating with analysts and shareholders.* Valuation concepts facilitate communication and discussion among company management, shareholders, and analysts on a range of corporate issues affecting company value.
- *Appraising private businesses.* Valuation of the equity of private businesses is important for transactional purposes (e.g., acquisitions of such companies or buy–sell agreements for the transfer of equity interests among owners when one of them dies or retires) and tax-reporting purposes (e.g., for the taxation of estates), among others. The absence of a market price imparts distinctive characteristics to such valuations, although the fundamental models are shared with public equity valuation. An analyst encounters these characteristics when evaluating initial public offerings, for example.
- *Share-based payment (compensation).* Share-based payments (e.g., restricted stock grants) are sometimes part of executive compensation. Estimation of their value frequently depends on using equity valuation tools.

Inferring Market Expectations

On 2 January 2019, Apple Inc. (AAPL) lowered its revenue guidance citing a variety of reasons, one of which was the weakening economies in some of its Asian markets. Apple's share price fell approximately 10%. When Biogen Inc. announced on 21 March 2019 that its experimental drug for Alzheimer's had failed in late-stage clinical trials, the company's share price dropped approximately 30%. What contributes to such large single-day price movements—changes in estimates of underlying intrinsic value, or market overreaction to negative news?

A rich stream of academic research probes overall market overreaction and underreaction based on large samples—for example, De Bondt and Thaler (1985), Abarbanell and Bernard (1992), and more recently, Bordalo et al. (2017) and Bouchaud et al. 2018). However, one classic research study addresses the topic with a case study of a single such dramatic price drop. This case study, shown in Exhibit 1, is useful for studying equity valuation.

Exhibit 1

Cornell's (2001) case study focuses on the 21 September 2000 press release by Intel Corporation containing information about its expected revenue growth for the third quarter of 2000. The announced growth fell short of the company's prior prediction by 2 to 4 percentage points and short of analysts' projections by 3 to 7 percentage points. In response to the announcement, Intel's stock price fell nearly 30% during the following five days—from $61.50 just prior to the press release to only $43.31 five days later.

To assess whether the information in Intel's announcement was sufficient to explain such a large loss of value, Cornell (2001) estimated the value of a company's equity as the present value of expected future cash flows from operations minus the expenditures needed to maintain the company's growth. (We will discuss such *free cash flow models* in detail at a later stage.)

Using a conservatively low discount rate, Cornell estimated that Intel's price before the announcement, $61.50, was consistent with a forecasted growth rate of 20% a year for the subsequent 10 years and then 6% per year thereafter. Intel's price after the announcement, $43.31, was consistent with a decline of the 10-year growth rate to well under 15% per year. In the final year of the

Exhibit 1 (Continued)

forecast horizon (2009), projected revenues with the lower growth rate would be $50 billion below the projected revenues based on the pre-announcement price. Because the press release did not obviously point to any changes in Intel's fundamental long-run business conditions (Intel attributed the quarterly revenue growth shortfall to a cyclical slowing of demand in Europe), Cornell's detailed analysis left him skeptical that the stock market's reaction could be explained in terms of fundamentals.

Assuming Cornell's methodology was sound, one interpretation is that investors' reaction to the press release was irrational. An alternative interpretation is that Intel's stock was overvalued prior to the press release and that the press release was "a kind of catalyst that caused movement toward a more rational price, even though the release itself did not contain sufficient long-run valuation information to justify that movement" (Cornell 2001, p. 134).

EXAMPLE 1

Referring to Exhibit 1 on Cornell's study of the Intel stock price reaction, explain how an analyst could evaluate the two possible interpretations.

Solution:

To evaluate whether the market reaction to Intel's announcement was an irrational reaction or a rational reduction of a previously overvalued price, one could compare the expected 20% growth implicit in the pre-announcement stock price to some benchmark—for example, the company's actual recent revenue growth, the industry's recent growth, and/or forecasts for the growth of the industry or the economy. Finding the growth rate implied in the company's stock price is an example of using a valuation model and a company's actual stock price to infer market expectations.

Note: Cornell (2001) observed that the 20% revenue growth rate implied by the pre-announcement stock price was much higher than Intel's average growth rate during the previous five years, which occurred when the company was much smaller. He concluded that Intel's stock was overvalued prior to the press release.

These examples illustrate the role of expectations in equity valuation and typical situations in which a given set of facts may be given various interpretations. These examples also illustrate that differences between market price and intrinsic value can occur suddenly, offering opportunities for astute investment managers to generate alpha.

3 THE VALUATION PROCESS, UNDERSTANDING THE BUSINESS AND INDUSTRY AND COMPETITIVE ANALYSIS

e describe questions that should be addressed in conducting an industry and competitive analysis;

In general, the valuation process involves the following five steps:

1 *Understanding the business*. Industry and competitive analysis, together with an analysis of financial statements and other company disclosures, provides a basis for forecasting company performance.
2 *Forecasting company performance*. Forecasts of sales, earnings, dividends, and financial position (pro forma analysis) provide the inputs for most valuation models.
3 *Selecting the appropriate valuation model*. Depending on the characteristics of the company and the context of valuation, some valuation models may be more appropriate than others.
4 *Converting forecasts to a valuation*. Beyond mechanically obtaining the "output" of valuation models, estimating value involves judgment.
5 *Applying the valuation conclusions*. Depending on the purpose, an analyst may use the valuation conclusions to make an investment recommendation about a particular stock, provide an opinion about the price of a transaction, or evaluate the economic merits of a potential strategic investment.

Most of these steps are addressed in detail later. Here, we provide an overview of each.

3.1 Understanding the Business

To forecast a company's financial performance as a basis for determining the value of an investment in the company or its securities, it is helpful to understand the economic and industry contexts in which the company operates, the company's strategy, and the company's previous financial performance. Industry and competitive analysis, together with an analysis of the company's financial reports, provides a basis for forecasting performance.

3.1.1 *Industry and Competitive Analysis*

Because similar economic and technological factors typically affect all companies in an industry, industry knowledge helps analysts understand the basic characteristics of the markets served by a company and the economics of the company. An airline industry analyst will know that labor costs and jet fuel costs are the two largest expenses of airlines and that in many markets airlines have difficulty passing through higher fuel prices by raising ticket prices. Using this knowledge, the analyst may inquire about the degree to which different airlines hedge the commodity price risk inherent in jet fuel costs. With such information in hand, the analyst is better able to evaluate risk and forecast future cash flows. In addition, the analyst would run sensitivity analyses to determine how different levels of fuel prices would affect valuation.

Various frameworks exist for industry and competitive analysis. The primary usefulness of such frameworks is that they can help ensure that an analysis gives appropriate attention to the most important economic drivers of a business. In other words, the objective is *not* to prepare some formal framework representing industry structure or corporate strategy, but rather to use a framework to organize thoughts about an industry and to better understand a company's prospects for success in competition with other companies in that industry. Further, although frameworks can provide a template, obviously the informational content added by an analyst makes the framework relevant to valuation. Ultimately, an industry and competitive analysis should highlight which aspects of a company's business present the greatest challenges and opportunities and should thus be the subject of further investigation and/or more extensive **sensitivity analysis** (an analysis to determine how changes in an assumed input would affect the outcome of an analysis). Frameworks may be useful as analysts focus on questions relevant to understanding a business.

- *How attractive are the industries in which the company operates in terms of offering prospects for sustained profitability?*

Inherent industry profitability is one important factor in determining a company's profitability. Analysts should try to understand **industry structure**—the industry's underlying economic and technical characteristics—and the trends affecting that structure. Basic economic factors—supply and demand—provide a fundamental framework for understanding an industry. Porter's (1985, 1998, 2008) five forces that characterize industry structure—explained in detail at a later stage and summarized in Exhibit 2— can help analysts assess industry profitability and prospects for companies.

Exhibit 2 Summary of Porter's Forces

Force	Features
Rivalry (intra-industry)	Lower rivalry, few competitors and/or good brand identification
Threat of new entrants	High costs to enter (& other barriers)
Threat of substitutes	Few substitutes exist, or cost to switch is high
Bargaining power of suppliers	Many suppliers exist
Bargaining power of buyers	Many customers for an industry' s product exist

Analysts must also stay current on facts and news concerning all the industries in which the company operates, including recent developments (e.g., management, technological, or financial). Particularly important to valuation are any factors likely to affect the industry's longer term profitability and growth prospects, such as demographic trends.

- *What is the company's relative competitive position within its industry, and what is its competitive strategy?*

The level and trend of the company's market share indicate its relative competitive position within an industry. In general, a company's value is higher to the extent that it can create and sustain an advantage relative to its competition. Porter identifies several generic corporate strategies for achieving above-average performance:

i. Cost leadership—being the lowest cost producer while offering products comparable to those of other companies so that products can be priced at or near the industry average

ii. Differentiation—offering unique products or services along some dimensions that are widely valued by buyers so that the company can command premium prices

iii. Focus—seeking a competitive advantage within a target segment or segments of the industry based on either cost leadership (cost focus) or differentiation (differentiation focus)

The term "business model" refers generally to how a company makes money: which customers it targets, what products or services it will sell to those customers, and how it delivers those products or services (including how it finances its activities). The term is broadly used and sometimes encompasses aspects of the generic strategies just described. For example, an airline with a generic cost leadership strategy might have a business model characterized as a low-cost carrier. Low-cost carriers offer a single class of service and use a single type of aircraft to minimize training costs and maintenance charges.

- *How well has the company executed its strategy, and what are its prospects for future execution?*

Competitive success requires both appropriate strategic choices and competent execution. Analyzing the company's financial reports provides a basis for evaluating a company's performance against its strategic objectives and for developing expectations about a company's likely future performance. A historical analysis means more than just reviewing, say, the 10-year historical record in the most recent annual report. It often means looking at the annual reports from 10 years prior, 5 years prior, and the most recent 2 years. Why? Because looking at annual reports from prior years often provides useful insights into how management has historically foreseen challenges and has adapted to changes in business conditions through time. (In general, the investor relations sections of most publicly traded companies' websites provide electronic copies of their annual reports from at least the most recent years.)

In examining financial and operational strategic execution, two caveats merit mention. First, the importance of qualitative—that is, non-numeric factors—must be considered. Such non-numeric factors include the company's ownership structure, its intellectual and physical property, the terms of its intangible assets (e.g., licenses and franchise agreements), and the potential consequences of legal disputes or other contingent liabilities. Second, it is important to avoid simply extrapolating past operating results when forecasting future performance. In general, economic and technological forces can contribute to the phenomenon of "regression toward the mean." Specifically, successful companies tend to draw more competitors into their industries and find that their ability to generate above-average profits comes under pressure. Conversely, poorly performing companies are often restructured in such a manner as to improve their long-term profitability. Thus, in many cases, analysts making long-term horizon growth forecasts for a company's earnings and profits (e.g., forecasts beyond the next 10 years) plausibly assume company convergence toward the forecasted average growth rate for the underlying economy.

4 ANALYSIS OF FINANCIAL REPORTS AND SOURCES OF INFORMATION

The aspects of a financial report that are most relevant for evaluating a company's success in implementing strategic choices vary across companies and industries. For established companies, financial ratio analysis is useful. Individual drivers of profitability for merchandising and manufacturing companies can be evaluated against the company's stated strategic objectives. For example, a manufacturing company aiming to create a sustainable competitive advantage by building strong brand recognition could be expected to have substantial expenditures for advertising but relatively higher prices for its goods. Compared with a company aiming to compete on cost, the branded company would be expected to have higher gross margins but also higher selling expenses as a percentage of sales.

EXAMPLE 2

Competitive Analysis

The following companies are among the largest publicly-traded providers of oilfield services, based on revenues in the most recent fiscal year:

- Schlumberger Ltd. (executive offices in Paris, Houston, London, and the Hague)
  - Revenue: $32.8 billion
  - Net income: $2.2 billion
- Halliburton (executive offices in Houston)
  - Revenue: $24.0 billion
  - Net income: $1.7 billion
- Baker Hughes, a GE Company (executive offices in Houston)
  - Revenue: $22.9 billion
  - Net income: $0.3 billion
- Saipem S.p.A. (executive offices in Milan)
  - Revenue (2017): €9.0 billion
  - Net income (loss) (2017): –€0.3 billion
- National Oilwell Varco Inc. (executive offices in Houston)
  - Revenue: $8.5 billion
  - Net income (loss): –$0.02 billion
- Weatherford International plc (executive offices in Baar, Switzerland)
  - Revenue: $5.7 billion
  - Net income (loss): –$2.8 billion

Note: Financial data are for fiscal 2018, except where noted.
Sources: Companies' 10-K, 20-F, or Investor Relations websites.

These companies provide tools and services—often of a very technical nature—to expedite the drilling activities of oil and gas producers and drilling companies.

1 Discuss the economic factors that may affect demand for the services provided by oilfield services companies, and explain a logical framework for analyzing and forecasting revenue for these companies.

2 Explain how comparing the level and trend in profit margin (net income/sales) and revenue per employee for the companies shown may help in evaluating whether one of these companies is the cost leader in the peer group.

Solution to 1:

Because the products and services of these companies relate to oil and gas exploration and production, the levels of exploration and production activities by oil and gas producers are probably the major factors that determine the demand for their services. In turn, the prices of natural gas and crude oil are important in determining the level of exploration and production activities. Therefore, among other economic factors, an analyst should research those relating to supply and demand for natural gas and crude oil.

- Supply factors in natural gas, such as natural gas inventory levels.

- Demand factors in natural gas, including household and commercial use of natural gas and the amount of new power generation equipment being fired by natural gas.
- Supply factors in crude oil, including capacity constraints and production levels in OPEC and other oil-producing countries, as well as new discoveries of off-shore and land-based oil reserves.
- Demand factors in crude oil, such as household and commercial use of oil and the amount of new power generation equipment using oil products as its primary fuel.
- For both crude oil and natural gas, projected economic growth rates could be examined as a demand factor and depletion rates as a supply-side factor.

Note: Energy analysts should be familiar with sources for researching supply and demand information, such as the International Energy Agency (IEA), the European Petroleum Industry Association (EUROPIA), the Energy Information Administration (EIA), the American Gas Association (AGA), and the American Petroleum Institute (API).

Solution to 2:

Profit margin reflects cost structure. In interpreting profit margin, however, analysts should evaluate any differences in companies' abilities to affect profit margin through power over price. A successfully executed cost leadership strategy will lower costs and raise profit margins. All else equal, we would also expect a cost leader to have relatively high sales per employee, reflecting efficient use of human resources.

With newer companies, or companies involved in creating new products or markets, nonfinancial measures may be critical to obtaining an accurate picture of corporate prospects. For example, a biotechnology company's clinical trial results or an internet company's unique visitors per day may provide information helpful for evaluating future revenue.

4.1 Sources of Information

Important perspectives on industry and competition are sometimes provided by companies themselves in regulator-mandated disclosures, regulatory filings, company press releases, investor relations materials, and contacts with analysts. Analysts can compare the information provided directly by companies to their own independent research.

Regulatory requirements concerning disclosures and filings vary internationally. In some markets, such as Canada and the United States, regulations require management to provide industry and competitive information and access to those filings is freely available (e.g., www.sedar.com for Canadian filings, www.sec.gov for US filings, and individual companies' Investor Relations websites). To take the case of the United States, in annual filings with the Securities and Exchange Commission made on Form 10-K for US companies and Form 20-F for non-US companies, companies provide industry and competitive information in the business description section and in the management discussion and analysis (MD&A). Interim filings (e.g., the quarterly SEC Form 10-Q for US companies and Form 6-K for non-US companies) provide interim financial statements but typically less-detailed coverage of industry and competition. In other jurisdictions, listed companies' financial disclosures can be found on individual companies' Investor Relations websites or centrally at government websites (e.g. Companies House in the UK at https://www.gov.uk/government/organisations/

companies-house), stock exchange websites (e.g. Shenzhen Stock Exchange disclosures at http://www.szse.cn), or central banks' websites (e.g., National Bank of Belgium at https://www.nbb.be/en/central-balance-sheet-office). Required disclosures concerning industry and competitive information differ across jurisdictions.

So far as analyst–management contacts are concerned, analysts must be aware when regulations (e.g., Regulation FD in the United States) prohibit companies from disclosing material nonpublic information to analysts without also disseminating that information to the public. General management insights based on public information, however, can still be useful to analysts, and many analysts consider in-person meetings with a company's management essential to understanding a company.

The CFA Institute Code of Ethics and Standards of Professional Conduct prohibit use of material inside information, and Regulation FD (and similar regulations in other countries) is designed to prohibit companies from selectively offering such information. These ethical and legal requirements assist analysts by clarifying their main role and purpose.

Company-provided sources of information in addition to regulatory filings include press releases and investor relations materials. The press releases of most relevance to analysts are the press releases that companies issue to announce their periodic earnings. Companies typically issue these earnings press releases several weeks after the end of an accounting period and several weeks before they file their interim financial statements. Earnings press releases summarize the company's performance for the period and usually include explanations for the performance and financial statements (often abbreviated versions). Following their earnings press releases, many companies host conference calls in which they further elaborate on their reported performance and typically allocate some time to answer questions posed by analysts. On their corporate websites, many companies post audio downloads and transcripts of conference calls and presentations made in analyst conferences. The audio files and transcripts of conference calls and conference presentations provide access not only to the company's reports but also to analysts' questions and the company's answers to those questions.

Apart from company-provided sources of information, analysts also obtain information from third-party sources, such as industry organizations, regulatory agencies, and commercial providers of market intelligence.

Sources of ESG Information: The Case of the US Auto Industry

The evaluation of environmental, social, and governance (ESG) factors can help analysts identify potential business risks and practices that may produce long-term competitive advantages relative to peers. In the following example, we discuss the sources of ESG-related information that an analyst following US-domiciled automakers might consider.

The automotive industry is among the most resource-intensive manufacturing industries in the world. New vehicles are subject to multiple governmental standards concerning safety, fuel efficiency and emissions control, vehicle recycling, and theft prevention, among others. Manufacturing and assembly facilities must conform to strict standards for air emissions, water discharge, and hazardous waste management.

Because an auto company's manufacturing process and vehicles can significantly affect the environment, the industry is heavily regulated. The global nature of the automotive industry requires careful consideration of different regulatory environments within countries and regions. Regulatory bodies in the United States, such as the Environmental Protection Agency, as well as non-US regulatory bodies, such as the European Commission, the European Environment Agency, and the UK-based Environment Agency, help develop and track environmental standards and legislation.

The potential for serious injuries from manufacturing increases the importance of automobile worker safety. In addition, labor relations are also very important for US automakers because of the sizable representation of employees in labor unions. Avoiding costly lawsuits, lost production from work stoppages, and negative publicity are primary concerns for automakers.

Information relevant to analyzing ESG considerations for US automakers can be found in many sources that are common to most industries. These sources include corporate filings, press releases, investor calls and webcasts, and trade publications. Sustainability reports (often called corporate sustainability reports, or CSRs) are also relevant to analysts when examining ESG considerations. These reports address the economic, environmental, and social effects resulting from an organization's everyday activities and the organization's values and governance (see https://www.globalreporting.org/information/sustainability-reporting/Pages/default.aspx). Although there is no uniform standard for their issuance or disclosure by companies, sustainability reports can provide analysts with a better understanding of a company's sustainable business practices and whether a company's resource management supports an economically sustainable business model.

For more specific ESG-related information, analysts following US automakers may consult labor union boycott lists and disclosures from the Occupational Safety and Health Administration (OSHA) and the US Equal Employment Opportunity Commission (EEOC). As the federal agency responsible for overseeing working conditions for most private sector employers in the United States, OSHA can help analysts identify auto manufacturers that have demonstrated a history of safety violations or an improvement in workplace safety. The EEOC's litigation database helps in the investigation of any notable workplace discrimination issues that have affected individual automakers.

Several not-for-profit organizations can be valuable ESG resources to analysts of US automakers (or other industries, for that matter). The Sustainable Accounting Standards Board (SASB) sets industry-specific ESG standards and can help analysts identify ESG considerations that have a quantitative impact on companies' financial performance. The Carbon Disclosure Project collects and synthesizes self-reported environmental data that can provide for important information regarding automakers' exposure to climate change and water scarcity. Finally, Ceres, an organization committed to driving sustainability research and advocacy, can provide analysts with access to sustainability research reports for the auto industry.

5 CONSIDERATIONS IN USING ACCOUNTING INFORMATION

In evaluating a company's historical performance and developing forecasts of future performance, analysts typically rely heavily on companies' accounting information and financial disclosures. Companies' reported results vary in their persistence (i.e., sustainability). In addition, the information that companies disclose can vary substantially with respect to the *accuracy* of reported accounting results as reflections of economic performance and the *detail* in which results are disclosed.

The term **quality of earnings analysis** broadly includes the scrutiny of *all* financial statements, including the balance sheet, to evaluate both the sustainability of a company's performance and how accurately the reported information reflects economic reality. Equity analysts will generally develop better insights into a company and improve forecast accuracy by developing an ability to assess a company's quality of earnings. With regard to sustainability of performance, an analyst aims to identify aspects of reported performance that are less likely to recur. For example, earnings with significant components of nonrecurring events—such as positive litigation settlements, nonpermanent tax reductions, or gains on sales of nonoperating assets—are considered to be of lower quality than earnings derived mainly from the company's core business operations.

In addition to identifying nonrecurring events, an analyst aims to identify reporting decisions that may result in a level of reported earnings that is unlikely to continue. A good starting point for this type of quality of earnings analysis is a comparison of a company's net income with its operating cash flow. As a simple hypothetical example, consider a company that generates revenues and net income but no operating cash flow because it makes all sales on account and never collects its receivables. One systematic way to make the comparison is to decompose net income into a cash component (combining operating and investing cash flows) and an accrual component (defined as net income minus the cash component). Capital markets research shows that the cash component is more persistent than the accrual component of earnings, with the result that a company with a relatively higher amount of current accruals will have a relatively lower ROA in the future (Sloan 1996). Here, greater persistency means that compared to accruals in the current period, the cash component in the current period is more predictive of future net income. A relatively higher proportion of accruals can be interpreted as lower earnings quality.

A quality of earnings analysis for a particular company requires careful scrutiny of accounting statements, footnotes, and other relevant disclosures. Sources for studying quality of earnings analysis and accounting risk factors include Mulford and Comiskey (2005) and Schilit and Perler (2010). Examples of a few of the many available indicators of possible problems with a company's quality of earnings are provided in Exhibit 3.

Exhibit 3 Selected Quality of Earnings Indicators

Category	Observation	Potential Interpretation
Revenues and gains	Recognizing revenue early, for example: ■ bill-and-hold sales, and ■ recording sales of equipment or software prior to installation and acceptance by customer.	Acceleration in the recognition of revenue boosts reported income, masking a decline in operating performance.
	Classification of nonoperating income or gains as part of operations.	Income or gains may be nonrecurring and may not relate to true operating performance, possibly masking declines in operating performance.

(continued)

Exhibit 3 (Continued)

Category	Observation	Potential Interpretation
Expenses and losses	Recognizing too much or too little reserves in the current year, such as: ■ restructuring reserves, ■ loan-loss or bad-debt reserves, and ■ valuation allowances against deferred tax assets.	May boost current income at the expense of future income, or alternatively, may decrease current year's earnings to boost future years' performance.
	Deferral of expenses by capitalizing expenditures as an asset, for example: ■ customer acquisition costs and ■ product development costs.	May boost current income at the expense of future income. May mask problems with underlying business performance.
	Use of aggressive estimates and assumptions, such as: ■ asset impairments, ■ long depreciable lives, ■ long periods of amortization, ■ high assumed discount rate for pension liabilities, ■ low assumed rate of compensation growth for pension liabilities, and ■ high expected return on assets for pension.	Aggressive estimates may indicate actions taken to boost current reported income. Changes in assumptions may indicate an attempt to mask problems with underlying performance in the current period.
Balance sheet issues (may also affect earnings)	Use of off-balance sheet financing (financing that does not appear on the balance sheet), such as securitizing receivables.	Assets and/or liabilities may not be properly reflected on the balance sheet.
Operating cash flow	Characterization of an increase in a bank overdraft as operating cash flow.	Operating cash flow may be artificially inflated.

The following example illustrates the importance of accounting practices in influencing reported financial results and the need for analysts to exercise judgment when using those results in any valuation model.

EXAMPLE 3

Historical Example

Quality of Earnings Warning Signs: Aggressive Estimates

In the section of his 2007 letter to the shareholders of Berkshire Hathaway titled "Fanciful Figures—How Public Companies Juice Earnings," Warren Buffett referred to the investment return assumption (the anticipated return on a defined benefit pension plan's current and future assets):

> "Decades of option-accounting nonsense have now been put to rest, but other accounting choices remain—important among these [is] the investment-return assumption a company uses in calculating pension expense. It will come as no surprise that many companies continue

> to choose an assumption that allows them to report less-than-solid 'earnings.' For the 363 companies in the S&P that have pension plans, this assumption in 2006 averaged 8%."
>
> (www.berkshirehathaway.com/letters/2007ltr.pdf. See pp.18–19.)

In his explanation, Buffett assumes a 5% return on cash and bonds, which averaged 28% of US pension fund assets. Therefore, this implies that the remaining 72% of pension fund assets—predominately invested in equities—must earn a return of 9.2%, after all fees, to achieve the 8% overall return on the pension fund assets. To illustrate one perspective on an average pension fund achieving that 9.2% return, he estimates that the Dow Jones Industrial Index would need to close at about 2,000,000 on 31 December 2099 (compared to a level under 13,000 at the time of his writing) for this century's returns on that US stock index to match just the 5.3% average annual compound return achieved in the 20th century.

1. How do aggressively optimistic estimates for returns on pension assets affect pension expense?
2. Where can information about a company's assumed returns on its pension assets be found?

Solution to 1:

The amount of "expected return on plan assets" associated with the return assumption is a deduction in calculating pension expense. An aggressively optimistic estimate for the rate of return that pension assets will earn means a larger-than-warranted deduction in calculating pension expense, and subtraction will lead to understating pension expense and overstating net income. In fact, pension expense could become pension income depending on the numbers involved.

Solution to 2:

Information about a company's assumed return on its pension assets can be found in the footnotes to the company's financial statements.

The next examples of poor earnings quality, in which management made choices going beyond making an aggressive estimate, are reminiscent of a humorous vignette from Benjamin Graham (1936) in which the chair of a company outlines plans for return to profitability, as follows: "Contrary to expectations, no changes will be made in the company's manufacturing or selling policies. Instead, the bookkeeping system is to be entirely revamped. By adopting and further improving a number of modern accounting and financial devices, the corporation's earning power will be amazingly transformed."

EXAMPLE 4

Quality of Earnings Warning Signs: Extreme Cases

CASE A.

In 2018, the Securities and Exchange Commission (SEC) charged Tangoe Inc., a formerly publicly-traded telecommunications expense management company, with fraudulent accounting practices that had allowed the company to improperly recognize revenues. Among the violations cited by the SEC were improperly recording revenue from customers who were unlikely to pay and understating the allowance for bad debts (*Sources:* US Securities and Exchange Commission press release 2018-175, issued 4 September 2018, and the related SEC complaint.)

1 Describe the financial statement impact of the accounting violations cited by the SEC.

2 How would a company's Accounts Receivable turnover (or days receivable) serve as an early warning sign of the revenue accounting violations cited by the SEC?

Solution to 1:

On the income statement, improperly recognizing revenue from customers unlikely to pay would inflate reported revenue and—all else equal—reported earnings. On the balance sheet, the improper practices would result in inflated receivables. On the statement of cash flows, if the amount of revenues included in net income exceeds the amount of cash collected from customers—all else equal—net income will exceed operating cash flow. (In actuality, this was not the case with Tangoe, where the company had other adjustments.)

Solution to 2:

Improperly recognizing revenue from customers who are unlikely to pay and understating the allowance for bad debts—all else equal—would result in a lower Accounts Receivable turnover (and higher days receivable).

Note: Analysis of Tangoe's last years of publicly-reported data actually shows the following (all $ in thousands):

- Revenues increased 12% from 2013 to 2014 (from $188,914 to $212,476), while average receivables increased by 32% (from $40,701 to $50,110).
- Accounts receivable turnover decreased from 4.6x (= $188,914/$40,701) to 4.2x (= $212,476/$50,110).
- Days receivable increased from 79 days (= 365/4.6) to 87 days (= 365/4.2)

The SEC also charged the company with other revenue recognition violations, including improperly recording a loan from a business partner as revenue, counting contingency-fee receipts as revenue, and recording customers' prepayments for future services as current revenue. Violations like these would result in understating such liabilities as loans payable and unearned revenue. The company, which paid penalties to settle the SEC's charges, was delisted from the NASDAQ stock exchange in 2017 and then was subsequently purchased by a private investment firm.

CASE B.

Livent, Inc., was a publicly traded theatrical production company that staged a number of smash hits, such as Tony-award winning productions of *Showboat* and *Fosse*. Livent capitalized preproduction costs, including expenses for preopening advertising, publicity and promotion, set construction, props, costumes, and salaries and fees paid to the cast, crew, and musicians during rehearsals. The company then amortized these capitalized costs over the expected life of the theatrical production based on anticipated revenues.

1 State the effect of Livent's accounting for preproduction costs on its reported earnings per share.

2 State the effect of Livent's accounting for preproduction costs on its balance sheet.

3 If an analyst calculated EBITDA/interest expense and debt/EBITDA based on Livent's accounting for preproduction costs without adjustment, how might the analyst be misled in assessing Livent's financial strength? (Recall that EBITDA is defined as earnings before interest, taxes, depreciation, and amortization. Such ratios as EBITDA/interest expense and debt/EBITDA indicate one aspect of a company's financial strength: debt-paying ability.)

Solution to 1:

Livent's accounting for preproduction costs immediately increased reported earnings per share because it deferred expenses.

Solution to 2:

Instead of immediately expensing costs, Livent reported the amounts on its balance sheet as an asset. The warning signal—the deferral of expenses—can indicate aggressive accounting; preproduction costs should have been expensed immediately because of the tremendous uncertainty about revenues from theatrical productions. There was no assurance that there would be revenues against which expenses could be matched.

Solution to 3:

Livent did not deduct preproduction costs from earnings as expenses. If the amortization of capitalized preproduction costs were then added back to earnings, the EBITDA/interest and debt/EBITDA would not reflect in any way the cash outflows associated with such items as paying pre-opening salaries; but cash outflows reduce funds available to meet debt obligations. The analyst who mechanically added back amortization of preproduction costs to calculate EBITDA would be misled into overestimating Livent's financial strength. Based on a closer look at the company's accounting, the analyst would properly not add back amortization of preproduction expenses in computing EBITDA. If preproduction expenses are not added back, a very different picture of Livent's financial health would emerge.

Note: In 1996, Livent's reported debt/EBITDA was 1.7, but the ratio without adding back amortization for preproduction costs was 5.5. In 1997, debt/EBITDA was 3.7 based on a positive EBITDA of $58.3 million; however, EBITDA without the add-back was *negative* $52.6 million. In November 1998, Livent declared bankruptcy and is now defunct. The criminal trial, in Canada, concluded in 2009 with the conviction of Livent's co-founders on charges of fraud and forgery.

In general, growth in an asset account (such as accounts receivable in the Tangoe example and deferred costs in the Livent example) at a much faster rate than the growth rate of sales may indicate aggressive accounting.

Far more serious than aggressive accounting is the deliberate misstatement of financial reports (i.e., fraudulent financial reporting). In general, publicly-traded companies' annual financial statements are audited by certified, professional auditors. The official standards used by auditors can provide useful insights to analysts about a variety of risk factors that may signal possible future negative surprises. For example, both international auditing standards issued by the IAASB and US auditing standards issued by the PCAOB include examples of fraud risk indicators (IAASB 2018, PCAOB

2017). Fraud risk indicators are typically categorized as relating to incentives to commit fraud, opportunity to commit fraud, or attitude toward committing fraud. A working selection of risk factors for misreporting or misappropriation include the following:

- Excessive pressure on company personnel to make revenue or earnings targets, particularly when combined with a dominant, aggressive management team or individual.
- Management and/or directors' compensation tied to profitability or stock price (through ownership or compensation plans). Although such arrangements are usually desirable, they can be a risk factor for aggressive financial reporting.
- Economic, industry, or company-specific pressures on profitability, such as loss of market share or declining margins.
- Management pressure to meet debt covenants or earnings expectations, including "a practice by management of committing to analysts, creditors, and other third parties to achieve aggressive or unrealistic forecasts" (PCAOB, 2017).
- Existence of related-party transactions.
- Complex organizational structure, creating difficulty in determining who controls the company.
- High turnover—of management, directors, or legal counsel.
- Reported (through regulatory filings) disputes with and/or changes in auditors.
- A history of securities law violations, reporting violations, or persistent late filings.

6 FORECASTING COMPANY PERFORMANCE, SELECTING THE APPROPRIATE VALUATION METHOD, ABSOLUTE AND RELATIVE VALUATION MODELS

f contrast absolute and relative valuation models and describe examples of each type of model;

The second step in the valuation process—forecasting company performance—can be viewed from two perspectives: the economic environment in which the company operates and the company's own operating and financial characteristics.

Companies do business within larger contexts of particular industries, national economies, and world trade. Viewing a company within those larger contexts, a top-down forecasting approach moves from international and national macroeconomic forecasts to industry forecasts and then to individual company and asset forecasts. For example, a revenue forecast for a major home appliance manufacturer could start with industry unit sales forecasts that are, in turn, based on GDP forecasts. Forecasted company unit sales would equal forecasted industry unit sales multiplied by the appliance manufacturer's forecasted market share. A revenue projection would be based on forecasted company unit sales and sales prices.

Alternatively, a bottom-up forecasting approach aggregates forecasts at a micro level to larger scale forecasts, under specific assumptions. For example, a clothing retailer may have several stores in operation with two new stores about to open. Using information based on the sales per square meter of the existing stores (perhaps during their initial period of operation), the analyst could forecast sales per square meter of the new stores that, added to forecasts of a similar type for existing stores, would give a sales forecast for the company as a whole. In making such a bottom-up sales forecast, the analyst would be making assumptions about selling prices and merchandise costs. Forecasts for individual retailers could be aggregated into forecasts for the group, continuing in a bottom-up fashion.

In general, analysts integrate insights from industry and competitive analysis with financial statement analysis to formulate specific forecasts of such items as a company's sales, earnings, and cash flow. Analysts generally consider qualitative as well as quantitative factors in financial forecasting and valuation. For example, an analyst might modify his or her forecasts and valuation judgments based on qualitative factors, such as the analyst's opinion about the business acumen and integrity of management and/or the transparency and quality of a company's accounting practices. Such qualitative factors are necessarily subjective.

6.1 Selecting the Appropriate Valuation Model

This section discusses the third step in the valuation process—selecting the appropriate model for the valuation task at hand. Detailed descriptions of the valuation models are presented later. Absolute valuation models and relative valuation models are the two broad types of valuation models that incorporate a going-concern assumption. Here, we describe absolute and relative valuation models in general terms and discuss a number of issues in model selection. In practice, analysts frequently use more than one approach to estimate the value of a company or its common stock (Pinto, Robinson, and Stowe 2019).

6.1.1 *Absolute Valuation Models*

An **absolute valuation model** is a model that specifies an asset's intrinsic value. Such models are used to produce an estimate of value that can be compared with the asset's market price. The most important type of absolute equity valuation models are present value models. In finance theory, present value models are considered the fundamental approach to equity valuation. The logic of such models is that the value of an asset to an investor must be related to the returns that investor expects to receive from holding that asset. Generally speaking, those returns can be referred to as the asset's cash flows, and present value models are also referred to as discounted cash flow models.

A **present value model** or **discounted cash flow model** applied to equity valuation derives the value of common stock as the present or discounted value of its expected future cash flows (such models are known as income models of valuation in private business appraisal). For common stock, one familiar type of cash flow is dividends, which are discretionary distributions to shareholders authorized by a corporation's board of directors. Dividends represent cash flows at the shareholder level in the sense that they are paid directly to shareholders. Present value models based on dividends are called **dividend discount models**. Rather than defining cash flows as dividends, analysts frequently define cash flows at the company level. Common shareholders in principle have an equity ownership claim on the balance of the cash flows generated by a company after payments have been made to claimants senior to common equity, such as bondholders and preferred stockholders (and the government as well, which takes taxes), whether such flows are distributed in the form of dividends.

The two main company-level definitions of cash flow in current use are free cash flow and residual income. Free cash flow is based on cash flow from operations but takes into account the reinvestment in fixed assets and working capital necessary for a going concern. The **free cash flow to equity model** defines cash flow net of payments to providers of debt, whereas the **free cash flow to the firm model** defines cash flows before those payments. We will define free cash flow and each model with more precision later. A residual income model is based on accrual accounting earnings in excess of the opportunity cost of generating those earnings.

Because the present value approach is the familiar technique for valuing bonds (here, the term "bonds" refers to all debt securities and loans), it is helpful to contrast the application of present value models to equity valuation with present value models as applied to bond valuation. The application of present value models to common stock typically involves greater uncertainty than is the case with bonds. That uncertainty centers on two critical inputs for present value models—the cash flows and the discount rate(s). Bond valuation discounts a stream of cash payments specified in a legal contract (the **bond indenture**). In contrast, in equity valuation an analyst must define the specific cash flow stream to be valued—dividends or free cash flow—and then forecast the amounts of those cash flows. Unlike bond valuation, no cash flow stream is contractually owed to common stockholders. Clearly, a company's total cash flows—and therefore the cash flows potentially available to common stockholders—will be affected by business, financial, technological, and other factors and are subject to greater variation than the contractual cash flow of a bond. Furthermore, the forecasts for common stock cash flows extend indefinitely into the future because common stock has no maturity date. In addition to the greater uncertainty involved in forecasting cash flows for equity valuation, significant uncertainty exists in estimating an appropriate rate at which to discount those cash flows. In contrast with bond valuation, in which a discount rate can usually be based on market interest rates and bond ratings, equity valuation typically involves a more subjective and uncertain assessment of the appropriate discount rate. Finally, in addition to the uncertainty associated with cash flows and discount rates, the equity analyst may need to address other issues, such as the value of corporate control or the value of unused assets.

The present value approach applied to stock valuation, therefore, presents a high order of complexity. Present value models are ambitious in what they attempt—an estimate of intrinsic value—and offer many challenges in application. Graham and Dodd (1934) suggested that the analyst consider stating a range of intrinsic values, and that suggestion remains valid. To that end, **sensitivity analysis** is an essential tool in applying discounted cash flow valuation. We discuss sensitivity analysis in more detail next.

Another type of absolute valuation is **asset-based valuation**, which values a company on the basis of the market value of the assets or resources it controls. For appropriate companies asset-based valuation can provide an independent estimate of value, and an analyst typically finds alternative, independent estimates of value to be useful. Exhibit 4 describes instances in which this approach to absolute valuation could be appropriate.

Exhibit 4

Asset-Based Valuation

Analysts often apply asset-based valuation to natural resource companies. For example, a crude oil producer, such as Petrobras, might be valued on the basis of the market value of its current proven reserves in barrels of oil, minus a discount for estimated extraction costs. A forest industry company, such as Weyerhaeuser, might be valued on the basis of the board meters (or board feet) of timber it controls. Today, however, fewer companies than in the past are involved only in natural resources extraction or production. For example, Occidental Petroleum features petroleum in its name but also has substantial chemical manufacturing operations. For such cases, the total company might be valued as the sum of its divisions, with the natural resource division valued on the basis of its proven resources.

6.1.2 *Relative Valuation Models*

Relative valuation models constitute the second broad type of going-concern valuation models. A **relative valuation model** estimates an asset's value relative to that of another asset. The idea underlying relative valuation is that similar assets should sell at similar prices. Relative valuation is typically implemented using price multiples (ratios of stock price to a fundamental, such as cash flow per share) or enterprise multiples (ratios of the total value of common stock and debt net of cash and short-term investments to certain of a company's operating assets to a fundamental, such as operating earnings).

Perhaps the most familiar price multiple is the price-to-earnings ratio (P/E), which is the ratio of a stock's market price to the company's earnings per share. A stock selling at a P/E that is low relative to the P/E of another closely comparable stock (in terms of anticipated earnings growth rates and risk, for example) is *relatively undervalued* (a good buy) relative to the comparison stock. For brevity, an analyst might state simply *undervalued*, but the analyst must realize that if the comparison stock is overvalued (in an absolute sense, in relation to intrinsic value), so might be the stock being called undervalued. Therefore, it is useful to maintain the distinction between *undervalued* and *relatively undervalued*. Investing to exploit perceived mispricing in either case (absolute or relative mispricing) relies on a basis of differential expectations—that is, investor expectations that differ from and are more accurate than those reflected in market prices, as discussed earlier.

The more conservative investing strategies based on relative valuation involve overweighting (underweighting) relatively undervalued (overvalued) assets, with reference to benchmark weights. The more aggressive strategies allow short selling of perceived overvalued assets. Such aggressive approaches are known as relative value investing (or relative spread investing, if using implied discount factors). A classic example is **pairs trading** that utilizes pairs of closely related stocks (e.g., two automotive stocks), buying the relatively undervalued stock and selling short the relatively overvalued stock. Regardless of which direction the overall stock market goes, the investor will be better off to the extent that the relatively undervalued stock ultimately rises more (falls less) than the relatively overvalued stock.

Frequently, relative valuation involves a group of comparison assets, such as an industry group, rather than a single comparison asset. The application of relative valuation to equity is often called the method of comparables (or just comparables) and is the subject of a later reading.

EXAMPLE 5

Relative Valuation Models

While researching Smithson Genomics, Inc., a (fictitious) healthcare information services company, you encounter a difference of opinions. One analyst's report claims that Smithson is at least 15% *overvalued*, based on a comparison of its P/E with the median P/E of peer companies in the healthcare information services industry and taking account of company and peer group fundamentals. A second analyst asserts that Smithson is *undervalued* by 10%, based on a comparison of Smithson's P/E with the median P/E of the Russell 3000 Index, a broad-based US equity index. Both analyses appear to be carefully executed and reported. Can both analysts be right?

Solution:

Yes. The assertions of both analysts concern *relative* valuations, and their benchmarks for comparisons differ. The first analyst compared Smithson to its peers in the healthcare information services industry and considers the company to be *relatively overvalued* compared to that group. The second analyst compared Smithson to the overall market as represented by the Russell 3000 and considers the company to be *relatively undervalued* compared to that group. If the entire healthcare information services industry is undervalued in relation to the Russell 3000, both analysts can be right because they are making relative valuations.

The investment implications of each analyst's valuation generally would depend on additional considerations, including whether the market price of the Russell 3000 fairly represents that index's intrinsic value and whether the market liquidity of an otherwise attractive investment would accommodate the intended position size. The analyst in many cases may want to supplement relative valuation with estimates of intrinsic value.

The method of comparables is characterized by a wide range of possible implementation choices; a later reading discusses various alternative price and enterprise multiples. Practitioners will often examine a number of price and enterprise multiples for the complementary information they can provide. In summary, the method of comparables does not specify intrinsic value without making the further assumption that the comparison asset is fairly valued. The method of comparables has the advantages of being simple, related to market prices, and grounded in a sound economic principle (that similar assets should sell at similar prices). Price and enterprise multiples are widely recognized by investors, so analysts can communicate the results of an absolute valuation in terms of a price or enterprise multiple.

7 VALUATION OF THE TOTAL ENTITY AND ITS COMPONENTS AND ISSUES IN MODEL SELECTION AND INTERPRETATION

g describe sum-of-the-parts valuation and conglomerate discounts;

h explain broad criteria for choosing an appropriate approach for valuing a given company.

A variation to valuing a company as a single entity is to estimate its value as the sum of the estimated values of its various businesses considered as independent, going-concern entities. A valuation that sums the estimated values of each of the company's businesses as if each business were an independent going concern is known as a **sum-of-the-parts valuation**. (The value derived using a sum-of-the-parts valuation is sometimes called the **breakup value** or **private market value**.)

Sum-of-the-parts analysis is most useful when valuing a company with segments in different industries that have different valuation characteristics. Sum-of-the-parts analysis is also frequently used to evaluate the value that might be unlocked in a restructuring through a spin-off, split-off, tracking stock, or equity (IPO) carve-out.

Example 6 shows a case in which a sum-of-the-parts valuation could be used to gain insight into a company's future prospects. In practice, a detailed breakdown of each business segment's contribution to earnings, cash flow, and value would be needed.

EXAMPLE 6

Sum-of-the-Parts Valuation

Donaldson Company, Inc., is one of the largest and most successful filtration manufacturers in the world. Consistent with FASB guidance related to segment reporting, the company has identified two reportable segments: Engine Products and Industrial Products. Segment selection was based on the internal organizational structure, management of operations, and performance evaluation by management and the company's board of directors. 2018 10-K data (in millions of US dollars) for the segments appear in the following table.

Descriptions of the segments from the company's 2018 10-K are as follows:

The Engine Products segment sells to original equipment manufacturers (OEMs) in the construction, mining, agriculture, aerospace, defense, and truck markets and to independent distributors, OEM dealer networks, private label accounts, and large equipment fleets. Products include replacement filters for both air and liquid filtration applications, air filtration systems, liquid filtration systems for fuel, lube and hydraulic applications, and exhaust and emissions systems.

The Industrial Products segment sells to various industrial end-users, OEMs of gas-fired turbines, and OEMs and end-users requiring clean air. Products include dust, fume, and mist collectors; compressed air purification systems; gas and liquid filtration for food; beverage and industrial processes; air filtration systems for gas turbines; and specialized air and gas filtration systems for such applications as membrane-based products as well as specialized air and gas filtration systems for such applications as hard disk drives and semi-conductor manufacturing.

	Engine Products	Industrial Products	Total Company*
Fiscal 2018			
Net sales	$1,849.0	$885.2	$2,734.2
Earnings (loss) before income taxes	261.3	137.1	363.6
Assets	1,110.3	631.9	1,976.6
Capital expenditures	64.6	31.4	97.5
Fiscal 2017			
Net sales	$1,553.3	$818.6	$2,371.9
Earnings (loss) before income taxes	219.7	129.1	322.0
Assets	849.6	638.3	1,979.7
Capital expenditures	29.7	23.4	65.9
Fiscal 2016			
Net sales	$1,391.3	$829.0	$2,220.3
Earnings (loss) before income taxes	163.5	119.0	257.4

(continued)

	Engine Products	Industrial Products	Total Company*
Assets	841.4	646.9	1,787.0
Capital expenditures	37.5	27.3	72.9

* Total company results differ from the sum of the two divisions by allocated corporate and unallocated amounts.

1 Why might an analyst use a sum-of-the-parts approach to value Donaldson?

2 How might an analyst use the provided information in an analysis and valuation?

Solution to 1:

On the one hand, the Engine Products segment is already significantly larger than the Industrial Products segment and is growing at a much faster rate in terms of sales, income, assets, and capital expenditures. On the other hand, profit margins appear to be higher for Industrial Products. In 2018, the EBIT-to-sales ratio was 15.5% for the Industrial Products segment versus 14.1% for the Engine Products segment.

An investor presentation by Donaldson's management in May 2013 indicated that they expected Industrial Products to become 48% of the company's product portfolio by 2021. However, the recent results noted show that the Engine Products segment has become a larger and larger part of Donaldson's total business despite its lower margins. Whether or not the company will ultimately be successful in changing their product mix is fundamental to an analyst forming an opinion on Donaldson's share price.

Solution to 2:

An analyst might use the information from Example 6 to develop separate valuations for each of the segments based on forecasts for each segment's sales and profitability. The value of the company in total would be the sum of the value of each of the segments, adjusted for corporate items—such as taxes, overhead expenses, and assets/liabilities not directly attributable to the separate operating systems.

The concept of a conglomerate discount often arises in connection with situations warranting a sum-of-the parts valuation. **Conglomerate discount** refers to the concept that the market applies a discount to the stock of a company operating in multiple, unrelated businesses compared to the stock of companies with narrower focuses. Alternative explanations for the conglomerate discount include 1) inefficiency of internal capital markets (i.e., companies' allocation of investment capital among divisions does not maximize overall shareholder value); 2) endogenous factors (i.e., poorly performing companies tend to expand by making acquisitions in unrelated businesses); and 3) research measurement errors (i.e., conglomerate discounts do not actually exist, and evidence suggesting that they do is a result of flawed measurement). Examples in which conglomerate discounts appear most observable occur when companies divest parts of the company that have limited synergies with their core businesses.

Note that a break-up value in excess of a company's unadjusted going-concern value may prompt strategic actions, such as a divestiture or spin-off.

7.1 Issues in Model Selection and Interpretation

How does one select a valuation model? The broad criteria for model selection are that the valuation model be:

- consistent with the characteristics of the company being valued;
- appropriate given the availability and quality of data; and
- consistent with the purpose of valuation, including the analyst's perspective.

Note that using more than one model can yield incremental insights.

Selection of a model consistent with the characteristics of the company being valued is facilitated by having a good understanding of the business, which is the first step in the valuation process. Part of understanding a company is understanding the nature of its assets and how it uses those assets to create value. For example, a bank is composed largely of marketable or potentially marketable assets and securities. Thus, for a bank, a relative valuation based on assets (as recognized in accounting) has more relevance than a similar exercise for a service company with few marketable assets.

In selecting a model, data availability and quality can be limiting factors. For example, a dividend discount model is the simplest discounted cash flow model; but if a company has never paid dividends and no other information exists to assess a company's future dividend policy, an analyst may have more confidence applying an apparently more complex present value model. Similar considerations also apply in selecting a specific relative valuation approach. For example, meaningful comparisons using P/Es may be hard to make for a company with highly volatile or persistently negative earnings.

Model selection can also be influenced by the purpose of the valuation or the perspective of the analyst. For example, an investor seeking a controlling equity position in a company may elect to value the company based on forecasted free cash flows rather than forecasted dividends because such flows might potentially be redirected by such an acquirer without affecting the value of the acquisition (this valuation approach will be discussed in detail in another reading). When an analyst reads valuations and research reports prepared by others, the analyst should consider how the writer's perspective (and potential biases) may have affected the choice of a particular valuation approach and/or valuation inputs. Specific guidance on model selection will be offered later when discussing present value models and price multiples.

As a final note to this introduction of model selection, it is important to emphasize that professionals frequently use multiple valuation models or factors in common stock selection. According to the *Merrill Lynch Institutional Factor Survey* (2018), respondent institutional investors report using an average of approximately 17 valuation factors in selecting stocks. (*Note:* In this report, the term "factor" covers market-based metrics, such as price multiples, as well as accounting-based metrics, such as return on equity.) There are a variety of ways in which multiple factors can be used in stock selection. One prominent way, stock screens, will be discussed in a later reading. As another example, analysts can rank each security in a given investment universe by relative attractiveness according to a particular valuation factor. The rankings for individual securities could be combined into a single composite ranking by assigning weights to the individual factors. Analysts may use a quantitative model to assign those weights.

8 CONVERTING FORECASTS TO A VALUATION AND APPLYING THE VALUATION CONCLUSION: THE ANALYST'S ROLE AND RESPONSIBILITIES

Converting forecasts to valuation involves more than inputting the forecast amounts to a model to obtain an estimate of the value of a company or its securities. Two important aspects of converting forecasts to valuation are sensitivity analysis and situational adjustments.

Sensitivity analysis is an analysis to determine how changes in an assumed input would affect the outcome. Some sensitivity analyses are common to most valuations. For example, a sensitivity analysis can be used to assess how a change in assumptions about a company's future growth—for example, decomposed by sales growth forecasts and margin forecasts—and/or a change in discount rates would affect the estimated value. Other sensitivity analyses depend on the context. For example, assume an analyst is aware that a competitor to the target company plans to introduce a competing product. Given uncertainty about the target company's competitive response—whether it will lower prices to retain market share, offer discounts to its distributors, increase advertising, or change a product feature—the analyst could create a baseline forecast and then analyze how different competitive responses would affect the forecasted financials and, in turn, the estimated valuation.

Situational adjustments may be required to incorporate the valuation impact of specific issues. Three such issues that could affect value estimates are control premiums, lack of marketability discounts, and illiquidity discounts. A controlling ownership position in a company (e.g., more than 50% of outstanding shares, although a far smaller percentage often affords an investor the ability to significantly influence a company) carries with it control of the board of directors and the valuable options of redeploying the company's assets or changing the company's capital structure. The value of a stock investment that would give an investor a controlling position will generally reflect a **control premium**; that is, it will be higher than a valuation produced by a generic quantitative valuation expression that did not explicitly model such a premium. A second issue generally not explicitly modeled is that investors require an extra return to compensate for lack of a public market or lack of marketability. The value of non-publicly traded stocks generally reflects a **lack of marketability discount**. Among publicly traded (i.e., marketable) stocks, the prices of shares with less depth to their markets (less liquidity) often reflect an **illiquidity discount**. An illiquidity discount would also apply if an investor wishes to sell an amount of stock that is large relative to that stock's trading volume (assuming it is not large enough to constitute a controlling ownership). The price that could be realized for that block of shares would generally be lower than the market price for a smaller amount of stock, a so-called **blockage factor**.

8.1 Applying the Valuation Conclusion: The Analyst's Role and Responsibilities

As noted earlier, the purposes of valuation and the intended consumer of the valuation vary:

- Analysts associated with investment firms' brokerage operations are perhaps the most visible group of analysts offering valuation judgments. Their research reports are widely distributed to current and prospective retail and institutional brokerage clients. The term brokerage typically means the business of acting as agents for buyers and sellers. Analysts who work at brokerage firms are known as **sell-side analysts** because brokerage firms sell investments and services to such institutions as investment management firms.

- In investment management firms, trusts and bank trust departments, and similar institutions, an analyst may report valuation judgments to a portfolio manager or to an investment committee as input to an investment decision. Such analysts are widely known as **buy-side analysts**. The analyst's valuation expertise is important not only in investment disciplines involving security selection based on detailed company analysis but also in highly quantitative investment disciplines. Quantitative analysts work in developing, testing, and updating security selection methodologies. Ranking stocks by some measure(s) of relative attractiveness (subject to a risk control discipline), as we will discuss in more detail later, forms one key part of quantitative equity investment disciplines.
- Analysts at corporations may perform some valuation tasks similar to those of analysts at money management firms (e.g., when the corporation manages in-house a sponsored pension plan). Both corporate analysts and investment bank analysts may also identify and value companies that could become acquisition targets.
- Analysts at independent vendors of financial information usually offer valuation information and opinions in publicly distributed research reports, although some focus solely on organizing and analyzing corporate information.

In conducting their valuation activities, investment analysts play a critical role in collecting, organizing, analyzing, and communicating corporate information, and in some contexts, recommending appropriate investment actions based on sound analysis. When they do those tasks well, analysts help their clients, the capital markets, and the suppliers of capital:

- Analysts help their clients achieve their investment objectives by enabling those clients to make better buy and sell decisions.
- Analysts contribute to the efficient functioning of capital markets by providing analysis that leads to informed buy and sell decisions and thus to asset prices that better reflect underlying values. When asset prices accurately reflect underlying values, capital flows more easily to its highest-value uses.
- Analysts benefit the suppliers of capital, including shareholders, when they are effective monitors of management's performance. This monitoring can serve to keep managers' actions more closely aligned with shareholders' best interests [see Jensen and Meckling (1976) for classic analysis of the costs of stockholder–manager conflicts].

What Are Analysts Expected to Do?

When analysts at brokerage firms recommend a stock to the public that later performs very poorly, or when they fail to uncover negative corporate activities, they can sometimes come under public scrutiny. Industry leaders may then be asked to respond to such criticism and to comment on expectations about the role and responsibilities of analysts. One such instance occurred in the United States as a consequence of the late 2001 collapse of Enron Corporation, an energy, utility, trading, and telecommunication company. In testimony before the US Senate (excerpted below), the President and CEO of AIMR (predecessor organization of CFA Institute) offered a summary of the working conditions and responsibilities of brokerage analysts. In the following passage, **due diligence** refers to investigation and analysis in support of a recommendation; the failure to exercise due diligence may sometimes result in liability according to various securities laws. "Wall Street analysts" refers to analysts working in the US brokerage industry (sell-side analysts).

> What are Wall Street analysts expected to do? These analysts are assigned companies and industries to follow, are expected to research fully these companies and the industries in which they operate, and to forecast their future prospects. Based on this analysis, and using appropriate valuation models, they must then determine an appropriate fair price for the company's securities. After comparing this fair price to the current market price, the analyst is able to make a recommendation. If the analyst's "fair price" is significantly above the current market price, it would be expected that the stock be rated a "buy" or "market outperform."
>
> How do Wall Street analysts get their information? Through hard work and due diligence. They must study and try to comprehend the information in numerous public disclosure documents, such as the annual report to shareholders and regulatory filings . . . and gather the necessary quantitative and qualitative inputs to their valuation models.
>
> This due diligence isn't simply reading and analyzing annual reports. It also involves talking to company management, other company employees, competitors, and others, to get answers to questions that arise from their review of public documents. Talking to management must go beyond participation in regular conference calls. Not all questions can be voiced in those calls because of time constraints, for example, and because analysts, like journalists, rightly might not wish to "show their cards," and reveal the insights they have gotten through their hard work, by asking a particularly probing question in the presence of their competitors.
>
> Wall Street analysts are also expected to understand the dynamics of the industry and general economic conditions before finalizing a research report and making a recommendation. Therefore, in order for their firm to justify their continued employment, Wall Street analysts must issue research reports on their assigned companies and must make recommendations based on their reports to clients who purchase their firm's research
>
> (*Source:* Thomas A. Bowman, CFA. Testimony to the Committee on Governmental Affairs (excerpted) US Senate, 27 February 2002).

From the beginnings of the movement to organize financial analysis as a profession rather than as a commercial trade, one guiding principle has been that the analyst must hold himself accountable to both standards of competence and standards of conduct. Competence in investment analysis requires a high degree of training, experience, and discipline (as reflected in the examination and work experience requirements that are prerequisites for obtaining the CFA designation). Additionally, the investment professional is in a position of trust, requiring ethical conduct toward the public, clients, prospects, employers, employees, and fellow analysts. For CFA Institute members, this position of trust is reflected in the Code of Ethics and Standards of Professional Conduct, as well as in the Professional Conduct Statement that they submit annually. The Code and Standards guide the analyst to independent, well-researched, and well-documented analysis and are described in the following sections.

COMMUNICATING VALUATION RESULTS

9

Writing is an important part of an analyst's job. Whether for review by an investment committee or a portfolio manager in an investment management firm or for distribution to the retail or institutional clients of a brokerage firm, research reports share several common elements. In this section, we briefly discuss the content and format of an effective research report and the analyst's responsibilities for preparing a report.

9.1 Contents of a Research Report

A primary determinant of a research report's contents is what the intended readers seek to gain from reading the report. From a sell-side analyst's report, an intended reader would be interested in the investment recommendation. In evaluating how much attention and weight to give to a recommendation, the reader will look for persuasive supporting arguments. A key element supporting any recommendation is the intrinsic value of the security.

Given the importance of the estimated intrinsic value of the security, most research reports provide the reader with information about the key assumptions and expectations underlying that estimated intrinsic value. The information typically includes an update on the company's financial and operating results, a description of relevant aspects of the current macroeconomic and industry context, and an analysis and forecast for the industry and company. Because some readers of research reports are interested in background information, some reports contain detailed historical descriptive statistics about the industry and company.

A report can include specific forecasts, key valuation inputs (e.g., the estimated cost of capital), a description of the valuation model, and a discussion of qualitative factors and other considerations that affect valuation. Superior research reports also objectively address the uncertainty associated with investing in the security and/or the valuation inputs involving the greatest amount of uncertainty. By converting forecasts into estimated intrinsic value, a comparison between intrinsic value and market price provides the basis for an investment recommendation. When a research report states a target price for a stock (based on its intrinsic value) in its investment recommendation, the report should clarify the basis for computing the target, a time frame for reaching the target, and information on the uncertainty of reaching the target. An investment recommendation may be accompanied by an explanation of the underlying rationale (i.e., investment thesis), which summarizes why a particular investment offer would provide a way to profit from the analyst's outlook.

Although a well-written report cannot compensate for a poor analysis, a poorly written report can detract from the credibility of an excellent analysis. Writing an effective research report is a challenging task. In summary, an effective research report:

- contains timely information;
- is written in clear, incisive language;
- is objective and well researched, with key assumptions clearly identified;
- distinguishes clearly between facts and opinions;
- contains analysis, forecasts, valuation, and a recommendation that are internally consistent;
- presents sufficient information to allow a reader to critique the valuation;
- states the key risk factors involved in an investment in the company; and
- discloses any potential conflicts of interests faced by the analyst.

Although these general characteristics are all desirable attributes of a useful and respected report, in some situations the requirements are more specific. For example, regulations governing disclosures of conflicts and potential conflicts of interest vary across countries, so an analyst must remain up-to-date on relevant disclosure requirements. In some situations, investment recommendations are affected by policies of the firm employing an analyst; for example, a policy might require that a security's price must be *X*% below its estimated intrinsic value to be considered a "buy." Even in the absence of such a policy, an analyst needs to maintain a conceptual distinction between a "good company" and a "good investment" because returns on a common stock investment always depend on the price paid for the stock, whether the business prospects of the issuing company are good, bad, or indifferent. Exhibit 5 provides a small sample of possible research report content.

Exhibit 5

Research Reports

The following two passages are closely based on the valuation discussions of actual companies in two actual short research notes. The dates and company names used in the passages, however, are fictional.

A At a recent multiple of 6.5, our earnings per share multiple for 2020, the shares were at a discount to our projection of 14% growth for the period … MXI has two operating segments … In valuing the segments separately, employing relative acquisition multiples and peer mean values, we found fair value to be above recent market value. In addition, the shares trade at a discount to book value (0.76). Based on the value indicated by these two valuation metrics, we view the shares as worth holding. However, in light of a weaker economy over the near term, dampening demand for MXI's services, our enthusiasm is tempered. [*Elsewhere in the report, MXI is evaluated as being in the firm's top category of investment attractiveness*.]

B Although TXI outperformed the overall stock market by 20% since the start of the year, it definitely looks undervalued, as shown by its low multiples … [*the values of the P/E and another multiple are stated*]. According to our dividend discount model valuation, we get to a valuation of €3.08, implying an upside potential of 36.8% based on current prices. The market outperform recommendation is reiterated. [*In a parenthetical expression, the current dividend, assumed dividend growth rates, and their time horizons are given. The analyst also briefly explains and calculates the discount rate. Elsewhere in the report the current price of TXI is given as €2.25*.]

Although some of the concepts mentioned in the two passages may not yet be familiar, you can begin to assess the two reporting efforts.

Passage A communicates the analysis awkwardly. The meaning of "the shares were at a discount to our projection of 14% growth for the period" is not completely clear. Presumably, the analyst is projecting the earnings growth rate for 2020 and stating that the P/E is low in relation to that expected growth rate. The analyst next discusses valuing MXI as the sum of its divisions. In describing the method as "employing relative acquisition multiples and peer mean values," the analyst does not convey a clear picture of what was done. It is probable that companies similar to each of MXI's divisions were identified; then, the mean or average value of some unidentified multiple for those comparison companies was calculated and used as the basis for valuing MXI. The writer is vague, however, on the extent of MXI's undervaluation. The analyst states that MXI's price is

Exhibit 5 (Continued)

below its book value (an accounting measure of shareholders' investment) but draws no comparison with the average price-to-book value ratio for stocks similar to MXI, for example. (The price-to-book ratio is discussed in a later reading.) Finally, the verbal summation is feeble and hedged. Although filled with technical verbiage, Passage A does not communicate a coherent valuation of MXI.

In the second sentence of Passage B, by contrast, the analyst gives an explicit valuation of TXI and the information needed to critique it. The reader can also see that €3.08, which is elsewhere stated in the research note as the target price for TXI, implies the stated price appreciation potential for TXI [(€3.08/€2.25) – 1, approximately 37%]. In the first sentence in Passage B, the analyst gives information that might support the conclusion that TXI is undervalued, although the statement lacks strength because the analyst does not explain why the P/E is "low." Nevertheless, the verbal summary is clear. Using less space than the analyst in Passage A, the analyst in Passage B has done a better job of communicating the results of his valuation.

9.2 Format of a Research Report

Equity research reports may be logically presented in several ways. The firm in which the analyst works sometimes specifies a fixed format for consistency and quality control purposes. Without claiming superiority to other ways to organize a report, we offer Exhibit 6 as an adaptable format by which the analyst can communicate research and valuation findings in detail. (Shorter research reports and research notes obviously may employ a more compact format.)

Exhibit 6 A Format for Research Reports

Section	Purpose	Content	Comments
Table of Contents	■ Show report's organization	■ Consistent with narrative in sequence and language	This is typically used only in very long research reports.
Summary and Investment Conclusion	■ Communicate the large picture ■ Communicate major specific conclusions of the analysis ■ Recommend an investment course of action	■ Capsule description of the company ■ Major recent developments ■ Earnings projections ■ Other major conclusions ■ Valuation summary ■ Investment action	An executive summary; may be called simply "Summary."
Business Summary	■ Present the company in more detail ■ Communicate a detailed understanding of the company's economics and current situation ■ Provide and explain specific forecasts[a]	■ Company description to the divisional level ■ Industry analysis ■ Competitive analysis ■ Historical performance ■ Financial forecasts	Reflects the first and second steps of the valuation process. Financial forecasts should be explained adequately and reflect quality of earnings analysis.

(continued)

Exhibit 6 (Continued)

Section	Purpose	Content	Comments
Risks	■ Alert readers to the risk factors in investing in the security	■ Possible negative industry developments ■ Possible negative regulatory and legal developments ■ Possible negative company developments ■ Risks in the forecasts ■ Other risks	Readers should have enough information to determine how the analyst is defining and assessing the risks specific to investing in the security.
Valuation	■ Communicate a clear and careful valuation	■ Description of model(s) used ■ Recapitulation of inputs ■ Statement of conclusions	Readers should have enough information to critique the analysis.
Historical and Pro Forma Tables	■ Organize and present data to support the analysis in the Business Summary		This is generally a separate section only in longer research reports. Many reports fold all or some of this information into the Business Summary section.

[a] Actual outcomes can and generally will differ from forecasts. A discussion of key random factors and an examination of the sensitivity of outcomes to the outcomes of those factors are useful.

9.3 Research Reporting Responsibilities

All analysts have an obligation to provide substantive and meaningful content in a clear and comprehensive report format. Analysts who are CFA Institute members, however, have an additional and overriding responsibility to adhere to the Code of Ethics and the Standards of Professional Conduct in all activities pertaining to their research reports. The CFA Institute Code of Ethics states:

> Members of CFA Institute must . . . use reasonable care and exercise independent professional judgment when conducting investment analysis, making investment recommendations, taking investment actions, and engaging in other professional activities.

Going beyond this general statement of responsibility, some specific Standards of Professional Conduct particularly relevant to an analyst writing a research report are shown in Exhibit 7.

Exhibit 7 Selected CFA Institute Standards of Professional Conduct Pertaining to Research Reports*

Standard of Professional Conduct	Responsibility
I(B)	Members and Candidates must use reasonable care and judgment to achieve and maintain independence and objectivity in their professional activities. Members and Candidates must not offer, solicit, or accept any gift, benefit, compensation, or consideration that reasonably could be expected to compromise their own or another's independence and objectivity.
I(C)	Members and Candidates must not knowingly make any misrepresentations relating to investment analysis, recommendations, actions, or other professional activities.
V(A)1	Members and Candidates must exercise diligence, independence, and thoroughness in analyzing investments, making investment recommendations, and taking investment actions.
V(A)2	Members and Candidates must have a reasonable and adequate basis, supported by appropriate research and investigation, for any investment analysis, recommendation, or action.
V(B)1	Members and Candidates must disclose to clients and prospective clients the basic format and general principles of the investment processes used to analyze investments, select securities, and construct portfolios and must promptly disclose any changes that might materially affect those processes.
V(B)2	Members and Candidates must disclose to clients and prospective clients significant limitations and risks associated with the investment process.
V(B)3	Members and Candidates must use reasonable judgment in identifying which factors are important to their investment analyses, recommendations, or actions and include those factors in communications with clients and prospective clients.
V(B)4	Members and Candidates must distinguish between fact and opinion in the presentation of investment analysis and recommendations.
V(C)	Members and Candidates must develop and maintain appropriate records to support their investment analysis, recommendations, actions, and other investment-related communications with clients and prospective clients.

* See the most recent edition of the CFA Institute *Standards of Practice Handbook* (www.cfainstitute.org).

SUMMARY

In this reading, we have discussed the scope of equity valuation, outlined the valuation process, introduced valuation concepts and models, discussed the analyst's role and responsibilities in conducting valuation, and described the elements of an effective research report in which analysts communicate their valuation analysis.

- Valuation is the estimation of an asset's value based on either variables perceived to be related to future investment returns or comparisons with closely similar assets.
- The intrinsic value of an asset is its value given a hypothetically complete understanding of the asset's investment characteristics.
- The assumption that the market price of a security can diverge from its intrinsic value—as suggested by the rational efficient markets formulation of efficient market theory—underpins active investing.
- Intrinsic value incorporates the going-concern assumption, that is, the assumption that a company will continue operating for the foreseeable future. In contrast, liquidation value is the company's value if it were dissolved and its assets sold individually.
- Fair value is the price at which an asset (or liability) would change hands if neither buyer nor seller were under compulsion to buy/sell and both were informed about material underlying facts.
- In addition to stock selection by active traders, valuation is also used for:
  - inferring (extracting) market expectations;
  - evaluating corporate events;
  - issuing fairness opinions;
  - evaluating business strategies and models; and
  - appraising private businesses.
- The valuation process has five steps:
  1. Understanding the business.
  2. Forecasting company performance.
  3. Selecting the appropriate valuation model.
  4. Converting forecasts to a valuation.
  5. Applying the analytical results in the form of recommendations and conclusions.
- Understanding the business includes evaluating industry prospects, competitive position, and corporate strategies—all of which contribute to making more accurate forecasts. Understanding the business also involves analysis of financial reports, including evaluating the quality of a company's earnings.
- In forecasting company performance, a top-down forecasting approach moves from macroeconomic forecasts to industry forecasts and then to individual company and asset forecasts. A bottom-up forecasting approach aggregates individual company forecasts to industry forecasts, which in turn may be aggregated to macroeconomic forecasts.
- Selecting the appropriate valuation approach means choosing an approach that is:
  - consistent with the characteristics of the company being valued;
  - appropriate given the availability and quality of the data; and

- consistent with the analyst's valuation purpose and perspective.

- Two broad categories of valuation models are absolute valuation models and relative valuation models.
  - Absolute valuation models specify an asset's intrinsic value, supplying a point estimate of value that can be compared with market price. Present value models of common stock (also called discounted cash flow models) are the most important type of absolute valuation model.
  - Relative valuation models specify an asset's value relative to the value of another asset. As applied to equity valuation, relative valuation is also known as the method of comparables, which involves comparison of a stock's price multiple to a benchmark price multiple. The benchmark price multiple can be based on a similar stock or on the average price multiple of some group of stocks.
- Two important aspects of converting forecasts to valuation are sensitivity analysis and situational adjustments.
  - Sensitivity analysis is an analysis to determine how changes in an assumed input would affect the outcome of an analysis.
  - Situational adjustments include control premiums (premiums for a controlling interest in the company), discounts for lack of marketability (discounts reflecting the lack of a public market for the company's shares), and illiquidity discounts (discounts reflecting the lack of a liquid market for the company's shares).
- Applying valuation conclusions depends on the purpose of the valuation.
- In performing valuations, analysts must hold themselves accountable to both standards of competence and standards of conduct.
- An effective research report:
  - contains timely information;
  - is written in clear, incisive language;
  - is objective and well researched, with key assumptions clearly identified;
  - distinguishes clearly between facts and opinions;
  - contains analysis, forecasts, valuation, and a recommendation that are internally consistent;
  - presents sufficient information that the reader can critique the valuation;
  - states the risk factors for an investment in the company; and
  - discloses any potential conflicts of interest faced by the analyst.
- Analysts have an obligation to provide substantive and meaningful content. CFA Institute members have an additional overriding responsibility to adhere to the CFA Institute Code of Ethics and relevant specific Standards of Professional Conduct.

PRACTICE PROBLEMS

1 Critique the statement: "No equity investor needs to understand valuation models because real-time market prices for equities are easy to obtain online."

2 The reading defined intrinsic value as "the value of an asset given a hypothetically complete understanding of the asset's investment characteristics." Discuss why "hypothetically" is included in the definition and the practical implication(s).

3 A Explain why liquidation value is generally not relevant to estimating intrinsic value for profitable companies.

B Explain whether making a going-concern assumption would affect the value placed on a company's inventory.

4 Explain how the procedure for using a valuation model to infer market expectations about a company's future growth differs from using the same model to obtain an independent estimate of value.

5 Exhibit 1, based on a study of Intel Corporation that used a present value model (Cornell 2001), examined what future revenue growth rates were consistent with Intel's stock price of $61.50 just prior to its earnings announcement and $43.31 only five days later. "Using a conservatively low discount rate, Cornell estimated that Intel's price before the announcement, $61.50, was consistent with a forecasted growth rate of 20% a year for the subsequent 10 years and then 6% per year thereafter." Discuss the implications of using a higher discount rate than Cornell did.

6 Discuss how understanding a company's business (the first step in equity valuation) might be useful in performing a sensitivity analysis related to a valuation of the company.

7 In a research note on the ordinary shares of the (fictitious) company Milan Fashion Group (MFG) dated early July 2019 when the price was €7.73 and projected annual dividends were €0.05, an analyst stated a target price of €9.20. The research note did not discuss how the target price was obtained or how it should be interpreted. Assume the target price represents the expected price of MFG. What further specific pieces of information would you need to form an opinion on whether MFG was fairly valued, overvalued, or undervalued?

8 You are researching (hypothetical) company XMI Corporation (XMI). XMI has shown steady earnings per share growth (18% a year during the last seven years) and trades at a very high multiple to earnings (its P/E is currently 40% above the average P/E for a group of the most comparable stocks). XMI has generally grown through acquisition, using XMI stock to purchase other companies whose stock traded at lower P/Es. In investigating the financial disclosures of these acquired companies and talking to industry contacts, you conclude that XMI has been forcing the companies it acquires to accelerate the payment of expenses before the acquisition deals are closed. As one example, XMI asks acquired companies to immediately pay all pending accounts payable, whether or not they are due. Subsequent to the acquisition, XMI reinstitutes normal expense payment patterns.

© 2016 CFA Institute. All rights reserved.

A What are the effects of XMI's pre-acquisition expensing policies?

B The statement is made that XMI's "P/E is currently 40% above the average P/E for a group of the most comparable stocks." What type of valuation model is implicit in that statement?

The following information relates to Questions 9–16

Global-Guardian Capital is a rapidly growing international investment firm. The firm's research team is responsible for identifying undervalued and overvalued publicly-traded equities that have a market capitalization greater than $500 million.

Due to the rapid growth of assets under management, Global-Guardian Capital recently hired a new analyst, Jack Richardson, to support the research process. At the new analyst orientation meeting, the director of research made the following statements about equity valuation at the firm:

Statement 1 "Analysts at Global-Guardian Capital seek to identify mispricing, relying on price eventually converging to intrinsic value. However, convergence of the market price to an analyst's estimate of intrinsic value may not happen within the portfolio manager's investment time horizon. So, besides evidence of mispricing, analysts should look for the presence of a particular market or corporate event—that is, a catalyst—that will cause the marketplace to re-evaluate the subject firm's prospects."

Statement 2 "An active investment manager attempts to capture positive alpha. But mispricing of assets is not directly observable. It is therefore important that you understand the possible sources of perceived mispricing."

Statement 3 "For its distressed securities fund, Global-Guardian Capital screens its investable universe of securities for companies in financial distress."

Statement 4 "For its core equity fund, Global-Guardian Capital selects financially sound companies that are expected to generate significant positive free cash flow from core business operations within a multiyear forecast horizon."

Statement 5 "Global-Guardian Capital's research process requires analysts to evaluate the reasonableness of the expectations implied by the market price by comparing the market's implied expectations to his or her own expectations."

After the orientation meeting, the director of research asks Richardson to evaluate three companies that are retailers of men's clothing: Diamond Co., Renaissance Clothing, and Deluxe Men's Wear.

Richardson starts his analysis by evaluating the characteristics of the men's retail clothing industry. He finds few barriers to new retail entrants, high intra-industry rivalry among retailers, low product substitution costs for customers, and a large number of wholesale clothing suppliers.

While conducting his analysis, Richardson discovers that Renaissance Clothing included three non-recurring items in their most recent earnings release: a positive litigation settlement, a one-time tax credit, and the gain on the sale of a non-operating asset.

To estimate each firm's intrinsic value, Richardson applies appropriate discount rates to each firm's estimated free cash flows over a ten-year time horizon and to the estimated value of the firm at the end of the ten-year horizon.

Michelle Lee, a junior technology analyst at Global-Guardian, asks the director of research for advice as to which valuation model to use for VEGA, a fast growing semiconductor company that is rapidly gaining market share.

The director of research states that "the valuation model selected must be consistent with the characteristics of the company being valued."

Lee tells the director of research that VEGA is not expected to be profitable for several more years. According to management guidance, when the company turns profitable, it will invest in new product development; as a result, it does not expect to initiate a dividend for an extended period of time. Lee also notes that she expects that certain larger competitors will become interested in acquiring VEGA because of its excellent growth prospects. The director of research advises Lee to consider that in her valuation.

9 Based on Statement 2, which of the following sources of perceived mispricing do active investment managers attempt to identify? The difference between:

- **A** intrinsic value and market price.
- **B** estimated intrinsic value and market price.
- **C** intrinsic value and estimated intrinsic value.

10 With respect to Statements 3 and 4, which of the following measures of value would the distressed securities fund's analyst consider that a core equity fund analyst might ignore?

- **A** Fair value
- **B** Liquidation value
- **C** Fair market value

11 With respect to Statement 4, which measure of value is *most* relevant for the analyst of the fund described?

- **A** Liquidation value
- **B** Investment value
- **C** Going-concern value

12 According to Statement 5, analysts are expected to use valuation concepts and models to:

- **A** value private businesses.
- **B** render fairness opinions.
- **C** extract market expectations.

13 Based on Richardson's industry analysis, which of the following characteristics of men's retail clothing retailing would *positively* affect its profitability? That industry's:

- **A** entry costs.
- **B** substitution costs.
- **C** number of suppliers.

14 Which of the following statements about the reported earnings of Renaissance Clothing is *most accurate*? Relative to sustainable earnings, reported earnings are likely:

- **A** unbiased.
- **B** upward biased.
- **C** downward biased.

15 Which valuation model is Richardson applying in his analysis of the retailers?

A Relative value

B Absolute value

C Sum-of-the-parts

16 Which valuation model would the director of research *most likely* recommend Lee use to estimate the value of VEGA?

A Free cash flow

B Dividend discount

C P/E relative valuation

The following information relates to Questions 17–20

Bruno Santos is an equity analyst with a regional investment bank. Santos reviews the growth prospects and quality of earnings for Phoenix Enterprises, one of the companies he follows. He has developed a stock valuation model for this firm based on its forecasted fundamentals. His revenue growth rate estimate is less than that implied by the market price.

Phoenix's financial statements over the past five years show strong performance, with above average growth. Santos has decided to use a lower forecasted growth rate in his models, reflecting the effect of "regression to the mean" over time. He notes two reasons for his lower growth rate forecast:

Reason 1 Successful companies tend to draw more competition, putting their high profits under pressure.

Reason 2 Phoenix's intellectual property and franchise agreements will be weakening over time.

Santos meets with Walter Hartmann, a newly hired associate in his department. In their conversation, Hartmann states, "Security analysts forecast company performance using both top-down and bottom-up analysis. I can think of three examples:

1 A restaurant chain forecasts its sales to be its market share times forecast industry sales.

2 An electric utility company forecasts that its sales will grow proportional to increases in GDP.

3 A retail furniture company forecasts next year's sales by assuming that the sales in its newly built stores will have similar sales per square meter to that of its existing stores."

Hartmann is reviewing some possible trades for three stocks in the health care industry based on a pairs-trading strategy. Hartmann's evaluations are as follows:

- HG Health is 15% overvalued.
- Corgent Cell Sciences is 10% overvalued.
- Johnson Labs is 15% undervalued.

17 Based on Santos's revenue growth rate estimate, the shares of Phoenix are *most likely*:

A undervalued.

B fairly valued.

C overvalued.

18 Which of the reasons given by Santos *most likely* justifies a reduction in Phoenix's forecasted growth rate?

A Reason 1 only

B Reason 2 only

C Both Reason 1 and Reason 2

19 Which of Hartmann's examples of company performance forecasting *best* describes an example of bottom-up forecasting?

A Restaurant chain

B Electric utility company

C Retail furniture company

20 Based on his trading strategy, which of the following should Hartmann recommend?

A Short HG Health and Corgent Cell Sciences

B Buy Johnson Labs and Corgent Cell Sciences

C Buy Johnson Labs and short Corgent Cell Sciences

The following information relates to questions 21–24

Abby Dormier is a sell-side analyst for a small Wall Street brokerage firm; she covers publicly and actively traded companies with listed equity shares. Dormier is responsible for issuing either a buy, hold, or sell rating for the shares of Company A and Company B. The appropriate valuation model for each company was chosen based on the following characteristics of each company:

> **Company A** is an employment services firm with no debt and has fixed assets consisting primarily of computers, servers, and commercially available software. Many of the assets are intangible, including human capital. The company has a history of occasionally paying a special cash dividend.
>
> **Company B** operates in three unrelated industries with differing rates of growth: tobacco (60% of earnings), shipbuilding (30% of earnings), and aerospace consulting (10% of earnings). The company pays a regular dividend that is solely derived from the earnings produced by the tobacco division.

Dormier considers the following development in making any necessary adjustments to the models before assigning ratings:

> Company B has finalized the terms to acquire 70% of the outstanding shares of Company X, an actively traded tobacco company, in an all-stock deal.

Dormier assigns ratings to each of the companies and provides a rationale for each rating. The director of research asks Dormier: "How did you arrive at these recommendations? Describe how you used a top-down approach, which is the policy at our company."

Dormier replies, "I arrived at my recommendations through my due diligence process. I have studied all of the public disclosure documents; I have participated in the company conference calls, being careful with my questions in such a public forum; and I have studied the dynamics of the underlying industries. The valuation models are robust and use an extensive set of company-specific quantitative and qualitative inputs."

21 Based on Company A's characteristics, which of the following absolute valuation models is *most* appropriate for valuing that company?

A Asset based

B Dividend discount

C Free cash flow to the firm

22 Based on Company B's characteristics, which of the following valuation models is *most* appropriate for valuing that company?

A Asset based

B Sum of the parts

C Dividend discount

23 Which of the following is *most likely* to be appropriate to consider in Company B's valuation of Company X?

A Blockage factor

B Control premium

C Lack of marketability discount

24 Based on Dormier's response to the director of research, Dormier's process could have been more consistent with the firm's policy by:

A incorporating additional micro-level inputs into her valuation models.

B evaluating the impact of general economic conditions on each company.

C asking more probing questions during publicly available company conference calls.

SOLUTIONS

1 The statement is flawed in at least two ways. First, active investors believe that stock prices do not always accurately reflect all relevant information on the security; for such investors, knowledge of equity valuation models is important for identifying investment opportunities because they represent a way to translate the investor's forecasts into value estimates for comparison with market prices. Thus, the "all" in "all investors" is misleading. Second, not all equities are publicly traded and have market prices, and the most recent market price can be stale for the many public equities that trade only infrequently.

2 No matter how diligent the analyst, some uncertainty always exists concerning 1) the accuracy of the analyst's forecasts and 2) whether an intrinsic value estimate accounts for all sources of risk reflected in market price. Thus, knowledge of a stock's investment characteristics is always incomplete. The practical consequences are that an investor can only estimate intrinsic value and active security selection carries the risk of making mistakes in estimating value.

3 **A** Liquidation value is typically not relevant to estimating intrinsic value for profitable companies because, in general, value would be destroyed by selling such a company's assets individually. Stated another way, the value added by being a going concern is a relevant investment characteristic that an intrinsic value estimate would recognize.

B A going-concern assumption generally increases the value placed on a company's inventory relative to not making that assumption. Usually, inventory that can be sold in the company's regular distribution channels would realize higher amounts than inventory that must be sold immediately because a company is being liquidated.

4 The key difference is that for inferring investor expectations the market price is used as the model input for value, whereas for obtaining an independent estimate of value, value is left as the unknown in the model. In the latter case, value is estimated based on the analyst's estimates for the variables that determine value.

5 Consider the present value of a single cash flow. If one increased the discount rate, one would also need to increase the cash flow if a constant present value were to be maintained. By a similar argument, if Cornell had used a higher discount rate, he would have needed to project a higher level of assumed future cash flows than he did for their present value to have been consistent with the given pre-announcement price of \$61.50. Thus, the implied growth rate consistent with a price of \$61.50 would have been higher than the 20% growth rate estimated by Cornell.

6 An understanding of the company's business facilitates a focus on the key business aspects that affect value, and from a practical perspective, it highlights the critical inputs to a forecast that should be tested using sensitivity analysis.

7 You need to know 1) the time horizon for the price target and 2) the required rate of return on MFG. The price target of €9.20 represents a potential 20% return from investing in the stock if the time horizon is one year, calculated as (€9.20 + €0.05)/€7.73 – 1.0 = 0.197; without a time frame, however, you cannot evaluate the attractiveness of that return. Given that the time frame for the return is established, you need to have an estimate of the required rate of return over the same time horizon.

If the expected return of 19.7% exceeds the security's required return for the same horizon—in other words, if the share's expected alpha is positive—then MFG would appear to be undervalued.

8 **A** Accelerating the payment of expenses reduces the acquired companies' last reported pre-acquisition cash flow. Accelerating expense recognition reduces the acquired companies' last reported pre-acquisition earnings. XMI's cash flow and earnings growth rates following the acquisitions would be expected to be biased upwards because of the depressed levels for the acquirees.

B That is an example of a relative valuation model (or the method of comparables), which compares a company's market multiple to the multiples of similar companies.

9 A is correct. The difference between the true (real) but unobservable intrinsic value and the observed market price contributes to the abnormal return or alpha, which is the concern of active investment managers.

10 B is correct. The measure of value the distressed securities fund's analyst would consider that the core equity fund analyst might ignore is liquidation value. The liquidation value of a company is its value if it were dissolved and its assets sold individually.

11 C is correct. For its core equity fund, Global-Guardian Capital screens its investable universe of securities for well-capitalized companies that are expected to generate significant future free cash flow from core business operations. The concern with future free cash flows implies that going-concern value is relevant.

12 C is correct. Market prices reflect the expectations of investors about the future performance of companies. The analyst can evaluate the reasonableness of the expectations implied by the market price by comparing the market's implied expectations to his own expectations. This process assumes a valuation model, as discussed in the text.

13 C is correct. The men's retail clothing industry is characterized by a large number of wholesale clothing suppliers. When many suppliers of the products needed by industry participants exist, competition among suppliers should limit their ability to raise input prices. Thus, the large number of suppliers is a factor that should positively affect industry profitability.

14 B is correct. The effects of favorable nonrecurring events in reported earnings would tend to bias reported earnings upward relative to sustainable earnings because non-recurring items are by definition not expected to repeat. Renaissance Clothing included three non-recurring items in their most recent earnings release that all led to higher earnings for the current period: a positive litigation settlement, a one-time tax credit, and the gain on the sale of a non-operating asset.

15 B is correct. An absolute valuation model is a model that specifies an asset's intrinsic value. The most important type of absolute equity valuation models are present value models (also referred to as discounted cash flow models), and the model described by Richardson is of that type.

16 A is correct. The broad criteria for model selection are that a valuation model be consistent with the characteristics of the company being valued—that it be appropriate given the availability and quality of the data and consistent with the purpose of the valuation. VEGA currently has negative earnings, making the use of P/E relative valuation difficult if not impossible. As VEGA does not pay a dividend and is not expected to for the foreseeable future, the application of a dividend discount model is problematic. However, the lack of a dividend would not be an obstacle to free cash flow valuation. Furthermore, the director of research has advised that the possibility that competitors may seek to acquire VEGA be taken in to account in valuing VEGA. The reading states that free cash flow valuation can be appropriate in such circumstances. Thus, the director of research would be most likely to recommend free cash flow valuation.

17 C is correct. If the revenue growth rate inferred by the market price exceeds the growth rate that the firm could reasonably expect, Santos should conclude that the market price is too high and thus that the firm is overvalued.

18 C is correct. Increased competition for successful firms can cause a regression to the mean of a company's growth rate. Expiring and weakening intellectual property and franchise agreements can also reduce potential growth.

19 C is correct. The retail furniture company forecasting sales based on sales per square meter is an example of bottom-up forecasting because it aggregates forecasts at a micro level to larger-scale forecasts.

20 C is correct. Pairs trading involves buying an undervalued stock and shorting an overvalued stock in the same industry. Hartmann should buy Johnson Labs (15% undervalued) and short Corgent Cell Sciences (10% overvalued).

21 C is correct. The free cash flow to the firm model is the most appropriate of the choices because it can be used whether the company has significant marketable assets or consistently pays a cash dividend. Much of Company A's assets are intangible, and although the company has a history of paying a dividend, it has been only occasionally and in the form of a special dividend (i.e., not a consistent cash dividend).

22 B is correct. This valuation model would be consistent with the characteristics of the company. Company B is a conglomerate operating in three unrelated industries with significantly different expected revenue growth rates. The sum-of-the-parts valuation model sums the estimated values of each of the company's businesses as if each business were an independent going concern. Sum-of-the-parts analysis is most useful when valuing a company with segments in different industries that have different valuation characteristics.

23 B is correct. A control premium may be reflected in the value of a stock investment that would give an investor a controlling position. Company B acquired 70% of the outstanding stock of Company X; more than 50% is considered a controlling ownership position.

24 B is correct. A top-down forecasting approach moves from macroeconomic forecasts to industry forecasts and then to individual company and asset forecasts. Analysts are expected to understand the general economic conditions before finalizing a research report and making a recommendation. According to Dormier's response, she did not comment on the general economic conditions—although such considerations would be consistent with the firm's policy of using a top-down approach.

Return Concepts

by Jerald E. Pinto, PhD, CFA, Elaine Henry, PhD, CFA, Thomas R. Robinson, PhD, CFA, CAIA, and John D. Stowe, PhD, CFA

Jerald E. Pinto, PhD, CFA, is at CFA Institute (USA). Elaine Henry, PhD, CFA, is at Stevens Institute of Technology (USA). Thomas R. Robinson, PhD, CFA, CAIA is at Robinson Global Investment Management LLC, (USA). John D. Stowe, PhD, CFA, is at Ohio University (USA).

LEARNING OUTCOMES

Mastery	*The candidate should be able to:*
☐	**a.** contrast realized holding period return, expected holding period return, required return, return from convergence of price to intrinsic value, discount rate, and internal rate of return;
☐	**b.** calculate and interpret an equity risk premium using historical and forward-looking estimation approaches;
☐	**c.** determine the required return on an equity investment using the capital asset pricing model, the Fama–French model, the Pastor–Stambaugh model, macroeconomic multifactor models, and the build-up method (e.g., bond yield plus risk premium);
☐	**d.** explain beta estimation for public companies, thinly traded public companies, and non-public companies;
☐	**e.** describe strengths and weaknesses of methods used to estimate the required return on an equity investment;
☐	**f.** explain international considerations in required return estimation;
☐	**g.** explain and calculate the weighted average cost of capital for a company;
☐	**h.** evaluate the appropriateness of using a particular rate of return as a discount rate, given a description of the cash flow to be discounted and other relevant facts.

1 RETURN CONCEPTS

a contrast realized holding period return, expected holding period return, required return, return from convergence of price to intrinsic value, discount rate, and internal rate of return;

The return on an investment is a fundamental element in evaluating an investment:

- Investors evaluate an investment in terms of the return they expect to earn on it compared with a level of return viewed as fair given everything they know about the investment, including its risk.
- Analysts need to specify the appropriate rate or rates with which to discount expected future cash flows when using present value models of stock value.

We present and illustrate key return measures relevant to valuation, starting with an overview of return concepts. The subsequent section presents the main approaches to estimating the equity risk premium, a key input in determining the required rate of return on equity in several important models. With a means to estimate the equity risk premium in hand, the next sections discuss and illustrate the major models for estimating the required return on equity. We then present the weighted average cost of capital, a discount rate used when finding the present value of cash flows to all providers of capital, and also explain certain facts concerning discount rate selection. We then conclude the coverage of return concepts with a summary and practice problems.

1.1 Return Concepts

A sound investment decision depends critically on the correct use and evaluation of rate of return measures. The following sections explain the major return concepts most relevant to valuation. Please note that this is by no means an exhaustive list of return concepts used in finance. Also, references to *return* in this context refer to *rate of return*, not a money amount of return.

1.1.1 *Holding Period Return*

The holding period rate of return (for short, the **holding period return**) is the return earned from investing in an asset over a specified period. The specified period is the holding period under examination, whether it is one day, two weeks, four years, or any other length of time. To use a hypothetical return figure of 0.8% for a one-day holding period, we would say that "the one-day holding period return is 0.8%" (or equivalently, "the one-day return is 0.8%" or "the return is 0.8% over one day"). Such returns can be separated into investment income and price appreciation (also referred to as "capital gain") components. If the asset is a share purchased now (at $t = 0$, with t denoting time) and sold at $t = H$, the holding period is $t = 0$ to $t = H$ and the holding period return is

$$\begin{aligned} r &= \frac{D_H + P_H}{P_0} - 1 \\ &= \frac{D_H}{P_0} + \frac{P_H - P_0}{P_0} \qquad (1) \\ &= \text{Dividend yield} + \text{Price appreciation return} \end{aligned}$$

where D_t and P_t are per-share dividends and share price at time t. Equation 1 shows that the holding period return is the sum of two components: dividend yield (D_H/P_0) and price appreciation return ($[P_H - P_0]/P_0$), also known as the capital gains yield.

Equation 1 assumes, for simplicity, that any dividend is received at the end of the holding period. More generally, the holding period return would be calculated based on reinvesting any dividend received between $t = 0$ and $t = H$ in additional shares on the date the dividend was received at the price then available. Holding period returns are sometimes annualized—e.g., the return for a specific holding period may be converted to an annualized return, usually based on compounding at the holding period rate. For example, $(1.008)^{365} - 1 = 17.3271$, or 1,732.71%, is one way to annualize a one-day 0.80% return. As the example shows, however, annualizing holding period returns, when the holding period is a fraction of a year, are unrealistic when the reinvestment rate is not an actual, available reinvestment rate.

1.1.2 *Realized and Expected (Holding Period) Return*

In the expression for the holding period return, the selling price, P_H, and in general, the dividend, D_H, are not known as of $t = 0$. For a holding period in the past, the selling price and the dividend are known, and the return is called a realized holding period return or, more simply, a realized return. For example, with a beginning price of €50.00, an ending or selling price of €52.00 six months later, and a dividend equal to €1.00 (all amounts referring to the past), the realized return is €1.00/€50.00 + (€52.00 − €50.00)/€50.00 = 0.02 + 0.04 = 0.06, or 6% over six months. In forward-looking contexts, holding-period returns are random variables because future selling prices and dividends may both take on a range of values. Nevertheless, an investor can form an expectation concerning the dividend and selling price and thereby have an **expected holding-period return**, or simply expected return, for the stock that consists of the expected dividend yield and the expected price appreciation return.

Although professional investors often formulate expected returns based on explicit valuation models, a return expectation does not have to be based on a model or on specific valuation knowledge. Any investor can have a personal viewpoint on the future returns on an asset. In fact, because investors formulate expectations in varying ways and on the basis of different information, different investors generally have different expected returns for an asset. The comparison point for interpreting the investment implication of the expected return for an asset is its required return, the subject of the next section.

1.1.3 *Required Return*

A **required rate of return** (for short, required return) is the minimum level of expected return that an investor requires in order to invest in the asset over a specified period, given the asset's riskiness. It represents the opportunity cost for investing in the asset—the highest level of expected return available elsewhere from investments of similar risk. As the opportunity cost for investing in the asset, the required return represents a threshold value for being fairly compensated for the asset's risk. If the investor's expected return exceeds the required return, the asset will appear to be undervalued because it is expected to return more-than-fair compensation for the asset's risk. By contrast, if the expected return on the asset falls short of the required rate of return, the asset will appear to be overvalued.

The valuation examples presented in our coverage will illustrate the use of required return estimates grounded in market data (such as observed asset returns) and explicit models for required return. We will refer to any such estimate of the required return used in an example as *the* required return on the asset for the sake of simplicity, although other estimates are usually defensible. For example, under the capital asset pricing model (discussed in more detail later), the required return for an asset is equal to the risk-free rate of return plus a premium (or discount) related to the asset's sensitivity to market returns. That sensitivity can be estimated based on returns for an observed market portfolio and the asset. That is one example of a required return estimate grounded in a formal model based on marketplace variables (rather than a single investor's return requirements). Market variables should contain information about investors' asset risk perceptions and their level of risk aversion, both of which are important in determining fair compensation for risk.

The concept of risk-free rate mentioned in the previous paragraphs is important in valuation. "Risk-free rate" in financial theory is the rate of return on an asset that produces the same, known rate of return in all future economic states. In investment practice, "risk-free rate" typically refers to a rate of return on an investment with assured (or nearly assured) payments. This risk-free rate then serves as a reference rate for practical purposes such as valuing other investments. In a given market, the yield on a sovereign debt instrument (e.g., Treasury bills or Treasury bonds in the United States and German Treasury bills [Schätze] in the eurozone) is typically used by practitioners to represent the risk-free rate for valuation purposes. Note that the concept of a risk-free rate for purposes of equity valuation differs from the concept of risk-free rates used as official benchmarks in pricing rate-linked products and contracts. For example, the recommended risk-free reference rate for rate-linked products and contracts in the eurozone is the euro short-term rate €STR, as of 2018, as a replacement for the previously used euro overnight index average EONIA.

We use the notation r for the required rate of return on the asset being discussed. The required rate of return on common stock and debt are also known as the **cost of equity** and **cost of debt**, respectively, taking the perspective of the issuer. To raise new capital, the issuer would have to price the security to offer a level of expected return that is competitive with the expected returns being offered by similarly risky securities. The required return on a security is therefore the issuer's marginal cost for raising additional capital of the same type.

The difference between the expected return and the required rate of return on an asset is the asset's expected alpha (or *ex ante* alpha) or expected abnormal return:

$$\text{Expected alpha} = \text{Expected return} - \text{Required return} \tag{2a}$$

When an asset is efficiently priced (its price equals its intrinsic value), expected return should equal required return and the expected alpha is zero. In investment decision-making and valuation, the focus is on expected alpha. To evaluate the actual results of an investment discipline, however, the analyst would examine realized alpha. Realized alpha (or *ex post* alpha) over a given holding period is

$$\begin{aligned}\text{Realized alpha} = {} & \text{Actual holding-period return} \\ & - \text{Contemporaneous required return}\end{aligned} \tag{2b}$$

Estimates of required returns are essential for using present value models of value. Present value models require the analyst to establish appropriate discount rates for determining the present values of expected future cash flows.

Expected return and *required rate of return* are sometimes used interchangeably in conversation and writing. As discussed, doing so is not necessarily correct. When current price equals perceived value, expected return should be the same as the required rate of return. When price is below (above) the perceived value, however, expected return will exceed (be less than) the required return as long as the investor expects price to converge to value over her time horizon.

Given an investor's expected holding-period return, we defined expected alpha in relation to a required return estimate. In the next section, we show the conversion of a value estimate into an estimate of expected holding-period return.

1.1.4 *Expected Return Estimates from Intrinsic Value Estimates*

When an asset is mispriced, one of several outcomes is possible. Take the case of an asset that an investor believes is 25% undervalued in the marketplace. Over the investment time horizon, the mispricing may

- increase (the asset may become more undervalued);

- stay the same (the asset may remain 25% undervalued);
- be partially corrected (e.g., the asset may become undervalued by 15%);
- be corrected (the asset price changes to exactly reflect value); or
- reverse or be overcorrected (the asset may become overvalued).

Generally, convergence of price to value is the equilibrium and anticipated outcome when the investor's value estimate is more accurate than the market's, as reflected in the market price. In that case, the investor's expected rate of return has two components: the required return (earned on the asset's current market price) and a return from convergence of price to value.

We can illustrate how expected return may be estimated when an investor's value estimate, V_0, is different from the market price. Suppose the investor expects price to fully converge to value over τ years. $(V_0 - P_0)/P_0$ is an estimate of the return from convergence over the period of that length, essentially the expected alpha for the asset stated on a per-period basis. With r_τ being the required return on a periodic (not annualized) basis and $E(R_\tau)$ the expected holding-period return on the same basis, then:

$$E(R_\tau) \approx r_\tau + \frac{V_0 - P_0}{P_0}$$

Although only an approximation, the expression does illustrate that an expected return can be viewed as the sum of two returns: the required return and a return from convergence of price to intrinsic value. (Note that the expression assumes that the required rate of return and intrinsic value are static over the holding period and that convergence happens either smoothly over the holding period or all at once at its end.)

To illustrate, assume that an investor estimates the required return for an investment in the shares of the (fictitious) Mixama Motors Company is 6.3%. The investor estimates that the intrinsic value of the company's shares is $176.30 per share, and the current market price is $127.97. Thus, in the investor's view, Mixama Motors's shares are undervalued by $V_0 - P_0$ = \$176.30 − \$127.97 = \$48.33, or 37.77% as a fraction of the market price (\$48.33/\$127.97). If price were expected to converge to value in exactly one year, an investor would earn 37.77% + 6.3% = 44.07%. Alternatively, if the investor expected the undervaluation to disappear by the end of nine months, then the investor would earn approximately 42.5% over the nine-month period which is the sum of the 37.77% price appreciation and the required return on a nine-month basis. The required return on a nine-month basis (τ = 9/12 = 0.75) is $(1.063)^{0.75} - 1 = 0.0469$, or 4.69%. The total expected return is

$$\begin{aligned} E(R_\tau) &\approx r_\tau + \frac{V_0 - P_0}{P_0} \\ &= 4.69\% + 37.77\% \\ &= 42.46\% \end{aligned}$$

In other words, the sum of the price appreciation of 37.77% on a nine-month basis, when added to the required return of 4.69% on a nine-month basis, gives an estimate of the nine-month holding period return of approximately 42.5%. Another possibility is that price converges to value in two years. The expected two-year holding-period return would be 13.00% + 37.77% = 50.77%, in which the required return component is calculated as $(1.063)^2 - 1 = 0.1300$. This expected return based on two-year convergence could be compared to the expected return based on one-year convergence of 44.07% by annualizing it: $(1.5077)^{1/2} - 1 = 0.2279$, or 22.79% per year.

Active investors essentially "second-guess" the market price. The risks of that activity include the risks that 1) their value estimates are not more accurate than the market price and 2) even if they are more accurate, the value discrepancy may not narrow over the investors' time horizon. Clearly, the convergence component of expected return can be quite risky.

EXAMPLE 1

Required Return

Thomas Weeramantry is a co-manager of a diversified global equity portfolio. He is researching Microsoft Corporation, one of the largest US-headquartered technology companies. Weeramantry gathered a number of research reports on Microsoft and began his analysis of the company in February 2019, when the current share price for Microsoft was \$112.17. In one research report, the analyst offered the following facts, opinions, and estimates concerning Microsoft:

- The most recent quarterly dividend was \$0.46 per share.
- Microsoft's required return on equity is estimated to be 7.0%.
- A one-year target price for Microsoft shares is estimated at \$126.40.

An analyst's target price is the price at which the analyst believes the security should sell at a stated future point in time. Based only on the information given, answer the following questions concerning Microsoft. For both questions, ignore returns from reinvesting the quarterly dividends.

1 What is the analyst's one-year expected return?

2 What is a target price that is *most* consistent with Microsoft being fairly valued?

Solution to 1:

Over one year, the analyst expects Microsoft to pay \$1.84 in dividends (4 quarters × \$0.46). Using the target price of \$126.40 and dividends of \$1.84, the analyst's expected return is (\$1.84/\$112.17) + (\$126.40 − \$112.17)/\$ 112.17 = 0.016 + 0.127 = 0.143, or 14.3%.

Solution to 2:

If Microsoft is fairly valued, it should return its cost of equity (required return), which is 7.0%. Under that assumption, Target price = Current price × (1 + Required return) − Dividend = \$112.17 × 1.07 − \$1.84 = \$118.18; the dividend is subtracted to isolate the return from price appreciation. Another solution approach involves subtracting the dividend yield from the required return to isolate the anticipated price appreciation return: 7.0% − 1.6% = 5.4%. Thus, 1.054 × \$112.17 = \$118.23.

1.1.5 *Discount Rate*

Discount rate is a general term for any rate used in finding the present value of a future cash flow. A discount rate reflects the compensation required by investors for delaying consumption—generally assumed to equal the risk-free rate—and their required compensation for the risk of the cash flow. Generally, the discount rate used to determine intrinsic value depends on the characteristics of the investment rather than on the characteristics of the purchaser. That is, *for the purposes of estimating intrinsic value*, a required return based on marketplace variables is used rather than a personal required return influenced by such factors as whether the investor is diversified in his personal portfolio. On the other hand, some investors will make judgmental adjustments to such required return estimates, knowing the limitations of the finance models used to estimate such returns.

In principle, because of varying expected future inflation rates and the possibly varying risk of expected future cash flows, a distinct discount rate could be applicable to each distinct expected future cash flow. Similarly, when expected future annual cash flows are grouped into multi-year subperiods—each with a different assumed growth rate—analysts sometimes apply different required returns to discount the different subperiods' expected cash flows. In practice, a single required return is generally used to discount all expected future cash flows.

Sometimes an internal rate of return is used as a required return estimate, as discussed in the next section.

1.1.6 *Internal Rate of Return*

The **internal rate of return** (IRR) on an investment is the discount rate that equates the present value of the asset's expected future cash flows to the asset's price—that is, the amount of money needed today to purchase a right to those cash flows.

In a model that views the intrinsic value of a common equity share as the present value of expected future cash flows, if price is equal to current intrinsic value—the condition of market informational efficiency—then, generally, a discount rate can be found (usually by iteration) that equates that present value to the market price. An IRR computed under the assumption of market efficiency has been used to estimate the required return on equity. An example is the historical practice of many US state regulators of estimating the cost of equity for regulated utilities using the model illustrated in Equation 3b below. The issue of cost of equity arises because regulators set prices sufficient for utilities to earn their cost of capital (see Fernandez 2019 for a description of methodology for required return used by various European utilities regulators).

To illustrate, the simplest version of a present value model results from defining cash flows as dividends and assuming a stable dividend growth rate for the indefinite future. The stable growth rate assumption reduces the sum of results in a very simple expression for intrinsic value:

$$\text{Intrinsic value} = \frac{\text{Year-ahead dividend}}{\text{Required return} - \text{Expected dividend growth rate}} \tag{3a}$$

If the asset is correctly valued now (Market price = Intrinsic value), given consensus estimates of the year-ahead dividend and future dividend growth rate (which are estimates of the dividend expectations built into the price), we can solve for a required return—an IRR implied by the market price:

$$\text{Required return estimate} = \frac{\text{Year-ahead dividend}}{\text{Market price}} + \text{Expected dividend growth rate} \tag{3b}$$

The use of such an IRR as a required return estimate assumes not only market efficiency but also the correctness of the particular present value model (in the foregoing example, the stable growth rate assumption is critical) and the estimated inputs to the selected model. In Equation 3b and similar cases, although the asset's risk is incorporated indirectly into the required return estimate via the market price, the adjustment for risk is not explicit as it is in many competing models that will be presented.

Finally, obtaining an IRR from a present value model should not be confused with the somewhat similar-looking exercise that involves inferring what the market price implies about future growth rates of cash flows, given an independent estimate of required return: That exercise has the purpose of assessing the reasonableness of the market price.

2 EQUITY RISK PREMIUM: HISTORICAL AND FORWARD-LOOKING ESTIMATES

b calculate and interpret an equity risk premium using historical and forward-looking estimation approaches;

The equity risk premium is the incremental return (*premium*) that investors require for holding equities rather than a risk-free asset. Thus, it is the difference between the required return on equities and a specified expected risk-free rate of return. The equity risk premium, like the required return, depends strictly on expectations for the future because the investor's returns depend only on the investment's future cash flows. Possibly confusingly, *equity risk premium* is also commonly used to refer to the realized excess return of stocks over a risk-free asset over a given past period. The realized excess return could be very different from the premium that, based on available information, was contemporaneously being expected by investors.

Using the equity risk premium, the required return on the broad equity market or an average-systematic-risk equity security is

Required return on equity = Current expected risk-free return + Equity risk premium

where, for consistency, the definition of risk-free asset (e.g., government bills or government bonds) used in estimating the equity risk premium should correspond to the one used in specifying the current expected risk-free return.

The importance of the equity risk premium in valuation is that, in perhaps a majority of cases in practice, analysts estimate the required return on a common equity issue as either

$$\begin{aligned}\text{Required return on share } i &= \text{Current expected risk-free return} \\ &\quad + \beta_i(\text{Equity risk premium})\end{aligned} \tag{4}$$

or

$$\begin{aligned}\text{Required return on share } i &= \text{Current expected risk-free return} \\ &\quad + \text{Equity risk premium} \\ &\quad \pm \text{Other risk premia (or discounts)} \\ &\qquad \text{appropriate for } i\end{aligned} \tag{5}$$

- Equation 4 adjusts the equity risk premium for the share's particular level of systematic risk as measured by beta (β_i)—an average systematic risk security has a beta of 1, whereas beta values above and below 1 indicate greater-than-average and smaller-than-average systematic risk. Equation 4 will be explained later as the capital asset pricing model.
- Equation 5 does not make a beta adjustment to the equity risk premium but adds premia/discounts required to develop an overall equity risk adjustment. Equation 5 will be explained later as the build-up method for estimating the required return. It is particularly useful in the valuation of private businesses.

In practice, analysts may use more than one approach to develop the cost of equity. A survey of analysts shows that the CAPM approach is used by 68% of respondents, while a build-up approach (bond yield plus a premium) is used by 43% of respondents (Pinto, Robinson, and Stowe 2019). Typically, analysts estimate the equity risk premium for the national equity market of the issues being analyzed (but if a global CAPM is being used, a world equity premium is estimated that takes into account the totality of equity markets).

Even for the longest-established developed markets, the magnitude of the equity risk premium is difficult to estimate and can be a reason for differing investment conclusions among analysts. Therefore, we will introduce the topic of estimation in some detail. Whatever estimates analysts decide to use, when an equity risk premium estimate enters into a valuation, analysts should be sensitive to how their value conclusions could be affected by estimation error.

Two broad approaches are available for estimating the equity risk premium. One is based on historical average differences between equity market return and government debt returns, and the other is based on current expectational data. Survey data in Pinto, Robinson, and Stowe (2019) indicate that the approaches are almost equally widespread among analysts, with around 36% of respondents using historical estimates and 35% using forward-looking estimates. The following sections describe the two approaches.

2.1 Historical Estimates

A historical equity risk premium estimate is usually calculated as the mean value of the differences between broad-based equity-market-index returns and government debt returns over some selected sample period. When reliable long-term records of equity returns are available, historical estimates have been a familiar and popular choice of estimation. If investors do not make systematic errors in forming expectations, then, over the long term, average returns should be an unbiased estimate of what investors expected. The fact that historical estimates are based on data also gives them an objective quality.

In using a historical estimate to represent the equity risk premium going forward, the analyst is assuming that returns are stationary—that is, the parameters that describe the return-generating process are constant over the past and into the future.

The analyst's major decisions in developing a historical equity risk premium estimate include the selection of:

- the equity index to represent equity market returns;
- the period for computing the estimate;
- the type of mean calculated; and
- the proxy for the risk-free return.

Analysts try to select an equity index that accurately represents the average returns earned by equity investors in the market being examined. Broad-based, market-value-weighted indexes are typically selected.

Specifying the length of the sample period typically involves trade-offs. Dividing a data period of a given length into smaller subperiods does not increase precision in estimating the mean—only extending the length of the dataset can increase precision. (Note that this result contrasts with the estimation of variance and covariance, in which higher frequency of estimation for a given time span *does* increase the precision in estimating variance and covariance.) Thus, a common choice is to use the longest reliable returns series available. The assumption of stationarity is usually more difficult to maintain, however, as the series starting point is extended to the distant past. The specifics of the type of non-stationarity are also important. For a number of equity markets, research has brought forth abundant evidence of non-constant underlying return volatility. Non-stationarity—in which the equity risk premium has fluctuated in the short term but around a central value—is a less serious impediment to using a long data series than the case in which the risk premium has shifted to a permanently different level (Cornell 1999). Empirically, the expected equity risk premium is countercyclical in the United States—that is, the expected premium is high during bad times but low during good times (Fama and French 1989, Ferson and Harvey

1991). This property leads to some interesting challenges: For example, when a series of strong market returns has increased enthusiasm for equities and raised historical-mean equity risk premium estimates, the forward-looking equity risk premium may have actually declined.

Practitioners taking a historical approach to equity premium estimation often focus on the type of mean calculated and the proxy for the risk-free return. There are two choices for computing the mean and two broad choices for the proxy for the risk-free return.

The mean return of a historical set of annual return differences between equities and government debt securities can be calculated using either a geometric mean or an arithmetic mean:

- A geometric mean equity risk premium estimate equal to the compound annual excess return of equities over the risk-free return, or
- An arithmetic mean equity risk premium estimate equal to the sum of the annual return differences divided by the number of observations in the sample.

The risk-free rate can also be represented in two ways:

- as a long-term government bond return, or
- as a short-term government debt instrument (Treasury bill) return.

Dimson, Marsh, and Staunton (2008) presented evidence on realized excess returns of stocks over government debt ("historical equity risk premia") using survivorship-bias-free return datasets for 17 developed markets for the 108 years extending from 1900 through 2007. (Note that in a given year, the excess return of stocks over government debt is calculated as [(1 + Equity market return)/(1 + Risk-free rate of return)] − 1 ≈ Equity market return − Risk-free rate of return, where a specified government debt instrument return represents the risk-free rate of return.) In their 2018 update, the authors provided the risk premiums for 21 markets (Dimson, Marsh, and Staunton 2018, published as *Credit Suisse Global Investment Returns Sourcebook*, 2018). Exhibit 1 excerpts their findings, showing results for the four combinations of mean computation and risk-free return representation (two mean return choices × two risk-free return choices). In the table, *standard error* and *standard deviation* are those of the annual excess return series.

Exhibit 1 Historical Equity Risk Premia: Twenty-One Major Markets, 1900–2017

Panel A: Historical Equity Risk Premia Relative to Bonds, 1900–2017

Country	Geometric Mean	Arithmetic Mean	Standard Error	Standard Deviation
Australia	5.0%	6.6%	1.7%	18.1%
Austria	2.9	21.5	14.1	151.5
Belgium	2.2	4.3	1.9	20.8
Canada	3.5	5.1	1.7	18.2
Denmark	2.2	3.8	1.7	18.0
Finland	5.2	8.7	2.7	29.7
France	3.1	5.4	2.1	22.5
Germany	5.1	8.4	2.6	28.2
Ireland	2.7	4.7	1.8	19.7
Italy	3.2	6.5	2.7	29.1
Japan	5.1	9.1	3.0	32.2

Exhibit 1 (Continued)

Panel A: Historical Equity Risk Premia Relative to Bonds, 1900–2017

Country	Geometric Mean	Arithmetic Mean	Standard Error	Standard Deviation
Netherlands	3.3	5.6	2.0	22.1
New Zealand	4.0	5.6	1.6	17.7
Norway	2.5	5.4	2.5	27.4
Portugal	5.3	9.4	2.9	31.4
South Africa	5.3	7.1	1.8	19.4
Spain	1.8	3.8	1.9	20.5
Sweden	3.1	5.3	2.0	21.2
Switzerland	2.2	3.7	1.6	17.4
United Kingdom	3.7	5.0	1.6	17.0
United States	4.4	6.5	1.9	20.7
Europe	3.0	4.3	1.4	15.7
World ex US	2.8	3.8	1.3	14.4
World	3.2	4.4	1.4	15.3

Panel B: Historical Equity Risk Premia Relative to Bills, 1900–2017

Country	Geometric Mean	Arithmetic Mean	Standard Error	Standard Deviation
Australia	6.1%	7.4%	1.5%	16.3%
Austria	5.8	10.6	3.4	37.0
Belgium	3.0	5.4	2.2	23.5
Canada	4.2	5.6	1.5	16.8
Denmark	3.4	5.3	1.9	20.5
Finland	6.0	9.5	2.7	29.5
France	5.6	8.1	2.2	23.9
Germany	6.2	9.9	2.9	31.1
Ireland	3.7	6.0	2.0	21.2
Italy	5.8	9.6	2.9	31.2
Japan	6.3	9.4	2.5	27.3
Netherlands	4.6	6.7	2.0	22.2

Exhibit 1 (Continued)

Panel B: Historical Equity Risk Premia Relative to Bills, 1900–2017				
Country	**Geometric Mean**	**Arithmetic Mean**	**Standard Error**	**Standard Deviation**
World ex US	3.6	5.2	1.7	18.4
World	4.3	5.7	1.6	16.9

Note: "World" represents a market-capitalization-weighted (in early decades, GDP-weighted) average of country results in USD terms. Statistics for Austria exclude 1921–22, and statistics for Germany exclude 1922–23.

The following excerpt from Exhibit 1 presents a comparison of historical equity risk premium estimates for the United States and Japan. This comparison highlights some of the issues that can arise in using historical estimates. As background to the discussion, note that as a mathematical fact, the geometric mean is always less than (or equal to) the arithmetic mean; furthermore, the yield curve is typically upward sloping (long-term bond yields are typically higher than short-term yields).

Exhibit 1 Historical Equity Risk Premia: 1900–2017 (excerpted)

	United States		Japan	
	Geometric Mean	**Arithmetic Mean**	**Geometric Mean**	**Arithmetic Mean**
Premium relative to bills	5.6%	7.5%	6.3%	9.4%
Premium relative to bonds	4.4	6.5	5.1	9.1

For the United States, estimates of the equity risk premium relative to long-term government bonds run from 4.4% (geometric mean relative to bonds) to 7.5% (arithmetic mean relative to bills). The United States illustrates the typical case in which realized values relative to bills, for any definition of mean, are higher than those relative to bonds.

The premium estimates for Japan are notably higher than for the United States. Because the promised yield on long-term bonds is usually higher than that on short-term bills, the nearly equal arithmetic mean premium relative to bonds compared with bills in the case of Japan is atypical and suggests a historically flatter yield curve. The analyst would need to consider whether similar conditions would apply to the future before using the estimate as a forecast. In all markets, the geometric mean premium relative to long-term bonds gives the smallest risk premium estimate (an exception is Portugal). Note the following:

- For each market, the variation in year-to-year results is very large as shown by the standard deviations. As a result, the sample mean estimates the true mean with potentially substantial error. For example, the standard error relative to bills is 1.6% for the World index and ranges from 1.5% for Australia and Canada to 3.4% for Austria. So, for the World index, a two standard deviation interval for the underlying mean (an interval within which the underlying mean is expected to lie with a 0.95 probability) is a wide 2.5% to 8.9% (i.e., 5.7% arithmetic mean ± 3.2% standard deviation) even with 118 years of data. This problem of sampling error becomes more acute, the shorter the series on which the mean estimate is based.

- The variation in the historical equity risk premium estimates across countries is substantial. Based on geometric mean data in Panel A of Exhibit 1, the histogram in Exhibit 2 lists markets within 1% return intervals. For more than half of the markets, the realized equity risk premium was between 2% and 4%. As Exhibit 1, Panel A shows, the mean ("World") value is 3.2%. Approximately one-third of the values fall between the two extreme intervals, however.

Exhibit 2 Distribution of Realized Premium (Geometric Mean, Relative to Bonds)

		Interval for Realized Premium x (%)				
		$1 \le x < 2$	$2 \le x < 3$	$3 \le x < 4$	$4 \le x < 5$	$5 \le x < 6$
	6		Belgium	France		Australia
	5		Denmark	Sweden		Germany
Number of markets	4		Switzerland	Italy		Japan
	3		Norway	Netherlands		Finland
	2		Ireland	Canada	New Zealand	Portugal
	1	Spain	Austria	United Kingdom	United States	South Africa

The next two sections discuss choices related to the calculation of a historical equity risk premium estimate.

2.1.1 *Arithmetic Mean or Geometric Mean*

A decision with an important impact on the risk premium estimate is the choice between an arithmetic mean and a geometric mean. The geometric mean is smaller by an amount equal to about one half the variance of returns, so it is always smaller than the arithmetic mean given any variability in returns. (The geometric mean equals the arithmetic mean when the returns for all periods are equal).

In actual professional practice, both geometric and arithmetic means have been used in equity risk premium estimation.

The arithmetic mean return as the average one-period return best represents the mean return in a single period. There are two traditional arguments in favor of using the arithmetic mean in equity risk premium estimation, one relating to the type of model in which the estimates are used and the second relating to a statistical property. The major finance models for estimating required return—in particular, the CAPM and multifactor models—are single-period models; so the arithmetic mean, with its focus on single-period returns, appears to be a model-consistent choice. A statistical argument has also been made for the arithmetic mean: With serially uncorrelated returns and a *known* underlying arithmetic mean, the unbiased estimate of the expected terminal value of an investment is found by compounding forward at the arithmetic mean. For example, if the arithmetic mean is 8%, an unbiased estimate of the expected terminal value of a €1 million investment in five years is €1(1.08)^5 = €1.47 million. In practice, however, the underlying mean is not known. It has been established that compounding forward using the *sample* arithmetic mean, whether or not returns are serially uncorrelated, overestimates the expected terminal value of wealth (see Hughson, Stutzer, and Yung 2006 for a proof). Note that even when returns are not serially uncorrelated, using the arithmetic mean (even a known value) tends to overestimate the expected value of terminal wealth. Returns that revert to the mean are one example of serial correlation of practical concern. In the example, if 8% is merely the sample arithmetic mean (used as an estimate of the unknown underlying mean), we would expect terminal wealth to be less than €1.47 million. Practically, only the first traditional argument still has force.

The geometric mean return of a sample represents the compound rate of growth that equates the beginning value to the ending value of one unit of money initially invested in an asset. Present value models involve the discounting over multiple periods. Discounting is just the reverse side of compounding in terms of finding amounts of equivalent worth at different points in time; because the geometric mean is a compound growth rate, it appears to be a logical choice for estimating a required return in a multiperiod context, even when using a single-period required return model. In contrast to the sample arithmetic mean, using the sample geometric mean does not introduce bias in the calculated expected terminal value of an investment (Hughson, Stutzer, and Yung 2006). Equity risk premium estimates based on the geometric mean have tended to be closer to supply-side and demand-side estimates from economic theory than arithmetic mean estimates. For the foregoing reasons, the geometric mean is increasingly preferred for use in historical estimates of the equity risk premium.

2.1.2 *Long-Term Government Bonds or Short-Term Government Bills*

The choices for the risk-free rate are a short-term government debt rate, such as a 30-day T-bill rate, or a long-term government bond yield to maturity (YTM). Government bonds are preferred to even the highest-rated corporate bonds because they typically have less (near zero) default and equity market risk.

A bond-based equity risk premium estimate in almost all cases is smaller than a bill-based estimate (see Exhibit 1). But a normal upward-sloping yield curve tends to offset the effect of the risk-free rate choice on a required return estimate, because the current expected risk-free rate based on a bond will be larger than the expectation based on a bill. With an inverted yield curve, however, the short-term yields exceed long-term yields and the required return estimate based on using a risk-free rate based on a bill can be much higher.

Industry practice has tended to favor use of a long-term government bond rate in premium estimates despite the fact that such estimates are often used in one-period models such as the CAPM. A risk premium based on a bill rate may produce a better estimate of the required rate of return for discounting a one-year-ahead cash flow, but a premium relative to bonds should produce a more plausible required return/discount rate in a multiperiod context of valuation.

To illustrate a reason for the preference, take the case of bill-relative and bond-relative premia estimates of 5.5% and 4.5%, respectively, for a given market. Assume the yield curve is inverted: The current rates are 9% and 6% on the bill and bond, respectively. The required return on average-risk equity based on bills is 14.5% (9% + 5.5%), compared with 10.5% based on bonds (6% + 4.5%). That 14.5% rate may be appropriate for discounting a one-year-ahead cash flow in a current high interest and inflation environment. The inverted yield curve, however, predicts a downward path for short-rates and inflation. Most of the cash flows lie in the future, and the premium for expected average inflation rates built into the long-bond rate is more plausible. A practical principle is that for the purpose of valuation, the analyst should try to match the duration of the risk-free-rate measure to the duration of the asset being valued. If the analyst has adopted a short-term risk-free rate definition, nevertheless, a practical approach to dealing with the situation just presented would be to use an expected average short-term bill rate rather than the current 9% rate. Advocates of using short-term rates point out that long-term government bonds are subject to risks, such as interest rate risk, that complicate their interpretation.

In practice, many analysts use the current YTM on a long-term government bond as an approximation for the expected return on it. The analyst needs to be clear that she is using a current yield observation, reflecting current inflation expectations. The yield on a recently issued ("on the run") bond mitigates distortions related to liquidity and discounts/premiums relative to face value. The available maturities of liquid government bonds change over time and differ among national markets. If a 20-year maturity is available and trades in a liquid market, however, its yield is a reasonable choice as an estimate of the risk-free rate for equity valuation. (Note that the Ibbotson US long-term government bond yield is based on a portfolio of 20-year average maturity T-bonds. We use that series in the suggested historical estimate of the US equity risk premium.) In many international markets, only bonds of shorter maturity are available or have a liquid market. A 10-year government bond yield is another common choice.

Valuation requires definite estimates of required returns. The data in Exhibit 1 provide one practical starting point for an estimate of equity risk premium for the markets given. As discussed, one mainstream choice among alternative estimates of the historical equity risk premium is the geometric mean historical equity risk premium relative to government bonds.

2.1.3 *Adjusted Historical Estimates*

A historical risk premium estimate may be adjusted in several ways to neutralize the effect of biases that may be present in the underlying equity market return series. One type of adjustment is made to offset the effect of biases in the data series being used to estimate the equity risk premium. A second type of adjustment is made to take account of an independent estimate of the equity risk premium. In both cases, the adjustment could be upward or downward.

One issue is **survivorship bias** in equity market data series. This bias arises when poorly performing or defunct companies are removed from membership in an index, so that only relative winners remain. Survivorship bias tends to inflate historical estimates of the equity risk premium. For many developed markets, equity returns series are now available that are free or nearly free of survivorship bias. When using a series that has such bias, however, the historical risk premium estimate should be adjusted downward. Guidance for such adjustment based on research is sometimes available but is beyond the scope of this discussion. A conceptually related issue with historical estimates can arise when a market has experienced a string of unexpectedly positive or negative events and the surprises do not balance out over the period of sampled data. For example, a string of positive inflation and productivity surprises may result in a series of high returns that increase the historical mean estimate of the equity risk premium. In such cases, a forward-looking model estimate may suggest a much lower value of the equity risk premium. To mitigate that concern, the analyst may adjust the historical estimate downward based on an independent forward-looking estimate (or upward, in the case of a string of negative surprises). Many experts believe that the historical record for various major world markets has benefited from a majority of favorable circumstances that cannot be expected to be duplicated in the future; their recommended adjustment to historical mean estimates is downward. Dimson, Marsh, and Staunton (2002) have argued that historical returns have been advantaged by re-pricings as increasing scope for diversification has led to a lower level of market risk. In the case of the United States, Ibbotson and Chen (2003) recommended a 1.25 percentage point downward adjustment to the Morningstar (Ibbotson) historical mean US equity risk premium estimate based on a lower estimate from a supply-side analysis of the equity risk premium.

Example 2 illustrates difficulties in historical data that could lead to a preference for an adjusted historical or forward-looking estimate.

EXAMPLE 2

The Indian Equity Risk Premium: Historical Estimates of the Equity Risk Premium in a Developing Market

Historical estimates of the equity risk premium in developing markets are often attended by a range of concerns. The case of India can serve as an example. A number of equity indexes are available, and each has possible limitations. Although not as broad-based as the alternatives, the S&P BSE Sensex Index (Sensex), a market-capitalization-weighted index of the shares of 30 leading companies, has the longest available record: Compiled since 1986, returns go back to 1979. Note the following facts concerning this index and other issues relevant to estimating the equity risk premium:

- The backfilled returns from 1979 to 1985 are based on the initial 30 issues selected in 1986, which were among the largest market cap as of 1986.
- The Sensex is a price index; a total return version of the index incorporating dividends is available from 1997 forward.
- Interest rates in India were suppressed by regulation prior to 1991 and were much more volatile thereafter. The benchmark interest rate reported by the Reserve Bank of India averaged 6.57% from 2000 until 2013, reaching an all-time high of 14.50% in August 2000 and a record low of 4.25% in April 2009. In April 2019, the rate was 6.00%. The post-regulation period appears to be associated with higher stock market volatility.
- In 2000, the exchange used this index to open its derivatives market via the trading of Sensex futures contracts. The development of Sensex options followed in 2001.
- Valuation levels have changed significantly in the last two decades. The price-to-earnings ratio for the Sensex was 45.5 in 1994 and reached a low of 13.0 in 1998. In April 2019, the price-to-earnings ratio was 28.4.
- Objective estimates of the extent of any bias can be developed.

(Sources: for institutional background: Varma and Barua 2006; https://tradingeconomics.com/india/interest-rate; andhttps://www.bseindia.com/markets/keystatics/Keystat_index.aspx)

Based only on the information given, address the following.

1 What factors could bias an unadjusted historical risk premium estimate upward?

2 What factors could bias an unadjusted historical risk premium estimate downward?

3 State and explain two indications that the historical time series is non-stationary.

4 Recommend and justify a preference for a historical or an adjusted historical equity risk premium estimate.

Solution to 1:

The backfilling of returns from 1979 to 1985 based on companies selected in 1986 could bias the estimate upward because of survivorship bias. The companies selected in 1986 are likely to have been among the most successful of the companies on the exchange as of 1979. Less clearly, another factor is the suppression of interest rates prior to 1991. An artificially low risk-free rate would bias the equity risk premium estimate upward unless the required return on equity were smaller by an equal amount. Finally, derivative contracts on the Sensex have been available only since the early 2000s. The ability to hedge market risk may result in future equity risk premiums being lower.

Solution to 2:

The failure to incorporate the return from dividends biases the equity risk premium estimate downward. Risk premiums are also generally believed to be inversely related to valuation ratios. The price-to-earnings ratio is currently well below its 1994 level, suggesting that the historical premium estimate may be biased downward.

Solution to 3:

The different levels of interest rates before and after the lifting of regulation in 1991 is one indication that the equity risk premium pre- and post-1991 could be different and that the overall series is non-stationary. A second is the higher level of stock market volatility pre- and post-regulation.

Solution to 4:

Given that objective estimates of the extent of biases can be developed, an adjusted historical estimate would be preferred because such an estimate is more likely to be unbiased and accurate.

In Example 2, one criticism that could be raised concerning any historical estimate is the shortness of the period in the dataset—the post-1991 reform period—that is definitely relevant to the present. Sampling error in any mean estimate—even one based on clean data—would be a major concern for this dataset; recall that the earlier discussion of a two standard deviation interval for the US equity risk premium was based on 113 years of data. The analyst might address specific concerns through an adjusted historical estimate. The analyst may also decide to investigate one or more forward-looking estimates. Forward-looking estimates are the subject of the next section. A later section on international issues will have more information on equity risk premium estimation for emerging markets such as India.

2.2 Forward-Looking Estimates

Because the equity risk premium is based only on expectations for economic and financial variables from the present going forward, it is logical to estimate the premium directly based on current information and expectations concerning such variables. Such estimates are often called forward-looking or *ex ante* estimates. In principle, such estimates may agree with, be higher than, or be lower than historical equity risk premium estimates. *Ex ante* estimates are likely to be less subject to an issue such as non-stationarity or data biases than historical estimates. Such estimates are often subject to other potential errors, however, related to financial and economic models and potential behavioral biases in forecasting.

2.2.1 *Gordon Growth Model Estimates*

Probably the most frequently encountered forward-looking estimate of the equity risk premium is based on a very simple form of a present value model called the constant growth dividend discount model or Gordon growth model, already shown as Equation 3a. For mature developed equity markets such as the Eurozone, United Kingdom, and North American markets, this model's assumptions are often met, at least approximately. Broad-based equity indexes are nearly always associated with a dividend yield, and year-ahead dividend payment may be fairly predictable. The expected dividend growth rate may be inferred based on published analyst or economic expectations, such as consensus analyst expectations of the earnings growth rate for an equity market index (which may be based on forecasts for the constituent companies or a top-down forecast). Specifically, the Gordon growth model (GGM) equity risk premium estimate is as follows:

GGM equity risk premium estimate
= Dividend yield on the index based on year-ahead aggregate forecasted dividends and aggregate market value
+ Consensus long-term earnings growth rate
– Current long-term government bond yield (6)

We can illustrate with the case of the United States. As of July 2019, the dividend yield on the S&P 500 Index as defined in Equation 6 was approximately 1.9% based on a price level of the S&P 500 of 3,020. The consensus analyst view was that earnings on the S&P 500 would actually fall over the next year (see www.standardandpoors.com). We will use the 7% long-term average growth rate as the long-term earnings growth forecast. Note that dividend growth should track earnings growth over the long term. The 30-year US government bond yield was 2.6%. Therefore, according to Equation 6, the Gordon growth model estimate of the US equity risk premium was 1.9% + 7.0% – 2.6%, or 6.3%. Like historical estimates, Gordon growth model estimates generally change through time. For example, this calculation carried out in 2001 and 2009 produced a GGM estimate of 2.4% (computed as 1.2% + 7.0% – 5.8%) and 3.9% (computed as 1.9% + 7.0% – 5.0%), respectively.

Equation 6 is based on an assumption of earnings growth at a stable rate. An assumption of multiple earnings growth stages is more appropriate for very rapidly growing economies. Taking an equity index in such an economy, the analyst may forecast a fast growth stage for the aggregate of companies included in the index, followed by a transition stage in which growth rates decline and a mature growth stage characterized by growth at a moderate, sustainable rate. The discount rate r that equates the sum of the present values of the expected cash flows of the three stages to the current market price of the equity index defines an IRR. Letting PVFastGrowthStage(r) stand for the present value of the cash flows of the fast earnings growth stage with the present value shown as a function of the discount rate r, and using a self-explanatory notation for the present values of the other phases, the equation for IRR is as follows:

$$\begin{aligned}\text{Equity index price} &= \text{PVFastGrowthStage}(r) + \text{PVTransition}(r)\\ &\quad + \text{PVMatureGrowthStage}(r)\end{aligned}$$

The IRR is computable using a spreadsheet's IRR function. Using the IRR as an estimate of the required return on equities (as described earlier), subtracting a government bond yield gives an equity risk premium estimate.

A consequence of the model underlying Equation 6, making assumptions of a constant dividend payout ratio and efficient markets, is that earnings, dividends, and prices are expected to grow at dividend growth rate, so that the P/E is constant. The analyst may believe, however, that the P/E will expand or contract. Some analysts make an adjustment to the estimate in Equation 6 to reflect P/E multiple expansion or contraction. From a given starting market level associated with a given level of earnings and a given P/E, the return from capital appreciation cannot be greater than the earnings growth rate unless the P/E multiple expands. P/E multiple expansion can result from an increase in the earnings growth rate and/or a decrease in risk.

2.2.2 *Macroeconomic Model Estimates*

Using relationships between macroeconomic variables and the financial variables that figure in equity valuation models, analysts can develop equity risk premium estimates. Such models may be more reliable when public equities represent a relatively large share of the economy, as in many developed markets. Many such analyses focus on the supply-side variables that fuel GDP growth (and are thus known as supply-side estimates). The Gordon growth model estimate, when based on a top-down economic analysis rather than using consensus analyst estimates, can be viewed as a supply-side estimate.

To illustrate a supply-side analysis, the total return to equity can be analyzed into four components as explained by Ibbotson and Chen (2003):

- expected inflation: EINFL;
- expected growth rate in real earnings per share: EGREPS;
- expected growth rate in the P/E (the ratio of share price to earnings per share): EGPE; and
- expected income component (including return from reinvestment of income): EINC.

The growth in P/E arises as a factor from a decomposition of the capital appreciation portion of returns—that is, $(P_t/P_t - 1) - 1.0 = [(P_t/E_t)/(P_t - 1/E_t - 1)](E_t/E_t - 1) - 1.0 = (1 + \text{EGPE})(1 + \text{EGREPS}) - 1.0$. So,

$$\text{Equity risk premium} = \left\{\left[(1 + \text{EINFL})(1 + \text{EGREPS})(1 + \text{EGPE}) - 1.0\right] + \text{EINC}\right\} - \text{Expected risk-free return} \tag{7}$$

In the following we illustrate this type of analysis using data for US equity markets as represented by the S&P 500.

- *Expected inflation.* A market forecast is available from the US Treasury and US Treasury inflation-protected securities (TIPS) yield curve:

$$\begin{aligned}\text{Implicit inflation forecast} &\approx \frac{1 + \text{YTM of 20-year maturity T-bonds}}{1 + \text{YTM of 20-year maturity TIPS}} - 1\\ &= \frac{1.023}{1.0066} - 1\\ &= 0.016 \text{ or } 1.6 \text{ percent.}\end{aligned}$$

  We will use an estimate of 1.6% per year, consistent with the TIPS analysis and other long-term forecasts. So, 1 + EINFL = 1.016.

- *Expected growth in real earnings per share.* This quantity should approximately track the real GDP growth rate. An adjustment upward or downward to the real GDP growth rate can be made for any expected differential growth between the companies represented in the equity index being used to represent the stock market and the overall economy.

  According to economic theory, the real GDP growth rate should equal the sum of labor productivity growth and the labor supply growth rate (which can be estimated as the sum of the population growth rate and the increase in the labor force participation rate). A forecasted 2% per year US labor productivity growth rate and 1% per year labor supply growth rate produces a 3% overall real GDP growth rate estimate of 3%. So, 1 + EGREPS = 1.03.

- *Expected growth in the P/E*. The baseline value for this factor is zero, reflecting an efficient markets view. When the analyst views a current P/E level as reflecting overvaluation or undervaluation, however, a negative or positive value, respectively, can be used, reflecting the analyst's investment time horizon. So, without presenting a case for misevaluation, 1 + EGPE = 1.
- *Expected income component*. Historically, for US markets the long-term value has been close to 4.5%, including reinvestment return of 20 bps (see Ibbotson and Chen (2003), p. 90). As of July 2019, however, the S&P 500 dividend yield is below the long-term average. A forward-looking estimate based on the forward expected dividend yield of 2.1% and 10 bps reinvestment return is 2.2%. So, EINC = 0.022.

Using the Ibbotson–Chen format and a risk-free rate of 3%, an estimate of the US equity risk premium estimate is

$$\left\{\left[(1.016)(1.03)(1) - 1.0\right] + 0.022\right\} - 0.025 = 0.0685 - 0.025 = 4.35\%$$

The supply side estimate of 4.35% is very close to the historical geometric mean estimate of 4.4% (see Exhibit 1).

2.2.3 *Survey Estimates*

One way to gauge expectations is to ask people what they expect. Survey estimates of the equity risk premium involve asking a sample of people—frequently, experts—about their expectations for it, or for capital market expectations from which the premium can be inferred.

For example, every year, Fernandez and colleagues conduct a global survey of finance professors, analysts, and managers of companies concerning what value they use for the equity risk premium. The 2018 survey revealed that the average was around 5.4% in the United States, Germany, and many other developed markets but was in excess of 10% for countries such as Argentina, Egypt, Greece, Iran, Pakistan, and Venezuela (Fernandez, Pershin, and Acin 2018).

The monograph *Rethinking the Equity Risk Premium* (Hammond, Leibowitz, and Siegel 2011) included the opinions of many financial experts regarding the future US equity risk premium. The range of equity risk premium estimates was 2.5% to 6.0%. Siegel (2017) describes the 2011 results as having converged around 4% for the equity risk premium, compared with an average of 3.7% estimated by roughly the same group of experts convened in 2002 by the Association of Investment Management and Research (later renamed as CFA Institute). Another source that surveys institutional investors reported risk premia estimates of 4.0% in 2012 and 4.6% in 2014 (Damodaran, 2016). One issue with survey risk premia estimates is that they are sensitive to recent market returns.

3 CAPITAL ASSET PRICING MODEL (CAPM)

c determine the required return on an equity investment using the capital asset pricing model, the Fama–French model, the Pastor–Stambaugh model, macroeconomic multifactor models, and the build-up method (e.g., bond yield plus risk premium);

d explain beta estimation for public companies, thinly traded public companies, and non-public companies;

e describe strengths and weaknesses of methods used to estimate the required return on an equity investment;

With means to estimate the equity risk premium in hand, the analyst can estimate the required return on the equity of a particular issuer. The choices include the following:

- the CAPM;
- a multifactor model such as the Fama–French or related models; and
- a build-up method, such as the bond yield plus risk premium method.

3.1 The Capital Asset Pricing Model

The CAPM is an equation for required return that should hold in **equilibrium** (the condition in which supply equals demand) if the model's assumptions are met; among the key assumptions are that investors are risk averse and that they make investment decisions based on the mean return and variance of returns of their total portfolio. The model's chief insight is that investors evaluate the risk of an asset in terms of the asset's contribution to the systematic risk of their total portfolio (systematic risk is risk that cannot be shed by portfolio diversification). Because the CAPM provides an economically grounded and relatively objective procedure for required return estimation, it has been widely used in valuation.

The expression for the CAPM that is used in practice was given earlier as Equation 4:

$$\text{Required return on share } i = \text{Current expected risk-free return} + \beta_1(\text{Equity risk premium})$$

For example, if the current expected risk-free return is 3%, the asset's beta is 1.20, and the equity risk premium is 4.5%, then the asset's required return is

$$\text{Required return on share } i = 0.030 + 1.20(0.045) = 0.084, \text{ or } 8.4\%$$

The asset's beta measures its market or systematic risk, which in theory is the sensitivity of its returns to the returns on the "market portfolio" of risky assets. Concretely, beta equals the covariance of returns with the returns on the market portfolio divided by the market portfolio's variance of returns. In typical practice for equity valuation, the market portfolio is represented by a broad value-weighted equity market index. The asset's beta is estimated by a least squares regression of the asset's returns on the index's returns and is available also from many vendors. In effect, in Equation 4 the analyst is adjusting the equity risk premium up or down for the asset's level of systematic risk by multiplying it by the asset's beta, adding that asset-specific risk premium to the current expected risk-free return to obtain a required return estimate.

In the typical case in which the equity risk premium is based on a national equity market index and estimated beta is based on sensitivity to that index, the assumption is being made implicitly that equity prices are largely determined by *local* investors. When equities markets are *segmented* in that sense (i.e., local market prices are largely determined by local investors rather than by investors worldwide), two issues with the same risk characteristics can have different required returns if they trade in different markets.

The opposite assumption is that all investors worldwide participate equally in setting prices (perfectly integrated markets). That assumption results in the international CAPM (or world CAPM), in which the risk premium is relative to a world market portfolio. Taking an equity view of the market portfolio, the world equity risk premium can be estimated historically based on the MSCI World index (returns available from 1970), for example, or indirectly as (US equity risk premium estimate)/(Beta of US stocks relative to MSCI World) = 4.5%/0.81 = 5.6%. Computing beta relative to MSCI World and using a national risk-free interest rate, the analyst can obtain international CAPM estimates of required return. In practice, the international CAPM is not commonly relied on for required return on equity estimation.

3.1.1 *Beta Estimation for a Public Company*

The simplest estimate of beta results from an ordinary least squares regression of the return on the stock on the return on the market. The result is often called an unadjusted or "raw" historical beta. The actual values of beta estimates are influenced by several choices:

- *The choice of the index used to represent the market portfolio.* For a number of markets, there are traditional choices. For US equities, the S&P 500 and NYSE Composite have been traditional choices.
- *The length of data period and the frequency of observations.* The most common choice is five years of monthly data, yielding 60 observations

  (a number of vendors including Morningstar and Compustat make that choice). Value Line uses five years of weekly observations. The Bloomberg default is two years of weekly observations, which can be changed at the user's option. One study of US stocks found support for five years of monthly data over alternatives (Bartholdy and Peare 2003). An argument can be made that the Bloomberg default can be especially appropriate in fast-growing markets.

The beta value in a future period has been found to be on average closer to the mean value of 1.0, the beta of an average-systematic-risk security, than to the value of the raw beta. Because valuation is forward looking, it is logical to adjust the raw beta so it more accurately predicts a future beta. The most commonly used adjustment was introduced by Blume (1971):

$$\text{Adjusted beta} = (2/3)(\text{Unadjusted beta}) + (1/3)(1.0) \quad (8)$$

For example, if the beta from a regression of an asset's returns on the market return is 1.30, adjusted beta is (2/3)(1.30) + (1/3)(1.0) = 1.20. Vendors of financial information often report raw and adjusted beta estimates together. Although most vendors use the Blume adjustment, some do not. For example, Morningstar (Ibbotson) adjusts raw beta toward the peer mean value (rather than toward the overall mean value of 1.0). The analyst of course needs to understand the basis behind the presentation of any data that he uses.

The following examples apply the CAPM to estimate the required return on equity.

EXAMPLE 3

Required Return with Adjusted Beta

Daphne Delacour, an equity analyst, is investigating the required return on a (fictitious) Indian construction company Treedle & Weer Ltd. Delacour's data source uses the Sensex (Indian stock market index) as the equity index for estimating beta, which generates a raw beta of 1.537. (The raw beta is the slope of the regression line running through the scatterplot of data points denoting the return on TWLT [*y*-axis] for different returns on the Sensex [*x*-axis].) Delacour's data source also displays a figure for R^2, which in this scenario indicates that beta explains more than 73% of variation in LT returns—an exceptionally good fit. The data source also displays a standard error of beta at 0.121—relatively small compared with the magnitude of the raw estimate, 1.537, and indicative that the beta has been estimated with accuracy.

Delacour also decides to use the CAPM to estimate LT stock's required return. As inputs, she has decided to use her own adjusted historical estimate of 4.0% for the Indian equity risk premium and the 10-year Indian government bond yield of 6.4% as the risk-free rate.

Based only on the information given, address the following:

1 Demonstrate the calculation of adjusted beta using the Blume method.

2 Estimate the required return on LT using the CAPM with an adjusted beta.

Solution to 1:

The calculation for adjusted beta is (2/3)(1.537) + (1/3)(1.0) = 1.358.

Solution to 2:

r = 6.4% + 1.358(4%) = 11.8%.

EXAMPLE 4

Calculating the Required Return on Equity Using the CAPM (1)

Exxon Mobil Corporation, BP p.l.c., and Total S.A. are three "super major" integrated oil and gas companies headquartered, respectively, in the United States, the United Kingdom, and France. An analyst estimates that the equity risk premium in the United States, the United Kingdom, and the Eurozone are, respectively, 4.4%, 5.5%, and 5.9%. Other information is summarized in Exhibit 3 (source: Bloomberg; Fernandez 2018 survey).

Exhibit 3 ExxonMobil, BP, and Total

Company	Beta	Estimated Equity Risk Premium	Risk-Free Rate
Exxon Mobil Corporation	0.90	4.4%	2.8%
BP p.l.c.	0.78	5.5	2.0
Total S.A.	0.71	5.9	1.7

Using the capital asset pricing model, calculate the required return on equity for:

1 Exxon Mobil Corporation.

2 BP p.l.c.

3 Total S.A.

Solution to 1:

The required return on ExxonMobil according to the CAPM is 2.8% + 0.90(4.4%) = 6.76%.

Solution to 2:

The required return on BP according to the CAPM is 2.0% + 0.78(5.5) = 6.29%.

Solution to 3:

The required return on Total stock according to the CAPM is 1.7% + 0.71(5.9) = 5.89%.

EXAMPLE 5

Calculating the Required Return on Equity Using the CAPM (2): Non-Traded Asset Case

Jill Adams is an analyst at a hedge fund that has been offered an equity stake in a privately held US property and liability insurer. Adams identifies Alleghany Corporation as a publicly traded comparable company and intends to use information about Alleghany in evaluating the offer. One sell-side analyst that Adams contacts puts Alleghany's required return on equity at 8.0%. Researching the required return herself, Adams determines that Alleghany has the historical betas shown in Exhibit 4 as of early 2019:

Exhibit 4 Alleghany Corporation: Historical Adjusted Betas

5-Year Adjusted Beta	10-Year Adjusted Beta
0.84	0.79

Source: Bloomberg.

The estimated US equity risk premium (relative to bonds) is 4.4%. The YTM for:

- 91-day US Treasury bills is 2.3%.
- 2-year US government bonds is 2.6%.
- 10-year US government bonds is 2.8%.

Adams follows the most common industry practices concerning the period for estimating beta and adjustments to beta.

1 Estimate Alleghany Corporation's required return based on the CAPM.
2 Is the sell-side analyst's estimate of 10% for Alleghany's cost of equity *most* consistent with Alleghany shares having above-average or below-average systematic risk?

Solution to 1:

Using a five-year horizon for calculating beta is the most common practice. Consistent with the definition of the equity risk premium, a long-bond yield is used in the CAPM: 2.80% + 0.84(4.40%) = 6.496% or 6.5%, approximately.

Solution to 2:

The analyst's estimate implies above-average systematic risk. A beta of 1 by definition represents the beta of the market and so shares of average systematic risk. A beta of 1 implies a required return of 2.80% + 1.0(4.40%) = 7.2%.

When a share issue trades infrequently, the most recent transaction price may be stale and not reflect underlying changes in value. If beta is estimated based on, for example, a monthly data series in which missing values are filled with the most recent transaction price, the estimated beta will be too small and the required return on equity will be underestimated. Several econometric techniques can be used to estimate the beta of infrequently traded securities (see Elton, Gruber, Brown, and Goetzmann 2014 for a summary). A practical alternative is to base the beta estimate on the beta of a comparable security.

3.1.2 *Beta Estimation for Thinly Traded Stocks and Non-public Companies*

Analysts do not have access to a series of market price observations for non-public companies with which to calculate a regression estimate of beta. However, using an industry classification system such as the MSCI/Standard & Poor's Global Industry Classification Standard (GICS) or the FTSE Industry Classification Benchmark (ICB) to identify publicly traded peer companies, the analyst can estimate indirectly the beta of the non-public company on the basis of the public peer's beta.

The procedure must take into account the effect on beta of differences in financial leverage between the non-public company and the benchmark. First, the benchmark beta is unlevered to estimate the beta of the benchmark's assets—reflecting just the systematic risk arising from the economics of the industry. Then, the asset beta is re-levered to reflect the financial leverage of the non-public company.

Let β_E be the equity beta before removing the effects of leverage, if any. This is the benchmark beta. If the debt of the benchmark is high quality (so an assumption that the debt's beta is zero should be approximately true), analysts can use the following expression for unleveraging the beta:

$$\beta_U \approx \left[\frac{1}{1+(1-t)\left(\frac{D}{E}\right)}\right]\beta_E \tag{9a}$$

where β_U is unlevered, also known as asset beta. Note that Equation 9a comes from the expression $\beta_U \approx [1 + (1 - t)(D/E)]^{-1} \times [\beta_E + (1 - t)(D/E)\beta_D]$, making the assumption that $\beta_D = 0$. This expression can be used when the debt's beta is known to be definitely non-zero.Then, if the subject company has debt and equity levels D' and E', respectively, and assuming the subject company's debt is high grade, the subject company's equity beta, β'_E ,is estimated as follows:

$$\beta'_E \approx \left[1+(1-t)\left(\frac{D'}{E'}\right)\right]\beta_U \tag{9b}$$

Expressions 9a and 9b hold under the assumption that the level of debt adjusts to the target capital structure weight as total firm value changes, consistent with the definition for the weighted average cost of capital that will be presented later. Exhibit 5 summarizes the steps.

Exhibit 5 Estimating a Beta for a Non-Traded Company

Step 1
Select the benchmark (comparable)
⬇
Step 2
Estimate benchmark's beta
⬇
Step 3
Unlever the benchmark's beta
⬇
Step 4
Lever the beta to reflect the subject company's financial leverage

To illustrate, suppose that a benchmark company is identified (Step 1) that is 40% funded by debt. By contrast, the weight of debt in the subject company's capital structure is only 20%. The benchmark's beta is estimated at 1.2 (Step 2). The 40% weight of debt in the benchmark implies that the weight of equity is 100% – 40% = 60%. Assume that the marginal rate of tax is 19%. Unlevering the benchmark beta (Step 3):

$$\beta_U \approx \left[\frac{1}{1+(1-t)\left(\frac{D}{E}\right)}\right]\beta_E = \left[\frac{1}{1+(1-0.19)\left(\frac{40}{60}\right)}\right]1.2 = 0.65 \times 1.2 = 0.78$$

Next, the unlevered beta of 0.78 is re-levered according to the financial leverage of the subject company, which uses 20% debt and 80% equity:

$$\beta'_E \approx \left[1+(1-t)\left(\frac{D'}{E'}\right)\right]\beta_U = \left[1+(1-0.19)\left(\frac{20}{80}\right)\right]0.72 = 1.2025 \times 0.72 = 0.87$$

$$\beta'_E \approx \left[1+(1-t)\left(\frac{D'}{E'}\right)\right]\beta_U = \left[1+(1-0.1)\left(\frac{20}{80}\right)\right]0.77 = 1.213 \times 0.77 = 0.93$$

Sometimes, instead of using an individual company as a benchmark, the required return will be benchmarked on a median or average industry beta. A process of unlevering and re-levering can be applied to such a beta based on the median or average industry capital structure.

EXAMPLE 6

Calculating the Required Return on Equity Using the CAPM (3)

Adams turns to determining a beta for use in evaluating the offer of an equity stake in a private insurer and rounds her beta estimate of Alleghany, the public comparable, to 0.85. Assume that as of the valuation date, Alleghany Corporation has 10% debt and 90% equity in its capital structure. The private insurer is 20% funded by debt.

If a beta of 0.85 is assumed for the comparable, what is the estimated beta of the private insurer? Assume marginal tax rate of 20%.

Solution:

The unlevered beta for Alleghany is calculated as [1/(1 + (1 − 0.2)(10/90)] × 0.85 = 0.918 × 0.85 = 0.78. For the private insurer, if debt is 20% of capital then equity is 80% of capital and D′/E′ = 20/80 = 0.25. Therefore, the estimate of the private insurer's equity beta is [1 + (1 – 0.2) × 0.25] × 0.78 = 1.2 × 0.78, or 0.936.

The CAPM is a simple, widely accepted, theory-based method of estimating the cost of equity. Beta, its measure of risk, is readily obtainable for a wide range of securities from a variety of sources and can be estimated easily when not available from a vendor. In portfolios, the idiosyncratic risk of individual securities tends to offset against each other leaving largely beta (market) risk. For individual securities, idiosyncratic risk can overwhelm market risk and, in that case, beta may be a poor predictor of future average return. Thus, the analyst needs to have multiple tools available.

MULTIFACTOR MODELS FOR EQUITY RETURN

4

c determine the required return on an equity investment using the capital asset pricing model, the Fama–French model, the Pastor–Stambaugh model, macroeconomic multifactor models, and the build-up method (e.g., bond yield plus risk premium);

d explain beta estimation for public companies, thinly traded public companies, and non-public companies;

e describe strengths and weaknesses of methods used to estimate the required return on an equity investment;

f explain international considerations in required return estimation;

A substantial amount of evidence has accumulated that the CAPM beta describes risk incompletely. In practice, coefficients of determination (R-squared) for individual stocks' beta regressions may range from 2% to 40%, with many under 10%. For many markets, evidence suggests that multiple factors drive returns. At the cost of greater complexity and expense, the analyst can consider a model for required return based on multiple factors. Greater complexity does not ensure greater explanatory power, however, and any selected multifactor model should be examined for the value it is adding.

Whereas the CAPM adds a single risk premium to the risk-free rate, arbitrage pricing theory (APT) models add a set of risk premia. APT models are based on a multifactor representation of the drivers of return. Formally, APT models express the required return on an asset as follows:

$$r = R_F + (\text{Risk premium})_1 + (\text{Risk premium})_2 + \ldots + (\text{Risk premium})_K \quad (10)$$

where $(\text{Risk premium})_i = (\text{Factor sensitivity})_i \times (\text{Factor risk premium})_i$. **Factor sensitivity** or **factor beta** is the asset's sensitivity to a particular factor (holding all other factors constant). In general, the **factor risk premium** for factor i is the expected return in excess of the risk-free rate accruing to an asset with unit sensitivity to factor i and zero sensitivity to all other factors.

One of the best-known models based on multiple factors expands on the CAPM with two additional factors. That model, the Fama–French model, is discussed next.

4.1 The Fama–French Model

By the end of the 1980s, empirical evidence had accumulated that, at least over certain long periods, in the United States and several other equity markets, investment strategies biased toward small-market-capitalization securities and/or value might generate higher returns over the long run than the CAPM predicts.

In 1993, researchers Eugene Fama and Kenneth French addressed these perceived weaknesses of the CAPM in a model with three factors, known as the Fama–French model (FFM). The FFM is among the most widely known non-proprietary multifactor models. The factors are as follows:

- RMRF, standing for $R_M - R_F$, the return on a market value-weighted equity index in excess of the one-month T-bill rate—this is one way the equity risk premium can be represented and is the factor shared with the CAPM.
- SMB (small minus big), a size (market capitalization) factor. SMB is the average return on three small-cap portfolios minus the average return on three large-cap portfolios. Thus SMB represents a small-cap return premium.
- HML (high minus low), the average return on two high book-to-market portfolios minus the average return on two low book-to-market portfolios. With high book-to-market (equivalently, low price-to-book) shares representing a value bias and low book-to-market representing a growth bias, in general, HML represents a value return premium.

Each of the factors can be viewed as the mean return to a zero-net investment, long–short portfolio. SMB represents the mean return to shorting large-cap shares and investing the proceeds in small-cap shares; HML is the mean return from shorting low book-to-market (high P/B) shares and investing the proceeds in high book-to-market shares. The FFM estimate of the required return is as follows:

$$r_i = R_F + \beta_i^{\text{mkt}}\text{RMRF} + \beta_i^{\text{size}}\text{SMB} + \beta_i^{\text{value}}\text{HML} \tag{11}$$

Historical data on the factors are publicly available for several countries. The historical approach is frequently used in estimating the risk premia of this model. The definitions of RMRF, SMB, and HML have a specificity that lends itself to such estimation. Nevertheless, the range of estimation approaches discussed earlier could also be applied to estimating the FFM factors. Note the definition of RMRF in terms of a short-term rate; available historical series are in terms of a premium over a short-term government debt rate. In using Equation 11, we would take a current short-term risk-free rate. Note as well that because other factors besides the market factor are included in Equation 11, the beta on the market in Equation 11 is generally not exactly the same value as the CAPM beta for a given stock.

We can illustrate the FFM using the case of the US equity market. Assume the short-term interest rate is 1.80%. Historical market, size, and value premiums based on Fama–French data from 1926 to 2018 are 8.3%, 3.2%, and 4.7%, respectively. In a more recent subperiod (1998 through 2018), however, the realized RMRF has averaged 6.6%, the SMB premium has averaged 2.1%, and the realized HML premium has averaged 1.2%. Thus, based on risk premiums for the last 20 years, one estimate of the FFM expected return for the US market as of year-end 2018 is

$$r_i = 0.018 + \beta_i^{\text{mkt}}0.066 + \beta_i^{\text{size}}0.021 + \beta_i^{\text{value}}0.012$$

Consider the case of a small-cap issue with value characteristics and above-average market risk—assume its FFM market beta is 1.20. If the issue's market capitalization is small, we expect it to have a positive size beta; for example, $\beta_i^{\text{size}} = 0.5$. If the shares sell cheaply in relation to book equity (i.e., they have a high book-to-market ratio), the value beta is also expected to be positive; for example, $\beta_i^{\text{value}} = 0.8$. For both the size and value betas, zero is the neutral value, in contrast with the market beta, where the neutral value is 1. Thus, according to the FFM, the shares' required return is close to 12%:

$$r_i = 0.0180 + 1.20(0.066) + 0.5(0.021) + 0.8(0.012) = 0.1173$$

The FFM market beta of 1.2 could be above or below the CAPM beta, but for this comparison, suppose the CAPM beta is 1.20. The CAPM estimate would be 0.0180 + 1.20(0.066) = 0.0972 or less by about 11.73 − 9.72, or 2.01 percentage points. In this case, positive size and value exposures help account for the different estimates in the two models.

Returning to the specification of the FFM to discuss its interpretation, note that the FFM factors are of two types:

- an equity market factor, which is identified with systematic risk as in the CAPM; and
- two factors related to company characteristics and valuation, size (SMB) and value (HML).

The FFM views the size and value factors as representing ("proxying for") a set of underlying risk factors. For example, small market-cap companies may be subject to risk factors such as less ready access to private and public credit markets and competitive disadvantages. High book-to-market may represent shares with depressed prices because of exposure to financial distress. The FFM views the return premiums to small size and value as compensation for bearing types of systematic risk. Many practitioners and researchers believe, however, that those return premiums arise from market inefficiencies rather than compensation for systematic risk.

EXAMPLE 7

Required Return: CAPM and FFM

Charlene Wei is an analyst researching a large, growing US-based technology company. The next task in her valuation is to estimate a required return on equity (which is also the required return on total capital, because this technology company has no long-term debt). Wei's approach is to use an equally weighted average of the CAPM and FFM estimates unless one method appears to be superior as judged by more than a five-point difference in adjusted R^2; in that case, only the estimate with superior explanatory power is used. Exhibit 6 shows the cost of equity information for the company. All the beta estimates in Exhibit 6 are significant at the 5% level.

Exhibit 6 CAPM and FFM Required Return Estimates

	Model A	Model B
1) Current risk-free rate	1.80%	1.80%
2) Beta with respect to market	0.93	0.96
3) Market (equity) risk premium	6.60%	6.60%
Premium for stock: (2) × (3) =	6.14%	6.34%
4) Size beta	—	−0.17
5) Size Premium (SMB)	—	2.10%
Premium for stock: (4) × (5) =	—	−0.36%
6) Value beta	—	−0.15

(continued)

Exhibit 6 (Continued)

	Model A	Model B
7) Value Premium	—	1.20%
Premium for stock: (6) × (7) =	—	−0.18%
R^2	0.54	0.55
Adjusted R^2	0.53	0.52

Sources: This example uses assumed values for the hypothetical company's size and value betas.

Wei is apprised that her firm's economic unit expects that the marketplace will favor growth-oriented equities over the coming year. Reviewing all the information, Wei makes the following statements:

- "This company's cost of equity benefits from the company's above-average market capitalization."
- "If our economic unit's analysis is correct, growth-oriented portfolios are expected to outperform value-oriented portfolios over the next year. As a consequence, we should favor the CAPM required return estimate over the Fama–French estimate."

Using only the foregoing information, address the following.

1 Estimate Microsoft's cost of equity using the:

A CAPM.

B Fama–French model.

2 Judge whether Wei's first statement, concerning the company's cost of equity, is accurate.

3 Judge whether Wei's second statement, concerning the expected relative performance of growth-oriented portfolios and the use of the CAPM and FFM required return estimates, is correct.

Solution to 1:

A The required return according to the CAPM is 1.80% + 0.93(6.60%) = 1.80% + 6.14% = 7.94%

B The required return according to the FFM is 1.80% + 0.96(6.60%) + (−0.17)(2.10%) + (−0.15)(1.20%) = 1.80% + 6.34% + (−0.36%) + (−0.18%) = 7.60%.

Solution to 2:

The statement is accurate. The SMB premium is positive, and the company has negative exposure to it, resulting in the required return estimate being lower by 44 bps.

Solution to 3:

The statement is incorrect. It suggests that computing a required return using a positive value premium is questionable when the investor short-term forecast is for growth to outperform value. Required return estimates should reflect the expected or long-run compensation for risk. The positive value of the value premium in the FFM reflects expected compensation for bearing risk over the long run, consistent with the company's cash flows extending out to the indefinite future. The economic unit's prediction for a short-term time horizon does not invalidate the use of a positive value premium for the Fama–French model.

The regression fit statistics for both the CAPM and FFM in Example 7 were relatively high. There is more to learn about the relative merits of the CAPM and FFM in practice, but the FFM appears to have the potential for being a practical addition to the analyst's toolkit. One study contrasting the CAPM and FFM for US markets found that whereas differences in the CAPM beta explained on average 3% of the cross-sectional differences in returns of the stocks over the next year, the FFM betas explained on average 5% of the differences (Bartholdy and Peare 2003). Neither performance appears impressive, but keep in mind that equity returns are subject to a very high degree of randomness over short horizons.

Researchers have also examined the relative usefulness of domestic versus global versions of the FFM. One study, using data from the United States, Japan, Canada, and the United Kingdom, concludes that domestic (i.e., home-country) versions of the Fama–French three-factor model are more useful than global versions for explaining time series variation in market returns of individual stocks or portfolios (Griffin 2002).

4.2 Extensions to the Fama–French Model

Other researchers have extended the thought process behind the FFM of extending the CAPM to capture observed patterns in equity returns that differences in the CAPM beta appear not to explain. One well-established relationship is that investors demand a return premium for assets that are relatively illiquid—assets that cannot be quickly sold in quantity without high explicit or implicit transaction costs. Pastor and Stambaugh (2003) extended the FFM to encompass compensation for the degree of liquidity of an equity investment.

This model has been applied to public security investment as well as certain private security investments (Metrick 2007). The Pastor–Stambaugh model (PSM) adds to the FFM a fourth factor, LIQ, representing the excess returns to a portfolio that invests the proceeds from shorting high-liquidity stocks in a portfolio of low-liquidity stocks:

$$r_i = R_F + \beta_i^{\text{mkt}}\text{RMRF} + \beta_i^{\text{size}}\text{SMB} + \beta_i^{\text{value}}\text{HML} + \beta_i^{\text{liq}}\text{LIQ} \quad (12)$$

An estimate of the liquidity premium for US equity markets is 4.5% (Metrick 2007). An estimate of the PSM model for US markets is as follows:

$$r_i = 0.003 + \beta_i^{\text{mkt}}0.059 + \beta_i^{\text{size}}0.003 + \beta_i^{\text{value}}0.027 + \beta_i^{\text{liq}}0.045$$

An average-liquidity equity should have a liquidity beta of 0, with no impact on required return. But below-average liquidity (positive liquidity beta) and above-average liquidity (negative liquidity beta) will tend to increase and decrease required return, respectively.

EXAMPLE 8

The Required Return for a Common Stock Investment

A common stock has the following characteristics:

Market beta	1.50
Size beta	0.15
Value beta	–0.52
Liquidity beta	0.20

Based only on the information given, infer the style characteristics of the above common stock issue.

Solution:

The issue appears to be small cap and have a growth orientation. The positive size beta indicates sensitivity to small-cap returns, as would characterize small-cap stocks. (A positive liquidity beta, as shown, would also be typical for small-cap stocks because they usually trade in less liquid markets than do large-cap stocks.) The negative value beta indicates a growth orientation.

The concept of liquidity may be distinguished from marketability. With reference to equities, liquidity relates to the ease and potential price impact of the sale of an equity interest into the market. Liquidity is a function of several factors including the size of the interest and the depth and breadth of the market and its ability to absorb a block (i.e., a large position) without an adverse price impact. In the strictest sense, marketability relates to the right to sell an asset.

Barring securities law or other contractual restrictions, all equity interests are potentially marketable—that is, they can be potentially marketed for sale in the sense of the existence of a market into which the security can be sold. In private business valuation, however, the two terms are often used interchangeably. The typical treatment in that context is to take a discount for lack of marketability (liquidity) from the value estimate, where justified, rather than incorporate the effect in the discount rate, as in the PSM (see Hitchner 2006).

4.3 Macroeconomic and Statistical Multifactor Models

The FFM and PSM are examples of one type of a range of models for required return that are based on multiple fundamental factors (factors that are attributes of the stocks or companies themselves, e.g., the P/E for a share or the company's financial leverage); the group includes several proprietary models as well. Models for required return have also been based on macroeconomic and statistical factors.

- In macroeconomic factor models, the factors are economic variables that affect the expected future cash flows of companies and/or the discount rate that is appropriate to determining their present values.
- In statistical factor models, statistical methods are applied to historical returns to determine portfolios of securities (serving as factors) that explain those returns in various senses.

A specific example of macroeconomic factor models is the five-factor BIRR model, presented in Burmeister, Roll, and Ross (1994), with factor definitions as follows:

1. Confidence risk: the unanticipated change in the return difference between risky corporate bonds and government bonds, both with maturities of 20 years. To explain the factor's name, when their confidence is high, investors are willing to accept a smaller reward for bearing the added risk of corporate bonds.
2. Time horizon risk: the unanticipated change in the return difference between 20-year government bonds and 30-day Treasury bills. This factor reflects investors' willingness to invest for the long term.
3. Inflation risk: the unexpected change in the inflation rate. Nearly all stocks have negative exposure to this factor, as their returns decline with positive surprises in inflation.

4 Business cycle risk: the unexpected change in the level of real business activity. A positive surprise or unanticipated change indicates that the expected growth rate of the economy, measured in constant dollars, has increased.
5 Market timing risk: The portion of the total return of an equity market proxy (e.g., the S&P 500 for the United States) that remains unexplained by the first four risk factors. Almost all stocks have positive sensitivity to this factor.

The fifth factor acknowledges the uncertainty surrounding the correct set of underlying variables for asset pricing; this factor captures influences on the returns to the market proxy not explained by the first four factors. For example, using such a model, the required return for a security could have the following form:

r_i = T-bill rate + (Sensitivity to confidence risk × 2.59%) − (Sensitivity to time horizon risk × 0.66%) − (Sensitivity to inflation risk × 4.32%) + (Sensitivity to business-cycle risk × 1.49%) + (Sensitivity to market-timing risk × 3.61%)

where the risk premia estimates are developed using econometric techniques referenced in Burmeister et al. (1994). Similar to models based on fundamental factors, models based on macroeconomic and statistical factors have various proprietary implementations.

4.4 Build-Up Method Estimates of the Required Return on Equity

Widely used by valuators of closely held businesses, the build-up method estimates the required return on an equity investment as the sum of the risk-free rate and a set of risk premia:

r_i = Risk-free rate + Equity risk premium ± One or more premia (discounts)

The build-up method parallels the risk premium approach embodied in multifactor models, with the difference that specific beta adjustments are not applied to factor risk premiums.

4.5 Build-Up Approaches for Private Business Valuation

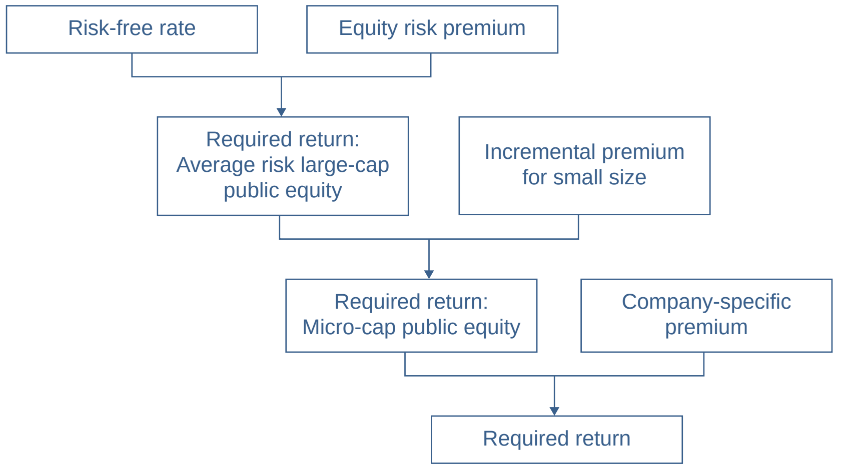
The need for estimates of the required return on the equity of a private business arises when present value models—known in such contexts as income models—are used in the process of valuing business interests. Because the valuation of such interests takes place not only for completely private investment purposes but where courts and tax authorities may play a role—such as in the valuation of a business included in an estate or the valuation of an equity interest for a legal dispute—the valuator may need to research which methods such authorities have found to be acceptable.

Standard approaches to estimating the required return on equity for publicly traded companies, such as the CAPM and the FFM, are adaptable for estimating the required rate of return for non-publicly traded companies. However, valuators often use an approach to valuation that relies on building up the required rate of return as a set of premia added to the risk-free rate. The premia include the equity risk premium and one or more additional premia, often based on factors such as size and perceived company-specific risk, depending on the facts of the exercise and the valuator's analysis of them. An expression for the build-up approach was presented in Equation 5. A traditional specific implementation is as follows (Hitchner 2006):

$$r_i = \text{Risk-free rate} + \text{Equity risk premium} + \text{Size premium}_i + \text{Specific-company premium}_i$$

Exhibit 7 explains the logic for a typical case. The equity risk premium is often estimated with reference to equity indexes of publicly traded companies. The market's largest market-capitalization companies typically constitute a large fraction of such indexes' value. With a beta of 1.0 implicitly multiplying the equity risk premium, the sum of the risk-free rate and equity risk premium is effectively the required return on an average-systematic-risk large-cap public equity issue. In the great majority of cases, private business valuation concerns companies much smaller in size than public large-cap issues. Valuators often add a premium related to the excess returns of small stocks over large stocks, reflecting an incremental return for small size. (The premium is typically after adjustment for the differences in the betas of small- and large-cap stocks to isolate the effect of size—a beta-adjusted size premium.) The level of the size premium is typically assumed to be inversely related to the size of the company being valued. When the size premium estimate is appropriately based on the lowest market-cap decile—frequently the case because many private businesses are small relative to publicly traded companies—the result corresponds to the return on an average-systematic-risk micro-cap public equity issue. An analysis of risk factors that are incremental to those captured by the previously included premia may lead the valuator to add a specific-company premium. This risk premium sometimes includes a premium for unsystematic risk of the subject company under the premise that such risk related to a privately held company may be less easily diversified away.

Exhibit 7 Required Return Estimate for a Privately Held Business



Two additional issues related to required return estimation for private companies are 1) consideration of the relative values of controlling versus minority interests in share value and 2) the effect on share value of the lack of ready marketability for a small equity interest in a private company. Lack of marketability is the inability to immediately sell shares resulting from lack of access to public equity markets because the shares are not registered for public trading. (Marketability may also be restricted by contractual or other reasons.)

With respect to the potential adjustment for the relative control associated with an equity interest in a private company, any adjustments related to the type of interest (controlling or minority) are traditionally made not in the required return but, if appropriate, directly to the preliminary value estimate. The issues involved in such adjustments are complex with some diversity of viewpoints among practitioners. Given these considerations, a detailed discussion is outside the scope of our coverage. Similarly, adjustments for lack of marketability are traditionally taken as an adjustment to the estimated value for an equity interest after any adjustment for the degree of control of the equity interest.

To illustrate, suppose an analyst is valuing a private integrated document management solutions company. The risk-free rate is 3.00%; the analyst's estimate of the equity risk premium is 4.20%; and based on assets and revenues, the company appears to correspond to the top half of the 10th decile of US public companies—decile 10a in Exhibit 8 with market capitalizations of equity ranging from over $129 million to about $207 million.

Exhibit 8 Estimates of US Beta Adjusted Size Premia

Market Cap Decile	Market Cap of Largest Company (in thousands)	Size Premium
6	$1,620,860	1.75%
7	1,090,515	1.77
8	682,750	2.51
9	422,811	2.80
10	206,795	6.10
	Breakdown of the 10th Decile	
10a	206,795	4.34%
10b	128,672	9.81

Source: SBBI Valuation Yearbook (2012), pp. 86–90.

Thus, ignoring any appropriate specific-company premium, an estimate of the required return on equity is 3.00% + 4.20% + 4.34% = 11.54%. A caution is that the size premium for the smallest decile (and especially the 10b component) may reflect not only the premium for healthy small-cap companies but also former large-cap companies that are in financial distress. If that is the case, the historical estimate may not be applicable without a downward adjustment for estimating the required return for a small but financially healthy private company.

A so-called modified CAPM formulation would seek to capture departures from average systematic risk. For example, if the analyst estimated that the company would have a beta of 1.2 if publicly traded, based on its publicly traded peer group, the required return estimate would be

Risk-free rate + Beta × Equity risk premium + Size premium,

or 3.00% + 1.2 × 4.20% + 4.34% = 12.38%. This result could be reconciled to a simple build-up estimate by including a differential return of (1.2 − 1.0)(4.20%) = 0.84% in the specific-company premium.

4.6 Bond Yield Plus Risk Premium

For companies with publicly traded debt, the **bond yield plus risk premium method** provides a quick estimate of the cost of equity. The estimate is

$$\text{BYPRP cost of equity} = \text{YTM on the company's long-term debt} + \text{Risk premium} \quad (13)$$

The YTM on the company's long-term debt includes

- a real interest rate and a premium for expected inflation, which are also factors embodied in a government bond yield; and
- a default risk premium.

The default risk premium captures factors such as profitability, the sensitivity of profitability to the business cycle, and leverage (operating and financial) that also affect the returns to equity. The risk premium in Equation 13 is the premium that compensates for the additional risk of the equity issue compared with the debt issue (recognizing that debt has a prior claim on the cash flows of the company). In US markets, the typical risk premium added is 3%–4%, based on experience.

EXAMPLE 9

The Cost of Equity of Vodafone from Two Perspectives

You are valuing the stock of Vodafone Group Plc as of early 2019, and you have gathered the following information:

UK gilt 30-year yield	1.70%
Vodafone Group Plc 7.875% 02/15/2030	4.64%

The Vodafone bonds, you note, are rated BBB+ by Standard & Poor's and Baa2 by Moody's Investors Service. The beta on Vodafone's stock is 0.70. As a matter of judgment, you have decided to use a risk premium of 3% in the bond yield plus risk premium approach.

1. Calculate the cost of equity using the CAPM. Assume that the equity risk premium is 5.20%.
2. Estimate the cost of equity using the bond yield plus risk premium approach, with a risk premium of 3.0%.
3. Suppose you found that Vodafone's stock, which closed at £140.52 on 8 April 2019, was slightly undervalued based on a DCF valuation using the CAPM cost of equity from Question 1. Does the alternative estimate of the cost of equity from Question 2 support the conclusion based on Question 1?

Solution to 1:

1.70% + 0.70(5.20%) = 5.34%.

Solution to 2:

Add 3.0% to the Vodafone bond YTM: 4.64% + 3.0% = 7.64%. Note that the difference between the Vodafone bond YTM and the long gilt YTM is 2.94%. This amount plus 3.0% is the total estimated risk premium versus UK treasury debt, 2.94% + 3.0% = 5.94%.

Solution to 3:

Not necessarily; *undervalued* means that the value of a security is greater than market price. All else equal, the lower the discount rate, the higher the estimate of value. The inverse relationship between discount rate and value, holding all else constant, is a basic relationship in valuation. If Vodafone appears to be undervalued using the CAPM cost of equity estimate of 5.34%, that does not necessarily mean it will also appear to be undervalued using a 7.64% cost of equity based on the bond yield plus risk premium method.

The bond yield plus risk premium method can be viewed as a build-up method applying to companies with publicly traded debt. The estimate provided can be a useful check when the explanatory power of more-rigorous models is low. Given that a company's shares have positive systematic risk, the yield on its long-term debt is revealing as a check on cost of equity estimate. For example, the 8.375% bonds of Koninklijke KPN N.V. due 1 October 2030 (rated BBB by Standard & Poor's and Baa3 by Moody's) were priced to yield 5.2% as of early April 2019, so an estimated required return for its stock not greater than 5.20% would be suspect.

4.7 The Required Return on Equity: International Issues

Among the issues that concern analysts estimating the required return of equities in a global context are

- exchange rates, and
- data and model issues in emerging markets.

An investor is ultimately concerned with returns and volatility stated in terms of her own currency. Historical returns are often available or can be constructed in local currency and home currency terms. Equity risk premium estimates in home currency terms can be higher or lower than estimates in local currency terms because exchange rate gains and losses from the equity component are generally not exactly offset by gains and losses from the government security component of the equity risk premium. For example, Dimson, Marsh, and Staunton (2018) report that the real (inflation-adjusted) return on Swiss equities from 1900 to 2017, using the geometric mean, was approximately 4.5% in Swiss franc terms, but for a US investor it was approximately 5.3% because the franc appreciated in value relative to the dollar. The US dollar estimate more accurately reflects a US investor's historical experience. A sound approach for any investor is to focus on the local currency record, incorporating any exchange rate forecasts.

The difficulty of required return and risk premium estimation in emerging markets has been previously mentioned. Of the numerous approaches that have been proposed to supplement or replace traditional historical and forward-looking methods, we can mention two.

- The country spread model for the equity risk premium. For an emerging equity market, this model states the following:

$$\text{Equity risk premium estimate} = \text{Equity risk premium for a developed market} + \text{Country premium}$$

The country premium represents a premium associated with the expected greater risk of the emerging market compared with the benchmark developed market. Typically, analysts hope that a sovereign bond yield spread is adequate for approximating this premium. Thus, the country premium is often estimated as the yield on emerging market bonds (denominated in the currency of the developed market) minus the yield on developed market government bonds.

To illustrate, the yield premium on Indian companies' dollar bonds over US Treasuries decreased to 3.19% in March 2013. Taking this premium as the country premium for India and using an estimate of 4.20% for the US equity risk premium, the Indian equity risk premium equals 4.20% + 3.19% = 7.39%.

- The country risk rating model provides a regression-based estimate of the equity risk premium based on the empirical relationship between developed equity market returns and Institutional Investor's semi-annual risk ratings for those markets. The estimated regression equation is then used with the risk ratings for less developed markets to predict the required return for those markets. This model has been recommended by Morningstar (Ibbotson).

5 WEIGHTED AVERAGE COST OF CAPITAL (WACC)

g explain and calculate the weighted average cost of capital for a company;

h evaluate the appropriateness of using a particular rate of return as a discount rate, given a description of the cash flow to be discounted and other relevant facts.

The cost of capital is most commonly estimated using the company's after-tax weighted average cost of capital, WACC for short: a weighted average of required rates of return for the component sources of capital.

The cost of capital is relevant to equity valuation when an analyst takes an indirect, total firm value approach using a present value model. Using the cost of capital to discount expected future cash flows available to debt and equity, the total value of these claims is estimated. The balance of this value after subtracting off the market value of debt is the estimate of the value of equity.

In many jurisdictions, corporations may deduct net interest expense from income in calculating taxes owed, but they cannot deduct payments to shareholders, such as dividends.

If the suppliers of capital are creditors and common stockholders, the expression for WACC is

$$\text{WACC} = \frac{\text{MVD}}{\text{MVD} + \text{MVCE}} r_d (1 - \text{Tax rate}) + \frac{\text{MVCE}}{\text{MVD} + \text{MVCE}} r, \quad (14)$$

where MVD and MVCE are the current market values of debt and (common) equity, not their book or accounting values. Dividing MVD or MVCE by the total market value of the firm, which is MVD + MVCE, gives the proportions of the company's total capital from debt or equity, respectively. These weights will sum to 1.0. Multiplying the before-tax required return on debt (r_d) by 1 minus the marginal corporate tax rate (1 − Tax rate) adjusts the pretax rate r_d downward to reflect the tax deductibility of corporate interest payments that is being assumed. Because distributions to equity are assumed not to be deductible by the corporations, a corporation's before and after-tax costs of equity are the same; no adjustment to r involving the corporate tax rate is appropriate. Generally speaking, it is appropriate to use a company's marginal tax rate rather than its current effective tax rate (reported taxes divided by pretax income) because the effective tax rate can reflect non-recurring items. A cost of capital based on the marginal tax rate usually better reflects a company's future costs in raising funds.

Because the company's capital structure (the proportions of debt and equity financing) can change over time, analysts often use *target* weights instead of the current market-value weights when calculating WACC. Target weights provide a good approximation of the WACC for cases in which the current weights misrepresent the company's normal capital structure.

The before-tax required return on debt is typically estimated using the expected YTM of the company's debt based on current market values. Analysts can choose from any of the methods presented for estimating the required return on equity, *r*. No tax adjustment is appropriate for the cost of equity, assuming payments to shareholders such as dividends are not tax deductible by companies.

EXAMPLE 10

The Weighted Average Cost of Capital for Vodafone

Taking an indirect, total firm value approach to valuing equity, suppose you have the inputs for estimating the cost of capital shown in Exhibit 9. Based only on the information given, estimate Vodafone's WACC.

Exhibit 9 Cost of Capital Data: Vodafone

Panel A: Capital Structure	Value
Long-term debt as a percentage of total capital, at market value	43%
Tax rate	19%

Panel B: Component Costs of Capital	Value
Cost of equity: CAPM estimate	5.34%
YTM of Vodafone long bond	4.64%

Solution:

Long-term debt as a percentage of total capital stated at market value is the weight to be applied to Vodafone's after-tax cost of debt in the WACC calculation. Therefore, Vodafone's WACC based on the data provided is approximately 5.73%, calculated as follows:

$$\begin{aligned}\text{WACC} &= 0.43(4.64\%)(1 - 0.19) + 0.57(5.34\%)\\ &= 1.616\% + 3.044\% = 4.66\%\end{aligned}$$

5.1 Discount Rate Selection in Relation to Cash Flows

When used as discount rates in valuation, required returns need to be defined appropriately relative to the cash flows to be discounted.

A cash flow after more-senior claims (e.g., promised payments on debt and taxes) have been fulfilled is a cash flow to equity. When a cash flow to equity is discounted, the required return on equity is an appropriate discount rate. When a cash flow is available to meet the claims of all of a company's capital providers—usually called a cash flow to the firm—the firm's weighted-average cost of capital is the appropriate discount rate.

Cash flows may be stated in nominal or real terms. When cash flows are stated in real terms, amounts reflect offsets made for actual or anticipated changes in the purchasing power of money. Nominal discount rates must be used with nominal cash flows, and real discount rates must be used with real cash flows. In valuing equity, we will use only nominal cash flows, and therefore we will make use of nominal discount rates. Because the tax rates applying to corporate earnings are generally stated in nominal money terms—such and such tax rates applying at stated levels of nominal pretax earnings—using nominal quantities is an exact approach because it reflects taxes accurately.

Equation 14 presents an after-tax weighted average cost of capital using the after-tax cost of debt. At a later stage, we will present cash flow to the firm definitions for which it is appropriate to use that definition of the cost of capital as the discount rate (i.e., rather than a pretax cost of capital reflecting a pretax cost of debt).

In short, in later sections we will be able to illustrate present value models of stock value using only two discount rates: the nominal required return on equity when the cash flows are those available to common shareholders, and the nominal after-tax weighted average cost of capital when the cash flows are those available to all the company's capital providers.

SUMMARY

We introduced several important return concepts. Required returns are important because they are used as discount rates in determining the present value of expected future cash flows. When an investor's intrinsic value estimate for an asset differs from its market price, the investor generally expects to earn the required return plus a return from the convergence of price to value. When an asset's intrinsic value equals price, however, the investor expects to earn only the required return.

For two important approaches to estimating a company's required return, the CAPM and the build-up model, the analyst needs an estimate of the equity risk premium. We examined realized equity risk premia for a group of major world equity markets and also explained forward-looking estimation methods. For determining the required return on equity, the analyst may choose from the CAPM and various multifactor models such as the Fama–French model and its extensions, examining regression fit statistics to assess the reliability of these methods. For private companies, the analyst can either adapt public equity valuation models for required return using public company comparables or use a build-up model, which starts with the risk-free rate and the estimated equity risk premium and adds additional appropriate risk premia.

When the analyst approaches the valuation of equity indirectly, by first valuing the total firm as the present value of expected future cash flows to all sources of capital, the appropriate discount rate is a weighted average cost of capital based on all sources of capital. Discount rates must be on a nominal (real) basis if cash flows are on a nominal (real) basis.

Among the major points are the following:

- The return from investing in an asset over a specified period is called the *holding period return*. *Realized return* refers to a return achieved in the past, and *expected return* refers to an anticipated return over a future period. A *required return* is the minimum level of expected return that an investor requires to invest in the asset over a specified period, given the asset's riskiness. The (*market*) *required return*, a required rate of return on an asset that is inferred using market prices or returns, is typically used as the *discount rate* in finding the present values of expected future cash flows. If an asset is perceived (is not perceived) as fairly priced in the marketplace, the required return should (should not) equal the investor's expected return. When an asset is believed to be mispriced, investors should earn a *return from convergence of price to intrinsic value.*

- An estimate of the equity risk premium—the incremental return that investors require for holding equities rather than a risk-free asset—is used in the CAPM and in the build-up approach to required return estimation.
- Approaches to equity risk premium estimation include historical, adjusted historical, and forward-looking approaches.
- In historical estimation, the analyst must decide whether to use a short-term or a long-term government bond rate to represent the risk-free rate and whether to calculate a geometric or arithmetic mean for the equity risk premium estimate. Forward-looking estimates include Gordon growth model estimates, supply-side models, and survey estimates. Adjusted historical estimates can involve an adjustment for biases in data series and an adjustment to incorporate an independent estimate of the equity risk premium.
- The CAPM is a widely used model for required return estimation that uses beta relative to a market portfolio proxy to adjust for risk. The Fama–French model is a three-factor model that incorporates the market factor, a size factor, and a value factor. The Pastor–Stambaugh extension to the FFM adds a liquidity factor. The bond yield plus risk premium approach finds a required return estimate as the sum of the YTM of the subject company's debt plus a subjective risk premium (often 3% to 4%).
- When a stock is thinly traded or not publicly traded, its beta may be estimated on the basis of a peer company's beta. The procedure involves unlevering the peer company's beta and then re-levering it to reflect the subject company's use of financial leverage. The procedure adjusts for the effect of differences of financial leverage between the peer and subject company.
- Emerging markets pose special challenges to required return estimation. The country spread model estimates the equity risk premium as the equity risk premium for a developed market plus a country premium. The country risk rating model approach uses risk ratings for developed markets to infer risk ratings and equity risk premiums for emerging markets.
- The weighted average cost of capital is used when valuing the total firm and is generally understood as the nominal after-tax weighted average cost of capital, which is later used in discounting nominal cash flows to the firm. The nominal required return on equity is used in discounting cash flows to equity.

PRACTICE PROBLEMS

1 A Canada-based investor buys shares of a company for C$72.08 on 15 October 20X0 with the intent of holding them for a year. The dividend rate was C$2.11 per year. The investor actually sells the shares on 5 November 20X0 for C$69.52. The investor notes the following additional facts:

- No dividends were paid between 15 October and 5 November.
- The required return on the company's equity was 8.7% on an annual basis and 0.161% on a weekly basis.

A State the lengths of the expected and actual holding periods.

B Given that the company's stock was fairly priced, calculate the price appreciation return (capital gains yield) anticipated by the investor given his initial expectations and initial expected holding period.

C Calculate the investor's realized return.

D Calculate the realized alpha.

2 At the time of valuation, the estimated betas for JPMorgan Chase & Co. and The Boeing Company were 1.50 and 0.80, respectively. The risk-free rate of return was 4.35%, and the equity risk premium was 8.04%. Based on these data, calculate the required rates of return for these two stocks using the CAPM.

3 The estimated factor sensitivities of Clearful Energy (a fictitious company) to Fama–French factors and the risk premia associated with those factors appear in the following table:

	Factor Sensitivity	Risk Premium (%)
Market factor	1.20	4.5
Size factor	−0.50	2.7
Value factor	−0.15	4.3

A Based on the Fama–French model, calculate the required return for Clearful Energy using these estimates. Assume that the Treasury bill rate is 4.7%.

B Describe the expected style characteristics of Clearful Energy based on its factor sensitivities.

4 An analyst's data source shows that Newmont Mining (NEM) has an estimated beta of −0.2. The risk-free rate of return is 2.5%, and the equity risk premium is estimated to be 4.5%.

A Using the CAPM, calculate the required rate of return for investors in NEM.

B The analyst notes that the current yield to maturity on corporate bonds with a credit rating similar to NEM is approximately 3.9%. How should this information affect the analyst's estimate?

5 An analyst wants to account for financial distress and market capitalization as well as market risk in his cost of equity estimate for a particular traded company. Which of the following models is *most appropriate* for achieving that objective?

A The CAPM.

B The Fama–French model.

C A macroeconomic factor model.

© 2021 CFA Institute. All rights reserved.

6 An analyst assembles the following facts concerning an Indian company's component costs of capital and capital structure. Based on the information given, calculate the company's WACC.

Component Costs of Capital	(%)
Cost of equity based on the CAPM	15.6
Pretax cost of debt	8.28
Tax rate	30
Target weight in capital structure	Equity 80, Debt 20

The following information relates to Questions 7–12

An equity index is established in 2001 for a country that has relatively recently established a market economy. The index vendor constructed returns for the five years prior to 2001 based on the initial group of companies constituting the index in 2001. From 2012 to 2016, a series of military confrontations concerning a disputed border disrupted the economy and financial markets. The dispute is conclusively arbitrated at the end of 2016. In total, 20 years of equity market return history is available as of the beginning of 2017. The geometric mean return relative to 10-year government bond returns over 20 years is 2% per year. The forward dividend yield on the index is 1%. Stock returns over 2012 to 2016 reflect the setbacks, but economists predict the country will be on a path of a 4% real GDP growth rate by 2019. Earnings in the public corporate sector are expected to grow at a 5% per year real growth rate. Consistent with that, the market P/E is expected to grow at 1% per year. Although inflation is currently high at 6% per year, the long-term forecast is for an inflation rate of 4% per year. The yield curve has usually been upward sloping, but currently the government yield curve is inverted; at the short end, yields are 9% and at 10-year maturities, yields are 7%.

7 The inclusion of index returns prior to 2001 would be expected to:

A bias the historical equity risk premium estimate upward.

B bias the historical equity risk premium estimate downward.

C have no effect on the historical equity risk premium estimate.

8 The events of 2012 to 2016 would be expected to:

A bias the historical equity risk premium estimate upward.

B bias the historical equity risk premium estimate downward.

C have no effect on the historical equity risk premium estimate.

9 In the current interest rate environment, using a required return estimate based on the short-term government bond rate and a historical equity risk premium defined in terms of a short-term government bond rate would be expected to:

A bias long-term required return on equity estimates upward.

B bias long-term required return on equity estimates downward.

C have no effect on long-term required return on equity estimates.

10 A supply side estimate of the equity risk premium as presented by the Ibbotson–Chen earnings model is *closest* to:

A 3.2%.

B 4.0%.

C 4.3%.

11 Common stock issues in the aforementioned market with average systematic risk are *most likely* to have required rates of return:

A between 2% and 7%.

B between 7% and 9%.

C of 9% or greater.

12 Which of the following statements is *most accurate*? If two equity issues have the same market risk but the first issue has higher leverage, greater liquidity, and a higher required return, the higher required return *is most likely* the result of the first issue's:

A greater liquidity.

B higher leverage.

C higher leverage and greater liquidity.

Questions 13 through 19 relate to Horizon Asset Management

Judy Chen is the primary portfolio manager of the global equities portfolio at Horizon Asset Management. Lars Johansson, a recently hired equity analyst, has been assigned to Chen to assist her with the portfolio.

Chen recently sold shares of Novo-Gemini, Inc. (a fictitious company) from the portfolio. Chen tasks Johansson with assessing Novo-Gemini's return performance, with specific trade information provided in Exhibit 1.

Exhibit 1 Novo-Gemini, Inc. Trade Details

1. Novo-Gemini shares were purchased for $20.75 per share.
2. At the time of purchase, research by Chen suggested that Novo-Gemini shares were expected to sell for $29.00 per share at the end of a three-year holding period.
3. At the time of purchase, the required return for Novo-Gemini based on the CAPM was estimated to be 12.6% on an annual basis.
4. Exactly three years after the purchase date, the shares were sold for $30.05 per share.
5. No dividends were paid by Novo-Gemini over the three-year holding period.

Chen explains to Johansson that, at the time of purchase, the CAPM used to estimate a required return for Novo-Gemini incorporated an unadjusted historical equity risk premium estimate for the US equity market. Chen notes that the US equities market has experienced a meaningful string of favorable inflation and productivity surprises in the past. She asks Johansson whether the historical equity risk premium should have been adjusted before estimating the required return for Novo-Gemini.

For another perspective on the reward for bearing risk, Chen asks Johansson to calculate a forward-looking equity risk premium for the US equity market using data on the S&P 500 in Exhibit 2.

Exhibit 2 S&P 500 Index Data	
Dividend yield, based on year-ahead aggregate forecasted dividends	1.2%
Consensus long-term earnings growth rate	4%
20-year US government bond yield	3%

Chen is now considering adding shares of Bezak, Inc. (a fictitious company) to the portfolio. Chen asks Johansson to calculate Bezak's weighted average cost of capital using the CAPM with the information provided in Exhibit 3.

Exhibit 3 Bezak, Inc.	
Pretax cost of debt	4.9%
Long-term debt as a percentage of total capital, at market value	25%
Marginal tax rate	30%
Bezak, Inc. beta	2.00
Estimated equity risk premium	5.5%
Risk-free rate	3.0%

Lastly, Chen asks Johansson to evaluate Twin Industries (a fictitious company), a privately owned US company that may initiate a public stock offering. Johansson decides to adapt the CAPM to estimate the required return on equity for Twin Industries. Using the MSCI/Standard & Poor's Global Industry Classification Standard (GICS), Johansson identifies a publicly traded peer company with an estimated beta of 1.09 that is much larger but otherwise similar to Twin Industries. Twin Industries is funded 49% by debt, whereas the publicly traded peer company is funded 60% by debt.

13 Based on Exhibit 1, the expected three-year holding period return for Novo-Gemini Inc. at the time of purchase was *closest* to:

A 39.76%.

B 42.76%.

C 44.82%.

14 Based on Exhibit 1, the realized three-year holding period return for Novo-Gemini Inc. was *closest* to:

A 39.76%.

B 42.76%.

C 44.82%.

15 Based on the historical record of surprises in inflation and productivity, the historical equity risk premium for the US equity market, if it is used as an estimate of the forward-looking equity risk premium, should *most likely* be:

A left unchanged.

B adjusted upward.

C adjusted downward.

16 Based on Exhibit 2, the forward-looking estimate for the US equity risk premium is *closest* to:

A 2.2%.

B 5.8%.

C 8.2%.

17 Based on Exhibit 3, and assuming interest on debt is tax-deductible, the WACC for Bezak, Inc. is *closest* to:

A 10.87%.

B 11.36%.

C 13.61%.

18 The estimate of beta for Twin Industries is *closest* to:

A 0.44.

B 0.85.

C 0.89.

19 A potential weakness of Johansson's approach to estimating the required return on equity for Twin Industries is that the return estimate:

A does not include a size premium.

B may overstate potential returns over the long term.

C does not consider systematic risk arising from the economics of the industry.

The following information relates to Questions 20–24

Erica Silverstein is evaluating a spinoff by Acme Manufacturing, Inc., a US industrial company. Acme will spin off one of its subsidiaries, LED Light Company, in a public offering. Silverstein uses the following information and assumptions in her analysis:

- The risk-free rate is 2%.
- LED Light's marginal tax rate is 30%.
- LED Light's debt-to-equity ratio is 0.5.
- The estimated equity risk premium is 6%.
- The yield to maturity on LED Light's long-term debt is forecasted to be 4%.
- The beta of the closest peer firm to LED Light is 0.8, and the firm has a debt-to-equity ratio of 0.4.

As part of her evaluation, Silverstein estimates the required return for LED Light using several approaches.

Approach 1 The CAPM using the beta of a peer firm of LED Light. The peer firm's beta is 0.8, and the firm has a debt-to-equity ratio of 0.4.

Approach 2 The Fama–French three-factor model using the estimated factor sensitivities and factor risk premiums presented in Exhibit 1.

Exhibit 1 Estimated Fama–French Factor Sensitivities and Premiums

Factor	Factor Sensitivity	Factor Premium (%)
Excess return on the market	1.5	6.0
Size (small minus big, SMB)	–0.1	5.0
Value (high minus low, HML)	0.5	4.0

Approach 3 A build-up method using an estimated risk premium of 6.5% that compensates for the additional risk of the equity issue compared with LED Light's long-term debt.

Silverstein is concerned that the required rates of return using these three approaches do not consider the relative liquidity anticipated for LED Light. So, she also estimates the required return using the Pastor–Stambaugh model, which yields an estimate of 14%.

Silverstein discusses her set of required return estimates for LED Light with a colleague. The colleague notes that Silverstein estimated the equity risk premium of 6% using historical data and suggests that Silverstein consider estimating a forwarding-looking estimate to use in her analysis.

Silverstein proceeds with estimating a forward-looking equity risk premium using the Gordon Growth Model approach, given the following additional assumptions:

- Dividend yield on the market index based on one-year-ahead aggregate forecasted dividends is 2.3%.
- Consensus long-term earnings growth rate is 5.9%.
- Expected growth rate in the P/E ratio is 0.1%.
- The 30-year Treasury yield is 2.8%.

20 Using Approach 1, LED Light's estimated required rate of return is *closest* to:

A 6.55%.

B 7.06%.

C 8.48%.

21 Using Approach 2, LED Light's estimated required rate of return is *closest* to:

A 10.5%.

B 12.5%.

C 13.5%.

22 Using Approach 3, LED Light's estimated required rate of return is *closest* to:

A 8.5%.

B 10.5%.

C 12.8%.

23 Using Silverstein's required return estimate based on the Pastor–Stambaugh model as the cost of equity, the weighted average cost of capital (WACC) for LED Light is *closest* to:

A 8.4%.

B 10.3%.

C 10.7%.

24 Silverstein should estimate the Gordon Growth Model (GGM) equity risk premium as:

A 4.3%.

B 5.4%.

C 9.3%.

SOLUTIONS

1 A The expected holding period was one year. The actual holding period was from 15 October 2017 to 5 November 2017, which is three weeks.

B Given fair pricing, the expected return equals the required return, 8.7%. The expected return from price appreciation over the initial anticipated one-year holding period must be equal to the required return minus the dividend yield, 2.11/72.08 = 0.0293, or 2.93%. Thus, expected price appreciation return was 8.7% – 2.93% = 5.77%.

C The realized return was ($69.52 – $72.08)/$72.08 = –0.03552, or –3.55% over three weeks. There was no dividend yield return over the actual holding period.

D The required return over a three-week holding period was $(1.00161)^3 - 1$ = 0.484%. Using the answer to C, the realized alpha was –3.552 – 0.484 = –4.036, or –4.04%.

2 For JPMorgan Chase, the required return is

$$r = R_F + \beta\left[E\left(R_M\right) - R_F\right] = 4.35\% + 1.50(8.04\%) = 4.35\% + 12.06\%$$
$$= 16.41\%$$

For Boeing, the required return is

$$r = R_F + \beta\left[E\left(R_M\right) - R_F\right] = 4.35\% + 0.80(8.04\%) = 4.35\% + 6.43\%$$
$$= 10.78\%$$

3 A The Fama–French model gives the required return as

$$\begin{aligned} r = {} & \text{T-bill rate} \\ & + (\text{Sensitivity to equity market factor} \times \text{Equity risk premium}) \\ & + (\text{Sensitivity to size factor} \times \text{Size risk premium}) \\ & + (\text{Sensitivity to value factor} \times \text{Value risk premium}) \end{aligned}$$

For Clearful Energy, the required return is

$$\begin{aligned} r &= 4.7\% + (1.20 \times 4.5\%) + (-0.50 \times 2.7\%) + (-0.15 \times 4.3\%) \\ &= 4.7\% + 5.4\% - 1.35\% - 0.645\% \\ &= 8.1\% \end{aligned}$$

B Clearful Energy appears to be a large-cap, growth-oriented, high-market-risk stock as indicated by its negative size beta, negative value beta, and market beta above 1.0.

4 A The required return is given by

$$r = 0.025 + (-0.2)(0.045) = 2.5\% - 0.9\% = 1.6\%$$

This example indicates that Newmont Mining has a required return of 1.6%. When beta is negative, the CAPM calculation yields a required rate of return that is below the risk-free rate, which is arguably not meaningful. Cases of equities with negative betas are relatively rare.

B The fact that the NEM's cost of debt is higher than the calculated required return on equity is another indicator that the return estimated using CAPM is not useful for valuing the company's equity.

5 B is correct. The Fama–French model incorporates market, size, and value risk factors. One possible interpretation of the value risk factor is that it relates to financial distress.

6 The company's WACC is 13.64% calculated as follows:

	Equity		Debt	WACC
Weight	0.80		0.20	
After-Tax Cost	15.6%		(1 – 0.30)8.28%	
Weight × Cost	12.48%	+	1.16%	= 13.64%

7 A is correct. The backfilling of index returns using companies that have survived to the index construction date is expected to introduce a positive survivorship bias into returns.

8 B is correct. The events of 2012 to 2016 depressed share returns but 1) are not a persistent feature of the stock market environment, 2) were not offset by other positive events within the historical record, and 3) have led to relatively low valuation levels, which are expected to rebound.

9 A is correct. The required return reflects the magnitude of the historical equity risk premium, which is generally higher when based on a short-term interest rate (as a result of the normal upward-sloping yield curve), and the current value of the rate being used to represent the risk-free rate. The short-term rate is currently higher than the long-term rate, which will also increase the required return estimate. The short-term interest rate, however, overstates the long-term expected inflation rate. Using the short-term interest rate, estimates of the long-term required return on equity will be biased upward.

10 C is correct. According to this model, the equity risk premium is

$$\text{Equity risk premium} = \left\{\left[(1 + \text{EINFL})(1 + \text{EGREPS})(1 + \text{EGPE}) - 1.0\right] + \text{EINC}\right\} - \text{Expected risk-free return}$$

Here,

$$\begin{aligned}
\text{EINFL} &= 4\% \text{ per year (long-term forecast of inflation)}\\
\text{EGREPS} &= 5\% \text{ per year (growth in real earnings)}\\
\text{EGPE} &= 1\% \text{ per year (growth in market P/E)}\\
\text{EINC} &= 1\% \text{ per year (dividend yield or the income portion)}\\
\text{Risk-free return} &= 7\% \text{ per year (for 10-year maturities)}
\end{aligned}$$

By substitution, we find:

$\{[(1.04)(1.05)(1.01)\text{-}1.0] + 0.01\} - 0.07 = 0.113 - 0.07 = 0.043$ or 4.3%.

11 C is correct. Based on a long-term government bond yield of 7%, a beta of 1, and any of the risk premium estimates that can be calculated from the givens (e.g., a 2% historical risk premium estimate or 4.3% supply-side equity risk premium estimate), the required rate of return would be at least 9%. Based on using a short-term rate of 9%, C is the correct choice.

12 B is correct. All else equal, the first issue's greater liquidity would tend to make its required return lower than the second issue's. However, the required return on equity increases as leverage increases. The first issue's higher required return must result from its higher leverage, more than offsetting the effect of its greater liquidity, given that both issues have the same market risk.

13 A is correct. This is the expected three-year holding period return, calculated as

$$\begin{aligned}\text{3-year expected return} &= (V_0 - P_0)/P_0 = (\$29.00 - \$20.75)/\$20.75\\ &= 39.76\%.\end{aligned}$$

14 C is correct. The realized holding period return (note that no dividends were paid during the three-year holding period) is 44.82%. Specifically, the realized three-year holding period is calculated as

$$\begin{aligned}\text{3-Year realized return} &= (P_H - P_0)/(P_0) = (30.05 - 20.75)/20.75\\ &= 44.82\%.\end{aligned}$$

15 C is correct. A string of favorable inflation and productivity surprises may result in a series of high returns that increase the historical mean estimate of the equity risk premium. To mitigate that concern, the analyst may adjust the historical estimate downward based on an independent forward-looking estimate.

16 A is correct. Given the data presented, the equity risk premium can be estimated as

Equity risk premium = Dividend yield on the index based on year-ahead aggregate forecasted dividends and aggregate market value + Consensus long-term earnings growth rate – Current long-term government bond yield.

The equity risk premium is 1.2% + 4.0% – 3.0% = 2.2%.

17 B is correct. The weighted average cost of capital is taking the sum product of each component of capital multiplied by the component's after-tax cost.

First, estimate the cost of equity using the CAPM:

Cost of equity = Risk-free rate + [Equity risk premium × Beta]

Cost of equity = 3.0% + [5.5% × 2.00] = 14%

Now, calculate Bezak's WACC:

	Equity		Debt	WACC
Weight	0.75		0.25	
After-tax cost	14%		(1 – 0.30) × 4.9%	
Weight × After-tax cost	10.5%	+	0.8575%	= 11.36%

18 B is correct. The steps to estimating a beta for a non-traded company are as follows:

Step 1 Select the comparable benchmark

Step 2 Estimate benchmark's beta

Step 3 Unlever the benchmark's beta

Step 4 Lever the beta to reflect the subject company's financial leverage

The beta of the benchmark peer company data is given as 1.09. Next, this beta needs to be unlevered, calculated as follows:

$$\beta_u = \left[\frac{1}{1 + (1 - t)\left(\frac{D}{E}\right)}\right]\beta_l$$

$$\beta_u\left[\frac{1}{1+(1-0.3)\left(\frac{0.60}{0.40}\right)}\right](1.09)$$

$$\beta_u = 0.532, \text{ or } 0.53$$

Then, the unlevered beta needs to be levered up to reflect the financial leverage of Twin Industries, calculated as follows:

$$\beta'_E \approx \left[1+(1-t)\left(\frac{D'}{E'}\right)\right]\beta_u$$

$$\beta'_E \approx \left[1+(1-t)\left(\frac{0.49}{0.51}\right)\right](0.532)$$

$$\beta_u = 0.889, \text{ or } 0.89$$

19 A is correct. Johansson intends to estimate a required return on equity using a modified CAPM approach. Twin Industries is stated to be smaller than the chosen proxy benchmark being used, and there is no size premium adjustment in the CAPM framework. The framework adjusts the beta for leverage differences but not for firm size differences. The build-up method may be more appropriate because it includes the equity risk premium and one or more additional premia, often based on factors such as size and perceived company-specific risk.

20 B is correct. The required return for LED Light using Approach 1 (CAPM using the beta of a peer firm) is calculated as follows:

First, compute the unlevered beta from the peer firm beta:

$$\beta_U = \left[\frac{1}{1+\left((1-t)\frac{D}{E}\right)}\right]\beta_E$$

$$\beta_U = \left[\frac{1}{1+((1-0.30)0.4)}\right]0.8 = \left[\frac{1}{1+0.28}\right]0.8 = 0.625$$

Second, compute the levered beta given the debt-to-equity of LED Light of 0.5:

$$\beta'_E = \left[1+\left((1-t)\frac{D'}{E'}\right)\right]\beta_U$$

$$\beta'_E = \left[1+((1-0.3)0.5)\right]0.625 = 0.84375$$

Finally, compute the required return with the levered beta:

Required rate of return = Current expected risk – free return + β_i (Equity risk premium)

Required rate of return = 0.02 + 0.84375 (0.06) = 0.070625 ≈ 7.06%

A is incorrect because the wrong debt-to-equity ratio is used in the unlevering and levering calculations:

$$\beta_U = \left[\frac{1}{1 + ((1 - 0.30)0.5)}\right]0.8 = \left[\frac{1}{1 + 0.35}\right]0.8 = 0.59259$$

β_E = [1 + ((1 – 0.3)0.4)]0.59259 = 0.7585152

Required rate of return on share i = 0.02 + 0.7585152 (0.06) = 0.065511 ≈ 6.55%

C is incorrect because the beta of the peer firm is not unlevered before applying the levering by LED Light's debt-to-equity ratio.

β_E = [1 + ((1 – 0.3) 0.5)] 0.8 = 1.08

Required rate of return on share i = 0.02 + 1.08 (0.06) = 0.0848 = 8.48%

21 B is correct. The required return for LED Light using Approach 2 (Fama–French three-factor model) is calculated as follows:

$$r_{LED} = R_F + \left[\beta_i^{mkt}(RMRF)\right] + \left[\beta_i^{size}(SMB)\right] + \left[\beta_i^{value}(HML)\right]$$

r_{LED} = 0.02 + [1.5 (0.06)] + [–0.1 (0.05)] + [0.5 (0.04)]

r_{LED} = 0.02 + 0.09 – 0.005 + 0.02 = 0.125 = 12.5%

A is incorrect because the risk-free rate is omitted from the calculation:

r_{LED} = [15 (0.06)] + [–0.1 (0.05)] + [0.5 (0.04)] = 0.09 – 0.005 + 0.02 = 0.105 = 10.5%

C is incorrect because the expected return on the market is used (that is, 0.02 + 0.06 = 0.08) instead of the market risk premium of 0.06, and the risk-free rate is omitted from the calculation:

r_{LED} = [1.5 (0.08)] + [–0.1 (0.05)] + [0.5 (0.04)] = 0.12 – 0.005 + 0.02 = 0.135 = 13.5%

22 B is correct. The required return for LED Light using Approach 3 (bond yield plus risk premium approach) is calculated as follows:

Required rate of return = Expected long-term yield + Equity risk premium

Required rate of return = 0.04 + 0.065 = 0.105 = 10.5%

A is incorrect because the risk-free rate is added to the equity risk premium. The premium should be relative to the company's long-term debt, not the risk-free rate.

Required rate of return on share i = 0.02 + 0.065 = 0.085 = 8.5%

C is incorrect because the beta has been incorrectly multiplied by the equity risk premium before being added to LED Light's long-term bond yield:

Required rate of return on share i = 0.04 + (1.35 × 0.065) = 0.12775 ≈ 12.8%

23 B is correct. The after-tax WACC for LED Light is calculated as:

$$WACC = \frac{MVD}{MVD + MVCE} r_d\left(1 - t) + \frac{MVCE}{MVD + MVCE}\right) r_e$$

Given LED Light's debt-to-equity ratio of 0.5, the weight of debt capital is 0.5/1.5, and the weight of equity common equity capital is 1.0/1.5.

$$WACC = \left[\left(\frac{0.5}{0.5+1.0}\right)0.04(1-0.30)\right] + \left[\left(\frac{1.0}{0.5+1.0}\right)0.14\right]$$

$$WACC = 0.009333 + 0.09333 = 0.102666 \approx 10.3\%$$

A is incorrect because the wrong capital weights are used (the given debt-to-equity ratio of 0.5 is treated as equal weights):

$$WACC = [(0.5)\ 0.04\ (1 - 0.30)] + [(0.5)\ 0.14]$$

$$WACC = 0.014 + 0.07 = 0.084000 = 8.4\%$$

C is incorrect because the adjustment for the after-tax cost of debt is omitted, resulting in an overstatement of the cost of debt and the weighted average cost of capital:

$$WACC = \left[\left(\frac{0.5}{0.5+1.0}\right)0.04\right] + \left[\left(\frac{1.0}{0.5+1.0}\right)0.14\right]$$

$$WACC = 0.01333 + 0.09333 = 0.10666 \approx 10.7\%$$

24 B is correct. The equity risk premium estimate based on the GGM equity risk premium approach is calculated as:

GGM equity risk premium estimate = Dividend yield on the market index based on one-year-ahead aggregate forecasted dividends and aggregate market value + consensus long-term earnings growth rate – current long-term government bond yield

GGM equity risk premium estimate = 2.3% + 5.9% – 2.8% = 5.4%

A is incorrect because the expected growth rate in the P/E ratio of 0.1% (inserted in the equation as 1.1% based on its treatment in the Ibbotson and Chen forward-looking, supply-side estimate equation) is incorrectly subtracted:

GGM equity risk premium estimate = 2.3% + 5.9% – 1.1% – 2.8% = 4.3%

C is incorrect because the expected growth rate in the P/E ratio of 0.1% (inserted in the equation as 1.1% based on its treatment in the Ibbotson and Chen forward-looking, supply-side estimate equation) is incorrectly added, and the long-term government bond yield of 2.8% is incorrectly omitted:

GGM equity risk premium estimate = 2.3% + 5.9% + 1.1% = 9.3%

EQUITY VALUATION

STUDY SESSION

9

Equity Valuation (2)

This study session focuses on financial modeling including the development of forecast model inputs using available industry and corporate information. Approaches for analyzing key balance sheet, income, and cash flow statement items are presented. Other factors affecting financial forecasts such as competition, inflation, deflation, and technology are considered. An example using pro forma financial statements to build a financial model is shown. The session ends with coverage of discounted cash flow (DCF) valuation models and an emphasis on the dividend discount model (DDM).

READING ASSIGNMENTS

Reading 22	Industry and Company Analysis by Matthew L. Coffina, CFA, Anthony M. Fiore, CFA, and Antonius J. van Ooijen, MSc, CFA
Reading 23	Discounted Dividend Valuation by Jerald E. Pinto, PhD, CFA, Elaine Henry, PhD, CFA, Thomas R. Robinson, PhD, CFA, CAIA, and John D. Stowe, PhD, CFA

Industry and Company Analysis

by Matthew L. Coffina, CFA, Anthony M. Fiore, CFA, and Antonius J. van Ooijen, MSc, CFA

Matthew L. Coffina, CFA, is at Morningstar Investment Management LLC (USA). Anthony M. Fiore, CFA, is at Silvercrest Asset Management (USA). Antonius J. van Ooijen, MSc, CFA, is at APG Asset Management (Netherlands).

LEARNING OUTCOMES

Mastery	*The candidate should be able to:*
☐	**a.** compare top-down, bottom-up, and hybrid approaches for developing inputs to equity valuation models;
☐	**b.** compare "growth relative to GDP growth" and "market growth and market share" approaches to forecasting revenue;
☐	**c.** evaluate whether economies of scale are present in an industry by analyzing operating margins and sales levels;
☐	**d.** demonstrate methods to forecast the following costs: cost of goods sold, selling general and administrative costs, financing costs, and income taxes;
☐	**e.** describe approaches to balance sheet modeling;
☐	**f.** describe the relationship between return on invested capital and competitive advantage;
☐	**g.** explain how competitive factors affect prices and costs;
☐	**h.** evaluate the competitive position of a company based on a Porter's five forces analysis;
☐	**i.** explain how to forecast industry and company sales and costs when they are subject to price inflation or deflation;
☐	**j.** evaluate the effects of technological developments on demand, selling prices, costs, and margins;
☐	**k.** explain considerations in the choice of an explicit forecast horizon;
☐	**l.** explain an analyst's choices in developing projections beyond the short-term forecast horizon;
☐	**m.** demonstrate the development of a sales-based pro forma company model.

1 INTRODUCTION AND INCOME STATEMENT MODELING: REVENUE

a compare top-down, bottom-up, and hybrid approaches for developing inputs to equity valuation models;

b compare “growth relative to GDP growth” and “market growth and market share” approaches to forecasting revenue;

Industry and company analysis is a key step in the process of valuing companies and the securities they have issued. We will focus on how analysts use industry information and corporate disclosures to forecast a company’s future financial results.

Financial forecasts are the basis for fundamental equity valuation based on discounted cash flows and/or market multiples. An effective forecast model must be based on a thorough understanding of a company’s business, management, strategy, external environment, and historical results. Thus, an analyst begins with a review of the company and its environment—its industry, key products, strategic position, management, competitors, suppliers, and customers. Using this information, an analyst identifies key revenue and cost drivers and assesses the likely impact of relevant trends, such as economic conditions and technological developments. An analyst’s understanding of the fundamental drivers of the business and an assessment of future events provide a basis for developing inputs to the forecast model.

We begin our discussion with an overview of developing a forecast model. We then describe the general approach to forecasting each component of the income statement (revenue, operating costs, and non-operating costs), balance sheet, and cash flow statement. We then turn to special topics: the impact of competitive factors on prices and costs; the effects of inflation and deflation; technological developments; long-term forecasting; and building a company model. We then conclude and present a summary.

1.1 Financial Modeling: An Overview

For most companies, financial modeling begins with the income statement. The income statement is a logical starting point because most companies derive the majority of their value from future cash flow generation, which is primarily determined by the amount of net income generated by the business. Exceptions include banks and insurance companies, for which the value of existing assets and liabilities on the balance sheet may be more relevant to the companies’ overall value than projected future income. The income statement also provides a useful starting point for modeling a company’s balance sheet and cash flow statement.

1.1.1 *Income Statement Modeling: Revenue*

Most companies receive revenue from multiple sources. For analyzing revenue, segment disclosures in companies’ financial reports are often the richest source of information. Both International Financial Reporting Standards (IFRS) and US Generally Accepted Accounting Principles (US GAAP) require companies to disclose certain information about business segments. This information includes how segments are defined; segment revenues, expenses, assets, and liabilities; analysis of revenue by geographical area; and reconciliation of segment accounts to the consolidated financial statement. According to accounting standards, separate financial information must be provided for any segment whose revenue, operating income, or assets account for 10% or more of the revenue, operating income, or assets of the combined company. In addition to the interim and annual financial reports issued by the company, important information can often be found in other disclosures, such as regulatory filings, management presentations, and conference calls, as well as in external data sources.

Revenue can be analyzed by geographical source, business segment, or product line. In a geographic analysis, the analyst places a company's revenue into various geographic "buckets" (groupings). These buckets may be narrowly defined, such as by individual countries, or more broadly defined, such as by region of the world. A geographic analysis can be particularly useful for global companies operating in multiple countries with different underlying growth rates or competitive dynamics. For example, a company may be experiencing relatively slow growth in one region of the world and relatively fast growth in other regions. By examining each region of the world separately, analysts can enhance their understanding of overall growth.

In a breakdown by segment, the analyst classifies a company's revenue into various business segments. Many companies operate in more than one industry or market niche with widely differing economics. Although information is often available for the different business segments, analysts should make an independent judgment about whether a company's chosen segmentation of its business is relevant and material. Sometimes analysts can regroup reported information in a manner that helps make important points.

Finally, a product line analysis provides the most granular level of detail. A product line analysis is most relevant for a company with a manageably small number of products that behave differently, but when combined, they account for most of the company's sales.

Example 1 introduces the first of many examples and exhibits that we use. Please note that many numbers have been rounded; so, in replicating results based on the numbers given in the text and exhibits, small apparent discrepancies may reflect the rounding error.

EXAMPLE 1

Analysis of Revenue (1)

Novo Nordisk is a Denmark-based biopharmaceutical company with a focus on diabetes drugs. The company provides detailed disclosure of revenue along geographic, business segment, and product lines. All figures are in millions of Danish krone (DKK).

In its 2018 annual report, Novo Nordisk provided the following geographic breakdown of sales for the previous three years.

Exhibit 1 Novo Nordisk's Sales by Geographic Region (DKK millions)

	2016	2017	2018
North America	59,242	58,009	56,908
Europe	20,682	21,189	21,679
Latin America	3,593	3,699	4,009
Japan and Korea	6,225	6,072	5,797
China	10,458	10,709	11,285

(continued)

Exhibit 1 (Continued)

	2016	2017	2018
AAMEO (Africa, Asia, Middle East, and Oceania)	11,580	12,018	12,153
Total Sales	111,780	111,696	111,831

The company also classified revenue into business segments it defined: diabetes care (including obesity products) and biopharmaceuticals. Within each segment, disclosure on several individual product lines was also provided.

Exhibit 2 Novo Nordisk's Sales by Business Segment (DKK millions)

	2016	2017	2018
Modern insulins	51,969	53,047	50,391
Human insulins	10,745	9,793	9,265
GLP-1	20,046	23,173	26,129
Other diabetes products	4,612	4,302	4,250
Obesity products	1,577	2,562	3,869
Total diabetes & obesity care	88,949	92,877	93,904
Haemophilia products	10,472	10,469	9,576
Growth disorder products	8,770	6,655	6,834
Other biopharmaceuticals	3,589	1,695	1,517
Total biopharmaceuticals	22,831	18,819	17,927
Total Sales	111,780	111,696	111,831

The company also reported that in local currencies (excluding the impact of exchange rate changes on the figures reported in DKK terms), overall sales rose 5% and the total diabetes and obesity care segment grew 6%.

Use the data in Exhibit 2 to answer the following questions:

1 Modern insulins provide certain advantages over the more traditional human insulins, such as having a faster or longer-lasting effect on blood sugar levels. GLP-1 analogs are even newer products that help the human body produce more insulin. Compare Novo Nordisk's recent sales growth rate of GLP-1 products with those of modern insulins and human insulins.

2 How did Novo Nordisk's sales breakdown change over the last two years? How did the relative contributions from diabetes care and biopharmaceuticals change?

Solution to 1:

Between 2016 and 2018, Novo Nordisk's sales of modern insulins dropped slightly: 50,391/51,969 – 1 ≈ -0.03 or 3%.. Human insulin sales dropped more substantially: 9,265/10,745 – 1 ≈ 0.138 or 13.8%. In contrast, sales of GLP-1 analogs grew by 26,129/20,046 -1 ≈ 30.3% between 2016 and 2018. To calculate a compound annual growth rate, take $(26,129/20,046)^{1/2} - 1 = 0.142$ or 14.2%.

Solution to 2:

In the past two years, Novo Nordisk's total sales remained broadly unchanged (in the reporting currency Danish krone, DKK). Diabetes care and obesity segment increased as a percentage of the total from 80% (88.9 bn/111.8 bn) to 84% (93.9 bn/111.8 bn), while biopharmaceuticals' share of revenue declined from 20% (22.8 bn/111.8 bn) to 16% (17.9 bn/111.8 bn).

Once the analyst has an understanding of the important components of a company's revenue, he must decide whether to use a top-down, bottom-up, or hybrid approach to projecting future revenue. A **top-down approach** usually begins at the level of the overall economy. Forecasts can then be made at more narrowly defined levels, such as sector, industry, and market for a specific product, to arrive at a revenue projection for the individual company. In contrast, a **bottom-up approach** begins at the level of the individual company or a unit within the company, such as individual product lines, locations, or business segments. Analysts then aggregate their projections for the individual products or segments to arrive at a forecast of total revenue for the company. Moreover, analysts also aggregate their revenue projections for individual companies to develop forecasts for a product market, industry, or the overall economy. A **hybrid approach** combines elements of both top-down and bottom-up analysis and can be useful for uncovering implicit assumptions or errors that may arise from using a single approach.

1.1.1.1 Top-Down Approaches to Modeling Revenue Two common top-down approaches to modeling revenue are "growth relative to GDP growth" and "market growth and market share."

In a growth relative to GDP growth approach, the analyst first forecasts the growth rate of nominal gross domestic product. The analyst then considers how the growth rate of the specific company being examined will compare with nominal GDP growth. The analyst may use a forecast for real GDP growth to project volumes and a forecast for inflation to project prices. Analysts often think in terms of percentage point premiums or discounts derived from a company's position in the industrial life cycle (e.g., embryonic, growth, shakeout, mature, or decline) or business cycle sensitivity. Thus, an analyst's conclusion may be that a health care company's revenue will grow at a rate of 200 bps above the nominal GDP growth rate. The forecast may also be in relative terms. Thus, if GDP is forecast to grow at 4% and the company's revenue is forecast to grow at a 15% faster rate, the forecast percent change in revenue would be 4% × (1 + 0.15) = 4.6%, or 60 bps higher in absolute terms.

In a market growth and market share approach, the analyst first forecasts growth in a particular market. The analyst then considers the company's current market share and how that share is likely to change over time. For example, if a company is expected to maintain an 8% market share of a given product market and the product market is forecast to grow from €18.75 billion to €20 billion in annual revenue, the forecast growth in company revenue is from a level of 8% × €18.75 billion = €1.5 billion to a level of 8% × €20 billion = €1.6 billion (considering this product market alone). If the product market revenue has a predictable relationship with GDP, regression analysis might be used to estimate the relationship.

1.1.1.2 Bottom-Up Approaches to Modeling Revenue Examples of bottom-up approaches to modeling revenue include the following:

- *Time series*: forecasts based on historical growth rates or time-series analysis.
- *Return on capital*: forecasts based on balance sheet accounts. For example, interest revenue for a bank may be calculated as loans multiplied by the average interest rate.
- *Capacity-based measure:* forecasts, for example, in retailing, based on same-store sales growth (for stores that have been open for at least 12 months) and sales related to new stores.

Time-series forecasts are among the simplest. For example, analysts may fit a trend line to historical data and then project sales over the desired time frame (e.g., using Excel's TREND formula). In such a case, analysts would be projecting historical growth rates to continue, but they might also use different assumptions—for example, they may project growth to decline linearly from current rates to some long-run rate. Note that time-series methods may also be used as tools in executing a top-down analysis, such as projecting GDP growth in a growth relative to GDP growth approach.

1.1.1.3 Hybrid Approaches to Modeling Revenue Hybrid approaches combine elements of both top-down and bottom-up analysis, and in practice they are the most commonly used approaches. For example, the analyst may use a market growth and market share approach to model individual product lines or business segments. Then, the analyst may aggregate the individual projections to arrive at a forecast for the overall company because the sum of forecast segment revenue equals the segment market size multiplied by the market share for all segments.

In a volume and price approach, the analyst makes separate projections for volumes (e.g., the number of products sold or the number of customers served) and average selling price. Depending on how these elements are forecast, this approach can be classified as top-down, bottom-up, or hybrid.

EXAMPLE 2

Analysis of Revenue (2)

Use the data in Example 1 on Novo Nordisk to answer the following questions:

1 Xiaoping Wu is an equity analyst covering European pharmaceutical companies for his clients in China. Wu projects that global nominal GDP will grow 3% annually over the long run, based on 2% real growth and 1% inflation. The incidence of diabetes is increasing globally because of increasingly unhealthy diets and sedentary lifestyles. As a result, Wu believes global sales of diabetes drugs will grow 100 bps faster than nominal GDP over the long run. Wu believes the revenue growth rate of Novo Nordisk's diabetes care segment will match the projected long-run growth rate of the diabetes drug market.

   A Is Wu using a top-down, bottom-up, or hybrid approach to modeling Novo Nordisk's revenue?

   B Based on Wu's projections for revenue growth, calculate the estimated revenue growth rate for the diabetes care segment in 2020. Assume no impact from exchange rate changes.

2 Helga Hansen is a buy-side analyst in Denmark. In 2019, Hansen was investigating Ozempic, a compound launched in 2018, in a class of diabetes drugs called GLP-1 analogs. As of 2019, Ozempic is one of several

products on the market, offered alongside Novo Nordisk's existing GLP-1 drug Victoza and competing with dulaglutide (Trulicity) by Eli Lilly and exenatide (brands Byetta & Bydureon) by AstraZeneca.

Eli Lilly and AstraZeneca reported global sales of their products in US dollars. Hansen converted the reported figures to euros using the annual average USD/EUR, GBP/EUR, and DKK/EUR exchange rates and compiled the following table comparing sales of the different GLP-1 products measured in millions of euros.

Compound/brand	Company	2016	2017	2018
Exenatide (Byetta & Bydureon)	AstraZeneca	751	664	601
Victoza	Novo Nordisk	2,692	3,115	3,264
Ozempic	Novo Nordisk	0	0	241
Dulaglutide (Trulicity)	Eli Lilly	836	1,796	2,709
Albiglutide (Tanzeum)	GSK	99	76	0

A What was the growth rate in total GLP-1 analog sales in 2018?

B What percentage of GLP-1 analog sales growth in 2018 was caused by Ozempic?

C A year earlier, Hansen projected that the growth rate of the GLP-1 analog market would slow to 18% in 2018. She also expected Trulicity to improve its market share by 10 percentage points. What was Hansen's estimate of 2018 Trulicity sales? How close was she to the actual result?

D Is Hansen's approach to modeling Novo Nordisk's sales best described as bottom-up, top-down, or hybrid?

Solution to 1A:

Wu's long-run revenue projections are based on Novo Nordisk's growth relative to nominal GDP growth, which is a top-down approach. However, his estimated growth rate is applied to only one of Novo Nordisk's segments (diabetes care), indicating a hybrid approach. Wu's four-year forecasts are also based in part on the historical growth rate of the diabetes care segment, which is a bottom-up approach. Wu is thus using a hybrid approach.

Solution to 1B:

The data in Example 1 indicate that Novo Nordisk's diabetes and obesity care segment grew approximately 1% in 2018 in DKK terms (= 93.90/92.88 − 1 ≈ 0.010) and, importantly, 6% in local currencies. Wu projects the long-run growth rate to be in line with the diabetes drug market growth at 4% (100 bps faster than GDP growth of 3%). The difference between the 2018 growth rate and projected long-run growth rate is 2% (= 6% − 4%), and Wu expects the modest deceleration in growth to occur linearly over four years, implying a reduction of 50 bps per year in the growth rate. The estimated growth rates by year are thus

2019 = 5.5%

2020 = 5%

2021 = 4.5%

2015 = 4%

Thereafter, 4%

The estimated revenue growth rate for 2020 is 5%.

Solution to 2A:

Total sales of GLP-1 analogs in 2018 were €6,815million (= 601 + 3,264 + 241 + 2,709), compared with total 2017 sales of €5,651million (= 664 + 3,115 +1,796 + 76). The growth rate was thus around 20.6% (= 6,815/5,651 − 1 ≈ 0.206).

Solution to 2B:

Total GLP-1 analog sales increased by €1,164 million (from €5,651 million to €6,815 million). The newly-launched Ozempic achieved sales of €241 million (starting from zero). So, Ozempic accounted for approximately 21% of the growth in sales of this drug class (= 241/1,164 ≈ 0.207, or 20.7%). Note that the figure for Trulicity was 78% (914/1,164 = 0.784).

Solution to 2C:

Based on 2017 sales of €5,651 million and a projected growth rate of 18%, Hansen projected the total GLP-1 analog market to be worth about €6,668 million in 2018 (= 5,651 × 1.18 ≈ 6,668). Trulicity's market share in 2017 was around 32%, which Hansen projected to improve by 10 percentage points, resulting in a 42% market share in 2018. Hansen thus projected 2018 Trulicity sales to be around €2,800 million (= 6,668 × 0.42 ≈ 2,800). Actual Trulicity sales in 2018 were €2,709 million, so Hansen's estimate was too high by €91 million (= 2,800 − 2,709 = 91).

Solution to 2D:

Hansen bases her estimates on market growth and market share, which would normally imply a top-down approach. The analysis, however, is applied to an individual product line, implying a bottom-up approach. Therefore, Hansen is using a hybrid approach.

2 INCOME STATEMENT MODELING: OPERATING COSTS

c evaluate whether economies of scale are present in an industry by analyzing operating margins and sales levels;

Disclosure about operating costs is frequently less detailed than disclosure about revenue. If relevant information is available, analysts may consider matching the cost analysis to the revenue analysis. For example, they might model costs separately for different geographic regions, business segments, or product lines. More frequently, analysts will be forced to consider costs at a more aggregated level than the level used to analyze revenue. Analysts should still keep in mind their revenue analysis when deriving cost assumptions. For instance, if a relatively low-margin product is expected to grow faster than a relatively high-margin product, analysts should project some level of overall margin deterioration, even if they are not certain about the precise margins earned on each product.

Once again, analysts can take a top-down, bottom-up, or hybrid view of costs. In a top-down approach, analysts may consider such factors as the overall level of inflation or industry-specific costs before making assumptions about the individual company. In contrast, in a bottom-up approach analysts would start at the company level, considering such factors as segment-level margins, historical cost growth rates, historical margin levels, or the costs of delivering specific products. A hybrid approach would incorporate both top-down and bottom-up elements.

When estimating costs, analysts should pay particular attention to fixed costs. Variable costs are directly linked to revenue growth, and they may be best modeled as a percentage of revenue or as projected unit volume multiplied by unit variable costs.

By contrast, increases in fixed costs are not directly related to revenue; rather, they are related to future investment in property, plant, and equipment (PP&E) and to total capacity growth. Practically, fixed costs may be assumed to grow at their own rate, based on an analysis of future PP&E growth. Analysts should determine whether, at its current level of output, the subject company has **economies of scale**, a situation in which average costs per unit of a good or service produced fall as volume rises. Factors that can lead to economies of scale include, at higher levels of production, greater bargaining power with suppliers, lower cost of capital, and lower per unit advertising expenses. Gross and operating margins tend to be positively correlated with sales levels in an industry that enjoys economies of scale.

Analysts must also be aware of any uncertainty surrounding estimates of costs. For example, banks and insurance companies create reserves against estimated future losses, while companies with large pension plans have long-duration liabilities, the true costs of which may not be known for many years. A review of disclosures about reserving practices related to future obligations and pensions can be helpful in assessing whether cost estimates are reasonable. But most of the time it is difficult for the external analyst to anticipate future revisions to cost estimates. Other aspects affecting the uncertainty of cost estimates include competitive factors and technological developments. This impact will be discussed in later sections.

EXAMPLE 3

Approaches to Modeling Operating Costs

Walgreens (full name Walgreens Boots Alliance Inc) and Rite Aid are two of the largest retail drugstore chains in the United States. For both companies, around two-thirds of their sales are from prescription pharmaceuticals, with the remaining third coming from front-of-store categories, such as beauty and wellness products and services, over-the-counter drugs, convenience foods, and administration of immunizations.

Although they are in the same industry and both operate predominantly in the United States, Walgreens and Rite Aid have very different operating margins. There is reason to believe that economies of scale exist in the drugstore business. For example, larger drugstore companies have greater bargaining leverage with suppliers and the ability to negotiate better reimbursement rates with third-party payers. Some relevant data are presented in Exhibit 3. The last column on the right includes results from the companies' 2018 fiscal year (ended in August 2018 for Walgreens and March 2018 for Rite Aid).

Exhibit 3 Financial Results for Walgreens and Rite Aid

	2016	2017	2018
Walgreens			
Revenue ($ millions)	117,351	118,214	131,537
Cost of goods sold ($ millions)	87,477	89,052	100,745

(continued)

Exhibit 3 (Continued)

	2016	2017	2018
Selling, general, and administrative ($ millions)	23,661	23,751	24,764
Operating income ($ millions)	6,001	5,557	6,414
End of period selling area square footage (millions sq. ft.)	112	112	150
Average selling area (millions sq. ft)	112	112	131
Same-store pharmacy sales growth	3.2%	3.1%	3.4%
Rite Aid			
Revenue ($ millions)	20,770	22,928	21,529
Cost of goods sold ($ millions)	15,778	17,863	16,749
Selling, general, and administrative ($ millions)	4,581	4,777	4,651
Operating income ($ millions)	337	242	133
End of period selling area square footage (millions sq. ft.)	45.2	44.9	26.8
Average selling area square footage (millions sq. ft.)	45.5	45.1	35.9
Same-store pharmacy sales growth	1.3%	-2.2%	-2.9%

(*Sources:* Rite Aid Form 10-K, Walgreens Alliance Boots 10-K, and www.ft.com.)

Customer service may be one driver of revenue for the retail drug business. Retail analysts commonly use a combination of qualitative and quantitative evidence to assess customer service. Qualitative evidence might come from personal store visits or customer surveys. Quantitative evidence may be based on such metrics as selling, general, and administrative (SG&A) expense per square foot. Too little spending on SG&A might indicate that stores are understaffed. Relatedly, same-store sales growth may be an indicator of customer satisfaction.

Use the data given to answer the following questions:

1 On the basis of the 2018 operating margins for Walgreens and Rite Aid, is there evidence suggesting that economies of scale exist in the retail drugstore business? If so, are economies of scale realized in cost of goods sold or SG&A expenses?

2 Marco Benitez is a US-based equity analyst with an independent research firm. Benitez is researching service levels in the US drugstore industry.

   A Calculate and interpret Walgreens' and Rite Aid's SG&A per average square foot for 2018 and 2016.

   B Assuming that customer satisfaction is a driver of sales growth, which company appears to have a more satisfied customer base over the period examined?

   C Benitez projects that Rite Aid's average selling area square footage will increase 2% annually over the next three years. He believes SG&A per average square foot will decrease 1% annually during this time. What is Benitez's projection for total SG&A expense in 2021?

3 Jason Lewis is another US-based equity analyst covering the retail drugstore industry. He is considering several approaches to forecasting Walgreens' and Rite Aid's' future costs. Classify each of the following as a bottom-up, top-down, or hybrid approach.

A Lewis believes government insurance programs in the United States will face budgetary pressures in the future, which will result in lower reimbursements across the retail drugstore industry. Lewis thinks this will lower all drugstores' gross margins.

B Lewis projects that Walgreens' historical rate of growth in SG&A expenses will continue for the next five years. But in the long-run, he projects SG&A to grow at the rate of inflation.

C To estimate Rite Aid's future lease expense, Lewis makes assumptions about square footage growth and average rent per square foot, based on past experience.

Solution to 1:

Walgreens 2018 operating margin (operating income divided by revenue) was 4.9% (= 6,414/131,537 ≈ 0.049). Rite Aid's operating margin in the comparable year was 0.6% (= 133/21,529 ≈ 0.006). Walgreens' much larger size ($131.5 bn in sales versus $21.5 bn for Rite Aid) combined with its much higher profitability provides evidence suggesting that there are economies of scale in the drugstore industry.

To answer the second part of the question, divide both companies' expense lines by revenue for 2018. Walgreens' cost of goods sold consumed 76.6% (≈ 100,745/131,537) of revenue, whereas Rite Aid's cost of goods sold consumed 77.8% (≈ 16,749/21,529). Walgreens' SG&A consumed 18.8% (≈ 24,764/131,537) of revenue, whereas Rite Aid's SG&A consumed 21.6% (≈ 4,651/21,529). The results indicate that there are economies of scale in both cost of goods sold and SG&A.

Solution to 2A:

Walgreens' average SG&A per square foot in 2018 and 2016 were $189 (≈ 24,764/131) and $211 (≈ 23,661/112), respectively. That is a decrease of approximately 10%. The same figures for Rite Aid were $129.6 (≈ 4,651/35.9) in 2018 and $100.7 (≈ 4,581/45.5) in 2016, an increase of 28.7%. The difference in the levels of SG&A per sq. ft. might be evidence of higher service levels at Walgreens compared to Rite Aid. Note that the change between 2016 and 2018 can be mostly attributed to acquisitions and disposals that the companies have been involved in.

Solution to 2B:

Walgreens appears to have the more satisfied customer base, considering just same-store sales. Comparing same-store sales growth for the two companies, Walgreens has consistently outperformed Rite Aid in the past three years. This result supports the hypothesis that Rite Aid's customers may be less satisfied than Walgreens' customers over the time period examined.

Solution to 2C:

Benitez projects Walgreens' selling area will be around 159 million square feet [= 150×1.02^3] by the end of fiscal 2021. He projects SG&A per average square foot will be $183.4 [= $189 \times (0.99)^3$]. He thus estimates total SG&A to be $29,160 million (159 × 183.4) in 2021.

Solution to 3A:

This case describes a top-down approach because Lewis considers the overall industry environment before individual companies.

Solution to 3B:

In this case, Lewis combines a bottom-up approach (projecting the historical rate of growth to continue) with a top-down approach (basing his long-run assumptions on the overall rate of inflation). Therefore, this is a hybrid approach.

Solution to 3C:

This case describes a bottom-up approach because Lewis bases his forecasts on Rite Aid's historical experience.

3 MODELING OPERATING COSTS: COGS AND SG&A

d demonstrate methods to forecast the following costs: cost of goods sold, selling general and administrative costs, financing costs, and income taxes;

The cost of goods sold (COGS) is typically the single largest cost for manufacturing and merchandising companies. For a manufacturer, COGS include raw materials along with the direct labor and overhead used in producing the goods.

Because sales minus COGS equals gross margin, COGS and gross margin vary inversely. Forecasting COGS as a percentage of sales and forecasting gross margin percentage are equivalent in that a value for one implies a value for the other.

Because COGS has a direct link with sales, forecasting this item as a percentage of sales is usually a good approach. Historical data on a company's COGS as a percentage of sales usually provide a useful starting point for estimates. For example, if a company is losing market share in a market in which the emergence of new substitute products are also putting the overall sector under pricing pressure, gross margins are likely to decline. But if the company is gaining market share because it has introduced new competitive and innovative products, especially if it has done so in combination with achieving cost advantages, gross margins are likely to improve.

Because cost of goods sold is relatively a large cost, a small error in this item can have a material impact on the forecasted operating profit. Thus, analysts should consider whether an analysis of these costs (e.g., by segment, by product category, or by volume and price components), when such an analysis is possible, can improve forecasting accuracy. For example, some companies face fluctuating input costs that can be passed on to customers only with a time lag. Particularly for companies that have low gross margins, sudden shocks in input costs can affect operating profit significantly. A good example is the sensitivity of airlines' profits to unhedged changes in jet fuel costs. In these cases, a breakdown of both costs and sales into volume and price components is essential for developing short-term forecasts, even if analysts use the overall relationship between sales and input cost for developing longer-term forecasts.

Analysts should also consider the impact of a company's hedging strategy. For example, commodity-driven companies' gross margins almost automatically decline if input prices increase significantly because of variable costs increasing at a faster rate than revenue growth. Assume a company's cost of goods sold as a percentage of sales equals 25%. If the input costs double and the company is able to pass the entire increase on to its clients through a 25% price increase, cost of goods sold as a percentage of sales will increase (to 40%) because an equal absolute amount has been added to the numerator and to the denominator. Thus, although the absolute amount of gross profit will remain constant, the gross margin will decrease (from 75% to 60%). Through various hedging strategies a company can mitigate the impact on profitability. For example, brewers often hedge the cost of barley, a key raw material needed for brewing beer, one year in advance. Although companies usually do not disclose their hedging positions, their general strategy is often revealed in the footnotes of the annual report. Further, the negative impact of increasing sales prices on sales volume can be mitigated by a policy of gradual sales price increases. For example, if the brewer expects higher barley prices because of a bad harvest, the brewer can slowly increase prices to avoid a strong price jump next year.

Competitors' gross margins can also provide a useful cross check for estimating a realistic gross margin. Gross margin differences among companies within a sector should logically relate to differences in their business operations. For example, in the Netherlands, supermarket chain Albert Heijn has a higher gross margin in the very competitive grocery sector because it can leverage its dominant 35% market share to achieve savings in purchases; it also has an ability to make higher margin private label products. All of these competitive advantages contribute to its structurally higher gross margin within the grocery sector. But if a new large competitor emerges (e.g., through consolidation of the fragmented market), Albert Heijn's above average gross margin could come under pressure. Also note that differences in competitors' gross margins does not always indicate a superior competitive position but instead could simply reflect differences in business models. For example, some companies in the grocery segment own and operate their own retail stores whereas other companies operate as wholesalers with franchised retail operations. In the franchised retailing business model, most of the operating costs are incurred by the franchisee; the wholesaler offers products with only a small markup to these franchisees. Compared with a grocer with its own stores, a supermarket wholesaler will have a much lower gross margin. The grocer with its own stores, however, will have much higher operating costs. Even though differences in business models can complicate direct comparisons, competitors' gross margins can nonetheless offer potentially useful insights.

3.1 Selling, General, and Administrative Expenses

Selling, general, and administrative (SG&A) expenses are the other main type of operating costs. In contrast to COGS, SG&A expenses have less of a direct relationship with the revenue of a company. As an illustration of the profit impact of COGS and SG&A, consider Thai cement and building materials company Siam Cement Group. A summary of its key income statement items is shown in Exhibit 4.

Exhibit 4 Siam Cement Group Financials

	2017 (Baht billions)	2018 (Baht billions)	YoY%	Percent of Sales 2017	Percent of Sales 2018
Net sales	450.92	478.44	6.1	100.0	100.0
Cost of goods sold	349.31	383.46	9.8	77.5	80.1
Gross profit	101.61	94.98	-6.5	22.5	19.9
SG&A	52.58	55.09	4.8	11.7	11.5
Selected SG&A items:					
Salary & personnel expenses	24.24	23.98	-1.0	5.4	5.0

(continued)

Exhibit 4 (Continued)

	2017 (Baht billions)	2018 (Baht billions)	YoY%	Percent of Sales 2017	Percent of Sales 2018
Freight costs	11.63	11.55	-0.6	2.6	2.4
Research & development	4.18	4.67	11.9	0.9	1.0
Promotion and advertising	2.62	2.58	-1.3	0.6	0.5
Operating income	62.4	51.7	-17.1	13.8	10.8

Note: "YoY%" means year-over-year percentage change.
Sources: Based on information in Siam Cement Group's annual reports.

As shown in the exhibit, Siam Cement was affected in 2018 by higher input costs that could not be fully passed on to customers. Consequently, despite reporting sales growth of 6.1%, gross profit fell by 6.5% and gross margin declined. The company was able to limit its other operating costs; SG&A expenses grew 4.8%, declining slightly as a percentage of revenue. Operating income fell 17.1%. This contrasted with the company's experience in 2016, when lower input costs resulted in widening of the gross margin to 24.7% from 22.3% in 2015 (not shown in the exhibit above).

Siam Cement's income statement illustrates that companies often disclose the different components of SG&A expenses. Siam Cement, for example, shows separate line items for a number of distribution cost items, such as freight and rental expenses, and a number of general and administrative expenses, such as depreciation, IT fees, professional fees, and research and development. Although SG&A expenses overall are generally less closely linked to revenue than COGS, certain expenses within SG&A are more variable than others. Specifically, selling and distribution expenses often have a large variable component and can be estimated, like COGS, as a percentage of sales. The largest component of selling expenses is often wages and salaries linked to sales. Therefore, selling expenses will usually increase with additional sales people and/or an overall increase in wages and benefits for the sales force.

Other general and administrative expenses are less variable. Overhead costs for employees, for example, are more related to the number of employees at the head office and supporting IT and administrative operations than to short-term changes in the level of sales. Research and development expense is another example of an expense that tends to fluctuate less than sales. Consequently, these expenses are more fixed in nature and tend to increase and decrease gradually over time than do corresponding changes in the company's revenue.

In addition to analyzing the historical relationship between a company's operating expenses and sales, benchmarking a company against its competitors can also be useful. By analyzing the cost structure of a company's competitors, the efficiency potential and margin potential of a specific company can be estimated. As a final measure, performing certain cross checks within a forecast model can be useful too. For example, in the supermarket sector the projected floor square footage (or metric equivalent) underlying the revenue projections should match with the floor space projections underlying the unit selling expense forecasts. Both sales and expense projections may be enhanced if the company provides a breakout of the product and/or geographical segments in the footnotes of the annual report.

EXAMPLE 4

L'Oréal's Operational Cost Structure vs. Competitors

As shown in Exhibit 5, L'Oréal reported an operating margin of 17.9% in 2018, which makes it the most profitable company among a selection of beauty companies. However, the average operating margin of 19.4% for home and personal goods companies operating in mass markets is even greater than that of L'Oréal. Luxury goods companies tend to have higher gross margin than mass market companies, but it is offset by high "go to market" costs for advertising and promotion (A&P) expenditures. With the exception of Avon, the business model of which is based on direct selling, A&P is substantially greater at the beauty companies than at the mass market producers.

L'Oréal is often considered to be a pure beauty company. But if the underlying business is considered in detail, the company's operations can be split 50/50 between a luxury beauty high-end part and a general consumer part. In the general consumer part, L'Oréal's products compete with such players as Colgate, Procter & Gamble, and Henkel in the mass market. Exhibit 5 presents relevant data.

Exhibit 5 European and US Home and Personal Care Companies, Beauty vs. Mass Market Companies: Simplified and Common Size Income Statement (2018)

Company	Sales (in millions for currencies given)	Sales	COGS	Gross Margin	A&P	SG&A/ Other	EBIT
Beauty							
L'Oréal	€26,937	100%	27.2%	72.8%	30.2%	24.7%	17.9%
Estée Lauder	$13,683	100	20.8	79.2	25.6	38.6	15.0
Beiersdorf	€7,233	100	42.5	57.5	21.2	21.0	15.3
Avon	$5,571	100	42.4	57.6	2.3	51.1	4.2
Average beauty		100%	33.2%	66.8%	19.8%	33.9%	13.1%
Mass market							
Colgate	$15,544	100%	40.6%	59.4%	10.2%	25.4%	23.8%
Reckitt Group	£12,597	100	39.4	60.6	12	24.4	24.2
Procter & Gamble	$66,832	100	51.3	48.7	10.6	17.6	20.5
Clorox	$6,124	100	56.3	43.7	9.3	15.9	18.5
Kimberly-Clark	$18,486	100	69.7	30.3	3.5	14.7	12.1
Henkel	€19,899	100	53.5	46.5	22.7	6.2	17.6
Average mass market		100%	51.8%	48.2%	9.4%	19.4%	19.4%

Notes: The COGS and SG&A expense percentages for some of the companies listed in Exhibit 5 have been adjusted to reflect differences in accounting choices. For example, some of the consumer product companies include shipping and handling expenses in cost of sales, whereas others include these costs as a component of SG&A expenses.
Sources: Based on information in company reports.

1 Assuming the following information, what will L'Oréal's new operating margin be?

- L'Oréal's beauty and mass market operations each represent half of revenues.
- L'Oréal will be able to bring the overall cost structure of its mass market operations in line with the average of mass market companies (EBIT = 19.4%).
- The cost structure of L'Oréal's beauty operations will remain stable (assumed EBIT = 17.9%).

2 What will happen to L'Oréal's operating margin if the company is able to adjust the operating cost structure of its mass market segment (50% of revenues) partly toward the average of its mass market peers but keep its high gross margin? Assume the following:

- The cost structure of half of the business, the beauty operations, will remain stable (EBIT = 17.9%).
- L'Oréal's mass market operations will have a gross margin of 60.3% (the average of the current gross margin of 72.8% and the 48.2% reported by its mass market peers).
- L'Oréal's A&P costs will fall by half from 30.2% of sales to 15.1% of sales, and other costs will remain stable.

Solution to 1:

Operating margin will increase from 17.9% to 18.7%, which is 50% of 19.4% (mass market EBIT) plus 50% of 17.9% (L'Oréal EBIT).

Solution to 2:

As shown in Exhibit 6, operating margin will increase from 17.9% to 19.3%. The operating margin of the mass market operations will improve by 170 bps to 20.7% because a 1,230 bps decline in gross margin (from 72.8% to 60.5%) will be more than offset by the 1,510 bps of decline in A&P expenditures (from 30.2% of sales to 15.1% of sales). The average of the EBIT for beauty (17.9%) and the new EBIT for mass market operations (20.7%) is 19.3%.

Exhibit 6 EBIT for L'Oréal Divisions

	L'Oréal	Beauty 50%	Mass Market 50%	Average
Sales	100%	100%	100%	100%
Cost of goods sold	27.2%	27.2%	40.7%	33.4%
Gross margin	72.8%	72.8%	60.5%	66.7%
A&P	30.2%	30.2%	15.1%	22.7%
SG&A/Other	24.7%	24.7%	24.7%	24.7%
EBIT	17.9%	17.9%	20.7%	19.3%

EXAMPLE 5

Analysis of the Consumer Goods Company Unilever

The consumer goods company Unilever reported an overall underlying operating margin of 18.4% in 2018. As shown in Exhibit 7, the operating margin is lowest in the fastest growing product category, home care products. The other parts of the business, personal care and foods categories, enjoy higher margins but are growing more slowly.

Exhibit 7 Unilever Revenue and Profit from Product Categories (€ millions, unless noted)

	2017	2018	18/17 YoY	Avg 2016–2018
Personal Care	20,697	20,624	3.1%	3.0%
Foods	22,444	20,227	2.0	2.4
Home Care	10,574	10,131	4.2	4.3
Total revenues	53,715	50,982	2.9	3.0
Underlying operating profit				
Personal Care	4,375	4,508	3.04%	
Foods	3,737	3,534	−5.4	
Home Care	1,288	1,317	2.25	
Total underlying operating profit	9,400	9,359	−0.4	
Underlying operating profit margin				
Personal Care	121.1%	21.9%		
Foods	16.7	17.5		
Home Care	12.2	13.0		
Total underlying operating profit margin	17.5%	18.4%		

Notes: USG is “underlying sales growth” (i.e., sales growth adjusted for currency, disposals, and acquisitions). USG is the organic sales growth based on volume, price, and mix changes. Underlying profit is operating profit adjusted for exceptional items, like restructuring costs

Source: Based on Unilever’s 2018 full year and fourth quarter results.

1 Determine the estimated sales, operating profit, and operating profit margin by using the following two approaches: (A) Assume consolidated sales growth of 3.0% (the average of the years 2017 and 2018) and overall stable operating margin of 18.4% for the next five years; and (B) assume each individual product’s sales growth and operating margin continue at the same rate reported in 2018. Which approach will result in a higher estimated operating profit after five years?

2 Compare and explain the results under the two alternative approaches described in Question 1 (A and B) with reference to the yearly growth rate in estimated total sales, the yearly growth rate in total operating profit, and the yearly profit margin.

3 Assume Unilever is able to grow revenues the next five years in each category in line with 2018 (Beauty & Personal Care 3.1%; Foods & Refreshments 2.0%; and Home Care 4.2%). But operating profit margins in Beauty and Personal Care will fall 20 bps annually for the next five years (as a result of high competition, limited growth, and costs resulting from the adoption of sustainable packaging) and operating profit margins in Foods & Refreshments and Home Care segments will increase by 15 and 50 bps, respectively, each year for the next five years (helped by increasing demand for the company's products and better utilization of its factories). Using approach (B), calculate the overall operating profit margin.

Solution to 1:

Exhibit 8 shows that operating profit after five years will be €10,850 million under the first approach (A) and €10,771 million under the second approach (B). The results of the calculation are shown in Exhibit 8.

Exhibit 8 Sales and Operating Profit for Unilever, 2018–2023E (€ millions, unless noted)

Approach A	2018	2019E	2020E	2021E	2022E	2023E
Sales	50,982	52,460	53,982	55,547	57,158	58,816
YoY %		3.0%	3.0%	3.0%	3.0%	3.0%

YoY change in underlying profit		2.84%	2.84%	2.85%	2.86%	2.86%
Beauty & Personal Care		21.9%	21.9%	21.9%	21.9%	21.9%
Foods & Refreshments		17.5	17.5	17.5	17.5	17.5
Home Care		13.0	13.0	13.0	13.0	13.0
Total underlying operating margin		18.35%	18.34%	18.33%	18.33%	18.32%

Solution to 2:

Under the first approach (A) a constant 3.0% sales growth rate and a stable 18.4% operating margin are assumed. As a consequence, the operating profit growth rate is in line with the revenue growth rate and constant at 3.0% (see Exhibit 9, Panel A). Under the second approach (see Exhibit 9, Panel B), the high sales growth of 4.2% occurs in the segment with the least amount of sales, Home Care. Because the operating margin in the fastest growing segment is less than the overall average (13.0% vs. 18.4% group average), operating margin for the group falls slightly from 18.4% in 2018 to 18.3% in 2023. This comparison illustrates that the higher sales growth in a lower margin segment puts the company's operating margin under structural pressure. The rate of operating profit growth continues to be slightly less than the rate of sales growth (2.84% vs. 2.88%). Exhibit 9 shows a summary of the sales, operating profit, sales growth, and margin growth.

Exhibit 9 Summary of Results in Exhibit 8

	2018	2019E	2020E	2021E	2022E	2023E
A. Sales and operating profit (€ millions)						
Sales A	50,982	52,511	54,087	55,709	57,381	59,102
Sales B	50,982	52,451	53,967	55,529	57,140	58,802
Sales A–B		60	120	180	240	300
Sales growth A		3.0%	3.0%	3.0%	3.0%	3.0%

Operating profit margin B		18.35%	18.34%	18.33%	18.33%	18.32%

Solution to 3

As shown in Exhibit 10, the overall underlying operating profit margin improves from 18.36% in 2018 to 18.75% in 2023 because the margin decline in Beauty & Personal Care is more than offset by the margin increase in Foods & Refreshments and the faster growing Home Care segments.

MODELING NON-OPERATING COSTS AND OTHER ITEMS

4

d demonstrate methods to forecast the following costs: cost of goods sold, selling general and administrative costs, financing costs, and income taxes;

Line items on the income statement that appear below operating profit also need to be modeled. Some of the most important items included here are interest income, interest expense, taxes, minority interest, and income from affiliates, share count, and unusual charges.

Interest income depends on the amount of cash and investments on the balance sheet as well as the rates of return earned on investments. Interest income is a key component of revenue for banks and insurance companies, but it is relatively less significant to most non-financial companies. Interest expense depends on the level of debt on the balance sheet as well as the interest rate associated with the debt. Analysts should be aware of the effect of changing interest rates on the market value of company's debt and interest expense in the future.

Taxes are primarily determined by jurisdictional regulations but can also be influenced by the nature of a business. Some companies benefit from special tax treatment—for example, from research and development tax credits or accelerated depreciation of fixed assets. Analysts should be aware of any differences between taxes reported on the income statement and cash taxes, which can result in deferred tax assets or liabilities. Analysts should also be aware of any governmental or business changes that can alter tax rates.

The two most significant non-operating expenses in income statement modeling are financing expenses (i.e., interest) and taxes.

4.1 Financing Expenses

When forecasting financing expenses, the capital structure of a company is a key determinant. For practical purposes, the debt level in combination with the interest rate are the main drivers in forecasting debt financing expenses. Usually the notes to the financial statements provide detail about the maturity structure of the company's debt and the corresponding interest rates. This information can be used to estimate future financing expenses.

EXAMPLE 6

Interest Expense Calculations

Dutch grocer Ahold Delhaize, operating in a number of regions, has a debt structure with a relatively high amount of cash on its balance sheet.

Exhibit 11 Ahold's Debt, Interest Income, and Expense

(€ millions)	31 Dec. 2017	30 Dec. 2018	Average
Loans	3,289	3,683	3,486
Other non-current financial liabilities (includes finance leases and cumulative preferred financing shares)	2,098	2,055	2,077
Current financial liabilities	2,210	1,232	1,721
Gross debt	7,597	6,970	7,284
Less: cash, cash equivalents, and short-term financial assets	3,360	5,042	4,201
Net debt	4,237	1,928	3,083
Interest income for 2018			70
Interest expense for 2018			310
Net interest expense			240

Source: Based on information in Ahold Delhaize 2018 annual report.

1 Calculate the interest rate on the average gross debt and interest rate on the average cash position.

2 Calculate the interest rate on the average net debt, assuming the other financial income and expenses are not related to the debt or cash balances.

Solution to 1:

Interest rate on average gross debt is calculated as interest expense divided by average gross debt: (€310 million/€7,284 million) = 4.26% or 4.3%. The interest rate on average cash position is interest income divided by the average cash position (€70 million/€4,201 million) = 1.67%.

Solution to 2:

The interest rate on the average net debt is calculated as net interest expense divided by average net debt (€240 million/€3,083 million) = 7.8%.

4.2 Corporate Income Tax

The final large non-operating item is the tax expense. This is often a large amount that affects profit substantially. Differences in tax rates can be an important driver of value. Generally, there are three types of tax rates:

- The statutory tax rate, which is the tax rate applying to what is considered to be a company's domestic tax base.
- The effective tax rate, which is calculated as the reported tax amount on the income statement divided by the pre-tax income.
- The cash tax rate, which is the tax actually paid (cash tax) divided by pre-tax income.

Differences between cash taxes and reported taxes typically result from timing differences between accounting and tax calculations and are reflected as a deferred tax asset or a deferred tax liability.

In forecasting tax expense and cash taxes, respectively, the effective tax rate and cash tax rate are key. A good understanding of their operational drivers and the financial structure of a company is useful in forecasting these tax rates.

Differences between the statutory tax rate and the effective tax rate can arise for many reasons. Tax credits, withholding tax on dividends, adjustments to previous years, and expenses not deductible for tax purposes are among the reasons for differences. Effective tax rates can differ when companies are active outside the country in which they are domiciled. The effective tax rate becomes a blend of the different tax rates of the countries in which the activities take place in relation to the profit generated in each country. If a company reports a high profit in a country with a high tax rate and a low profit in a country with a low tax rate, the effective tax rate will be the weighted average of the rates and higher than the simple average tax rate of both countries. In some cases, companies have also been able to minimize their taxes by using special purposes entities. For example, some companies create specialized financing and holding companies to minimize the amount of taxable profit reported in high tax rate countries. Although such actions could reduce the effective tax rate substantially, they also create risks if, for example, tax laws change. In general, an effective tax rate that is consistently lower than statutory rates or the effective tax rates reported by competitors may warrant additional attention when forecasting future tax expenses. The notes on the financial statements should disclose other types of items, some of which could contribute to a temporarily high or low effective tax rate. The cash tax rate is used for forecasting cash flows, and the effective tax rate is relevant for projecting earnings on the income statement. In developing an estimated tax rate for forecasts, analysts should adjust for any one-time events. If the income from equity method investees is a substantial part of pre-tax income and also a volatile component of it, the effective tax rate excluding this amount is likely to be a better estimate for the future tax costs for a company. The tax impact from income from participations is disclosed in the notes on the financial statements.

Often, a good starting point for estimating future tax expense is a tax rate based on normalized operating income, before the results from associates and special items. This normalized tax rate should be a good indication of the future tax expense, adjusted for special items, in an analyst's earnings model.

By building a model, the effective tax amount can be found in the profit and loss projections and the cash tax amount on the cash flow statement (or given as supplemental information). The reconciliation between the profit and loss tax amount and the cash flow tax figures should be the change in the deferred tax asset or liability.

EXAMPLE 7

Tax Rate Estimates

ABC, a hypothetical company, operates in Countries A and B. The tax rate in Country A is 40%, and the tax rate in Country B is 10%. In the first year, the company generates an equal amount of profit before tax in each country.

Exhibit 12 Tax Rates That Differ by Jurisdiction

	A	B	Total
Profit before tax	100	100	200
Effective tax rate	40%	10%	25%
Tax	40	10	50
Net profit	60	90	150

1. What will happen to the effective tax rate for the next three years if the profit in Country A is stable but the profit in Country B grows 15% annually?
2. Evaluate the cash tax and effective tax rates for the next three years if the tax authorities in Country A allow some costs (e.g., accelerated depreciation) to be taken sooner for tax purposes. For Country A, the result will be a 50% reduction in taxes paid in the current year but an increase in taxes paid by the same amount in the following year (this happens each year). Assume stable profit before tax in Country A and 15% annual before-tax-profit growth in Country B.
3. Repeat the exercise of Problem 2, but now assume that it is Country B not Country A that allows some costs to be taken sooner for tax purposes and that the tax effect described applies to Country B. Continue to assume stable profit before tax at Country A and 15% annual profit growth in Country B.

Solution to 1:

The effective tax rate will gradually decline because a higher proportion of profit will be generated in the country with the lower tax rate. In Exhibit 13, the effective tax rate declines from 25% in the beginning to 21.9% in the third year.

Exhibit 13 Worksheet for Problem 1

	Year			
	0	1	2	3
Profit before tax, Country A	100.0	100.0	100.0	100.0
Profit before tax, Country B	100.0	115.0	132.3	152.1
Total profit before tax	200.0	215.0	232.3	252.1
Tax, Country A (40%)	40.0	40.0	40.0	40.0
Tax, Country B (10%)	10.0	11.5	13.2	15.2
Total tax	50.0	51.5	53.2	55.2

Exhibit 13 (Continued)

	Year			
	0	1	2	3
Total tax rate %	25.0%	24.0%	22.9%	21.9%
Net profit	150.0	163.5	179.1	196.9

Solution to 2:

The combined cash tax rate (next to last line in Exhibit 14) will be 15% in the first year and then rebound in subsequent years. Only the rate for the first year will benefit from a tax deferral; in subsequent years, the deferral for a given year will be offset by the addition of the amount postponed from the previous year. The combined effective tax rate (last line in Exhibit 14) will be unaffected by the deferral. As shown in Exhibit 14, beginning with the second year, the combined cash tax and effective tax rates decline over time but remain identical to each other.

Exhibit 14 Worksheet for Problem 2

	Year			
	0	1	2	3
Profit before tax	200.0	215.0	232.3	252.1
Tax per income statement	50.0	51.5	53.2	55.2
Tax payment, Country A	20.0	20.0	20.0	20.0
Postponed tax payment, Country A		20.0	20.0	20.0
Tax payment Country B	10.0	11.5	13.2	15.2
Total tax payment	30.0	51.5	53.2	55.2
Cash tax rate	15.0%	24.0%	22.9%	21.9%
Tax rate per income statement	25.0%	24.0%	22.9%	21.9%

Solution to 3:

The combined effective tax rate (last line in Exhibit 15) remains unchanged from Exhibits 13 and 14. Because of the growth assumed for Country B, however, the annual tax postponement will result in a lower cash tax rate in Country B than the effective tax rate in Country B. Consequently, as shown in Exhibit 15, the combined cash tax rate will be less than the effective tax rate.

Exhibit 15 Worksheet for Problem 3

	Year			
	0	1	2	3
Profit before tax	200.0	215.0	232.3	252.1
Tax per income statements	50.0	51.5	53.2	55.2
Tax payment, Country A	40.0	40.0	40.0	40.0
Tax payment, Country B	5.0	5.8	6.6	7.6
Postponed tax payment, Country B		5.0	5.8	6.6
Total tax payment	45.0	50.8	52.4	54.2
Cash tax rate	22.5%	23.6%	22.5%	21.5%
Tax rate per income statement	25.0%	24.0%	22.9%	21.9%

The next section addresses several points to note in modeling dividends, share count, and unusual expenses.

4.3 Income Statement Modeling: Other Items

A company's stated dividend policy helps in modeling future dividend growth. Analysts will often assume that dividends grow each year by a certain dollar amount or as a proportion of net income.

If a company shares an ownership interest in a business unit with a third party, the company may report minority interest expense or income from consolidated affiliates on its income statement. If a company owns more than 50% of an affiliate, it will generally consolidate the affiliate's results with its own and report the portion of income that does not belong to the parent company as minority interest. If a company owns less than 50% of an affiliate, it will not consolidate results but will report its share of income from the affiliate under the equity method. If the affiliate is profitable, minority interest would be a deduction from net income, whereas if a consolidated affiliate generates losses, minority interest would be an addition to net income. In either case, income or expense from these jointly owned businesses can be material.

Share count (shares issued and outstanding) is a key input in the calculation of an intrinsic value estimate and earnings per share. Share count changes for three primary reasons: dilution related to stock options, convertible bonds, and similar securities; issuance of new shares; and share repurchases. The market price of a stock is an important determinant of future share count changes, which can complicate their estimation. Projections for share issuance and repurchases should fit within the analyst's broader analysis of a company's capital structure.

Finally, unusual charges can be almost impossible to predict, particularly past the next couple of years. For this reason, analysts typically exclude unusual charges from their forecasts. But if a company has a habit of frequently classifying certain recurring costs as "unusual," analysts should consider some normalized level of charges in their valuation model.

BALANCE SHEET AND CASH FLOW STATEMENT MODELING

5

e describe approaches to balance sheet modeling;

f describe the relationship between return on invested capital and competitive advantage;

Income statement modeling is the starting point for balance sheet and cash flow statement modeling. Analysts normally have a choice of whether to focus on the balance sheet or cash flow statement; the third financial statement will naturally result from the construction of the other two. Here, we focus on the balance sheet.

Some balance sheet line items—such as retained earnings—flow directly from the income statement, whereas other lines—such as accounts receivable, accounts payable, and inventory—are very closely linked to income statement projections.

A common way to model working capital accounts is through the use of efficiency ratios. For example, analysts may project future accounts receivable by assuming a number of days sales outstanding and combining that assumption with a sales projection. Days sales outstanding is a measure of the number of days, on average, it takes a company to collect revenue from its customers. For example, if annual revenue (assumed to be all credit sales) is \$25 billion and it normally takes 60 days to collect revenue from customers, accounts receivable would be estimated at \$4.1 billion (≈ \$25 billion × 60/365). Analysts can project future inventory by assuming an inventory turnover rate and combining that assumption with a cost of goods sold projection. Inventory turnover is a measure of how much inventory a company keeps on hand, or alternatively, how quickly a company sells through its inventory. In general, if efficiency ratios are held constant, working capital accounts will grow in line with the related income statement accounts.

Working capital projections can be modified by both top-down and bottom-up considerations. In the absence of a specific opinion about working capital, analysts can look at historical efficiency ratios and project recent performance or a historical average to persist in the future, which would be a bottom-up approach. Conversely, analysts may have a specific view of future working capital. For example, if they project economy-wide retail sales to decline unexpectedly, that could result in slower inventory turnover across the retail sector. Because the analysts began with a forecast for a large sector of the economy, this would be considered a top-down approach.

Projections for long-term assets—such as property, plant, and equipment (PP&E)—are less directly tied to the income statement for most companies. Net PP&E primarily changes as a result of capital expenditures and depreciation, both of which are important components of the cash flow statement. Depreciation forecasts are usually based on historical depreciation and disclosure about depreciation schedules, whereas capital expenditure forecasts depend on the analysts' judgment of the future need for new PP&E. Capital expenditures can be thought of as including both **maintenance capital expenditures**, which are necessary to sustain the current business, and **growth capital expenditures**, which are needed to expand the business. All else being equal, maintenance capital expenditure forecasts should normally be higher than depreciation because of inflation.

Finally, analysts must make assumptions about a company's future capital structure. Leverage ratios—such as debt-to-capital, debt-to-equity, and debt-to-EBITDA—can be useful for projecting future debt and equity levels. Analysts should consider historical company practice, management's financial strategy, and the capital requirements implied by other model assumptions when projecting the future capital structure.

Once future income statements and balance sheets are constructed, analysts can use them to determine the rate of **return on invested capital** (ROIC) implied by their assumptions. ROIC measures the profitability of the capital invested by the company's shareholders and debtholders. The numerator for ROIC is usually net operating profit less adjusted taxes (NOPLAT). NOPLAT is basically earnings before interest expense (i.e., earnings available to provide a return to both equityholders and debtholders). The denominator for ROIC is invested capital, which is calculated as operating assets less operating liabilities.(Note that this is just one way of calculating ROIC; there are many variations in the definition of ROIC.) Invested capital can be measured at the beginning of an accounting period or as an average of the beginning and end of the accounting period. ROIC is a better measure of profitability than return on equity because it is not affected by a company's degree of financial leverage. In general, sustainably high ROIC is a sign of a competitive advantage. To increase ROIC, a company must either increase earnings, reduce invested capital, or both. A closely related measure to ROIC, but focusing on pretax operating profit, is **return on capital employed** (ROCE), which is essentially ROIC before tax. This measure is defined as operating profit divided by capital employed (debt and equity capital). As a pretax measure, ROCE can be useful in several contexts, such as peer comparisons of companies in countries with different tax structures, because comparison of underlying profitability would not be biased in favor of companies benefitting from low tax rate regimes. (Note that as in the case of ROIC, the definition of ROCE provided here follows one line of analyst practice; there is no single "authoritative" definition.)

EXAMPLE 8

Balance Sheet Modeling

1 Management at a restaurant chain intends to maintain a 40% debt-to-capital ratio. Management has a track record of meeting its capital structure targets. The restaurant chain is solidly profitable, but earnings are expected to decline 2% annually over the next five years because of increasing competitive pressure. The company does not pay a dividend or repurchase shares, and all earnings are expected to be retained for the next five years. What is *most likely* to happen to the restaurant chain's total debt over this period?

   A Total debt will increase.

   B Total debt will decrease.

   C Total debt will remain the same.

2 Sophie Moreau, a buy-side analyst, is analyzing a French manufacturing company. Working capital and PP&E account for almost all of the company's assets. Moreau believes that the depreciation schedule used by the company is not reflective of economic reality. Rather, she expects PP&E to last twice as long as what is implied by the depreciation schedule, and as such, she projects capital expenditures to be significantly less than depreciation for the next five years. Moreau projects that both earnings and net working capital will grow at a low single-digit rate during this time. What do Moreau's assumptions *most likely* imply for returns on invested capital during the next five years?

   A ROIC will increase.

   B ROIC will decrease.

   C ROIC will stay the same.

Solution to 1:

A is correct. The restaurant chain is profitable and retains all of its earnings. These facts will lead to rising equity on the balance sheet. To maintain a constant debt-to-capital ratio, management will have to increase its debt.

Solution to 2:

A is correct. Earnings are expected to grow over the next five years. Working capital is expected to grow in line with earnings, which would imply a stable ROIC. But net PP&E is expected to decline because depreciation is expected to exceed capital expenditures. Total invested capital will thus grow more slowly than earnings or even shrink, implying improving returns on invested capital.

Once projected income statements and balance sheets have been constructed, future cash flow statements can be projected. Analysts will normally make assumptions about how a company will use its future cash flows—whether for share repurchases, dividends, additional capital expenditures, acquisitions, and so on.

6 SCENARIO ANALYSIS AND SENSITIVITY ANALYSIS

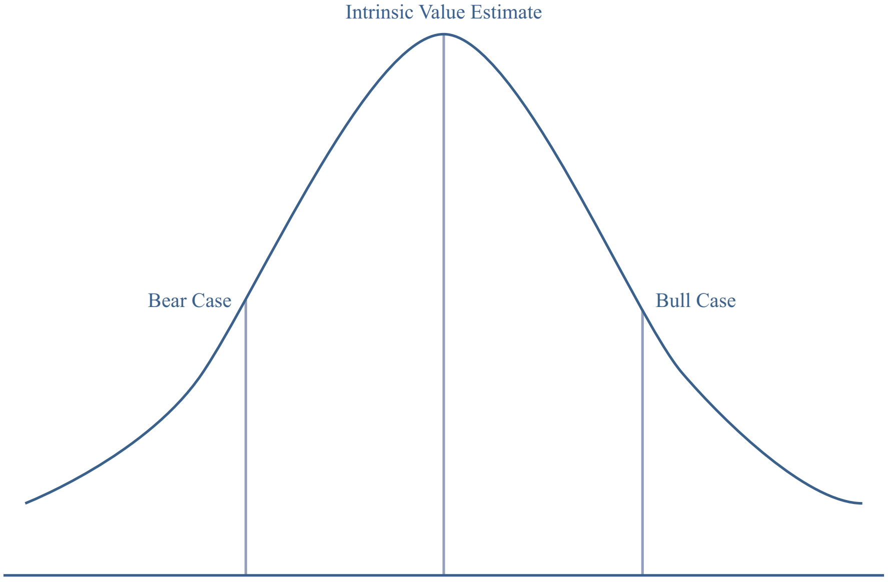
Regardless of the approach used, equity valuation involves a significant degree of uncertainty. Valuing businesses requires making assumptions about the future, which is inherently uncertain. Recognizing this uncertainty, effective analysis should always consider scenarios in addition to the most likely "base case" result.

Sensitivity analysis involves changing one assumption at a time to see the effect on the estimate of intrinsic value. For example, analysts might examine the impact of a different revenue growth rate on the company's valuation. **Scenario analysis** has the same goal but involves changing multiple assumptions at the same time. For example, analysts might simultaneously change assumptions for revenue growth, operating margin, and capital investment. Either sensitivity analysis or scenario analysis can be used to determine a range of potential intrinsic value estimates based on a variety of different assumptions about the future. Analysts can use either tool to estimate the effect on a company's valuation of different assumptions for economic growth, for inflation, for the success of a particular product, and so on.

Value estimates for companies involve varying degrees of uncertainty. Large, mature, slow growing, non-cyclical businesses with well-capitalized balance sheets may be relatively easy to value. In this case, intrinsic value estimates from upside and downside scenarios may be close to the base case. Conversely, for new ventures, companies exposed to technological or regulatory change, companies with significant operating or financial leverage, and so on, the range of potential intrinsic value estimates could be much wider. In this case, analysts may hesitate to make an investment recommendation without substantial confidence that intrinsic value differs markedly from market price.

Analysts should normally think of their valuations as a range of possibilities rather than an estimate at a single point. For most companies, the range will be approximately symmetrical and might be imagined as a bell curve. The base case estimate of intrinsic value would be at the middle of the distribution with, depending on the judgment of the analysts, similar probabilities of upside and downside outcomes, as shown in Exhibit 16. The width of the tails will depend on the level of uncertainty pertaining to forecasts. For example, the large, mature, slow-growing company would have a steep distribution with relatively thin tails, representing a relatively low likelihood of extreme values. The probability distribution of estimates need not be symmetrical. In addition, technically, a distribution of security values would be bounded on the left by zero.

Exhibit 16 Distribution of Intrinsic Value Estimates



For some companies, the range of potential outcomes might be skewed or highly irregular. For example, there might be a relatively high probability that a debt-laden company will have insufficient cash flow to cover interest and principal payments, in which case the value of the equity could be zero. A company with a single untested product may be worth very little or a lot, depending on whether the product turns out to be a success. Scenario analysis can be particularly useful in these cases because there may not be a meaningful "base case." A common approach is for analysts to value such companies by using a probability-weighted average of the various scenarios.

7 THE IMPACT OF COMPETITIVE FACTORS IN PRICES AND COSTS

g explain how competitive factors affect prices and costs;

h evaluate the competitive position of a company based on a Porter's five forces analysis;

Incorporating competition into financial forecasting can be a challenging task. Most of the items that analysts must forecast—including revenues, profit margin, and capital expenditures—are linked to the competitive environment, and competition can affect these items both separately and collectively. Analysts can use various conceptual tools in thinking about how competition will affect forecasts. Such tools provide a way to organize data and ideas. Although there are no "rules" for incorporating competitive analysis in forecasts, it is arguably the analysts' most important job.

Analysts' projections for revenue growth, margin development, capital expenditures, and working capital investment are all based on an estimate of a company's future competitive strength.

One of the tools that analysts can use to think about how competition will affect financial results is Michael Porter's widely used "five forces" framework (see Porter 1980). The framework identifies five forces that affect the intensity of a company's competitive environment and thus cost and price projections. These forces include the following: threat of substitute products, intensity of rivalry among incumbent companies, bargaining power of suppliers, bargaining power of customers, and threat of new entrants.

The first force is the threat of substitute products. If numerous substitutes exist and switching costs are low, companies have limited pricing power. Conversely, if few substitutes exist and/or switching costs are high, companies have greater pricing power.

The second force is the intensity of rivalry among incumbent companies. Pricing power is limited in industries that are fragmented, have limited growth, high exit barriers, high fixed costs, and have basically identical product offerings.

The third force is the bargaining power of suppliers. Companies (and overall industries) whose suppliers have greater ability to increase prices and/or limit the quality and quantity of inputs face downward pressure on profitability. Suppliers' bargaining power is generally a function of relative size, the relative importance the supplier places on a particular product, and the availability of alternatives.

The fourth force is the bargaining power of customers. Companies (and overall industries) whose customers have greater ability to demand lower prices and/or control the quality and quantity of end products face downward pressure on profitability. Buyer power is the reverse of supplier power. Bargaining power of customers is generally lower in markets with a fragmented customer base, a non-standardized product, and high switching costs for the customer.

The fifth force is the threat of new entrants. Companies in industries in which the threat of new entrants is high because of the presence of above-market returns face downward pressure on profitability. In contrast, if there are barriers to entry, it may be costly for new competitors to enter a market. It is easier for incumbents to raise prices and defend their market position when barriers to entry are high.

ANALYSIS OF ANHEUSER-BUSCH INBEV USING PORTER'S FIVE FORCES

The competitive structure a company faces can vary among countries, with implications for modeling revenue growth, profit margins, capital expenditures, and return on investments. For example, Anheuser-Busch (AB) InBev, the largest global brewer, operates in many countries, two of which are Brazil, the world's third largest beer market, and the United Kingdom. AB InBev's competitive position and prospects in the highly consolidated and growing Brazilian market are much more favorable than in the fragmented and declining UK market.

The Brazilian beer market is divided among four players. AmBev (AB InBev's subsidiary in Brazil in which it owns a 61.9% stake) is the dominant brewer with an estimated 65% market share in 2018 versus 20% for Heineken and 12% for Petropolis, Brazil's largest privately owned brewing group. Helped by its dominant market position and strong distribution network, AmBev was able to report an EBITDA margin of nearly 50.4% in 2018 (ri.ambev.com.br), the highest in the global beer industry. The industry participants focus less on price competition and more on expanding distribution and "premiumization" (i.e., selling more expensive beers.) Although the 2015–2018 time period saw challenging trading conditions due to subdued consumer demand, causing years of decline in the market by volume, Brazil is still considered to be a promising market. In this environment, an analyst would likely forecast solid revenue growth for AmBev. Exhibit 17 presents an analysis of the Brazilian beer market using Porter's five forces framework. Most of the competitive forces represent a low threat to profitability (consistent with AmBev's historical profitability), implying that analysts would most likely forecast continued above-average profitability.

Exhibit 17 Analysis of the Brazilian Beer Market Using Porter's Five Forces

Force	Degree	Factors to Consider
Threat of substitutes	Medium	• Beer consumers do not easily shift to other beverages, but such alternatives as wine and spirits are available. • Unlike many other countries, the range of beers is relatively limited.
Rivalry	Low	• AmBev dominates the market with a 65% market share. Its economies of scale in production and distribution yield significant cost advantages relative to competition. • Price competition is limited because of AmBev's cost advantages and because of typically increasing beer volumes.
Bargaining power of suppliers	Low	• The primary inputs (water, hops, barley, and packaging) are basically commodities.
Bargaining power of buyers	Low	• Beer is mostly consumed in bars and restaurants. The owners of these outlets represent a large and highly fragmented group of beer buyers. • The supermarket industry in Brazil is relatively fragmented, and supermarkets are less likely to offer alternatives, such as private labels.
Threat of new entrants	Low	• New entrants face relatively high barriers to entry because of the high costs of building a brewery, establishing a national distribution network, and establishing a nationally known brand name.

The UK beer market is also divided among four players, but the competitive structure is totally different in the United Kingdom than in Brazil. The market is more fragmented with smaller market shares held by the largest players. Heineken, MolsonCoors, AB InBev, and Carlsberg had market shares of 24% (adbrands.net), 18%, 18% (www.ab-inbev.com), and 11% (carlsberggroup.com), respectively, in 2018. Consequently, the British market has no dominant brewer. Given the high fixed costs of a brewery, declining volumes of UK beer consumption, and the highly consolidated customer base, which provides the clients with substantial purchasing power (particularly in the retail channels), price competition is usually intense. A gradual switch from drinking beer in pubs and restaurants ("on-trade") to consumption at home ("off-trade") is making brewers even more exposed to the bargaining power of the dominant retail supermarket (grocers) chains. Increasing taxes on beer and rents faced by pub landlords add to the burden faced by the industry, leading to a steady decline of Britain's pub industry. Profitability has been lower than the beer industry's global average; operating margins are believed to be less than 10%. In this kind of environment, analysts would most likely forecast only very cautious revenue growth, if any. Exhibit 18 presents an analysis of the UK beer market using Porter's five forces framework.

Exhibit 18 Analysis of the UK Beer Market Using Porter's Five Forces

Force	Degree	Factors to Consider
Threat of substitutes	Medium	• Beer consumers do not easily shift to other beverages, but such alternatives as wine, spirits, and cider are available.
Rivalry	High	• The market is relatively fragmented with no dominant market leader and large numbers of small breweries. • Declining beer volumes make price wars more likely.[a] • Brand loyalty is less developed because of the extensive range of alternative beers.
Bargaining power of suppliers	Low	• The primary inputs (water, hops, barley, and packaging) are basically commodities.
Bargaining power of buyers	High	• The large supermarket chains that dominate the grocery sector have significant bargaining power. • Large pub chains in the "on-trade" business (where beer is sold in pubs and restaurants) also have strong bargaining power.
Threat of new entrants	Low	• Barriers to entry are relatively high because of the high costs of building a brewery, establishing a national distribution network (particularly given the history of brewers owning pubs and bars), and establishing a nationally known brand. • Because the United Kingdom consists of islands, companies with breweries in other countries face higher transportation costs than existing participants.

[a] In some declining markets, companies focus on increasing prices to offset declining volumes. But in the case of beer, where the market is very fragmented and thus there is no price leadership, price increases are less viable.

There is a distinction between Porter's five forces and other factors that can affect profitability, such as government regulation and taxes:

> Industry structure, as manifested in the strength of the five competitive forces, determines the industry's long-run profit potential because it determines how the economic value created by the industry is divided… Government is not best understood as a sixth force because government involvement is neither inherently good nor bad for industry profitability. The best way to understand the influence of government on competition is to analyze how specific government policies affect the five competitive forces (Porter 2008, page 10).

EXAMPLE 9

EuroAlco case

In 20X2, EuroAlco was the beer market leader in Eurolandia (a hypothetical country) with a 35% market share. The other large players held 15%, 15%, 10%, and 7% share, respectively. The Eurolandia market is considered a growth market. It historically had high overall alcohol consumption but a relatively low per capita consumption of beer, a product that is attracting interest from the growing, younger population and is further supported by increasing disposable incomes.

Two years earlier, at the start of year 20X1, the Eurolandia government, in its fight to curb alcohol consumption, tripled the excise duty (a special tax) on beer from €0.3 per liter to €0.9 and announced that excise duty will further increase by €0.1 per liter.

In the following year, 20X2, EuroAlco made efforts to strengthen the position of the more expensive brands in its portfolio. These efforts led to a 20% increase in selling costs. Similar to most consumer staple companies, EuroAlco experienced higher production costs. Poor grain harvests put price pressure on buyers of almost all feedstocks, and rising oil prices resulted in higher packaging costs. In 20X2, competing companies were much more cautious with advertising and promotional spending than EuroAlco.

Two analysts research EuroAlco at the start of year 20X3. In making their EuroAlco forecasts, both analysts use market data and the published annual report from EuroAlco (see Exhibit 19). Based on the published data, they consider a number of scenarios and reach different conclusions.

Exhibit 19 EuroAlco Key Financial and Operational Data

(€ millions)	20X0	20X1	20X2	Change (%) 20X1/20X0	Change (%) 20X2/20X1
Retail revenues	9,180	10,248	11,504	11.6%	12.3%
Excise duty	900	2,520	2,900	180%	15.1%
Excise duty of retail price	9.8%	24.6%	25.2%		
VAT (20%)	1,380	1,288	1,434	−6.7	11.3

Cost of sales	3,150	2,800	3,190	−11.1	13.9
Gross profit	2,850	2,800	3,045	−1.8	8.7
Selling expenses	1,650	1,680	2,088	1.8	24.3

Exhibit 19 (Continued)

EuroAlco Key Financial Performance Indicators (€ millions, unless noted)

	20X0	20X1	20X2	Change (%) 20X1/20X0	Change (%) 20X2/20X1
Administrative expenses	150	140	145	−6.7	3.6
Operating profit	1,050	980	812	−6.7	−17.1
Gross margin	47.5%	50.0%	48.8%		
Selling expenses	27.5%	30.0%	33.5%		
Operating margin	17.5%	17.5%	13.0%		
ROCE	33.9%	32.7%	27.1%		
Capital employed	3,100	3,000	3,000	4	−8

[€ per hectoliter (hl)]	20X0	20X1	20X2	Change (%) 20X1/20X0	Change (%) 20X2/20X1
Retail price/hl	306	366	397	19.6%	8.4%
Excise duty/hl	30	90	100	200	11.1
VAT (value added/ sales tax)	46	46	49.5	0	7.5
Margin for retailer sales	30	30	32.3	0	7.5
Net revenue	200	200	215	0	7.5
Cost of sales	105	100	110	−4.8	10.0
Gross profit	95	100	105	5.3	5
Selling expenses	55	60	72	9.1	20
Administrative expenses	5	5	5	0	0
Operating profit	35	35	28	0	−20

Note: Capital employed includes debt and equity capital.
[a] This is the profit for all companies that buy beer direct from the manufacturers (brewers) for sale to any end user.

1 Both analysts assume that the government will impose a further increase in the excise duty (special tax on beer). They also assume that the excise duty increase will be borne by the consumers, who will face a 10% price increase that will allow the brewers to maintain their net (after-tax) revenues per hectoliter (hl). They assume that half the cost of sales is fixed per hl and half is variable based on volume, that selling expenses will remain unchanged as a percentage of sales, and that administrative expenses are fixed.

A Analyst A expects price elasticity of 0.8, indicating that volume will fall by 8% given the10% retail price increase. Calculate the impact on operating profit and operating profit margin in 20X3 using Exhibit 20.

B Analyst B expects price elasticity of 0.5, indicating that volume will fall by 5% given the 10% retail price increase. Calculate the impact on operating profit and operating profit margin in 20X3 using Exhibit 20.

Exhibit 20 EuroAlco's Costs Structure for 20X2–20X3E (€ millions, unless noted)

		Analyst A		Analyst B	
	20X2	**20X3E**	**YoY%**	**20X3E**	**YoY%**
Volume (million hl)	29	26.7	−8.0%	27.6	−5.0%
Net revenue (€ per hl)	215				
Revenues	6,235				
Cost of sales	3,190				
Gross profit	3,045				
Gross margin	48.8%				
Selling expenses	2,088				
Administrative expenses	145	145		145	
Operating profit	812				
Operating profit margin (%)	13.0				
Cost of sales (fixed)	1,595	1,595		1,595	
Cost of sales (variable)	1,595				
Cost of sales (variable)/hl	55	55		55	
Selling expenses as % of sales	33.5%	33.5%		33.5%	

2 Gross margin improved in 20X1 (50.0%) but fell in 20X2 (48.8%). Cost of sales was relatively high in 20X2 because of high barley costs, an important input for brewing beer. Assume that in 20X2 half of the cost of sales is fixed and half is based on volume. Of the variable part of the cost of sales, assume that half of the amount is related to the barley price in 20X2. Barley prices increased 25% in 20X2. Consider a scenario where no additional taxes are imposed in 20X3, revenues and volumes remain stable and barley prices return to their 20X1 level. Calculate EuroAlco's estimated gross margin for 20X3.

3 EuroAlco's selling expenses increased from 30% of sales in 20X1 to 33.5% of sales in 20X2. Which competitive forces most likely influenced EuroAlco's significant increase in selling expenses?

4 Retailers are the direct customers of brewers. They buy directly from the brewer and sell to the ultimate consumer. Analyst A expects that the increase in mass retailers in Eurolandia will cause brewers' margins to decline. He expects EuroAlco's operating margin will decrease from 13% in 20X2 to 8% in 20X6, with stable sales (€6,235 million) and an unchanged amount of invested capital (€3,000 million). Analyst B also sees the increasing importance of the larger food retailers but expects that EuroAlco can offset potential pricing pressure by offering more attractive trade credit (e.g., allowing the retailers longer payment terms). He thinks operating margin can remain stable at 13% with no sales growth. Capital employed (€3,000 million), however, will double because of the extra investments in inventory and receivables. Describe the analysts' expectations about the impact of large retailers on brewers in terms of Porter's five forces and ROCE. Which of the two scenarios would be better for EuroAlco?

Solution to 1:

Exhibit 21 shows the results for both analysts' projections. Analyst A predicts that operating profit will decrease by 25% to€608 in 20X3, resulting in an operating margin decline from 13.0% in 20X2 to 10.6% in 20X3. Analyst A calculates a revenue decline of 8% to €5,736 based on volume dropping by 8% and a constant price per hl of €215. The decrease in volume reflects the price elasticity of 0.8 and the price increase of 10% as a result of the excise duty increase. Cost of goods sold fell only 4% because part of the costs are fixed. Cost of goods as the sum of fixed and variable costs is €1,595 + [26.68 (hl volume) × €55 (hl cost)] = €1,595 + €1,467 (ignoring rounding error) or €3,062. Analyst A predicts selling expenses will decline in line with sales by 8% and administrative costs will remain unchanged because of their fixed character in the short term.

Analyst B forecasts that operating profit will decline by 16% to €684. Analyst B's calculations follow the same pattern as those of Analyst A, but Analyst B predicts a smaller, 5%, decline in volume. Analyst A's estimates are more pessimistic than those of Analyst B. Note that the net price/hl for the brewer is held constant while the price for the consumer increased 10% as a result of the excise duty increase. Because of Analyst B's more optimistic volume forecast, fixed costs are spread over a higher level of sales than is the case for Analyst A. Consequently, Analyst B will have a higher operating margin estimate than Analyst A. However, both analysts are predicting a decline in operating margin in 20X3.

Exhibit 21 Analysts' Results for EuroAlco's Cost Structure and Projection (€ millions, unless noted)

		Analyst A		Analyst B	
	20X2	20X3E	YoY%	20X3E	YoY%
Volume	29	26.7	–8.0%	27.7	–5.0%
Net revenue (€ per hl)	215	215	0.0	215	0.0
Net revenues	6,235	5,736	–8.0	5,923	–5.0
Cost of sales	3,190	3,062	–4.0	3,110	–2.5
Gross profit	3,045	2,674	–12.2	2,813	–7.6
Gross margin	48.8%	46.6%		47.5%	
Selling expenses	2,088	1,921	–8.0	1,984	–5.0
Administrative expenses	145	145	0.0	145	0.0
Operating profit	812	608	–25%	684	–16%
Operating profit (%)	13%	10.6%		11.55%	
Cost of sales (fixed)	1,595	1,595		1,595	
Cost of sales (variable)	1,595	1,467		1,515	
Cost of sales (per hl)	55	55		55	
Selling expenses as % of sales	33.5%	33.5%		33.5%	

Solution to 2:

If barley prices return to their 20X1 level, they will decline 20% in 20X3. Because volumes are assumed to remain constant, other variable costs will not change. Gross profit in 20X2 was 48.8% of sales, which indicates the cost of sales was 51.2% (100% − 48.8%). Barley is 25% of the cost of sales (because barley represents half of variable costs and variable cost of sales represents half of total cost of sales). Cost of sales is predicted to decline by 25% × 20% = 5%. New cost of sales will be 51.2% − (5% × 51.2%) or 48.6%. Consequently, gross margin is predicted to be 100% − 48.6% = 51.4% in 20X3. Compared with the gross margin of 48.8% in 20X2, gross margin is predicted to increase by 260 bps.

Exhibit 22 Percent of Sales

	20X2	20X3E	YoY%
Revenues	100.00	100.00	0.0
− Barley costs	12.8	10.23	−20.0
− Other costs	12.8	12.8	0.0
Variable cost of sales	25.6	23.02	−10.0
Fixed cost of sales	25.6	25.6	0.0
Total cost of sales	51.2	48.6	−5.0
Gross profit	48.8	51.4	5.2

Solution to 3:

Intra-industry rivalry and threat of substitutes most likely influenced EuroAlco's significant increase in selling costs. By spending more on advertising, EuroAlco wanted to enhance the brand loyalty of its products, thus improving its competitive position versus its brewer rivals and makers of other alcoholic beverages. Furthermore, buyers' bargaining power probably also influenced EuroAlco's increased spending to the extent that advertising creates demand by the ultimate consumer. Strong demand at the ultimate consumer level for EuroAlco's specific brands could enhance the company's bargaining position with its direct customers, the distributors who serve as intermediaries.

Solution to 4:

The increase in mass retailers in EuroAlco is expected to strengthen the bargaining power of buyers relative to brewers. According to Analyst A, this will lead to a lower operating margin of 8%, while Analyst B believes margins can be maintained if the company offers much more favorable credit terms reflected in doubling of capital employed. Analyst A expects operating profit on capital employed to fall from 27.1% (13% × €6,235/€3,000) to 16.6% (8% × €6,235/€3,000). Analyst B's assumptions indicate that the ROCE (operating profit divided by capital employed) in 20X2 of 27% will fall by half to 13.5% as the operating result is earned on double the amount of invested capital (i.e., 13% x €6,235/€6,000). The scenario envisioned by Analyst A is better for EuroAlco.

In summary, Porter's five forces framework and similar analytical tools can help analysts assess the relative profit potential of a company by helping them understand the company's industry and its position within that industry. Understanding the industry and competitive contexts of a company helps analysts estimate whether, for example, sales growth is likely to be relatively high or low (relative to history, relative to the overall growth in the economy or a sector, and/or relative to competing companies) and whether profit margins are likely to be relatively high or low (relative to historical profit margins and relative to competing companies). The process of incorporating an industry and competitive analysis into expectations for future financial performance requires judgment. Suppose analysts observe that a given company is the market leader in a moderately competitive industry with limited buyer and supplier power and relatively high barriers to entry. In broad terms, analysts might project that the company's future revenue growth will be in line with that of the overall industry and that its profit margins and ROIC might be somewhat higher than those of other companies in the industry. But there is no mechanical link between the analysts' observations and projecting the company's future sales growth and profit margin. Instead, the link is more subjective and probabilistic.

INFLATION AND DEFLATION 8

i. explain how to forecast industry and company sales and costs when they are subject to price inflation or deflation;

Inflation and deflation (i.e., the overall increase and decrease in the prices of goods and services) can significantly affect the accuracy of forecasts for a company's future revenue, profit, and cash flow. The impact of inflation or deflation on revenue and expenses differs from company to company. Even within a single company, the impact of inflation or deflation is generally different for revenue and expenses categories.

Some companies are better able to pass on higher input costs by raising the prices at which they sell their output. The ability to pass on price increases can be the result of, for example, strong branding (Coca-Cola) or proprietary technology (Apple). Companies that are well positioned to pass on price increases are, in turn, more likely to have higher and more stable profits and cash flow, relative to competitors.

We first consider the impact of inflation on sales and then on costs.

8.1 Sales Projections with Inflation and Deflation
