The company will capitalise as part of the cost of the machine all costs that are necessary to get the new machine ready for its intended use: €10,900 purchase price, €200 for delivery, €300 for installation and testing, and €350 to reinforce the factory floor and ceiling joists to accommodate the machine's weight (which was necessary to use the machine and does not increase the value of the factory). The €100 to train staff is not necessary to get the asset ready for its intended use and will be expensed.

The company will capitalise the expenditure of €1,500 to repair the factory roof because the repair is expected to extend the useful life of the factory. The company will expense the €1,000 to have the exterior of the factory and adjoining offices repainted because the painting does not extend the life or alter the productive capacity of the buildings.

Solution to 2:

The costs related to the machine that are capitalised—€10,900 purchase price, €200 for delivery, €300 for installation and testing, and €350 to prepare the factory—will increase the carrying amount of the machine asset as shown on the balance sheet and will be included as investing cash outflows. The item related to the factory that is capitalised—the €1,500 roof repair—will increase the carrying amount of the factory asset as shown on the balance sheet and is an investing cash outflow. The expenditures of €100 to train staff and €1,000 to paint are expensed in the period and will reduce the amount of income reported on the company's income statement (and thus reduce retained earnings on the balance sheet) and the operating cash flow.

Example 1 describes capitalising versus expensing in the context of purchasing property, plant, and equipment. When a company constructs an asset (or acquires an asset that requires a long period of time to get ready for its intended use), borrowing costs incurred directly related to the construction are generally capitalised. Constructing a building, whether for sale (in which case, the building is classified as inventory) or for the company's own use (in which case, the building is classified as a long-lived asset), typically requires a substantial amount of time. To finance construction, any borrowing costs incurred prior to the asset being ready for its intended use are capitalised as part of the cost of the asset. The company determines the interest rate to use on the basis of its existing borrowings or, if applicable, on a borrowing specifically incurred for constructing the asset. If a company takes out a loan specifically to construct a building, the interest cost on that loan during the time of construction would be capitalised as part of the building's cost. Under IFRS, but not under US GAAP, income earned on temporarily investing the borrowed monies decreases the amount of borrowing costs eligible for capitalisation.

Thus, a company's interest costs for a period are included either on the balance sheet (to the extent they are capitalised as part of an asset) or on the income statement (to the extent they are expensed). If the interest expenditure is incurred in connection with constructing an asset for the company's own use, the capitalised interest appears on the balance sheet as a part of the relevant long-lived asset (i.e., property, plant, and equipment). The capitalised interest is expensed over time as the property is depreciated and is thus part of subsequent years' depreciation expense rather than interest expense of the current period. If the interest expenditure is incurred in connection with constructing an asset to sell (for example, by a home builder), the capitalised interest appears on the company's balance sheet as part of inventory. The capitalised interest is expensed as part of the cost of goods sold when the asset is sold. Interest payments made prior to completion of construction that are capitalised are classified as an investing cash outflow. Expensed interest may be classified as an operating or financing cash outflow under IFRS and is classified as an operating cash outflow under US GAAP.

EXAMPLE 2

Capitalised Borrowing Costs

BILDA S.A., a hypothetical company, borrows €1,000,000 at an interest rate of 10 percent per year on 1 January 2010 to finance the construction of a factory that will have a useful life of 40 years. Construction is completed after two years, during which time the company earns €20,000 by temporarily investing the loan proceeds.

1 What is the amount of interest that will be capitalised under IFRS, and how would that amount differ from the amount that would be capitalised under US GAAP?

2 Where will the capitalised borrowing cost appear on the company's financial statements?

Solution to 1:

The total amount of interest paid on the loan during construction is €200,000 (= €1,000,000 × 10% × 2 years). Under IFRS, the amount of borrowing cost eligible for capitalisation is reduced by the €20,000 interest income from temporarily investing the loan proceeds, so the amount to be capitalised is €180,000. Under US GAAP, the amount to be capitalised is €200,000.

Solution to 2:

The capitalised borrowing costs will appear on the company's balance sheet as a component of property, plant, and equipment. In the years prior to completion of construction, the interest paid will appear on the statement of cash flows as an investment activity. Over time, as the property is depreciated, the capitalised interest component is part of subsequent years' depreciation expense on the company's income statement.

2

ACQUISITION OF INTANGIBLE ASSETS

b compare the financial reporting of the following types of intangible assets: purchased, internally developed, acquired in a business combination;

Intangible assets are assets lacking physical substance. Intangible assets include items that involve exclusive rights, such as patents, copyrights, trademarks, and franchises. Under IFRS, identifiable intangible assets must meet three definitional criteria. They must be (1) identifiable (either capable of being separated from the entity or arising from contractual or legal rights), (2) under the control of the company, and (3) expected to generate future economic benefits. In addition, two recognition criteria must be met: (1) It is probable that the expected future economic benefits of the asset will flow to the company, and (2) the cost of the asset can be reliably measured. Goodwill, which is not considered an identifiable intangible asset,[4] arises when one company purchases another and the acquisition price exceeds the fair value of the net identifiable assets (both the tangible assets and the identifiable intangible assets, minus liabilities) acquired.

Accounting for an intangible asset depends on how it is acquired. The following sections describe accounting for intangible assets obtained in three ways: purchased in situations other than business combinations, developed internally, and acquired in business combinations.

2.1 Intangible Assets Purchased in Situations Other Than Business Combinations

Intangible assets purchased in situations other than business combinations, such as buying a patent, are treated at acquisition the same as long-lived tangible assets; they are recorded at their fair value when acquired, which is assumed to be equivalent to the purchase price. If several intangible assets are acquired as part of a group, the purchase price is allocated to each asset on the basis of its fair value.

In deciding how to treat individual intangible assets for analytical purposes, analysts are particularly aware that companies must use a substantial amount of judgment and numerous assumptions to determine the fair value of individual intangible assets. For analysis, therefore, understanding the types of intangible assets acquired can often be more useful than focusing on the values assigned to the individual assets. In other words, an analyst would typically be more interested in understanding what assets a company acquired (for example, franchise rights) than in the precise portion of the purchase price a company allocated to each asset. Understanding the types of assets a company acquires can offer insights into the company's strategic direction and future operating potential.

---

[4] The IFRS definition of an intangible asset as an "identifiable non-monetary asset without physical substance" applies to intangible assets not specifically dealt with in standards other than IAS 38. The definition of intangible assets under US GAAP—"assets (other than financial assets) that lack physical substance"—includes goodwill in the definition of an intangible asset.

2.2 Intangible Assets Developed Internally

In contrast with the treatment of construction costs of tangible assets, the costs to internally develop intangible assets are generally expensed when incurred. There are some situations, however, in which the costs incurred to internally develop an intangible asset are capitalised. The general analytical issues related to the capitalising-versus-expensing decision apply here—namely, comparability across companies and the effect on an individual company's trend analysis.

The general requirement that costs to internally develop intangible assets be expensed should be compared with capitalising the cost of acquiring intangible assets in situations other than business combinations. Because costs associated with internally developing intangible assets are usually expensed, a company that has internally developed such intangible assets as patents, copyrights, or brands through expenditures on R&D or advertising will recognise a lower amount of assets than a company that has obtained intangible assets through external purchase. In addition, on the statement of cash flows, costs of internally developing intangible assets are classified as operating cash outflows whereas costs of acquiring intangible assets are classified as investing cash outflows. Differences in strategy (developing versus acquiring intangible assets) can thus impact financial ratios.

IFRS require that expenditures on research (or during the research phase of an internal project) be expensed rather than capitalised as an intangible asset.[5] Research is defined as "original and planned investigation undertaken with the prospect of gaining new scientific or technical knowledge and understanding."[6] The "research phase of an internal project" refers to the period during which a company cannot demonstrate that an intangible asset is being created—for example, the search for alternative materials or systems to use in a production process. In contrast with the treatment of research-phase expenditures, IFRS allow companies to recognise an intangible asset arising from development expenditures (or the development phase of an internal project) if certain criteria are met, including a demonstration of the technical feasibility of completing the intangible asset and the intent to use or sell the asset. Development is defined as "the application of research findings or other knowledge to a plan or design for the production of new or substantially improved materials, devices, products, processes, systems or services before the start of commercial production or use."[7]

Generally, US GAAP require that both research and development costs be expensed as incurred but require capitalisation of certain costs related to software development.[8] Costs incurred to develop a software product for sale are expensed until the product's technological feasibility is established and are capitalised thereafter. Similarly, companies expense costs related to the development of software for internal use until it is probable that the project will be completed and that the software will be used as intended. Thereafter, development costs are capitalised. The probability that the project will be completed is easier to demonstrate than is technological feasibility. The capitalised costs, related directly to developing software for sale or internal use, include the costs of employees who help build and test the software. The treatment of software development costs under US GAAP is similar to the treatment of all costs of internally developed intangible assets under IFRS.

---

[5] IAS 38 *Intangible Assets*.

[6] IAS 38 *Intangible Assets*, paragraph 8 [Definitions].

[7] IAS 38 *Intangible Assets*, paragraph 8 [Definitions].

[8] FASB ASC Section 350-40-25 [Intangibles—Goodwill and Other – Internal-Use Software – Recognition] and FASB ASC Section 985-20-25 [Software – Costs of Software to be Sold, Leased, or Marketed – Recognition] specify US GAAP accounting for software development costs for software for internal use and for software to be sold, respectively.

EXAMPLE 3

Software Development Costs

Assume REH AG, a hypothetical company, incurs expenditures of €1,000 per month during the fiscal year ended 31 December 2019 to develop software for internal use. Under IFRS, the company must treat the expenditures as an expense until the software meets the criteria for recognition as an intangible asset, after which time the expenditures can be capitalised as an intangible asset.

1. What is the accounting impact of the company being able to demonstrate that the software met the criteria for recognition as an intangible asset on 1 February versus 1 December?
2. How would the treatment of expenditures differ if the company reported under US GAAP and it had established in 2018 that the project was likely to be completed and the software used to perform the function intended?

Solution to 1:

If the company is able to demonstrate that the software met the criteria for recognition as an intangible asset on 1 February, the company would recognise the €1,000 expended in January as an expense on the income statement for the fiscal year ended 31 December 2019. The other €11,000 of expenditures would be recognised as an intangible asset (on the balance sheet). Alternatively, if the company is not able to demonstrate that the software met the criteria for recognition as an intangible asset until 1 December, the company would recognise the €11,000 expended in January through November as an expense on the income statement for the fiscal year ended 31 December 2019, with the other €1,000 of expenditures recognised as an intangible asset.

Solution to 2:

Under US GAAP, the company would capitalise the entire €12,000 spent to develop software for internal use.

2.3 Intangible Assets Acquired in a Business Combination

When one company acquires another company, the transaction is accounted for using the **acquisition method** of accounting.[9] Under the acquisition method, the company identified as the acquirer allocates the purchase price to each asset acquired (and each liability assumed) on the basis of its fair value. If the purchase price exceeds the sum of the amounts that can be allocated to individual identifiable assets and liabilities, the excess is recorded as goodwill. Goodwill cannot be identified separately from the business as a whole.

---

[9] Both IFRS and US GAAP require the use of the acquisition method in accounting for business combinations (IFRS 3 and FASB ASC Section 805).

Under IFRS, the acquired individual assets include identifiable intangible assets that meet the definitional and recognition criteria.[10] Otherwise, if the item is acquired in a business combination and cannot be recognised as a tangible or identifiable intangible asset, it is recognised as goodwill. Under US GAAP, there are two criteria to judge whether an intangible asset acquired in a business combination should be recognised separately from goodwill: The asset must be either an item arising from contractual or legal rights or an item that can be separated from the acquired company. Examples of intangible assets treated separately from goodwill include the intangible assets previously mentioned that involve exclusive rights (patents, copyrights, franchises, licenses), as well as such items as internet domain names and video and audiovisual materials.

Exhibit 1 describes how AB InBev allocated the $103 billion purchase consideration in its 2016 acquisition of SABMiller Group. The combined company was renamed Anheuser-Busch InBev SA/NV. The majority of the intangible asset valuation relates to brands with indefinite life ($19.9 billion of the $20.0 billion total). Of $63.0 billion total assets acquired, assets to be divested were valued at $24.8 billion and assets to be held for were valued at $38.2 billion. In total, intangible assets represent 52 percent of the total assets to be held for use. In addition, $74.1 billion of goodwill was recognized in the transaction.

Exhibit 1 Acquisition of Intangible Assets through a Business Combination

Excerpt from the 2016 annual report of AB InBev:

> "On 10 October 2016, AB InBev announced the … successful completion of the business combination with the former SABMiller Group ("SAB").
>
> "The transaction resulted in 74.1 billion US dollar of goodwill provisionally allocated primarily to the businesses in Colombia, Ecuador, Peru, Australia, South Africa and other African, Asia Pacific and Latin American countries. The factors that contributed to the recognition of goodwill include the acquisition of an assembled workforce and the premiums paid for cost synergies expected to be achieved in SABMiller. Management's assessment of the future economic benefits supporting recognition of this goodwill is in part based on expected savings through the implementation of AB InBev best practices such as, among others, a zero based budgeting program and initiatives that are expected to bring greater efficiency and standardization, generate cost savings and maximize purchasing power. Goodwill also arises due to the recognition of deferred tax liabilities in relation to the preliminary fair value adjustments on acquired intangible assets for which the amortization does not qualify as a tax deductible expense. None of the goodwill recognized is deductible for tax purposes.
>
> "The majority of the intangible asset valuation relates to brands with indefinite life, valued for a total amount of 19.9 billion US dollar. The valuation of the brands with indefinite life is based on a series of factors, including the brand history, the operating plan and the countries in which the brands are sold. The fair value of brands was estimated by applying a combination of known valuation methodologies, such as the royalty relief and excess earnings valuation approaches.

(continued)

---

[10] As previously described, the definitional criteria are identifiability, control by the company, and expected future benefits. The recognition criteria are probable flows of the expected economic benefits to the company and measurability.

Exhibit 1 (Continued)

> “The intangibles with an indefinite life mainly include the Castle and Carling brand families in Africa, the Aguila and Poker brand families in Colombia, the Cristal and Pilsner brand families in Ecuador, and the Carlton brand family in Australia.
>
> “Assets held for sale were recognized in relation to the divestiture of SABMiller’s interests in the MillerCoors LLC joint venture and certain of SABMiller’s portfolio of Miller brands outside of the U.S. to Molson Coors Brewing company; the divestiture of SABMiller’s European premium brands to Asahi Group Holdings, Ltd and the divestiture of SABMiller’s interest in China Resources Snow Breweries Ltd. to China Resources Beer (Holdings) Co. Ltd. ….” [Excerpt]

The following is a summary of the provisional allocation of AB InBev’s purchase price of SABMiller:

Assets	**$ million**
Property, plant and equipment	9,060
Intangible assets	20,040
Investment in associates	4,386
Inventories	977
Trade and other receivables	1,257
Cash and cash equivalents	1,410
Assets held for sale	24,805
All other assets	*1,087*
Total assets	*63,022*
Total liabilities	*–27,769*
Net identified assets and liabilities	**35,253**
Non-controlling interests	–6,200
Goodwill on acquisition	**74,083**
Purchase consideration	**103,136**

Table is excerpted from the company’s 2016 Annual Report. Portions of detail are omitted, and subtotals are shown in italics.

3 CAPITALIZATION VERSUS EXPENSING: IMPACT ON FINANCIAL STATEMENTS AND RATIOS

c explain and evaluate how capitalising versus expensing costs in the period in which they are incurred affects financial statements and ratios;

This section discusses the implications for financial statements and ratios of capitalising versus expensing costs in the period in which they are incurred. We first summarize the general financial statement impact of capitalising versus expensing and two analytical issues related to the decision—namely the effect on an individual company’s trend analysis and on comparability across companies.

In the period of the expenditure, an expenditure that is capitalised increases the amount of assets on the balance sheet and appears as an investing cash outflow on the statement of cash flows. After initial recognition, a company allocates the capitalised amount over the asset's useful life as depreciation or amortisation expense (except assets that are not depreciated, i.e., land, or amortised, e.g., intangible assets with indefinite lives). This expense reduces net income on the income statement and reduces the value of the asset on the balance sheet. Depreciation and amortisation are non-cash expenses and therefore, apart from their effect on taxable income and taxes payable, have no impact on the cash flow statement. In the section of the statement of cash flows that reconciles net income to operating cash flow, depreciation and amortisation expenses are added back to net income.

Alternatively, an expenditure that is expensed reduces net income by the after-tax amount of the expenditure in the period it is made. No asset is recorded on the balance sheet and thus no depreciation or amortisation occurs in subsequent periods. The lower amount of net income is reflected in lower retained earnings on the balance sheet. An expenditure that is expensed appears as an operating cash outflow in the period it is made. There is no effect on the financial statements of subsequent periods.

Example 4 illustrates the impact on the financial statements of capitalising versus expensing an expenditure.

EXAMPLE 4

General Financial Statement Impact of Capitalising Versus Expensing

Assume two identical (hypothetical) companies, CAP Inc. (CAP) and NOW Inc. (NOW), start with €1,000 cash and €1,000 common stock. Each year the companies recognise total revenues of €1,500 cash and make cash expenditures, excluding an equipment purchase, of €500. At the beginning of operations, each company pays €900 to purchase equipment. CAP estimates the equipment will have a useful life of three years and an estimated salvage value of €0 at the end of the three years. NOW estimates a much shorter useful life and expenses the equipment immediately. The companies have no other assets and make no other asset purchases during the three-year period. Assume the companies pay no dividends, earn zero interest on cash balances, have a tax rate of 30 percent, and use the same accounting method for financial and tax purposes.

The left side of Exhibit 2 shows CAP's financial statements; i.e., with the expenditure capitalised and depreciated at €300 per year based on the straight-line method of depreciation (€900 cost minus €0 salvage value equals €900, divided by a three-year life equals €300 per year). The right side of the exhibit shows NOW's financial statements, with the entire €900 expenditure treated as an expense in the first year. All amounts are in euro.

Exhibit 2 Capitalising versus Expensing

CAP Inc.				NOW Inc.			
Capitalise €900 as asset and depreciate				**Expense €900 immediately**			
For Year	**1**	**2**	**3**	**For Year**	**1**	**2**	**3**
Revenue	1,500	1,500	1,500	Revenue	1,500	1,500	1,500
Cash expenses	500	500	500	Cash expenses	1,400	500	500
Depreciation	300	300	300	Depreciation	0	0	0

(continued)

Exhibit 2 (Continued)

CAP Inc.

Capitalise €900 as asset and depreciate

For Year	1	2	3
Income before tax	700	700	700
Tax at 30%	210	210	210
Net income	490	490	490
Cash from operations	790	790	790
Cash used in investing	(900)	0	0
Total change in cash	(110)	790	790

NOW Inc.

Expense €900 immediately

For Year	1	2	3
Income before tax	100	1,000	1,000
Tax at 30%	30	300	300
Net income	70	700	700
Cash from operations	70	700	700
Cash used in investing	0	0	0
Total change in cash	70	700	700

As of	Time 0	End of Year 1	End of Year2	End of Year 3
Cash	1,000	890	1,680	2,470
PP & E (net)	—	600	300	—
Total Assets	1,000	1,490	1,980	2,470
Retained earnings	0	490	980	1,470
Common stock	1,000	1,000	1,000	1,000
Total shareholders' equity	1,000	1,490	1,980	2,470

Time	Time 0	End of Year 1	End of Year 2	End of Year 3
Cash	1,000	1,070	1,770	2,470
PP & E (net)	—	—	—	—
Total Assets	1,000	1,070	1,770	2,470
Retained earnings	0	70	770	1,470
Common stock	1,000	1,000	1,000	1,000
Total shareholders' equity	1,000	1,070	1,770	2,470

1 Which company reports higher net income over the three years? Total cash flow? Cash from operations?

2 Based on ROE and net profit margin, how does the profitability of the two companies compare?

3 Why does NOW report change in cash of €70 in Year 1, while CAP reports total change in cash of (€110)?

Solution to 1:

Neither company reports higher total net income or cash flow over the three years. The sum of net income over the three years is identical (€1,470 total) whether the €900 is capitalised or expensed. Also, the sum of the change in cash (€1,470 total) is identical under either scenario. CAP reports higher cash from operations by an amount of €900 because, under the capitalisation scenario, the €900 purchase is treated as an investing cash flow.

Note: Because the companies use the same accounting method for both financial and taxable income, absent the assumption of zero interest on cash balances, expensing the €900 would have resulted in higher income and cash flow for NOW because the lower taxes paid in the first year (€30 versus €210) would have allowed NOW to earn interest income on the tax savings.

Solution to 2:

In general, Ending shareholders' equity = Beginning shareholders' equity + Net income + Other comprehensive income − Dividends + Net capital contributions from shareholders. Because the companies in this example do not have other comprehensive income, did not pay dividends, and reported no capital contributions from shareholders, Ending retained earnings = Beginning retained earnings + Net income, and Ending shareholders' equity = Beginning shareholders' equity + Net income.

ROE is calculated as Net income divided by Average shareholders' equity, and Net profit margin is calculated as Net income divided by Total revenue. For example, CAP had Year 1 ROE of 39 percent (€490/[(€1,000 + €1,490)/2]), and Year 1 net profit margin of 33 percent (€490/€1,500).

CAP Inc.				**NOW Inc.**			
Capitalise €900 as asset and depreciate				**Expense €900 immediately**			
For year	**1**	**2**	**3**	**For year**	**1**	**2**	**3**
ROE	39%	28%	22%	ROE	7%	49%	33%
Net profit margin	33%	33%	33%	Net profit margin	5%	47%	47%

As shown, compared to expensing, capitalising results in higher profitability ratios (ROE and net profit margin) in the first year, and lower profitability ratios in subsequent years. For example, CAP's Year 1 ROE of 39 percent was higher than NOW's Year 1 ROE of 7 percent, but in Years 2 and 3, NOW reports superior profitability.

Note also that NOW's superior growth in net income between Year 1 and Year 2 is not attributable to superior performance compared to CAP but rather to the accounting decision to recognise the expense sooner than CAP. In general, all else equal, accounting decisions that result in recognising expenses sooner will give the appearance of greater subsequent growth. Comparison of the growth of the two companies' net incomes without an awareness of the difference in accounting methods would be misleading. As a corollary, NOW's income and profitability exhibit greater volatility across the three years, not because of more volatile performance but rather because of the different accounting decision.

Solution to 3:

NOW reports an increase in cash of €70 in Year 1, while CAP reports a decrease in cash of €110 because NOW's taxes were €180 lower than CAP's taxes (€30 versus €210).

Note that this problem assumes the accounting method used by each company for its tax purposes is identical to the accounting method used by the company for its financial reporting. In many countries, companies are allowed to use different depreciation methods for financial reporting and taxes, which may give rise to deferred taxes.

As shown, discretion regarding whether to expense or capitalise expenditures can impede comparability across companies. Example 4 assumes the companies purchase a single asset in one year. Because the sum of net income over the three-year period is identical whether the asset is capitalised or expensed, it illustrates that although capitalising results in higher profitability compared to expensing in the first year, it results in lower profitability in the subsequent years. Conversely, expensing results in lower profitability in the first year but higher profitability in later years, indicating a favorable trend.

Similarly, shareholders' equity for a company that capitalises the expenditure will be higher in the early years because the initially higher profits result in initially higher retained earnings. Example 4 assumes the companies purchase a single asset in one year and report identical amounts of total net income over the three-year period, so shareholders' equity (and retained earnings) for the firm that expenses will be identical to shareholders' equity (and retained earnings) for the capitalising firm at the end of the three-year period.

Although Example 4 shows companies purchasing an asset only in the first year, if a company continues to purchase similar or increasing amounts of assets each year, the profitability-enhancing effect of capitalising continues if the amount of the expenditures in a period continues to be more than the depreciation expense. Example 5 illustrates this point.

EXAMPLE 5

Impact of Capitalising Versus Expensing for Ongoing Purchases

A company buys a £300 computer in Year 1 and capitalises the expenditure. The computer has a useful life of three years and an expected salvage value of £0, so the annual depreciation expense using the straight-line method is £100 per year. Compared to expensing the entire £300 immediately, the company's pre-tax profit in Year 1 is £200 greater.

1 Assume that the company continues to buy an identical computer each year at the same price. If the company uses the same accounting treatment for each of the computers, when does the profit-enhancing effect of capitalising versus expensing end?

2 If the company buys another identical computer in Year 4, using the same accounting treatment as the prior years, what is the effect on Year 4 profits of capitalising versus expensing these expenditures?

Solution to 1:

The profit-enhancing effect of capitalising versus expensing would end in Year 3. In Year 3, the depreciation expense on each of the three computers bought in Years 1, 2, and 3 would total £300 (£100 + £100 + £100). Therefore, the total depreciation expense for Year 3 will be exactly equal to the capital expenditure in Year 3. The expense in Year 3 would be £300, regardless of whether the company capitalised or expensed the annual computer purchases.

Solution to 2:

There is no impact on Year 4 profits. As in the previous year, the depreciation expense on each of the three computers bought in Years 2, 3, and 4 would total £300 (£100 + £100 + £100). Therefore, the total depreciation expense for Year 4 will be exactly equal to the capital expenditure in Year 4. Pre-tax profits would be reduced by £300, regardless of whether the company capitalised or expensed the annual computer purchases.

Compared to expensing an expenditure, capitalising the expenditure typically results in greater amounts reported as cash from operations. Capitalised expenditures are typically treated as an investment cash outflow whereas expenses reduce operating cash flows. Because cash flow from operating activities is an important consideration in some valuation models, companies may try to maximise reported cash flow from operations by capitalising expenditures that should be expensed. Valuation models that use free cash flow will consider not only operating cash flows but also investing cash flows. Analysts should be alert to evidence of companies manipulating reported cash flow from operations by capitalising expenditures that should be expensed.

In summary, holding all else constant, capitalising an expenditure enhances current profitability and increases reported cash flow from operations. The profitability-enhancing effect of capitalising continues so long as capital expenditures exceed the depreciation expense. Profitability-enhancing motivations for decisions to capitalise should be considered when analyzing performance. For example, a company may choose to capitalise more expenditures (within the allowable bounds of accounting standards) to achieve earnings targets for a given period. Expensing a cost in the period reduces current period profits but enhances future profitability and thus enhances the profit trend. Profit trend-enhancing motivations should also be considered when analyzing performance. If the company is in a reporting environment which requires identical accounting methods for financial reporting and taxes (unlike the United States, which permits companies to use depreciation methods for reporting purposes that differ from the depreciation method required by tax purposes), then expensing will have a more favorable cash flow impact because paying lower taxes in an earlier period creates an opportunity to earn interest income on the cash saved.

In contrast with the relatively simple examples above, it is generally neither possible nor desirable to identify individual instances involving discretion about whether to capitalise or expense expenditures. An analyst can, however, typically identify significant items of expenditure treated differently across companies. The items of expenditure giving rise to the most relevant differences across companies will vary by industry. This cross-industry variation is apparent in the following discussion of the capitalisation of expenditures.

CAPITALISATION OF INTEREST COSTS

4

c explain and evaluate how capitalising versus expensing costs in the period in which they are incurred affects financial statements and ratios;

As noted above, companies generally must capitalise interest costs associated with acquiring or constructing an asset that requires a long period of time to get ready for its intended use.[11]

As a consequence of this accounting treatment, a company's interest costs for a period can appear either on the balance sheet (to the extent they are capitalised) or on the income statement (to the extent they are expensed).

---

[11] IAS 23 [Borrowing Costs] and FASB ASC Subtopic 835-20 [Interest – Capitalization of Interest] specify respectively IFRS and US GAAP for capitalisation of interest costs. Although the standards are not completely converged, the standards are in general agreement.

If the interest expenditure is incurred in connection with constructing an asset for the company's own use, the capitalised interest appears on the balance sheet as a part of the relevant long-lived asset. The capitalised interest is expensed over time as the property is depreciated—and is thus part of depreciation expense rather than interest expense. If the interest expenditure is incurred in connection with constructing an asset to sell, for example by a real estate construction company, the capitalised interest appears on the company's balance sheet as part of inventory. The capitalised interest is then expensed as part of the cost of sales when the asset is sold.

The treatment of capitalised interest poses certain issues that analysts should consider. First, capitalised interest appears as part of investing cash outflows, whereas expensed interest typically reduces operating cash flow. US GAAP reporting companies are required to categorize interest in operating cash flow, and IFRS reporting companies can categorize interest in operating, investing, or financing cash flows. Although the treatment is consistent with accounting standards, an analyst may want to examine the impact on reported cash flows. Second, interest coverage ratios are solvency indicators measuring the extent to which a company's earnings (or cash flow) in a period covered its interest costs. To provide a true picture of a company's interest coverage, the entire amount of interest expenditure, both the capitalised portion and the expensed portion, should be used in calculating interest coverage ratios. Additionally, if a company is depreciating interest that it capitalised in a previous period, income should be adjusted to eliminate the effect of that depreciation. Example 6 illustrates the calculations.

EXAMPLE 6

Effect of Capitalised Interest Costs on Coverage Ratios and Cash Flow

Melco Resorts & Entertainment Limited (NASDAQ: MLCO), a Hong Kong SAR based casino company which is listed on the NASDAQ stock exchange and prepares financial reports under US GAAP, disclosed the following information in one of the footnotes to its 2017 financial statements: "Interest and amortization of deferred financing costs associated with major development and construction projects is capitalized and included in the cost of the project. …. Total interest expenses incurred amounted to $267,065, $252,600, and $253,168, of which $37,483, $29,033, and $134,838 were capitalized during the years ended December 31, 2017, 2016, and 2015, respectively. Amortization of deferred financing costs of $26,182, $48,345, and $38,511, net of amortization capitalized of nil, nil, and $5,458, were recorded during the years ended December 31, 2017, 2016, and 2015, respectively." (Form 20-F filed 12 April 2018). Cash payments for deferred financing costs were reported in cash flows from financing activities.

Exhibit 3 Melco Resorts & Entertainment Limited Selected Data, as Reported (Dollars in thousands)

	2017	2016	2015
EBIT (from income statement)	544,865	298,663	58,553
Interest expense (from income statement)	229,582	223,567	118,330
Capitalized interest (from footnote)	37,483	29,033	134,838
Amortization of deferred financing costs (from footnote)	26,182	48,345	38,511

Exhibit 3 (Continued)

	2017	2016	2015
Net cash provided by operating activities	1,162,500	1,158,128	522,026
Net cash from (used) in investing activities	(410,226)	280,604	(469,656)
Net cash from (used) in financing activities	(1,046,041)	(1,339,717)	(29,688)

Notes: EBIT represents "Income (Loss) Before Income Tax" plus "Interest expenses, net of capitalized interest" from the income statement.

1 Calculate and interpret Melco's interest coverage ratio with and without capitalised interest.

2 Calculate Melco's percentage change in operating cash flow from 2016 to 2017. Assuming the financial reporting does not affect reporting for income taxes, what were the effects of capitalised interest on operating and investing cash flows?

Solution to 1:

Interest coverage ratios with and without capitalised interest were as follows:

For 2017

2.37 ($544,865 ÷ $229,582) without adjusting for capitalised interest; and

2.14 [($544,865 + $26,182) ÷ ($229,582 + $37,483)] including an adjustment to EBIT for depreciation of previously capitalised interest and an adjustment to interest expense for the amount of interest capitalised in 2017.

For 2016

1.34 ($298,663÷ $223,567) without adjusting for capitalised interest; and

1.37 [($298,663 + $48,345) ÷ ($223,567 + $29,033)] including an adjustment to EBIT for depreciation of previously capitalised interest and an adjustment to interest expense for the amount of interest capitalised in 2016.

For 2015

0.49 ($58,533÷ $118,330) without adjusting for capitalised interest; and

0.38 [($58,533 + $38,511) ÷ ($118,330+ $134,838)] including an adjustment to EBIT for depreciation of previously capitalised interest and an adjustment to interest expense for the amount of interest capitalised in 2015.

The above calculations indicate that Melco's interest coverage improved in 2017 compared to the previous two years. In both 2017 and 2015, the coverage ratio is lower when adjusted for capitalised interest.

Solution to 2:

If the interest had been expensed rather than capitalised, operating cash flows would have been lower in all three years. On an adjusted basis, but not an unadjusted basis, the company's operating cash flow declined in 2017 compared to 2016. On an unadjusted basis, for 2017 compared with 2016, Melco's operating cash flow increased by 0.4 percent in 2017 [($1,162,500 ÷ $1,158,128) – 1]. Including adjustments to expense all interest costs, Melco's operating cash flow also decreased by 0.4 percent in 2017 {[$1,162,500 – $37,483) ÷ ($1,158,128 – $29,033)] – 1}.

If the interest had been expensed rather than capitalised, financing cash flows would have been higher in all three years.

The treatment of capitalised interest raises issues for consideration by an analyst. First, capitalised interest appears as part of investing cash outflows, whereas expensed interest reduces operating or financing cash flow under IFRS and operating cash flow under US GAAP. An analyst may want to examine the impact on reported cash flows of interest expenditures when comparing companies. Second, interest coverage ratios are solvency indicators measuring the extent to which a company's earnings (or cash flow) in a period covered its interest costs. To provide a true picture of a company's interest coverage, the entire amount of interest, both the capitalised portion and the expensed portion, should be used in calculating interest coverage ratios.

Generally, including capitalised interest in the calculation of interest coverage ratios provides a better assessment of a company's solvency. In assigning credit ratings, rating agencies include capitalised interest in coverage ratios. For example, Standard & Poor's calculates the EBIT interest coverage ratio as EBIT divided by gross interest (defined as interest prior to deductions for capitalised interest or interest income).

Maintaining a minimum interest coverage ratio is a financial covenant often included in lending agreements, e.g., bank loans and bond indentures. The definition of the coverage ratio can be found in the company's credit agreement. The definition is relevant because treatment of capitalised interest in calculating coverage ratios would affect an assessment of how close a company's actual ratios are to the levels specified by its financial covenants and thus the probability of breaching those covenants.

5

CAPITALISATION OF INTEREST AND INTERNAL DEVELOPMENT COSTS

c explain and evaluate how capitalising versus expensing costs in the period in which they are incurred affects financial statements and ratios;

As noted above, accounting standards require companies to capitalise software development costs after a product's feasibility is established. Despite this requirement, judgment in determining feasibility means that companies' capitalisation practices may differ. For example, as illustrated in Exhibit 4, Microsoft judges product feasibility to be established very shortly before manufacturing begins and, therefore, effectively expenses—rather than capitalises—research and development costs.

Exhibit 4 Disclosure on Software Development Costs

Excerpt from Management's Discussion and Analysis (MD&A) of Microsoft Corporation, Application of Critical Accounting Policies, Research and Development Costs:

> "Costs incurred internally in researching and developing a computer software product are charged to expense until technological feasibility has been established for the product. Once technological feasibility is established, all software costs are capitalized until the product is available for general release to customers. Judgment is required in determining when technological feasibility of a product is established. We have determined that technological feasibility for our software products is reached after all high-risk development issues have been

Exhibit 4 (Continued)

resolved through coding and testing. Generally, this occurs shortly before the products are released to production. The amortization of these costs is included in cost of revenue over the estimated life of the products."

Source: Microsoft Corporation Annual Report on Form 10-K 2017, p. 45.

Expensing rather than capitalising development costs results in lower net income in the current period. Expensing rather than capitalising will continue to result in lower net income so long as the amount of the current-period development expenses is higher than the amortisation expense that would have resulted from amortising prior periods' capitalised development costs—the typical situation when a company's development costs are increasing. On the statement of cash flows, expensing rather than capitalising development costs results in lower net operating cash flows and higher net investing cash flows. This is because the development costs are reflected as operating cash outflows rather than investing cash outflows.

In comparing the financial performance of a company that expenses most or all software development costs, such as Microsoft, with another company that capitalises software development costs, adjustments can be made to make the two comparable. For the company that capitalises software development costs, an analyst can adjust (a) the income statement to include software development costs as an expense and to exclude amortisation of prior years' software development costs; (b) the balance sheet to exclude capitalised software (decrease assets and equity); and (c) the statement of cash flows to decrease operating cash flows and decrease cash used in investing by the amount of the current period development costs. Any ratios that include income, long-lived assets, or cash flow from operations—such as return on equity—will also be affected.

EXAMPLE 7

Software Development Costs

You are working on a project involving the analysis of JHH Software, a (hypothetical) software development company that established technical feasibility for its first product in 2017. Part of your analysis involves computing certain market-based ratios, which you will use to compare JHH to another company that expenses all of its software development expenditures. Relevant data and excerpts from the company's annual report are included in Exhibit 5.

Exhibit 5 JHH SOFTWARE (Dollars in Thousands, Except Per-Share Amounts)

CONSOLIDATED STATEMENT OF EARNINGS—abbreviated

For year ended 31 December:	2018	2017	2016
Total revenue	$91,424	$91,134	$96,293
Total operating expenses	78,107	78,908	85,624
Operating income	13,317	12,226	10,669
Provision for income taxes	3,825	4,232	3,172

(continued)

Exhibit 5 (Continued)

CONSOLIDATED STATEMENT OF EARNINGS—abbreviated

For year ended 31 December:	2018	2017	2016
Net income	$9,492	$7,994	$7,479
Earnings per share (EPS)	$1.40	$0.82	$0.68

STATEMENT OF CASH FLOWS—abbreviated

For year ended 31 December:	2018	2017	2016
Net cash provided by operating activities	$15,007	$14,874	$15,266
Net cash used in investing activities*	(11,549)	(4,423)	(5,346)
Net cash used in financing activities	(8,003)	(7,936)	(7,157)
Net change in cash and cash equivalents	($4,545)	$2,515	$2,763
**Includes software development expenses of and includes capital expenditures of*	*($6,000)* *($2,000)*	*($4,000)* *($1,600)*	*($2,000)* *($1,200)*

Additional information:

For year ended 31 December:	2018	2017	2016
Market value of outstanding debt	0	0	0
Amortisation of capitalised software development expenses	($2,000)	($667)	0
Depreciation expense	($2,200)	($1,440)	($1,320)
Market price per share of common stock	$42	$26	$17
Shares of common stock outstanding (thousands)	6,780	9,765	10,999

Footnote disclosure of accounting policy for software development:
Expenses that are related to the conceptual formulation and design of software products are expensed to research and development as incurred. The company capitalises expenses that are incurred to produce the finished product after technological feasibility has been established.

1 Compute the following ratios for JHH based on the reported financial statements for fiscal year ended 31 December 2018, with no adjustments. Next, determine the approximate impact on these ratios if the company had expensed rather than capitalised its investments in software. (Assume the financial reporting does not affect reporting for income taxes. There would be no change in the effective tax rate.)

A P/E: Price/Earnings per share

B P/CFO: Price/Operating cash flow per share

C EV/EBITDA: Enterprise value/EBITDA, where enterprise value is defined as the total market value of all sources of a company's financing, including equity and debt, and EBITDA is earnings before interest, taxes, depreciation, and amortisation.

2 Interpret the changes in the ratios.

Solution to 1:

(Dollars are in thousands, except per-share amounts.) JHH's 2019 ratios are presented in the following table:

	Ratios	As reported	As adjusted
A	P/E ratio	30.0	42.9
B	P/CFO	19.0	31.6
C	EV/EBITDA	16.3	24.7

A Based on the information as reported, the P/E ratio was 30.0 ($42 ÷ $1.40). Based on EPS adjusted to expense software development costs, the P/E ratio was 42.9 ($42 ÷ $0.98).

- Price: Assuming that the market value of the company's equity is based on its fundamentals, the price per share is $42, regardless of a difference in accounting.
- EPS: As reported, EPS was $1.40. Adjusted EPS was $0.98. Expensing software development costs would have reduced JHH's 2018 operating income by $6,000, but the company would have reported no amortisation of prior years' software costs, which would have increased operating income by $2,000. The net change of $4,000 would have reduced operating income from the reported $13,317 to $9,317. The effective tax rate for 2018 ($3,825 ÷ $13,317) is 28.72%, and using this effective tax rate would give an adjusted net income of $6,641 [$9,317 × (1 − 0.2872)], compared to $9,492 before the adjustment. The EPS would therefore be reduced from the reported $1.40 to $0.98 (adjusted net income of $6,641 divided by 6,780 shares).

B Based on information as reported, the P/CFO was 19.0 ($42 ÷ $2.21). Based on CFO adjusted to expense software development costs, the P/CFO was 31.6 ($42 ÷ $1.33).

- Price: Assuming that the market value of the company's equity is based on its fundamentals, the price per share is $42, regardless of a difference in accounting.
- CFO per share, as reported, was $2.21 (total operating cash flows $15,007 ÷ 6,780 shares).
- CFO per share, as adjusted, was $1.33. The company's $6,000 expenditure on software development costs was reported as a cash outflow from investing activities, so expensing those costs would reduce cash from operating activities by $6,000, from the reported $15,007 to $9,007. Dividing adjusted total operating cash flow of $9,007 by 6,780 shares results in cash flow per share of $1.33.

C Based on information as reported, the EV/EBITDA was 16.3 ($284,760 ÷ $17,517). Based on EBITDA adjusted to expense software development costs, the EV/EBITDA was 24.7 ($284,760 ÷ $11,517).

- Enterprise Value: Enterprise value is the sum of the market value of the company's equity and debt. JHH has no debt, and therefore the enterprise value is equal to the market value of its equity. The market value of its equity is $284,760 ($42 per share × 6,780 shares).
- EBITDA, as reported, was $17,517 (earnings before interest and taxes of $13,317 plus $2,200 depreciation plus $2,000 amortisation).
- EBITDA, adjusted for expensing software development costs by the inclusion of $6,000 development expense and the exclusion of $2,000 amortisation of prior expense, would be $11,517 (earnings before interest and taxes of $9,317 plus $2,200 depreciation plus $0 amortisation).

Solution to 2:

Expensing software development costs would decrease historical profits, operating cash flow, and EBITDA, and would thus increase all market multiples. So JHH's stock would appear more expensive if it expensed rather than capitalised the software development costs.

If the unadjusted market-based ratios were used in the comparison of JHH to its competitor that expenses all software development expenditures, then JHH might appear to be under-priced when the difference is solely related to accounting factors. JHH's adjusted market-based ratios provide a better basis for comparison.

For the company in Example 7, current period software development expenditures exceed the amortisation of prior periods' capitalised software development expenditures. As a result, expensing rather than capitalising software development costs would have the effect of lowering income. If, however, software development expenditures slowed such that current expenditures were lower than the amortisation of prior periods' capitalised software development expenditures, then expensing software development costs would have the effect of increasing income relative to capitalising it.

This section illustrated how decisions about capitalising versus expensing impact financial statements and ratios. Earlier expensing lowers current profits but enhances trends, whereas capitalising now and expensing later enhances current profits. Having described the accounting for acquisition of long-lived assets, we now turn to the topic of measuring long-lived assets in subsequent periods.

6

DEPRECIATION OF LONG-LIVED ASSETS: METHODS AND CALCULATION

d describe the different depreciation methods for property, plant, and equipment and calculate depreciation expense;

e describe how the choice of depreciation method and assumptions concerning useful life and residual value affect depreciation expense, financial statements, and ratios;

k explain and evaluate how impairment, revaluation, and derecognition of property, plant, and equipment and intangible assets affect financial statements and ratios;

Under the cost model of reporting long-lived assets, which is permitted under IFRS and required under US GAAP, the capitalised costs of long-lived tangible assets (other than land, which is not depreciated) and intangible assets with finite useful lives are allocated to subsequent periods as depreciation and amortisation expenses. Depreciation and amortisation are effectively the same concept, with the term depreciation referring to the process of allocating tangible assets' costs and the term amortisation referring to the process of allocating intangible assets' costs.[12] The alternative model of reporting long-lived assets is the **revaluation model**, which is permitted under IFRS but not under US GAAP. Under the revaluation model, a company reports the long-lived asset at fair value rather than at acquisition cost (historical cost) less accumulated depreciation or amortisation, as in the cost model.

An asset's carrying amount is the amount at which the asset is reported on the balance sheet. Under the cost model, at any point in time, the carrying amount (also called carrying value or net book value) of a long-lived asset is equal to its historical cost minus the amount of depreciation or amortisation that has been accumulated since the asset's purchase (assuming that the asset has not been impaired, a topic which will be addressed in Section 9). Companies may present on the balance sheet the total net amount of property, plant, and equipment and the total net amount of intangible assets. However, more detail is disclosed in the notes to financial statements. The details disclosed typically include the acquisition costs, the depreciation and amortisation expenses, the accumulated depreciation and amortisation amounts, the depreciation and amortisation methods used, and information on the assumptions used to depreciate and amortise long-lived assets.

6.1 Depreciation Methods and Calculation of Depreciation Expense

Depreciation methods include the **straight-line method**, in which the cost of an asset is allocated to expense evenly over its useful life; **accelerated methods**, in which the allocation of cost is greater in earlier years; and the **units-of-production method**, in which the allocation of cost corresponds to the actual use of an asset in a particular period. The choice of depreciation method affects the amounts reported on the financial statements, including the amounts for reported assets and operating and net income. This, in turn, affects a variety of financial ratios, including fixed asset turnover, total asset turnover, operating profit margin, operating return on assets, and return on assets.

Using the straight-line method, depreciation expense is calculated as depreciable cost divided by estimated useful life and is the same for each period. Depreciable cost is the historical cost of the tangible asset minus the estimated residual (salvage) value.[13] A commonly used accelerated method is the declining balance method, in which the amount of depreciation expense for a period is calculated as some percentage of the carrying amount (i.e., cost net of accumulated depreciation at the beginning of the period). When an accelerated method is used, depreciable cost is not used to calculate the depreciation expense but the carrying amount should not be reduced below the estimated residual value. In the units-of-production method, the amount of depreciation expense for a period is based on the proportion of the asset's production during the period compared with the total estimated productive capacity of the asset over its useful life. The depreciation expense is calculated as depreciable cost times production in the period divided by estimated productive capacity over the life of the asset. Equivalently, the company may estimate a depreciation cost per unit (depreciable cost divided by estimated productive capacity) and calculate depreciation expense as depreciation cost per unit times production in the period. Regardless of the depreciation method used, the carrying amount of the asset is not reduced below the estimated residual value. Example 8 provides an example of these depreciation methods.

---

[12] Depletion is the term applied to a similar concept for natural resources; costs associated with those resources are allocated to a period on the basis of the usage or extraction of those resources.

[13] The residual value is the estimated amount that an entity will obtain from disposal of the asset at the end of its useful life.

EXAMPLE 8

Alternative Depreciation Methods

You are analyzing three hypothetical companies: EVEN-LI Co., SOONER Inc., and AZUSED Co. At the beginning of Year 1, each company buys an identical piece of box manufacturing equipment for $2,300 and has the same assumptions about useful life, estimated residual value, and productive capacity. The annual production of each company is the same, but each company uses a different method of depreciation. As disclosed in each company's notes to the financial statements, each company's depreciation method, assumptions, and production are as follows:

Depreciation method

- EVEN-LI Co.: straight-line method
- SOONER Inc.: double-declining balance method (the rate applied to the carrying amount is double the depreciation rate for the straight-line method)
- AZUSED Co.: units-of-production method

Assumptions and production

- Estimated residual value: $100
- Estimated useful life: 4 years
- Total estimated productive capacity: 800 boxes
- Production in each of the four years: 200 boxes in the first year, 300 in the second year, 200 in the third year, and 100 in the fourth year

1 Using the following template for each company, record its beginning and ending net book value (carrying amount), end-of-year accumulated depreciation, and annual depreciation expense for the box manufacturing equipment.

Template:

	Beginning Net Book Value	Depreciation Expense	Accumulated Depreciation	Ending Net Book Value
Year 1				
Year 2				
Year 3				
Year 4				

2 Explain the significant differences in the timing of the recognition of the depreciation expense.

3 For each company, assume that sales, earnings before interest, taxes, depreciation, and amortization, and assets other than the box manufacturing equipment are as shown in the following table. Calculate the total asset turnover ratio, the operating profit margin, and the operating return on assets for each company for each of the four years. Discuss the ratios, comparing results within and across companies.

	Sales	Earnings before Interest, Taxes, Depreciation, and Amortization	Carrying Amount of Total Assets, Excluding the Box Manufacturing Equipment, at Year End*
Year 1	$300,000	$36,000	$30,000
Year 2	320,000	38,400	32,000
Year 3	340,000	40,800	34,000
Year 4	360,000	43,200	36,000

* Assume that total assets at the beginning of Year 1, *including* the box manufacturing equipment, had a value of $30,300. Assume that depreciation expense on assets other than the box manufacturing equipment totaled $1,000 per year.

Solution to 1:

For *each* company, the following information applies: Beginning net book value in Year 1 equals the purchase price of $2,300; accumulated year-end depreciation equals the balance from the previous year plus the current year's depreciation expense; ending net book value (carrying amount) equals original cost minus accumulated year-end depreciation (which is the same as beginning net book value minus depreciation expense); and beginning net book value in Years 2, 3, and 4 equals the ending net book value of the prior year. The following text and filled-in templates describe how depreciation *expense* is calculated for each company.

EVEN-LI Co. uses the straight-line method, so depreciation expense in each year equals $550, which is calculated as ($2,300 original cost – $100 residual value)/4 years. The net book value at the end of Year 4 is the estimated residual value of $100.

EVEN-LI Co.	Beginning Net Book Value	Depreciation Expense	Accumulated Year-End Depreciation	Ending Net Book Value
Year 1	$2,300	$550	$550	$1,750
Year 2	1,750	550	1,100	1,200
Year 3	1,200	550	1,650	650
Year 4	650	550	2,200	100

SOONER Inc. uses the double-declining balance method. The depreciation rate for the double-declining balance method is double the depreciation rate for the straight-line method. The depreciation rate under the straight-line method is 25 percent (100 percent divided by 4 years). Thus, the depreciation rate for the double-declining balance method is 50 percent (2 times 25 percent). The depreciation expense for the first year is $1,150 (50 percent of $2,300). Note that under this method, the depreciation rate of 50 percent is applied to the carrying amount (net book value) of the asset, without adjustment for expected residual value. Because the carrying amount of the asset is not depreciated below its estimated residual value, however, the depreciation expense in the final year of depreciation decreases the ending net book value (carrying amount) to the estimated residual value.

SOONER Inc.	Beginning Net Book Value	Depreciation Expense	Accumulated Year-End Depreciation	Ending Net Book Value
Year 1	$2,300	$1,150	$1,150	$1,150
Year 2	1,150	575	1,725	575
Year 3	575	288	2,013	287
Year 4	287	187	2,200	100

Another common approach (not required in this question) is to use an accelerated method, such as the double-declining method, for some period (a year or more) and then to change to the straight-line method for the remaining life of the asset. If SOONER had used the double-declining method for the first year and then switched to the straight-line method for Years 2, 3, and 4, the depreciation expense would be $350 [($1,150 – $100 estimated residual value)/3 years] a year for Years 2, 3, and 4. The results for SOONER under this alternative approach are shown below.

SOONER Inc.	Beginning Net Book Value	Depreciation Expense	Accumulated Year-End Depreciation	Ending Net Book Value
Year 1	$2,300	$1,150	$1,150	$1,150
Year 2	1,150	350	1,500	800
Year 3	800	350	1,850	450
Year 4	450	350	2,200	100

AZUSED Co. uses the units-of-production method. Dividing the equipment's total depreciable cost by its total productive capacity gives a cost per unit of $2.75, calculated as ($2,300 original cost – $100 residual value)/800. The depreciation expense recognised each year is the number of units produced times $2.75. For Year 1, the amount of depreciation expense is $550 (200 units times $2.75). For Year 2, the amount is $825 (300 units times $2.75). For Year 3, the amount is $550. For Year 4, the amount is $275.

AZUSED Co.	Beginning Net Book Value	Depreciation Expense	Accumulated Year-End Depreciation	Ending Net Book Value
Year 1	$2,300	$550	$550	$1,750
Year 2	1,750	825	1,375	925
Year 3	925	550	1,925	375
Year 4	375	275	2,200	100

Solution to 2:

All three methods result in the same total amount of accumulated depreciation over the life of the equipment. The significant differences are simply in the timing of the recognition of the depreciation expense. The straight-line method recognises the expense evenly, the accelerated method recognises most of the expense in the first year, and the units-of-production method recognises the expense on the basis of production (or use of the asset). Under all three methods, the ending net book value is $100.

Solution to 3:

Total asset turnover ratio = Total revenue ÷ Average total assets

Operating profit margin = Earnings before interest and taxes ÷ Total revenue

Operating return on assets = Earnings before interest and taxes ÷ Average total assets

Ratios are shown in the table below, and details of the calculations for Years 1 and 2 are described after discussion of the ratios.

	EVEN-LI Co.			SOONER Inc.			AZUSED Co.		
Ratio*	**AT**	**PM (%)**	**ROA (%)**	**AT**	**PM (%)**	**ROA (%)**	**AT**	**PM (%)**	**ROA (%)**
Year 1	9.67	11.48	111.04	9.76	11.28	110.17	9.67	11.48	111.04
Year 2	9.85	11.52	113.47	10.04	11.51	115.57	9.90	11.43	113.10
Year 3	10.02	11.54	115.70	10.17	11.62	118.21	10.10	11.54	116.64
Year 4	10.18	11.57	117.74	10.23	11.67	119.42	10.22	11.65	118.98

* AT = Total asset turnover ratio. PM = Operating profit margin. ROA = Operating return on assets.

For all companies, the asset turnover ratio increased over time because sales grew at a faster rate than that of the assets. SOONER had consistently higher asset turnover ratios than the other two companies, however, because higher depreciation expense in the earlier periods decreased its average total assets. In addition, the higher depreciation in earlier periods resulted in SOONER having lower operating profit margin and operating ROA in the first year and higher operating profit margin and operating ROA in the later periods. SOONER appears to be more efficiently run, on the basis of its higher asset turnover and greater increases in profit margin and ROA over time; however, these comparisons reflect differences in the companies' choice of depreciation method. In addition, an analyst might question the sustainability of the extremely high ROAs for all three companies because such high profitability levels would probably attract new competitors, which would likely put downward pressure on the ratios.

EVEN-LI Co.

Year 1:

Total asset turnover ratio = 300,000/[(30,300 + 30,000 + 1,750)/2]
= 300,000/31,025 = 9.67
Operating profit margin = (36,000 – 1,000 – 550)/300,000
= 34,450/300,000 = 11.48%
Operating ROA = 34,450/31,025 = 111.04%

Year 2:

Total asset turnover ratio = 320,000/[(30,000 + 1,750 + 32,000 + 1,200)/2]
= 320,000/32,475 = 9.85
Operating profit margin = (38,400 – 1,000 – 550)/320,000
= 36,850/320,000 = 11.52%
Operating ROA = 36,850/32,475 = 113.47%

SOONER Inc.

Year 1:

$$\begin{aligned}
\text{Total asset turnover ratio} &= 300{,}000/[(30{,}300 + 30{,}000 + 1{,}150)/2] \\
&= 300{,}000/30{,}725 = 9.76 \\
\text{Operating profit margin} &= (36{,}000 - 1{,}000 - 1{,}150)/300{,}000 \\
&= 33{,}850/300{,}000 = 11.28\% \\
\text{Operating ROA} &= 33{,}850/30{,}725 = 110.17\%
\end{aligned}$$

Year 2:

$$\begin{aligned}
\text{Total asset turnover ratio} &= 320{,}000/[(30{,}000 + 1{,}150 + 32{,}000 + 575)/2] \\
&= 320{,}000/31{,}862.50 = 10.04 \\
\text{Operating profit margin} &= (38{,}400 - 1{,}000 - 575)/320{,}000 \\
&= 36{,}825/320{,}000 = 11.51\% \\
\text{Operating ROA} &= 36{,}825/31{,}862.50 = 115.57\%
\end{aligned}$$

AZUSED Co.

Year 1:

$$\begin{aligned}
\text{Total asset turnover ratio} &= 300{,}000/[(30{,}300 + 30{,}000 + 1{,}750)/2] \\
&= 300{,}000/31{,}025 = 9.67 \\
\text{Operating profit margin} &= (36{,}000 - 1{,}000 - 550)/300{,}000 \\
&= 34{,}450/300{,}000 = 11.48\% \\
\text{Operating ROA} &= 34{,}450/31{,}025 = 111.04\%
\end{aligned}$$

Year 2:

$$\begin{aligned}
\text{Total asset turnover ratio} &= 320{,}000/[(30{,}000 + 1{,}750 + 32{,}000 + 925)/2] \\
&= 320{,}000/32{,}337.50 = 9.90 \\
\text{Operating profit margin} &= (38{,}400 - 1{,}000 - 825)/320{,}000 \\
&= 36{,}575/320{,}000 = 11.43\% \\
\text{Operating ROA} &= 36{,}575/32{,}337.50 = 113.10\%
\end{aligned}$$

In many countries, a company must use the same depreciation methods for both financial and tax reporting. In other countries, including the United States, a company need not use the same depreciation method for financial reporting and taxes. As a result of using different depreciation methods for financial and tax reporting, pre-tax income on the income statement and taxable income on the tax return may differ. Thus, the amount of tax expense computed on the basis of pre-tax income and the amount of taxes actually owed on the basis of taxable income may differ. Although these differences eventually reverse because the total depreciation is the same regardless of the timing of its recognition in financial statements versus on tax returns, during the period of the difference, the balance sheet will show what is known as deferred taxes. For instance, if a company uses straight-line depreciation for financial reporting and an accelerated depreciation method for tax purposes, the company's financial statements will report lower depreciation expense and higher pre-tax income in the first year, compared with the amount of depreciation expense and taxable income in its tax reporting. (Compare the depreciation expense in Year 1 for EVEN-LI Co. and SOONER Inc. in the previous example.) Tax expense calculated on the basis of the financial statements' pre-tax income will be higher than taxes payable on the basis of taxable income; the difference between the two amounts represents a deferred tax liability. The deferred tax liability will be reduced as the difference reverses (i.e., when depreciation for financial reporting is higher than the depreciation for tax purposes) and the income tax is paid.

Significant estimates required for calculating depreciation include the useful life of the asset (or its total lifetime productive capacity) and its expected residual value at the end of that useful life. A longer useful life and higher expected residual value decrease the amount of annual depreciation expense relative to a shorter useful life and lower expected residual value. Companies should review their estimates periodically to ensure they remain reasonable. IFRS require companies to review estimates annually.

Although no significant differences exist between IFRS and US GAAP with respect to the definition of depreciation and the acceptable depreciation methods, IFRS require companies to use a component method of depreciation.[14] Companies are required to separately depreciate the significant components of an asset (parts of an item with a cost that is significant in relation to the total cost and/or with different useful lives) and thus require additional estimates for the various components. For instance, it may be appropriate to depreciate separately the engine, frame, and interior furnishings of an aircraft. Under US GAAP, the component method of depreciation is allowed but is seldom used in practice.[15] The following example illustrates depreciating components of an asset.

EXAMPLE 9

Illustration of Depreciating Components of an Asset

CUTITUP Co., a hypothetical company, purchases a milling machine, a type of machine used for shaping metal, at a total cost of $10,000. $2,000 was estimated to represent the cost of the rotating cutter, a significant component of the machine. The company expects the machine to have a useful life of eight years and a residual value of $3,000 and that the rotating cutter will need to be replaced every two years. Assume the entire residual value is attributable to the milling machine itself, and assume the company uses straight-line depreciation for all assets.

1. How much depreciation expense would the company report in Year 1 if it uses the component method of depreciation, and how much depreciation expense would the company report in Year 1 if it does not use the component method?
2. Assuming a new cutter with an estimated two-year useful life is purchased at the end of Year 2 for $2,000, what depreciation expenses would the company report in Year 3 if it uses the component method and if it does not use the component method?
3. Assuming replacement of the cutter every two years at a price of $2,000, what is the total depreciation expense over the eight years if the company uses the component method compared with the total depreciation expense if the company does not use the component method?
4. How many different items must the company estimate in the first year to compute depreciation expense for the milling machine if it uses the component method, and how does this compare with what would be required if it does not use the component method?

---

[14] IAS 16 *Property, Plant and Equipment*, paragraphs 43–47 [Depreciation].

[15] According to KPMG's *IFRS Compared to US GAAP*, December 2017, kpmg.com.

Solution to 1:

Depreciation expense in Year 1 under the component method would be $1,625. For the portion of the machine excluding the cutter, the depreciable base is total cost minus the cost attributable to the cutter minus the estimated residual value = $10,000 – $2,000 – $3,000 = $5,000. Depreciation expense for the machine excluding the cutter in the first year equals $625 (depreciable cost divided by the useful life of the machine = $5,000/8 years). For the cutter, the depreciation expense equals $1,000 (depreciable cost divided by the useful life of the cutter = $2,000/2 years). Thus, the total depreciation expense for Year 1 under the component method is $1,625 (the sum of the depreciation expenses of the two components = $625 + $1,000). Depreciation expense in Year 2 would also be $1,625.

If the company does not use the component method, depreciation expense in Year 1 is $875 (the depreciable cost of the total milling machine divided by its useful life = [$10,000 – $3,000]/8 years). Depreciation expense in Year 2 would also be $875.

Solution to 2:

Assuming that at the end of Year 2, the company purchases a new cutter for $2,000 with an estimated two-year life, under the component method, the depreciation expense in Year 3 will remain at $1,625. If the company does not use the component method and purchases a new cutter with an estimated two-year life for $2,000 at the end of Year 2, the depreciation expense in Year 3 will be $1,875 [$875 + ($2,000/2) = $875 + $1,000].

Solution to 3:

Over the eight years, assuming replacement of the cutters every two years at a price of $2,000, the total depreciation expense will be $13,000 [$1,625 × 8 years] when the component method is used. When the component method is not used, the total depreciation expense will also be $13,000 [$875 × 2 years + $1,875 × 6 years]. This amount equals the total expenditures of $16,000 [$10,000 + 3 cutters × $2,000] less the residual value of $3,000.

Solution to 4:

The following table summarizes the estimates required in the first year to compute depreciation expense if the company does or does not use the component method:

Estimate	Required using component method?	Required if not using component method?
Useful life of milling machine	Yes	Yes
Residual value of milling machine	Yes	Yes
Portion of machine cost attributable to cutter	Yes	No
Portion of residual value attributable to cutter	Yes	No
Useful life of cutter	Yes	No

Total depreciation expense may be allocated between the cost of sales and other expenses. Within the income statement, depreciation expense of assets used in production is usually allocated to the cost of sales, and the depreciation expense of assets not used in production may be allocated to some other expense category. For instance, depreciation expense may be allocated to selling, general, and administrative expenses if depreciable assets are used in those functional areas. Notes to the financial statements sometimes disclose information regarding which income statement line items include depreciation expense, although the exact amount of detail disclosed by individual companies varies.

AMORTISATION OF LONG-LIVED ASSETS: METHODS AND CALCULATION

7

f describe the different amortisation methods for intangible assets with finite lives and calculate amortisation expense;

g describe how the choice of amortisation method and assumptions concerning useful life and residual value affect amortisation expense, financial statements, and ratios;

k explain and evaluate how impairment, revaluation, and derecognition of property, plant, and equipment and intangible assets affect financial statements and ratios;

Amortisation is similar in concept to depreciation. The term amortisation applies to intangible assets, and the term depreciation applies to tangible assets. Both terms refer to the process of allocating the cost of an asset over the asset's useful life. Only those intangible assets assumed to have finite useful lives are amortised over their useful lives, following the pattern in which the benefits are used up. Acceptable amortisation methods are the same as the methods acceptable for depreciation. Assets assumed to have an indefinite useful life (in other words, without a finite useful life) are not amortised. An intangible asset is considered to have an indefinite useful life when there is "no foreseeable limit to the period over which the asset is expected to generate net cash inflows" for the company.[16]

Intangible assets with finite useful lives include an acquired customer list expected to provide benefits to a direct-mail marketing company for two to three years, an acquired patent or copyright with a specific expiration date, an acquired license with a specific expiration date and no right to renew the license, and an acquired trademark for a product that a company plans to phase out over a specific number of years. Examples of intangible assets with indefinite useful lives include an acquired license that, although it has a specific expiration date, can be renewed at little or no cost and an acquired trademark that, although it has a specific expiration, can be renewed at a minimal cost and relates to a product that a company plans to continue selling for the foreseeable future.

As with depreciation for a tangible asset, the calculation of amortisation for an intangible asset requires the original amount at which the intangible asset is recognised and estimates of the length of its useful life and its residual value at the end of its useful life. Useful lives are estimated on the basis of the expected use of the asset, considering any factors that may limit the life of the asset, such as legal, regulatory, contractual, competitive, or economic factors.

---

[16] IAS 38 *Intangible Assets*, paragraph 88.

EXAMPLE 10

Amortisation Expense

IAS 38 *Intangible Assets* provides illustrative examples regarding the accounting for intangible assets, including the following:

> A direct-mail marketing company acquires a customer list and expects that it will be able to derive benefit from the information on the list for at least one year, but no more than three years. The customer list would be amortised over management's best estimate of its useful life, say 18 months. Although the direct-mail marketing company may intend to add customer names and other information to the list in the future, the expected benefits of the acquired customer list relate only to the customers on that list at the date it was acquired.

In this example, in what ways would management's decisions and estimates affect the company's financial statements?

Solution:

Because the acquired customer list is expected to generate future economic benefits for a period greater than one year, the cost of the list should be capitalised and not expensed. The acquired customer list is determined to not have an indefinite life and must be amortised. Management must estimate the useful life of the customer list and must select an amortisation method. In this example, the list appears to have no residual value. Both the amortisation method and the estimated useful life affect the amount of the amortisation expense in each period. A shorter estimated useful life, compared with a longer estimated useful life, results in a higher amortisation expense each year over a shorter period, but the *total* accumulated amortisation expense over the life of the intangible asset is unaffected by the estimate of the useful life. Similarly, the total accumulated amortisation expense over the life of the intangible asset is unaffected by the choice of amortisation method. The amortisation expense per period depends on the amortisation method. If the straight-line method is used, the amortisation expense is the same for each year of useful life. If an accelerated method is used, the amortisation expense will be higher in earlier years.

8

THE REVALUATION MODEL

h describe the revaluation model;

k explain and evaluate how impairment, revaluation, and derecognition of property, plant, and equipment and intangible assets affect financial statements and ratios;

The revaluation model is an alternative to the cost model for the periodic valuation and reporting of long-lived assets. IFRS permit the use of either the revaluation model or the cost model, but the revaluation model is not allowed under US GAAP. Revaluation changes the carrying amounts of classes of long-lived assets to fair value (the fair value must be measured reliably). Under the cost model, carrying amounts are historical costs less accumulated depreciation or amortisation. Under the revaluation model, carrying amounts are the fair values at the date of revaluation less any subsequent accumulated depreciation or amortisation.

IFRS allow companies to value long-lived assets either under a cost model at historical cost minus accumulated depreciation or amortisation or under a revaluation model at fair value. In contrast, US accounting standards require that the cost model be used. A key difference between the two models is that the cost model allows only decreases in the values of long-lived assets compared with historical costs but the revaluation model may result in increases in the values of long-lived assets to amounts greater than historical costs.

IFRS allow a company to use the cost model for some classes of assets and the revaluation model for others, but the company must apply the same model to all assets within a particular class of assets and must revalue all items within a class to avoid selective revaluation. Examples of different classes of assets include land, land and buildings, machinery, motor vehicles, furniture and fixtures, and office equipment. The revaluation model may be used for classes of intangible assets but only if an active market for the assets exists, because the revaluation model may only be used if the fair values of the assets can be measured reliably. For practical purposes, the revaluation model is rarely used for either tangible or intangible assets, but its use is especially rare for intangible assets.

Under the revaluation model, whether an asset revaluation affects earnings depends on whether the revaluation initially increases or decreases an asset class' carrying amount. If a revaluation initially decreases the carrying amount of the asset class, the decrease is recognised in profit or loss. Later, if the carrying amount of the asset class increases, the increase is recognised in profit or loss to the extent that it reverses a revaluation decrease of the same asset class previously recognised in profit or loss. Any increase in excess of the reversal amount will not be recognised in the income statement but will be recorded directly to equity in a revaluation surplus account. An upward revaluation is treated the same as the amount in excess of the reversal amount. In other words, if a revaluation initially increases the carrying amount of the asset class, the increase in the carrying amount of the asset class bypasses the income statement and goes directly to equity under the heading of revaluation surplus. Any subsequent decrease in the asset's value first decreases the revaluation surplus and then goes to income. When an asset is retired or disposed of, any related amount of revaluation surplus included in equity is transferred directly to retained earnings.

Asset revaluations offer several considerations for financial statement analyses. First, an increase in the carrying amount of depreciable long-lived assets increases total assets and shareholders' equity, so asset revaluations that increase the carrying amount of an asset can be used to reduce reported leverage. Defining leverage as average total assets divided by average shareholders' equity, increasing both the numerator (assets) and denominator (equity) by the same amount leads to a decline in the ratio. (Mathematically, when a ratio is greater than one, as in this case, an increase in both the numerator and the denominator by the same amount leads to a decline in the ratio.) Therefore, the leverage motivation for the revaluation should be considered in analysis. For example, a company may revalue assets up if it is seeking new capital or approaching leverage limitations set by financial covenants.

Second, assets revaluations that decrease the carrying amount of the assets reduce net income. In the year of the revaluation, profitability measures such as return on assets and return on equity decline. However, because total assets and shareholders' equity are also lower, the company may appear more profitable in future years. Additionally, reversals of downward revaluations also go through income, thus increasing earnings. Managers can then opportunistically time the reversals to manage earnings and increase income. Third, asset revaluations that increase the carrying amount of an asset initially increase depreciation expense, total assets, and shareholders' equity. Therefore, profitability measures, such as return on assets and return on equity, would decline. Although upward asset revaluations also generally decrease income (through higher depreciation expense), the increase in the value of the long-lived asset is presumably based on increases in the operating capacity of the asset, which will likely be evidenced in increased future revenues.

Finally, an analyst should consider who did the appraisal—i.e. an independent external appraiser or management—and how often revaluations are made. Appraisals of the fair value of long-lived assets involve considerable judgment and discretion. Presumably, appraisals of assets from independent external sources are more reliable. How often assets are revalued can provide an indicator of whether their reported value continues to be representative of their fair values.

The next two examples illustrate revaluation of long-lived assets under IFRS.

EXAMPLE 11

Revaluation Resulting in an Increase in Carrying Amount Followed by Subsequent Revaluation Resulting in a Decrease in Carrying Amount

UPFIRST, a hypothetical manufacturing company, has elected to use the revaluation model for its machinery. Assume for simplicity that the company owns a single machine, which it purchased for €10,000 on the first day of its fiscal period, and that the measurement date occurs simultaneously with the company's fiscal period end.

1 At the end of the first fiscal period after acquisition, assume the fair value of the machine is determined to be €11,000. How will the company's financial statements reflect the asset?

2 At the end of the second fiscal period after acquisition, assume the fair value of the machine is determined to be €7,500. How will the company's financial statements reflect the asset?

Solution to 1:

At the end of the first fiscal period, the company's balance sheet will show the asset at a value of €11,000. The €1,000 increase in the value of the asset will appear in other comprehensive income and be accumulated in equity under the heading of revaluation surplus.

Solution to 2:

At the end of the second fiscal period, the company's balance sheet will show the asset at a value of €7,500. The total decrease in the carrying amount of the asset is €3,500 (€11,000 – €7,500). Of the €3,500 decrease, the first €1,000 will reduce the amount previously accumulated in equity under the heading of revaluation surplus. The other €2,500 will be shown as a loss on the income statement.

EXAMPLE 12

Revaluation Resulting in a Decrease in Asset's Carrying Amount Followed by Subsequent Revaluation Resulting in an Increase in Asset's Carrying Amount

DOWNFIRST, a hypothetical manufacturing company, has elected to use the revaluation model for its machinery. Assume for simplicity that the company owns a single machine, which it purchased for €10,000 on the first day of its fiscal period, and that the measurement date occurs simultaneously with the company's fiscal period end.

1. At the end of the first fiscal period after acquisition, assume the fair value of the machine is determined to be €7,500. How will the company's financial statements reflect the asset?
2. At the end of the second fiscal period after acquisition, assume the fair value of the machine is determined to be €11,000. How will the company's financial statements reflect the asset?

Solution to 1:

At the end of the first fiscal period, the company's balance sheet will show the asset at a value of €7,500. The €2,500 decrease in the value of the asset will appear as a loss on the company's income statement.

Solution to 2:

At the end of the second fiscal period, the company's balance sheet will show the asset at a value of €11,000. The total increase in the carrying amount of the asset is an increase of €3,500 (€11,000 – €7,500). Of the €3,500 increase, the first €2,500 reverses a previously reported loss and will be reported as a gain on the income statement. The other €1,000 will bypass profit or loss and be reported as other comprehensive income and be accumulated in equity under the heading of revaluation surplus.

Exhibit 6 provides two examples of disclosures concerning the revaluation model. The first disclosure is an excerpt from the 2006 annual report of KPN, a Dutch telecommunications and multimedia company. The report was produced at a time during which any IFRS-reporting company with a US stock exchange listing was required to explain differences between its reporting under IFRS and its reporting if it had used US GAAP.[17] One of these differences, as previously noted, is that US GAAP do not allow revaluation of fixed assets held for use. KPN's disclosure states that the company elected to report a class of fixed assets (cables) at fair value and explained that under US GAAP, using the cost model, the value of the asset class would have been €350 million lower. The second disclosure is an excerpt from the 2017 annual report of Avianca Holdings S.A., a Latin American airline that reports under IFRS and uses the revaluation model for one component of its fixed assets.

---

[17] On 15 November 2007, the SEC approved rule amendments under which financial statements from foreign private issuers in the United States will be accepted without reconciliation to US GAAP if the financial statements are prepared in accordance with IFRS as issued by the International Accounting Standards Board. The rule took effect for the 2007 fiscal year. As a result, companies such as KPN no longer need to provide reconciliations to US GAAP.

Exhibit 6 Impact of Revaluation

1 Excerpt from the annual report of Koninklijke KPN N.V. explaining certain differences between IFRS and US GAAP regarding "Deemed cost fixed assets":

> KPN elected the exemption to revalue certain of its fixed assets upon the transition to IFRS to fair value and to use this fair value as their deemed cost. KPN applied the depreciated replacement cost method to determine this fair value. The revalued assets pertain to certain cables, which form part of property, plant & equipment. Under US GAAP, this revaluation is not allowed and therefore results in a reconciling item. As a result, the value of these assets as of December 31, 2006 under US GAAP is EUR 350 million lower (2005: EUR 415 million; 2004: EUR 487 million) than under IFRS.
>
> *Source*: KPN's Form 20-F, p. 168, filed 1 March 2007.

2 The 2017 annual report of Avianca Holdings S.A. and Subsidiaries shows $58.4 million of "Revaluation and Other Reserves" as a component of Equity on its balance sheet and $31.0 million in Other Comprehensive Income for the current year's "Revaluation of Administrative Property". The relevant footnote disclosure explains:

> "Administrative property in Bogota, Medellín, El Salvador, and San Jose is recorded at fair value less accumulated depreciation on buildings and impairment losses recognized at the date of revaluation. Valuations are performed with sufficient frequency to ensure that the fair value of a revalued asset does not differ materially from its carrying amount. A revaluation reserve is recorded in other comprehensive income and credited to the asset revaluation reserve in equity. However, to the extent that it reverses a revaluation deficit of the same asset previously recognized in profit or loss, the increase is recognized in profit and loss. A revaluation deficit is recognized in the income statement, except to the extent that it offsets an existing surplus on the same asset recognized in the asset revaluation reserve. Upon disposal, any revaluation reserve relating to the particular asset being sold is transferred to retained earnings.
>
> *Source*: AVIANCA HOLDINGS S.A. Form 20-F filed 01 May 2018.

Clearly, the use of the revaluation model as opposed to the cost model can have a significant impact on the financial statements of companies. This has potential consequences for comparing financial performance using financial ratios of companies that use different models.

9 IMPAIRMENT OF ASSETS

i. explain the impairment of property, plant, and equipment and intangible assets;

k. explain and evaluate how impairment, revaluation, and derecognition of property, plant, and equipment and intangible assets affect financial statements and ratios;

In contrast with depreciation and amortisation charges, which serve to allocate the depreciable cost of a long-lived asset over its useful life, impairment charges reflect an unanticipated decline in the value of an asset. Both IFRS and US GAAP require companies to write down the carrying amount of impaired assets. Impairment reversals for identifiable, long-lived assets are permitted under IFRS but typically not under US GAAP.

An asset is considered to be impaired when its carrying amount exceeds its recoverable amount. Although IFRS and US GAAP define recoverability differently (as described below), in general, impairment losses are recognised when the asset's carrying amount is not recoverable. The following paragraphs describe accounting for impairment for different categories of assets.

9.1 Impairment of Property, Plant, and Equipment

Accounting standards do not require that property, plant, and equipment be tested annually for impairment. Rather, at the end of each reporting period (generally, a fiscal year), a company assesses whether there are indications of asset impairment. If there is no indication of impairment, the asset is not tested for impairment. If there is an indication of impairment, such as evidence of obsolescence, decline in demand for products, or technological advancements, the recoverable amount of the asset should be measured in order to test for impairment. For property, plant, and equipment, impairment losses are recognised when the asset's carrying amount is not recoverable; the carrying amount is more than the recoverable amount. The amount of the impairment loss will reduce the carrying amount of the asset on the balance sheet and will reduce net income on the income statement. The impairment loss is a non-cash item and will not affect cash from operations.

IFRS and US GAAP differ somewhat both in the guidelines for determining that impairment has occurred and in the measurement of an impairment loss. Under IAS 36, an impairment loss is measured as the excess of carrying amount over the recoverable amount of the asset. The recoverable amount of an asset is defined as "the higher of its fair value less costs to sell and its value in use." Value in use is based on the present value of expected future cash flows. Under US GAAP, assessing recoverability is separate from measuring the impairment loss. The carrying amount of an asset "group" is considered not recoverable when it exceeds the undiscounted expected future cash flows of the group. If the asset's carrying amount is considered not recoverable, the impairment loss is measured as the difference between the asset's fair value and carrying amount.

EXAMPLE 13

Impairment of Property, Plant, and Equipment

Sussex, a hypothetical manufacturing company in the United Kingdom, has a machine it uses to produce a single product. The demand for the product has declined substantially since the introduction of a competing product. The company has assembled the following information with respect to the machine:

Carrying amount	£18,000
Undiscounted expected future cash flows	£19,000
Present value of expected future cash flows	£16,000
Fair value if sold	£17,000
Costs to sell	£2,000

1 Under IFRS, what would the company report for the machine?

2 Under US GAAP, what would the company report for the machine?

Solution to 1:

Under IFRS, the company would compare the carrying amount (£18,000) with the higher of its fair value less costs to sell (£15,000) and its value in use (£16,000). The carrying amount exceeds the value in use, the higher of the two amounts, by £2,000. The machine would be written down to the recoverable amount of £16,000, and a loss of £2,000 would be reported in the income statement. The carrying amount of the machine is now £16,000. A new depreciation schedule based on the carrying amount of £16,000 would be developed.

Solution to 2:

Under US GAAP, the carrying amount (£18,000) is compared with the undiscounted expected future cash flows (£19,000). The carrying amount is less than the undiscounted expected future cash flows, so the carrying amount is considered recoverable. The machine would continue to be carried at £18,000, and no loss would be reported.

In Example 13, a write down in the value of a piece of property, plant, and equipment occurred under IFRS but not under US GAAP. In Example 14, a write down occurs under both IFRS and US GAAP.

EXAMPLE 14

Impairment of Property, Plant, and Equipment

Essex, a hypothetical manufacturing company, has a machine it uses to produce a single product. The demand for the product has declined substantially since the introduction of a competing product. The company has assembled the following information with respect to the machine:

Carrying amount	£18,000
Undiscounted expected future cash flows	£16,000
Present value of expected future cash flows	£14,000
Fair value if sold	£10,000
Costs to sell	£2,000

1 Under IFRS, what would the company report for the machine?

2 Under US GAAP, what would the company report for the machine?

Solution to 1:

Under IFRS, the company would compare the carrying amount (£18,000) with the higher of its fair value less costs to sell (£8,000) and its value in use (£14,000). The carrying amount exceeds the value in use, the higher of the two amounts, by £4,000. The machine would be written down to the recoverable amount of £14,000, and a loss of £4,000 would be reported in the income statement. The carrying amount of the machine is now £14,000. A new depreciation schedule based on the carrying amount of £14,000 would be developed.

Solution to 2:

Under US GAAP, the carrying amount (£18,000) is compared with the undiscounted expected future cash flows (£16,000). The carrying amount exceeds the undiscounted expected future cash flows, so the carrying amount is considered not recoverable. The machine would be written down to fair value of £10,000, and a loss of £8,000 would be reported in the income statement. The carrying amount of the machine is now £10,000. A new depreciation schedule based on the carrying amount of £10,000 would be developed.

Example 14 shows that the write down to value in use under IFRS can be less than the write down to fair value under US GAAP. The difference in recognition of impairment losses is ultimately reflected in difference in book value of equity.

9.2 Impairment of Intangible Assets with a Finite Life

Intangible assets with a finite life are amortised (carrying amount decreases over time) and may become impaired. As is the case with property, plant, and equipment, the assets are not tested annually for impairment. Instead, they are tested only when significant events suggest the need to test. The company assesses at the end of each reporting period whether a significant event suggesting the need to test for impairment has occurred. Examples of such events include a significant decrease in the market price or a significant adverse change in legal or economic factors. Impairment accounting for intangible assets with a finite life is essentially the same as for tangible assets; the amount of the impairment loss will reduce the carrying amount of the asset on the balance sheet and will reduce net income on the income statement.

9.3 Impairment of Intangibles with Indefinite Lives

Intangible assets with indefinite lives are not amortised. Instead, they are carried on the balance sheet at historical cost but are tested at least annually for impairment. Impairment exists when the carrying amount exceeds its fair value.

9.4 Impairment of Long-Lived Assets Held for Sale

A long-lived (non-current) asset is reclassified as held for sale rather than held for use when management's intent is to sell it and its sale is highly probable. (Additionally, accounting standards require that the asset must be available for immediate sale in its present condition.)[18] For instance, assume a building is no longer needed by a company and management's intent is to sell it, if the transaction meets the accounting criteria, the building is reclassified from property, plant, and equipment to non-current assets held for sale. At the time of reclassification, assets previously held for use are tested for impairment. If the carrying amount at the time of reclassification exceeds the fair value less costs to sell, an impairment loss is recognised and the asset is written down to fair value less costs to sell. Long-lived assets held for sale cease to be depreciated or amortised.

---

[18] IFRS 5 *Non-current Assets Held for Sale and Discontinued Operations.*

9.5 Reversals of Impairments of Long-Lived Assets

After an asset has been deemed impaired and an impairment loss has been reported, the asset's recoverable amount could potentially increase. For instance, a lawsuit appeal may successfully challenge a patent infringement by another company, with the result that a patent previously written down has a higher recoverable amount. IFRS permit impairment losses to be reversed if the recoverable amount of an asset increases regardless of whether the asset is classified as held for use or held for sale. Note that IFRS permit the reversal of impairment losses only. IFRS do not permit the revaluation to the recoverable amount if the recoverable amount exceeds the previous carrying amount. Under US GAAP, the accounting for reversals of impairments depends on whether the asset is classified as held for use or held for sale.[19] Under US GAAP, once an impairment loss has been recognised for assets held for use, it cannot be reversed. In other words, once the value of an asset held for use has been decreased by an impairment charge, it cannot be increased. For assets held for sale, if the fair value increases after an impairment loss, the loss can be reversed.

10 DERECOGNITION

j explain the derecognition of property, plant, and equipment and intangible assets;

k explain and evaluate how impairment, revaluation, and derecognition of property, plant, and equipment and intangible assets affect financial statements and ratios;

A company derecognises an asset (i.e., removes it from the financial statements) when the asset is disposed of or is expected to provide no future benefits from either use or disposal. A company may dispose of a long-lived operating asset by selling it, exchanging it, abandoning it, or distributing it to existing shareholders. As previously described, non-current assets that management intends to sell or to distribute to existing shareholders and which meet the accounting criteria (immediately available for sale in current condition and the sale is highly probable) are reclassified as non-current assets held for sale.

10.1 Sale of Long-Lived Assets

The gain or loss on the sale of long-lived assets is computed as the sales proceeds minus the carrying amount of the asset at the time of sale. An asset's carrying amount is typically the net book value (i.e., the historical cost minus accumulated depreciation), unless the asset's carrying amount has been changed to reflect impairment and/or revaluation, as previously discussed.

---

[19] FASB ASC Section 360-10-35 [Property, Plant, and Equipment – Overall – Subsequent Measurement].

EXAMPLE 15

Calculation of Gain or Loss on the Sale of Long-Lived Assets

Moussilauke Diners Inc., a hypothetical company, as a result of revamping its menus to focus on healthier food items, sells 450 used pizza ovens and reports a gain on the sale of $1.2 million. The ovens had a carrying amount of $1.9 million (original cost of $5.1 million less $3.2 million of accumulated depreciation). At what price did Moussilauke sell the ovens?

A $0.7 million

B $3.1 million

C $6.3 million

Solution:

B is correct. The ovens had a carrying amount of $1.9 million, and Moussilauke recognised a gain of $1.2 million. Therefore, Moussilauke sold the ovens at a price of $3.1 million. The gain on the sale of $1.2 million is the selling price of $3.1 million minus the carrying amount of $1.9 million. Ignoring taxes, the cash flow from the sale is $3.1 million, which would appear as a cash inflow from investing.

A gain or loss on the sale of an asset is disclosed on the income statement, either as a component of other gains and losses or in a separate line item when the amount is material. A company typically discloses further detail about the sale in the management discussion and analysis and/or financial statement footnotes. In addition, a statement of cash flows prepared using the indirect method adjusts net income to remove any gain or loss on the sale from operating cash flow and to include the amount of proceeds from the sale in cash from investing activities. Recall that the indirect method of the statement of cash flows begins with net income and makes all adjustments to arrive at cash from operations, including removal of gains or losses from non-operating activities.

10.2 Long-Lived Assets Disposed of Other Than by a Sale

Long-lived assets to be disposed of other than by a sale (e.g., abandoned, exchanged for another asset, or distributed to owners in a spin-off) are classified as held for use until disposal or until they meet the criteria to be classified as held for sale or held for distribution.[20] Thus, the long-lived assets continue to be depreciated and tested for impairment, unless their carrying amount is zero, as required for other long-lived assets owned by the company.

When an asset is retired or abandoned, the accounting is similar to a sale, except that the company does not record cash proceeds. Assets are reduced by the carrying amount of the asset at the time of retirement or abandonment, and a loss equal to the asset's carrying amount is recorded.

When an asset is exchanged, accounting for the exchange typically involves removing the carrying amount of the asset given up, adding a fair value for the asset acquired, and reporting any difference between the carrying amount and the fair value as a gain or loss. The fair value used is the fair value of the asset given up unless the fair value of the asset acquired is more clearly evident. If no reliable measure of fair value exists, the acquired asset is measured at the carrying amount of the asset given up. A gain is reported when the fair value used for the newly acquired asset exceeds the carrying amount of the asset given up. A loss is reported when the fair value used for the newly acquired asset is less than the carrying amount of the asset given up. If the acquired asset is valued at the carrying amount of the asset given up because no reliable measure of fair value exists, no gain or loss is reported.

---

[20] In a spin-off, shareholders of the parent company receive a proportional number of shares in a new, separate entity.

When a spin-off occurs, typically, an entire cash generating unit of a company with all its assets is spun off. As an illustration of a spin-off, Fiat Chrysler Automobiles (FCA) spun off its ownership of Ferrari in 2016. Prior to the spinoff, FCA had sold 10 percent of its ownership of Ferrari in an IPO and recognized an increase in Shareholders' equity of € 873 million (the difference between the consideration it received in the IPO of € 866 million and the carrying amount of the equity interest sold of € 7 million.) In contrast, the spin-off, in which FCA distributed its ownership in Ferrari to the existing FCA shareholders, did not result in any gain or loss.

FCA's spinoff was completed on 3 January 2016, with each FCA shareholder receiving one common share of Ferrari N.V. for every ten common shares of FCA. In its financial statements for the prior fiscal year, FCA shows the assets and liabilities of Ferrari as held for distribution. Specifically, its balance sheet includes € 3,650 million Assets Held for Distribution as a component of current assets and € 3,584 million Liabilities Held for Distribution. Exhibit 7 includes excerpts from the company's 31 December 2015 annual report.

Exhibit 7 Fiat Chrysler Automobiles (FCA) Excerpts from Notes to the Consolidated Financial Statements - 2015 Annual Report

Ferrari Spin-off and Discontinued Operations

"As the spin-off of Ferrari N.V. became highly probable with the aforementioned shareholders' approval and since it was available for immediate distribution at that date, the Ferrari segment met the criteria to be classified as a disposal group held for distribution to owners and a discontinued operation pursuant to IFRS 5 - *Non-current Assets Held for Sale and Discontinued Operations*."

The following assets and liabilities of the Ferrari segment were classified as held for distribution at December 31, 2015:

	At December 31, 2015
Assets classified as held for distribution	(€ million)
Goodwill	786
Other intangible assets	297
Property, plant and equipment	627
Other non-current assets	134
Receivables from financing activities	1,176
Cash and cash equivalents	182
Other current assets	448
Total Assets held for distribution	**3,650**
Liabilities classified as held for distribution	
Provisions	224

Exhibit 7 (Continued)

	At December 31, 2015
Debt	2,256
Other current liabilities	624
Trade payables	480
Total Liabilities held for distribution	**3,584**

PRESENTATION AND DISCLOSURE REQUIREMENTS

11

l. describe the financial statement presentation of and disclosures relating to property, plant, and equipment and intangible assets;

Under IFRS, for each class of property, plant, and equipment, a company must disclose the measurement bases, the depreciation method, the useful lives (or, equivalently, the depreciation rate) used, the gross carrying amount and the accumulated depreciation at the beginning and end of the period, and a reconciliation of the carrying amount at the beginning and end of the period.[21] In addition, disclosures of restrictions on title and pledges as security of property, plant, and equipment and contractual agreements to acquire property, plant, and equipment are required. If the revaluation model is used, the date of revaluation, details of how the fair value was obtained, the carrying amount under the cost model, and the revaluation surplus must be disclosed.

The disclosure requirements under US GAAP are less exhaustive.[22] A company must disclose the depreciation expense for the period, the balances of major classes of depreciable assets, accumulated depreciation by major classes or in total, and a general description of the depreciation method(s) used in computing depreciation expense with respect to the major classes of depreciable assets.

Under IFRS, for each class of intangible assets, a company must disclose whether the useful lives are indefinite or finite. If finite, for each class of intangible asset, a company must disclose the useful lives (or, equivalently, the amortisation rate) used, the amortisation methods used, the gross carrying amount and the accumulated amortisation at the beginning and end of the period, where amortisation is included on the income statement, and a reconciliation of the carrying amount at the beginning and end of the period.[23] If an asset has an indefinite life, the company must disclose the carrying amount of the asset and why it is considered to have an indefinite life. Similar to property, plant, and equipment, disclosures of restrictions on title and pledges as security of intangible assets and contractual agreements to acquire intangible assets are required. If the revaluation model is used, the date of revaluation, details of how the fair value was obtained, the carrying amount under the cost model, and the revaluation surplus must be disclosed.

---

[21] IAS 16 *Property, Plant and Equipment*, paragraphs 73–79 [Disclosure].

[22] FASB ASC Section 360-10-50 [Property, Plant, and Equipment – Overall – Disclosure].

[23] IAS 38 *Intangible Assets*, paragraphs 118–128 [Disclosure].

Under US GAAP, companies are required to disclose the gross carrying amounts and accumulated amortisation in total and by major class of intangible assets, the aggregate amortisation expense for the period, and the estimated amortisation expense for the next five fiscal years.[24]

The disclosures related to impairment losses also differ under IFRS and US GAAP. Under IFRS, a company must disclose for each class of assets the amounts of impairment losses and reversals of impairment losses recognised in the period and where those are recognised on the financial statements.[25] The company must also disclose in aggregate the main classes of assets affected by impairment losses and reversals of impairment losses and the main events and circumstances leading to recognition of these impairment losses and reversals of impairment losses. Under US GAAP, there is no reversal of impairment losses for assets held for use. The company must disclose a description of the impaired asset, what led to the impairment, the method of determining fair value, the amount of the impairment loss, and where the loss is recognised on the financial statements.[26]

Disclosures about long-lived assets appear throughout the financial statements: in the balance sheet, the income statement, the statement of cash flows, and the notes. The balance sheet reports the carrying value of the asset. For the income statement, depreciation expense may or may not appear as a separate line item. Under IFRS, whether the income statement discloses depreciation expense separately depends on whether the company is using a 'nature of expense' method or a 'function of expense' method. Under the nature of expense method, a company aggregates expenses "according to their nature (for example, depreciation, purchases of materials, transport costs, employee benefits and advertising costs), and does not reallocate them among functions within the entity."[27] Under the function of expense method, a company classifies expenses according to the function, for example as part of cost of sales or of SG&A (selling, general, and administrative expenses). At a minimum, a company using the function of expense method must disclose cost of sales, but the other line items vary.

The statement of cash flows reflects acquisitions and disposals of fixed assets in the investing section. In addition, when prepared using the indirect method, the statement of cash flows typically shows depreciation expense (or depreciation plus amortisation) as a line item in the adjustments of net income to cash flow from operations. The notes to the financial statements describe the company's accounting method(s), the range of estimated useful lives, historical cost by main category of fixed asset, accumulated depreciation, and annual depreciation expense.

To illustrate financial statement presentation and disclosures, the following example provides excerpts relating to intangible assets and property, plant, and equipment from the annual report of Orange SA for the year ended 31 December 2017.

EXAMPLE 16

Financial Statement Presentation and Disclosures for Long-Lived Assets

The following exhibits include excerpts from the annual report for the year ended 31 December 2017 of Orange SA, an international telecommunications company based in France.

Excerpt* from Note 7.3 Key assumptions used to determine recoverable amounts as of 31 December 2017

The parameters used for the determination of recoverable amount of the main consolidated operations are set forth below:

	France	Spain	Poland	Belgium	Romania
Perpetuity growth rate	0.8%	1.5%	1.0%	0.5%	2.3%
Post-tax discount rate	5.5%	8.6%	8.3%	6.8%	8.8%

Excerpt* from Note 7.4 Sensitivity of recoverable amounts as of 31 December 2017

The level of sensitivity presented allows readers of the financial statements to estimate the impact in their own assessment.

(in billions of euros)	France	Spain	Poland	Belgium	Romania
Decrease by 1% in perpetuity growth rate	10.4	1.6	0.6	0.3	0.3
An increase by 1% in post-tax discount rate	11.4	2.0	0.6	0.3	0.3

* Table extracted presents only selected assumptions and selected countries.

The company's annual report provides more detail.

Goodwill is not amortized. It is tested for impairment at least annually and more frequently when there is an indication that it may be impaired .... These tests are performed at the level of each Cash Generating Unit (CGU) (or group of CGUs)... To determine whether an impairment loss should be recognized, the carrying value of the assets and liabilities of the CGUs or groups of CGUs is compared to recoverable amount, for which Orange uses mostly the value in use.... Value in use is the present value of the future expected cash flows. Cash flow projections are based on economic and regulatory assumptions, license renewal assumptions and forecast trading and investment activity drawn up by the Group's management...

Exhibit 10 **Orange**
Excerpt from the 2017 Analysis of the Group's financial position and earnings

"Orange group operating income stood at 4,077 million euros in 2016, compared with 4,742 million euros in 2015 on a historical basis, a drop of 14.0% or 665 million euros. This drop on a historical basis was largely attributable to:

- the recognition, in 2016, of 772 million euros in impairment loss of goodwill … and 207 million euros in impairment loss of fixed assets … primarily relating to:
  - Poland for 507 million euros. This impairment loss mainly reflects a decline in competitiveness in the ADSL market, a deterioration in revenue assumptions in the mobile market and an increase in the post-tax discount rate due to the downgrading of the country's sovereign rating by the rating agencies,
  - Egypt for 232 million euros. This impairment loss reflects the financial terms of the 4G license awarded in 2016, the sharp depreciation of the Egyptian pound and increased political and economic uncertainty,
  - in the Congo (DRC), for 109 million euros. This impairment loss reflects political and economic uncertainty, a decline in purchasing power with a knock-on effect on the consumption of telecommunications products and services and an increased regulatory burden (particularly connected with the implementation of customer identification),
  - Cameroon for 90 million euros. This impairment loss reflects a decline in voice revenues following the surge in messaging services and in VoIP of Over-The-Top (OTT) providers and heightened competition in the mobile market,

Exhibit 10 (Continued)

  - and Niger for 26 million euros;
- and the 263 million euro increase in depreciation and amortization

  …

1 What proportion of Orange's total assets as of December 31, 2017, is represented by goodwill and other intangible assets?

2 What is the largest component of the company's impairment losses during the year ending December 2016?

3 The company discloses that it determines whether an impairment loss should be recognized by comparing the carrying value of a unit's assets and liabilities to the "recoverable amount" for which the company uses mostly the value in use. How does the company determine value in use?

4 By what amount would the estimated recoverable value of the company's operations in France, Spain, Poland, Belgium and Romania change if the company decreased its estimate of the perpetuity growth rate by 1%? By what amount would the estimated recoverable value of these operations change if the company increased its estimate of the post-tax discount rate by 1%?

5 What are the largest components of other intangible assets as of December 31, 2017? What is the largest component of property, plant and equipment as of December 31, 2017?

Solution to 1:

As of 31 December 2017, goodwill represents 28% (= 27,095 ÷ 97,714) of Orange's total assets. Other intangible assets represent 15% (= 14,339 ÷ 97,714). Data are from the company's balance sheet in Exhibit 8.

Solution to 2:

The largest component of the € 772 impairment loss on goodwill and the € 207 million impairment loss of fixed assets related to a € 507 million loss in Poland. The company attributed the loss to a decline in the competitiveness of the market for its ADSL technology, a reduction in revenue assumptions, and an increase in the discount rate resulting from the downgrading of the country's debt rating. From Exhibit 10.

[The company's financial statements define ADSL (Asymmetrical Digital Subscriber Line) as a "broadband data transmission technology on the traditional telephone network. It enables broadband data transmission (first and foremost Internet access) via twisted paired copper cable (the most common type of telephone line found in buildings)."]

Solution to 3:

The company determines value in use – which it uses as a unit's assets and liabilities "recoverable amount" in impairment testing – as the present value of the future expected cash flows. The cash flow projections are based on management's assumptions. From Note 7.4 in Exhibit 9.

Solution to 4:

If the company decreased its estimate of the perpetuity growth rate by 1%, the estimated recoverable value of the company's operations in France, Spain, Poland, Belgium and Romania would change by €13.2 billion (=10.4 + 1.6 +

0.6 + 0.3 + 0.3). A decrease in estimated growth decreases the present value of the cash flows. If the company increased its estimate of the post-tax discount rate by 1%, the estimated recoverable value of these operations would change by €14.6 billion (=11.4 + 2.0 + 0.6 + 0.3 + 0.3). An increase in the discount rate decreases the present value of cash flows. Data are from Note 7.4 in Exhibit 9.

Solution to 5:

The largest components of other intangible assets as of December 31, 2017, are telecommunications licenses, software, and the Orange brand, reported at €6,233 million, €3,946 million, and €3,133 million, respectively. The largest component of property, plant and equipment as of December 31, 2017, is network and terminals (€22,880 million.) Data are from Note 8.3 and 8.4 in Exhibit 9.

Note that the exhibits in the previous example contain relatively brief excerpts from the company's disclosures. The complete text of the disclosures concerning the company's non-current assets spans numerous different footnotes, some of which are several pages long. Overall, an analyst can use the disclosures to understand a company's investments in tangible and intangible assets, how those investments changed during a reporting period, how those changes affected current performance, and what those changes might indicate about future performance.

12

USING DISCLOSURES IN ANALYSIS

m analyze and interpret financial statement disclosures regarding property, plant, and equipment and intangible assets;

Ratios used in analyzing fixed assets include the fixed asset turnover ratio and several asset age ratios. The fixed asset turnover ratio (total revenue divided by average net fixed assets) reflects the relationship between total revenues and investment in PPE. The higher this ratio, the higher the amount of sales a company is able to generate with a given amount of investment in fixed assets. A higher asset turnover ratio is often interpreted as an indicator of greater efficiency.

Asset age ratios generally rely on the relationship between historical cost and depreciation. Under the revaluation model (permitted under IFRS but not US GAAP), the relationship between carrying amount, accumulated depreciation, and depreciation expense will differ when the carrying amount differs significantly from the depreciated historical cost. Therefore, the following discussion of asset age ratios applies primarily to PPE reported under the cost model.

Asset age and remaining useful life, two asset age ratios, are important indicators of a company's need to reinvest in productive capacity. The older the assets and the shorter the remaining life, the more a company may need to reinvest to maintain productive capacity. The average age of a company's asset base can be estimated as accumulated depreciation divided by depreciation expense. The average remaining life of a company's asset base can be estimated as net PPE divided by depreciation expense. These estimates simply reflect the following relationships for assets accounted for on a historical cost basis: total historical cost minus accumulated depreciation equals net PPE; and, under straight-line depreciation, total historical cost less salvage value divided by estimated useful life equals annual depreciation expense. Equivalently, total historical cost less salvage value divided by annual depreciation expense equals estimated useful life. Assuming straight-line depreciation and no salvage value (for simplicity), we have the following:

Estimated total useful life = Time elapsed since purchase (Age) + Estimated remaining life

Historical cost ÷ annual depreciation expense = Estimated total useful life

Historical cost = Accumulated depreciation + Net PPE

Equivalently,

Estimated total useful life = Estimated age of equipment + Estimated remaining life

Historical cost ÷ annual depreciation expense = Accumulated depreciation ÷ annual depreciation expense + Net PPE ÷ annual depreciation expense

The application of these estimates can be illustrated by a hypothetical example of a company with a single depreciable asset. Assume the asset initially cost $100, had an estimated useful life of 10 years, and an estimated salvage value of $0. Each year, the company records a depreciation expense of $10, so accumulated depreciation will equal $10 times the number of years since the asset was acquired (when the asset is 7 years old, accumulated depreciation will be $70). Equivalently, the age of the asset will equal accumulated depreciation divided by the annual depreciation expense.

In practice, such estimates are difficult to make with great precision. Companies use depreciation methods other than the straight-line method and have numerous assets with varying useful lives and salvage values, including some assets that are fully depreciated, so this approach produces an estimate only. Moreover, fixed asset disclosures are often quite general. Consequently, these estimates may be primarily useful to identify areas for further investigation.

One further measure compares a company's current reinvestment in productive capacity. Comparing annual capital expenditures to annual depreciation expense provides an indication of whether productive capacity is being maintained. It is a very general indicator of the rate at which a company is replacing its PPE relative to the rate at which PPE is being depreciated.

EXAMPLE 17

Using Fixed Asset Disclosure to Compare Companies' Fixed Asset Turnover and Average Age of Depreciable Assets

You are analyzing the property, plant, and equipment of three international telecommunications companies:

- Orange SA, which we discussed previously, has been listed on Euronext Paris (symbol ORA) and on the New York Stock Exchange (symbol ORAN) since 1997. At December 31, 2017, the French government retained 22.95% of the share capital.

- BCE Inc., Canada's largest communications company, provides wireless, wireline, Internet, TV and business communications across Canada. BCE's shares are publicly traded on the Toronto Stock Exchange and on the New York Stock Exchange (TSX, NYSE: BCE).
- Verizon Communications Inc. is a US-based global provider of communications, information and entertainment products and services to consumers, businesses and governmental agencies. Verizon's shares are listed on the New York Stock Exchange and the NASDAQ Global Select Market (symbol VZ).

Exhibit 11 presents selected information from the companies' financial statements.

Exhibit 11

	Orange	BCE Inc	Verizon
Currency, Millions of:	**Euro €**	**Canadian $**	**US $**
Historical cost total PPE, end of year	€97,092	$69,230	$246,498
Accumulated depreciation, end of year	70,427	45,197	157,930
Net PPE, end of year	26,665	24,033	88,568
Net PPE, beginning of year	25,912	22,346	84,751
Revenues	41,096	22,719	126,034
Annual depreciation expense	4,708	3,037	14,741
Capital expenditure	5,677	4,149	17,247
Land included in PPE	Not separated	Not separated	806
Accounting standards	IFRS	IFRS	US GAAP
PPE measurement	Historical cost	Historical cost	Historical cost
Depreciation method	Straight-line	Straight-line	Straight-line

Sources: Companies' 2017 Annual Financial Reports.

1 Based on the above data for each company, estimate the total useful life, age, and remaining useful life of PPE.

2 Interpret the estimates. What items might affect comparisons across these companies?

3 How does each company's 2017 depreciation expense compare to its capital expenditures for the year?

4 Calculate and compare fixed asset turnover for each company.

Solution to 1:

The following table presents the estimated total useful life, estimated age, and estimated remaining useful life of PPE for each of the companies.

Estimates	Orange	BCE Inc	Verizon
Estimated total useful life (years)	20.6	22.8	16.7
Estimated age (years)	15.0	14.9	10.7
Estimated remaining life (years)	5.7	7.9	6.0

The computations are demonstrated using Verizon's data ($ millions). The estimated total useful life of PPE is total historical cost of PPE of $246,498 divided by annual depreciation expense of $14,741, giving 16.7 years. Estimated age and estimated remaining life are obtained by dividing accumulated depreciation of $157,930 and net PPE of $88,568 by the annual depreciation expense of $14,741, giving 10.7 years and 6.0 years, respectively.

Ideally, the estimates of asset lives illustrated in this example should exclude land, which is not depreciable, when the information is available; however, both Orange and BCE report Land and Buildings as a combined amount. We will use Verizon, for which land appeared to be disclosed separately in the above table, to illustrate the estimates with adjusting for land. As an illustration of the calculations to exclude land, excluding Verizon's land would give an estimated total useful life for the non-land PPE of 16.7 years [(total cost €246,498 minus land cost of $806) divided by annual depreciation expense of €14,741 million]. The estimate is essentially unchanged from the estimate including land because land represents such a small component of Verizon's PPE.

Solution to 2:

The estimated total useful life suggests that Orange and BCE depreciate PPE over a much longer period than Verizon: 20.6 and 22.8 years for Orange and BCE, respectively, versus 16.7 years for Verizon.

The estimated age of the equipment suggests that Verizon has the newest PPE with an estimated age of 10.7 years. Additionally, the estimates suggest that around 73 percent of Orange's assets' useful lives have passed (15.0 years ÷ 20.6 years, or equivalently, €70,427 million ÷ €97,092 million). In comparison, around 65 and 64 percent of the useful lives of the PPE of BCE and Verizon, respectively, have passed.

Items that can affect comparisons across the companies include business differences, such as differences in composition of the companies' operations and differences in acquisition and divestiture activity. This result can be compared, to an extent, to the useful lives and asset mix disclosed in the companies' footnotes; however, differences in disclosures, e.g. in the categories of assets disclosed, can affect comparisons.

Solution to 3:

All three companies' capital expenditure exceeds its depreciation expense. Rounding to the nearest 10%, capital expenditure as a percentage of depreciation is 120 percent for Orange, 140 percent for BCE, and 120 percent for Verizon. All three companies are replacing PPE at a faster rate than the PPE is being depreciated, consistent with the companies' somewhat older asset base.

Solution to 4:

Fixed asset turnover is calculated as total revenues divided by average net PPE. Orange's fixed asset turnover is 1.6 (= 41,096/((26,665 + 25,912)/2). BCE's fixed asset turnover is 1.0, and Verizon's fixed asset turnover is 1.5.

Orange's and Verizon's higher levels of fixed asset turnover indicate these companies, compared to BCE, are able to generate more sales per unit of investment in fixed assets.

13 INVESTMENT PROPERTY

- compare the financial reporting of investment property with that of property, plant, and equipment.

Investment property is defined under IFRS as property that is owned (or, in some cases, leased under a **finance lease**) for the purpose of earning rentals or capital appreciation or both.[28] An example of investment property is a building owned by a company and leased out to tenants. In contrast, other long-lived tangible assets (i.e., property considered to be property, plant, and equipment) are owner-occupied properties used for producing the company's goods and services or for housing the company's administrative activities. Investment properties do not include long-lived tangible assets held for sale in the ordinary course of business. For example, the houses and property owned by a housing construction company are considered to be its inventory.

Under IFRS, companies are allowed to value investment properties using either a cost model or a fair value model. The cost model is identical to the cost model used for property, plant, and equipment. If the cost model is used, the fair value of investment property must be disclosed.[29] The fair value model, however, differs from the revaluation model used for property, plant, and equipment. Under the revaluation model, whether an asset revaluation affects net income depends on whether the revaluation initially increases or decreases the carrying amount of the asset. In contrast, under the fair value model, all changes in the fair value of the asset affect net income. To use the fair value model, a company must be able to reliably determine the property's fair value on a continuing basis.

Example 18 presents an excerpt from the annual report of a property company reporting under IFRS.

EXAMPLE 18

Financial Statement Presentation and Disclosures for Long-Lived Assets

The following exhibit presents information and excerpts from the annual report for the year ended 31 December 2017 of intu properties plc, a property company headquartered in London that owns, develops and manages shopping centres in the United Kingdom and Spain. Its common stock is listed in London and Johannesburg.

Exhibit 12 Information and excerpts from the Annual Report of intu properties plc (Currency in £ millions)

Financial Information

Financial Statement	Item Label	Amount 2017	Amount 2016
Balance Sheet	Investment and development property	9,179.4	9,212.1
Balance Sheet	Plant and equipment	12.2	7.6

---

[28] IAS 40 *Investment Property* prescribes the accounting treatment for investment property.

[29] Ibid., paragraph 32.

Exhibit 12 (Continued)

Financial Statement	Item Label	Amount 2017	Amount 2016
Balance Sheet	Total assets	10,794.5	10,369.2
Income Statement	Net rental income	423.4	406.1
Income Statement	Revaluation of investment and development property	30.8	(78.0)

Excerpt from Note 2 Accounting policies

Investment and development property

Investment and development property is owned or leased by the Group and held for long-term rental income and capital appreciation.

The Group has elected to use the fair value model. Properties are initially recognised at cost and subsequently revalued at the balance sheet date to fair value as determined by professionally qualified external valuers on the basis of market value with the exception of certain development land where an assessment of fair value may be made internally. External valuations are received for significant development land once required planning permissions are obtained. The cost of investment and development property includes capitalised interest and other directly attributable outgoings incurred during development. Interest is capitalised on the basis of the average interest rate on the relevant debt outstanding. Interest ceases to be capitalised on the date of practical completion.

Gains or losses arising from changes in the fair value of investment and development property are recognised in the income statement. Depreciation is not provided in respect of investment and development property. Gains or losses arising on the sale of investment and development property are recognised when the significant risks and rewards of ownership have been transferred to the buyer. The gain or loss recognised is the proceeds received less the carrying value of the property and costs directly associated with the sale.

Plant and equipment

Plant and equipment consists of vehicles, fixtures, fittings and other equipment. Plant and equipment is stated at cost less accumulated depreciation and any accumulated impairment losses. Depreciation is charged to the income statement on a straight- line basis over an asset's estimated useful life up to a maximum of five years.

Excerpt from Note 14 Investment and development property

The market value of investment and development property at 31 December 2017 includes £8,831.9 million (31 December 2016: £9,088.6 million) in respect of investment property and £376.5 million (31 December 2016: £153.2 million) in respect of development property. …All the Group's significant investment and development property relates to prime shopping centres which are of a similar nature and share characteristics and risks.…

Valuation methodology

The fair value of the Group's investment and development property at 31 December 2017 was determined by independent external valuers … Fair values for investment properties are calculated using the present value income approach. …The key driver of the property valuations is the terms

> of the leases in place at the valuation date. These determine the majority of the cash flow profile of the property for a number of years and therefore form the base of the valuation…

1. How do the assets included in the balance sheet line item "Investment and development property" differ from the assets included in the balance sheet line item "Plant and equipment"?
2. How does the valuation model used by the company for its investment and development property differ from the valuation model used for its plant and equipment?
3. How does accounting for depreciation differ for investment and development property versus plant and equipment?
4. Do the revaluation gains and losses on investment and development properties indicate that the properties have been sold?

Solution to 1:

The assets included in the balance sheet line item "Investment and development property" are shopping centres which the company holds for long-term rental income and capital appreciation. In 2017, the company reported net rental income of £423.4 million. The balance sheet line item "Plant and equipment" includes vehicles, fixtures, fittings, and other equipment used by the company in its operations.

Solution to 2:

The valuation model used by the company for its investment and development property is the fair value model, in which properties are initially recognised at cost and subsequently revalued and shown on the balance sheet at fair value. All changes in the fair value of the asset affect net income. The company employs external valuation experts to determine the fair value, which is based on expected future cash flow from rental income.

The valuation model used for its plant and equipment is the historical cost model in which properties are shown on the balance sheet at cost minus accumulated depreciation and any impairment losses.

Solution to 3:

Depreciation in accounting refers to the allocation of the cost of a long-lived asset over its useful life. No depreciation is recorded for investment and development property. Depreciation expense for plant and equipment is calculated on a straight-line basis over the asset's estimated useful life.

Solution to 4:

No. The revaluation gains and losses on investment properties arise from changes in the fair value of properties that are owned by the company. The company reported a revaluation gain of £30.8 million in 2017 and a revaluation loss of £78.0 million in 2016.

Sales of property would have resulted in a gain or loss on disposal, calculated as the proceeds minus the carrying value of the property and related selling costs.

In general, a company must apply its chosen model (cost or fair value) to all of its investment property. If a company chooses the fair value model for its investment property, it must continue to use the fair value model until it disposes of the property or changes its use such that it is no longer considered investment property (e.g., it becomes owner-occupied property or part of inventory). The company must continue to use the fair value model for that property even if transactions on comparable properties, used to estimate fair value, become less frequent.

Certain valuation issues arise when a company changes the use of property such that it moves from being an investment property to owner-occupied property or part of inventory. If a company's chosen model for investment property is the cost model, such transfers do not change the carrying amount of the property transferred. If a company's chosen model is the fair value model, transfers from investment property to owner-occupied property or to inventory are made at fair value. In other words, the property's fair value at the time of transfer is considered to be its cost for ongoing accounting for the property. If a company's chosen model for investment property is the fair value model and it transfers a property from owner-occupied to investment property, the change in measurement of the property from depreciated cost to fair value is treated like a revaluation. If a company's chosen model is the fair value model and it transfers a property from inventory to investment property, any difference between the inventory carrying amount and the property's fair value at the time of transfer is recognised as profit or loss.

Investment property appears as a separate line item on the balance sheet. Companies are required to disclose whether they use the fair value model or the cost model for their investment property. If the company uses the fair value model, it must make additional disclosures about how it determines fair value and must provide reconciliation between the beginning and ending carrying amounts of investment property. If the company uses the cost model, it must make additional disclosures similar to those for property, plant, and equipment—for example, the depreciation method and useful lives must be disclosed. In addition, if the company uses the cost model, it must also disclose the fair value of investment property.

Under US GAAP, there is no specific definition of investment property. Most operating companies and real estate companies in the United States that hold investment-type property use the historical cost model.

SUMMARY

Understanding the reporting of long-lived assets at inception requires distinguishing between expenditures that are capitalised (i.e., reported as long-lived assets) and those that are expensed. Once a long-lived asset is recognised, it is reported under the cost model at its historical cost less accumulated depreciation (amortisation) and less any impairment or under the revaluation model at its fair value. IFRS permit the use of either the cost model or the revaluation model, whereas US GAAP require the use of the cost model. Most companies reporting under IFRS use the cost model. The choice of different methods to depreciate (amortise) long-lived assets can create challenges for analysts comparing companies.

Key points include the following:

- Expenditures related to long-lived assets are capitalised as part of the cost of assets if they are expected to provide future benefits, typically beyond one year. Otherwise, expenditures related to long-lived assets are expensed as incurred.
- Although capitalising expenditures, rather than expensing them, results in higher reported profitability in the initial year, it results in lower profitability in subsequent years; however, if a company continues to purchase similar or increasing amounts of assets each year, the profitability-enhancing effect of capitalisation continues.

- Capitalising an expenditure rather than expensing it results in a greater amount reported as cash from operations because capitalised expenditures are classified as an investing cash outflow rather than an operating cash outflow.
- Companies must capitalise interest costs associated with acquiring or constructing an asset that requires a long period of time to prepare for its intended use.
- Including capitalised interest in the calculation of interest coverage ratios provides a better assessment of a company's solvency.
- IFRS require research costs be expensed but allow all development costs (not only software development costs) to be capitalised under certain conditions. Generally, US accounting standards require that research and development costs be expensed; however, certain costs related to software development are required to be capitalised.
- When one company acquires another company, the transaction is accounted for using the acquisition method of accounting in which the company identified as the acquirer allocates the purchase price to each asset acquired (and each liability assumed) on the basis of its fair value. Under acquisition accounting, if the purchase price of an acquisition exceeds the sum of the amounts that can be allocated to individual identifiable assets and liabilities, the excess is recorded as goodwill.
- The capitalised costs of long-lived tangible assets and of intangible assets with finite useful lives are allocated to expense in subsequent periods over their useful lives. For tangible assets, this process is referred to as depreciation, and for intangible assets, it is referred to as amortisation.
- Long-lived tangible assets and intangible assets with finite useful lives are reviewed for impairment whenever changes in events or circumstances indicate that the carrying amount of an asset may not be recoverable.
- Intangible assets with an indefinite useful life are not amortised but are reviewed for impairment annually.
- Impairment disclosures can provide useful information about a company's expected cash flows.
- Methods of calculating depreciation or amortisation expense include the straight-line method, in which the cost of an asset is allocated to expense in equal amounts each year over its useful life; accelerated methods, in which the allocation of cost is greater in earlier years; and the units-of-production method, in which the allocation of cost corresponds to the actual use of an asset in a particular period.
- Estimates required for depreciation and amortisation calculations include the useful life of the equipment (or its total lifetime productive capacity) and its expected residual value at the end of that useful life. A longer useful life and higher expected residual value result in a smaller amount of annual depreciation relative to a shorter useful life and lower expected residual value.
- IFRS permit the use of either the cost model or the revaluation model for the valuation and reporting of long-lived assets, but the revaluation model is not allowed under US GAAP.
- Under the revaluation model, carrying amounts are the fair values at the date of revaluation less any subsequent accumulated depreciation or amortisation.
- In contrast with depreciation and amortisation charges, which serve to allocate the cost of a long-lived asset over its useful life, impairment charges reflect an unexpected decline in the fair value of an asset to an amount lower than its carrying amount.

- IFRS permit impairment losses to be reversed, with the reversal reported in profit. US GAAP do not permit the reversal of impairment losses.
- The gain or loss on the sale of long-lived assets is computed as the sales proceeds minus the carrying amount of the asset at the time of sale.
- Estimates of average age and remaining useful life of a company's assets reflect the relationship between assets accounted for on a historical cost basis and depreciation amounts.
- The average remaining useful life of a company's assets can be estimated as net PPE divided by depreciation expense, although the accounting useful life may not necessarily correspond to the economic useful life.
- Long-lived assets reclassified as held for sale cease to be depreciated or amortised. Long-lived assets to be disposed of other than by a sale (e.g., by abandonment, exchange for another asset, or distribution to owners in a spin-off) are classified as held for use until disposal. Thus, they continue to be depreciated and tested for impairment.
- Investment property is defined as property that is owned (or, in some cases, leased under a finance lease) for the purpose of earning rentals, capital appreciation, or both.
- Under IFRS, companies are allowed to value investment properties using either a cost model or a fair value model. The cost model is identical to the cost model used for property, plant, and equipment, but the fair value model differs from the revaluation model used for property, plant, and equipment. Unlike the revaluation model, under the fair value model, all changes in the fair value of investment property affect net income.
- Under US GAAP, investment properties are generally measured using the cost model.

PRACTICE PROBLEMS

1 JOOVI Inc. has recently purchased and installed a new machine for its manufacturing plant. The company incurred the following costs:

Purchase price	$12,980
Freight and insurance	$1,200
Installation	$700
Testing	$100
Maintenance staff training costs	$500

The total cost of the machine to be shown on JOOVI's balance sheet is *closest* to:

A $14,180.

B $14,980.

C $15,480.

2 Which costs incurred with the purchase of property and equipment are expensed?

A Delivery charges

B Installation and testing

C Training required to use the property and equipment

3 When constructing an asset for sale, directly related borrowing costs are *most likely*:

A expensed as incurred.

B capitalized as part of inventory.

C capitalized as part of property, plant, and equipment.

4 BAURU, S.A., a Brazilian corporation, borrows capital from a local bank to finance the construction of its manufacturing plant. The loan has the following conditions:

Borrowing date	1 January 2009
Amount borrowed	500 million Brazilian real (BRL)
Annual interest rate	14 percent
Term of the loan	3 years
Payment method	Annual payment of interest only. Principal amortization is due at the end of the loan term.

The construction of the plant takes two years, during which time BAURU earned BRL 10 million by temporarily investing the loan proceeds. Which of the following is the amount of interest related to the plant construction (in BRL million) that can be capitalized in BAURU's balance sheet?

A 130.

B 140.

C 210.

5 After reading the financial statements and footnotes of a company that follows IFRS, an analyst identified the following intangible assets:

- product patent expiring in 40 years;

© 2019 CFA Institute. All rights reserved.

- copyright with no expiration date; and
- goodwill acquired 2 years ago in a business combination.

Which of these assets is an intangible asset with a finite useful life?

	Product Patent	Copyright	Goodwill
A	Yes	Yes	No
B	Yes	No	No
C	No	Yes	Yes

6 Intangible assets with finite useful lives *mostly* differ from intangible assets with infinite useful lives with respect to accounting treatment of:

A revaluation.

B impairment.

C amortization.

7 Costs incurred for intangible assets are generally expensed when they are:

A internally developed.

B individually acquired.

C acquired in a business combination.

8 Under US GAAP, when assets are acquired in a business combination, goodwill *most likely* arises from:

A contractual or legal rights.

B assets that can be separated from the acquired company.

C assets that are neither tangible nor identifiable intangible assets.

9 All else equal, in the fiscal year when long-lived equipment is purchased:

A depreciation expense increases.

B cash from operations decreases.

C net income is reduced by the amount of the purchase.

10 Companies X and Z have the same beginning-of-the-year book value of equity and the same tax rate. The companies have identical transactions throughout the year and report all transactions similarly except for one. Both companies acquire a £300,000 printer with a three-year useful life and a salvage value of £0 on 1 January of the new year. Company X capitalizes the printer and depreciates it on a straight-line basis, and Company Z expenses the printer. The following year-end information is gathered for Company X.

	Company X **As of 31 December**
Ending shareholders' equity	£10,000,000
Tax rate	25%
Dividends	£0.00
Net income	£750,000

Based on the information given, Company Z's return on equity using year-end equity will be *closest* to:

A 5.4%.

B 6.1%.

C 7.5%.

11 A financial analyst is studying the income statement effect of two alternative depreciation methods for a recently acquired piece of equipment. She gathers the following information about the equipment's expected production life and use:

	Year 1	Year 2	Year 3	Year 4	Year 5	Total
Units of production	2,000	2,000	2,000	2,000	2,500	10,500

Compared with the units-of-production method of depreciation, if the company uses the straight-line method to depreciate the equipment, its net income in Year 1 will *most likely* be:

A lower.

B higher.

C the same.

12 A company purchases a piece of equipment for €1,500. The equipment is expected to have a useful life of five years and no residual value. In the first year of use, the units of production are expected to be 15% of the equipment's lifetime production capacity and the equipment is expected to generate €1,500 of revenue and incur €500 of cash expenses.

The depreciation method yielding the lowest operating profit on the equipment in the first year of use is:

A straight line.

B units of production.

C double-declining balance.

13 Juan Martinez, CFO of VIRMIN, S.A., is selecting the depreciation method to use for a new machine. The machine has an expected useful life of six years. Production is expected to be relatively low initially but to increase over time. The method chosen for tax reporting must be the same as the method used for financial reporting. If Martinez wants to minimize tax payments in the first year of the machine's life, which of the following depreciation methods is Martinez *most likely* to use?

A Straight-line method.

B Units-of-production method.

C Double-declining balance method.

The following information relates to Questions 14–15

Miguel Rodriguez of MARIO S.A., an Uruguayan corporation, is computing the depreciation expense of a piece of manufacturing equipment for the fiscal year ended 31 December 2009. The equipment was acquired on 1 January 2009. Rodriguez gathers the following information (currency in Uruguayan pesos, UYP):

Cost of the equipment	UYP 1,200,000
Estimated residual value	UYP 200,000
Expected useful life	8 years
Total productive capacity	800,000 units

Production in FY 2009	135,000 units
Expected production for the next 7 years	95,000 units each year

14 If MARIO uses the straight-line method, the amount of depreciation expense on MARIO's income statement related to the manufacturing equipment is *closest* to:

A 125,000.

B 150,000.

C 168,750.

15 If MARIO uses the units-of-production method, the amount of depreciation expense (in UYP) on MARIO's income statement related to the manufacturing equipment is *closest* to:

A 118,750.

B 168,750.

C 202,500.

---

16 Which of the following amortization methods is *most likely* to evenly distribute the cost of an intangible asset over its useful life?

A Straight-line method.

B Units-of-production method.

C Double-declining balance method.

17 Which of the following will cause a company to show a lower amount of amortization of intangible assets in the first year after acquisition?

A A higher residual value.

B A higher amortization rate.

C A shorter useful life.

18 A company purchases equipment for $200,000 with a five-year useful life and salvage value of zero. It uses the double-declining balance method of depreciation for two years, then shifts to straight-line depreciation at the beginning of Year 3. Compared with annual depreciation expense under the double-declining balance method, the resulting annual depreciation expense in Year 4 is:

A smaller.

B the same.

C greater.

19 An analyst in the finance department of BOOLDO S.A., a French corporation, is computing the amortization of a customer list, an intangible asset, for the fiscal year ended 31 December 2009. She gathers the following information about the asset:

Acquisition cost	€2,300,000
Acquisition date	1 January 2008
Expected residual value at time of acquisition	€500,000

The customer list is expected to result in extra sales for three years after acquisition. The present value of these expected extra sales exceeds the cost of the list.

If the analyst uses the straight-line method, the amount of accumulated amortization related to the customer list as of 31 December 2009 is *closest* to:

A €600,000.

B €1,200,000.

C €1,533,333.

20 A financial analyst is analyzing the amortization of a product patent acquired by MAKETTI S.p.A., an Italian corporation. He gathers the following information about the patent:

Acquisition cost	€5,800,000
Acquisition date	1 January 2009
Patent expiration date	31 December 2015
Total plant capacity of patented product	40,000 units per year
Production of patented product in fiscal year ended 31 December 2009	20,000 units
Expected production of patented product during life of the patent	175,000 units

If the analyst uses the units-of-production method, the amortization expense on the patent for fiscal year 2009 is *closest* to:

A €414,286.

B €662,857.

C €828,571.

21 A company acquires a patent with an expiration date in six years for ¥100 million. The company assumes that the patent will generate economic benefits that will decline over time and decides to amortize the patent using the double-declining balance method. The annual amortization expense in Year 4 is closest to:

A ¥6.6 million.

B ¥9.9 million.

C ¥19.8 million.

22 A company is comparing straight-line and double-declining balance amortization methods for a non-renewable six-year license, acquired for €600,000. The difference between the Year 4 ending net book values using the two methods is *closest to*:

A €81,400.

B €118,600.

C €200,000.

23 MARU S.A. de C.V., a Mexican corporation that follows IFRS, has elected to use the revaluation model for its property, plant, and equipment. One of MARU's machines was purchased for 2,500,000 Mexican pesos (MXN) at the beginning of the fiscal year ended 31 March 2010. As of 31 March 2010, the machine has a fair value of MXN 3,000,000. Should MARU show a profit for the revaluation of the machine?

A Yes.

B No, because this revaluation is recorded directly in equity.

C No, because value increases resulting from revaluation can never be recognized as a profit.

24 An analyst is studying the impairment of the manufacturing equipment of WLP Corp., a UK-based corporation that follows IFRS. He gathers the following information about the equipment:

Fair value	£16,800,000
Costs to sell	£800,000
Value in use	£14,500,000
Net carrying amount	£19,100,000

The amount of the impairment loss on WLP Corp.'s income statement related to its manufacturing equipment is *closest* to:

A £2,300,000.

B £3,100,000.

C £4,600,000.

25 Under IFRS, an impairment loss on a property, plant, and equipment asset is measured as the excess of the carrying amount over the asset's:

A fair value.

B recoverable amount.

C undiscounted expected future cash flows.

26 A financial analyst at BETTO S.A. is analyzing the result of the sale of a vehicle for 85,000 Argentine pesos (ARP) on 31 December 2009. The analyst compiles the following information about the vehicle:

Acquisition cost of the vehicle	ARP 100,000
Acquisition date	1 January 2007
Estimated residual value at acquisition date	ARP 10,000
Expected useful life	9 years
Depreciation method	Straight-line

The result of the sale of the vehicle is *most likely*:

A a loss of ARP 15,000.

B a gain of ARP 15,000.

C a gain of ARP 18,333.

27 CROCO S.p.A sells an intangible asset with a historical acquisition cost of €12 million and an accumulated amortization of €2 million and reports a loss on the sale of €3.2 million. Which of the following amounts is *most likely* the sale price of the asset?

A €6.8 million

B €8.8 million

C €13.2 million

28 The impairment of intangible assets with finite lives affects:

A the balance sheet but not the income statement.

B the income statement but not the balance sheet.

C both the balance sheet and the income statement.

29 The gain or loss on a sale of a long-lived asset to which the revaluation model has been applied is *most likely* calculated using sales proceeds less:

A carrying amount.

B carrying amount adjusted for impairment.

C historical cost net of accumulated depreciation.

30 According to IFRS, all of the following pieces of information about property, plant, and equipment must be disclosed in a company's financial statements and footnotes *except for*:

A useful lives.

B acquisition dates.

C amount of disposals.

31 According to IFRS, all of the following pieces of information about intangible assets must be disclosed in a company's financial statements and footnotes *except for*:

A fair value.

B impairment loss.

C amortization rate.

32 Which of the following is a required financial statement disclosure for long-lived intangible assets under US GAAP?

A The useful lives of assets

B The reversal of impairment losses

C Estimated amortization expense for the next five fiscal years

33 Which of the following characteristics is *most likely* to differentiate investment property from property, plant, and equipment?

A It is tangible.

B It earns rent.

C It is long-lived.

34 If a company uses the fair value model to value investment property, changes in the fair value of the asset are *least likely* to affect:

A net income.

B net operating income.

C other comprehensive income.

35 Investment property is *most likely* to:

A earn rent.

B be held for resale.

C be used in the production of goods and services.

36 A company is *most likely* to:

A use a fair value model for some investment property and a cost model for other investment property.

B change from the fair value model when transactions on comparable properties become less frequent.

C change from the fair value model when the company transfers investment property to property, plant, and equipment.

37 Under the revaluation model for property, plant, and equipment and the fair model for investment property:

A fair value of the asset must be able to be measured reliably.

B net income is affected by all changes in the fair value of the asset.

C net income is never affected if the asset increases in value from its carrying amount.

38 Under IFRS, what must be disclosed under the cost model of valuation for investment properties?

A Useful lives

B The method for determining fair value

C Reconciliation between beginning and ending carrying amounts of investment property

The following information relates to Questions 39–42

Melanie Hart, CFA, is a transportation analyst. Hart has been asked to write a research report on Altai Mountain Rail Company (AMRC). Like other companies in the railroad industry, AMRC's operations are capital intensive, with significant investments in such long-lived tangible assets as property, plant, and equipment. In November of 2008, AMRC's board of directors hired a new team to manage the company. In reviewing the company's 2009 annual report, Hart is concerned about some of the accounting choices that the new management has made. These choices differ from those of the previous management and from common industry practice. Hart has highlighted the following statements from the company's annual report:

Statement 1	"In 2009, AMRC spent significant amounts on track replacement and similar improvements. AMRC expensed rather than capitalised a significant proportion of these expenditures."
Statement 2	"AMRC uses the straight-line method of depreciation for both financial and tax reporting purposes to account for plant and equipment."
Statement 3	"In 2009, AMRC recognized an impairment loss of €50 million on a fleet of locomotives. The impairment loss was reported as 'other income' in the income statement and reduced the carrying amount of the assets on the balance sheet."

Exhibits 1 and 2 contain AMRC's 2009 consolidated income statement and balance sheet. AMRC prepares its financial statements in accordance with International Financial Reporting Standards.

Exhibit 1 Consolidated Statement of Income

	2009		2008	
For the Years Ended 31 December	**€ Millions**	**% Revenues**	**€ Millions**	**% Revenues**
Operating revenues	2,600	100.0	2,300	100.0
Operating expenses				
Depreciation	(200)	(7.7)	(190)	(8.3)
Other operating expense	(1,590)	(61.1)	(1,515)	(65.9)
Total operating expenses	(1,790)	(68.8)	(1,705)	(74.2)
Operating income	810	31.2	595	25.8
Other income	(50)	(1.9)	—	0.0
Interest expense	(73)	(2.8)	(69)	(3.0)
Income before taxes	687	26.5	526	22.8

(continued)

Exhibit 1 (Continued)

	2009		2008	
For the Years Ended 31 December	**€ Millions**	**% Revenues**	**€ Millions**	**% Revenues**
Income taxes	(272)	(10.5)	(198)	(8.6)
Net income	415	16	328	14.2

Exhibit 2 Consolidated Balance Sheet

As of 31 December	2009		2008	
Assets	**€ Millions**	**% Assets**	**€ Millions**	**% Assets**
Current assets	500	9.4	450	8.5
Property & equipment:				
Land	700	13.1	700	13.2
Plant & equipment	6,000	112.1	5,800	109.4
Total property & equipment	6,700	125.2	6,500	122.6
Accumulated depreciation	(1,850)	(34.6)	(1,650)	(31.1)
Net property & equipment	4,850	90.6	4,850	91.5
Total assets	5,350	100.0	5,300	100.0
Liabilities and Shareholders' Equity				
Current liabilities	480	9.0	430	8.1
Long-term debt	1,030	19.3	1,080	20.4
Other long-term provisions and liabilities	1,240	23.1	1,440	27.2
Total liabilities	2,750	51.4	2,950	55.7
Shareholders' equity				
Common stock and paid-in-surplus	760	14.2	760	14.3
Retained earnings	1,888	35.5	1,600	30.2
Other comprehensive losses	(48)	(0.9)	(10)	(0.2)
Total shareholders' equity	2,600	48.6	2,350	44.3
Total liabilities & shareholders' equity	5,350	100.0	5,300	100.0

39 With respect to Statement 1, which of the following is the *most likely* effect of management's decision to expense rather than capitalise these expenditures?

A 2009 net profit margin is higher than if the expenditures had been capitalised.

B 2009 total asset turnover is lower than if the expenditures had been capitalised.

C Future profit growth will be higher than if the expenditures had been capitalised.

40 With respect to Statement 2, what would be the *most likely* effect in 2010 if AMRC were to switch to an accelerated depreciation method for both financial and tax reporting?

A Net profit margin would increase.

B Total asset turnover would decrease.

C Cash flow from operating activities would increase.

41 With respect to Statement 3, what is the *most likely* effect of the impairment loss?

A Net income in years prior to 2009 was likely understated.

B Net profit margins in years after 2009 will likely exceed the 2009 net profit margin.

C Cash flow from operating activities in 2009 was likely lower due to the impairment loss.

42 Based on Exhibits 1 and 2, the *best estimate* of the average remaining useful life of the company's plant and equipment at the end of 2009 is:

A 20.75 years.

B 24.25 years.

C 30.00 years.

The following information relates to Questions 43–48

Brian Jordan is interviewing for a junior equity analyst position at Orion Investment Advisors. As part of the interview process, Mary Benn, Orion's Director of Research, provides Jordan with information about two hypothetical companies, Alpha and Beta, and asks him to comment on the information on their financial statements and ratios. Both companies prepare their financial statements in accordance with International Financial Reporting Standards (IFRS) and are identical in all respects except for their accounting choices.

Jordan is told that at the beginning of the current fiscal year, both companies purchased a major new computer system and began building new manufacturing plants for their own use. Alpha capitalised and Beta expensed the cost of the computer system; Alpha capitalised and Beta expensed the interest costs associated with the construction of the manufacturing plants.

Benn asks Jordan, "What was the impact of these decisions on each company's current fiscal year financial statements and ratios?"

Jordan responds, "Alpha's decision to capitalise the cost of its new computer system instead of expensing it results in lower net income, lower total assets, and higher cash flow from operating activities in the current fiscal year. Alpha's decision to capitalise its interest costs instead of expensing them results in a lower fixed asset turnover ratio and a higher interest coverage ratio."

Jordan is told that Alpha uses the straight-line depreciation method and Beta uses an accelerated depreciation method; both companies estimate the same useful lives for long-lived assets. Many companies in their industry use the units-of-production method.

Benn asks Jordan, "What are the financial statement implications of each depreciation method, and how do you determine a company's need to reinvest in its productive capacity?"

Jordan replies, “All other things being equal, the straight-line depreciation method results in the least variability of net profit margin over time, while an accelerated depreciation method results in a declining trend in net profit margin over time. The units-of-production can result in a net profit margin trend that is quite variable. I use a three-step approach to estimate a company’s need to reinvest in its productive capacity. First, I estimate the average age of the assets by dividing net property, plant, and equipment by annual depreciation expense. Second, I estimate the average remaining useful life of the assets by dividing accumulated depreciation by depreciation expense. Third, I add the estimates of the average remaining useful life and the average age of the assets in order to determine the total useful life.”

Jordan is told that at the end of the current fiscal year, Alpha revalued a manufacturing plant; this increased its reported carrying amount by 15 percent. There was no previous downward revaluation of the plant. Beta recorded an impairment loss on a manufacturing plant; this reduced its carrying by 10 percent.

Benn asks Jordan “What was the impact of these decisions on each company’s current fiscal year financial ratios?”

Jordan responds, “Beta’s impairment loss increases its debt to total assets and fixed asset turnover ratios, and lowers its cash flow from operating activities. Alpha’s revaluation increases its debt to capital and return on assets ratios, and reduces its return on equity.”

At the end of the interview, Benn thanks Jordan for his time and states that a hiring decision will be made shortly.

43 Jordan’s response about the financial statement impact of Alpha’s decision to capitalise the cost of its new computer system is most likely *correct* with respect to:

A lower net income.

B lower total assets.

C higher cash flow from operating activities.

44 Jordan’s response about the ratio impact of Alpha’s decision to capitalise interest costs is most likely *correct* with respect to the:

A interest coverage ratio.

B fixed asset turnover ratio.

C interest coverage and fixed asset turnover ratios.

45 Jordan’s response about the impact of the different depreciation methods on net profit margin is most likely *incorrect* with respect to:

A accelerated depreciation.

B straight-line depreciation.

C units-of-production depreciation.

46 Jordan’s response about his approach to estimating a company’s need to reinvest in its productive capacity is most likely *correct* regarding:

A estimating the average age of the asset base.

B estimating the total useful life of the asset base.

C estimating the average remaining useful life of the asset base.

47 Jordan’s response about the effect of Beta’s impairment loss is most likely *incorrect* with respect to the impact on its:

A debt to total assets.

B fixed asset turnover.

C cash flow from operating activities.

48 Jordan's response about the effect of Alpha's revaluation is most likely *correct* with respect to the impact on its:

A return on equity.

B return on assets.

C debt to capital ratio.

SOLUTIONS

1 B is correct. Only costs necessary for the machine to be ready to use can be capitalized. Therefore, Total capitalized costs = 12,980 + 1,200 + 700 + 100 = \$14,980.

2 C is correct. When property and equipment are purchased, the assets are recorded on the balance sheet at cost. Costs for the assets include all expenditures required to prepare the assets for their intended use. Any other costs are expensed. Costs to train staff for using the machine are not required to prepare the property and equipment for their intended use, and these costs are expensed.

3 B is correct. When a company constructs an asset, borrowing costs incurred directly related to the construction are generally capitalized. If the asset is constructed for sale, the borrowing costs are classified as inventory.

4 A is correct. Borrowing costs can be capitalized under IFRS until the tangible asset is ready for use. Also, under IFRS, income earned on temporarily investing the borrowed monies decreases the amount of borrowing costs eligible for capitalization. Therefore, Total capitalized interest = (500 million × 14% × 2 years) – 10 million = 130 million.

5 B is correct. A product patent with a defined expiration date is an intangible asset with a finite useful life. A copyright with no expiration date is an intangible asset with an indefinite useful life. Goodwill is no longer considered an intangible asset under IFRS and is considered to have an indefinite useful life.

6 C is correct. An intangible asset with a finite useful life is amortized, whereas an intangible asset with an indefinite useful life is not.

7 A is correct. The costs to internally develop intangible assets are generally expensed when incurred.

8 C is correct. Under both International Financial Reporting Standards (IFRS) and US GAAP, if an item is acquired in a business combination and cannot be recognized as a tangible asset or identifiable intangible asset, it is recognized as goodwill. Under US GAAP, assets arising from contractual or legal rights and assets that can be separated from the acquired company are recognized separately from goodwill.

9 A is correct. In the fiscal year when long-lived equipment is purchased, the assets on the balance sheet increase and depreciation expense on the income statement increases because of the new long-lived asset.

10 B is correct. Company Z's return on equity based on year-end equity value will be 6.1%. Company Z will have an additional £200,000 of expenses compared with Company X. Company Z expensed the printer for £300,000 rather than capitalizing the printer and having a depreciation expense of £100,000 like Company X. Company Z's net income and shareholders' equity will be £150,000 lower (= £200,000 × 0.75) than that of Company X.

$$\begin{aligned}\text{ROE} &= \left(\frac{\text{Net income}}{\text{Shareholders' Equity}}\right)\\ &= £600{,}000/£9{,}850{,}000\\ &= 0.61 = 6.1\%\end{aligned}$$

11 A is correct. If the company uses the straight-line method, the depreciation expense will be one-fifth (20 percent) of the depreciable cost in Year 1. If it uses the units-of-production method, the depreciation expense will be 19 percent (2,000/10,500) of the depreciable cost in Year 1. Therefore, if the company uses the straight-line method, its depreciation expense will be higher and its net income will be lower.

12 C is correct. The operating income or earnings before interest and taxes will be lowest for the method that results in the highest depreciation expense. The double-declining balance method results in the highest depreciation expense in the first year of use.

Depreciation expense:

Straight line = €1,500/5 = €300.

Double-declining balance = €1,500 × 0.40 = €600.

Units of production = €1,500 × 0.15 = €225.

13 C is correct. If Martinez wants to minimize tax payments in the first year of the machine's life, he should use an accelerated method, such as the double-declining balance method.

14 A is correct. Using the straight-line method, depreciation expense amounts to

Depreciation expense = (1,200,000 – 200,000)/8 years = 125,000.

15 B is correct. Using the units-of-production method, depreciation expense amounts to

Depreciation expense = (1,200,000 – 200,000) × (135,000/800,000) = 168,750.

16 A is correct. The straight-line method is the method that evenly distributes the cost of an asset over its useful life because amortization is the same amount every year.

17 A is correct. A higher residual value results in a lower total depreciable cost and, therefore, a lower amount of amortization in the first year after acquisition (and every year after that).

18 C is correct. Shifting at the end of Year 2 from double-declining balance to straight-line depreciation methodology results in depreciation expense being the same in each of Years 3, 4, and 5. Shifting to the straight-line methodology at the beginning of Year 3 results in a greater depreciation expense in Year 4 than would have been calculated using the double-declining balance method.

Depreciation expense Year 4 (Using double-declining balance method all five years)

= 2 × Annual depreciation % using straight-line method × Carrying amount at end of Year 3
= 40% × $43,200

Depreciation expense Year 4 with switch to straight-line method in Year 3

= ⅓ × Remaining depreciable cost at start of Year 3
= ⅓ × $72,000
= $24,000

19 B is correct. Using the straight-line method, accumulated amortization amounts to

$$\begin{aligned}\text{Accumulated amortization} &= [(2{,}300{,}000 - 500{,}000)/3\text{ years}] \times 2\text{ years}\\ &= 1{,}200{,}000\end{aligned}$$

20 B is correct. Using the units-of-production method, depreciation expense amounts to

$$\text{Depreciation expense} = 5{,}800{,}000 \times (20{,}000/175{,}000) = 662{,}857$$

21 B is correct. As shown in the following calculations, under the double-declining balance method, the annual amortization expense in Year 4 is closest to ¥9.9 million.

Annual amortization expense = 2 × Straight-line amortization rate × Net book value.

Amortization expense Year 4 = 33.3% × ¥29.6 million = ¥9.9 million.

22 A is correct. As shown in the following calculations, at the end of Year 4, the difference between the net book values calculated using straight-line versus double-declining balance is closest to €81,400.

Net book value end of Year 4 using straight-line method = €600,000 – [4 × (€600,000/6)] = €200,000.

Net book value end of Year 4 using double-declining balance method = €600,000 $(1 - 33.33\%)^4 \approx$ €118,600.

23 B is correct. In this case, the value increase brought about by the revaluation should be recorded directly in equity. The reason is that under IFRS, an increase in value brought about by a revaluation can only be recognized as a profit to the extent that it reverses a revaluation decrease of the same asset previously recognized in the income statement.

24 B is correct. The impairment loss equals £3,100,000.

$$\begin{aligned}\text{Impairment} &= \max(\text{Fair value less costs to sell; Value in use}) - \text{Net carrying amount}\\ &= \max(16{,}800{,}000 - 800{,}000;\ 14{,}500{,}000) - 19{,}100{,}000\\ &= -3{,}100{,}000.\end{aligned}$$

25 B is correct. Under IFRS, an impairment loss is measured as the excess of the carrying amount over the asset's recoverable amount. The recoverable amount is the higher of the asset's fair value less costs to sell and its value in use. Value in use is a discounted measure of expected future cash flows. Under US GAAP, assessing recoverability is separate from measuring the impairment loss. If the asset's carrying amount exceeds its undiscounted expected future cash flows, the asset's carrying amount is considered unrecoverable and the impairment loss is measured as the excess of the carrying amount over the asset's fair value.

26 B is correct. The result on the sale of the vehicle equals

$$\begin{aligned}\text{Gain or loss on the sale} &= \text{Sale proceeds} - \text{Carrying amount}\\ &= \text{Sale proceeds} - (\text{Acquisition cost} - \text{Accumulated depreciation})\\ &= 85{,}000 - \{100{,}000 - [((100{,}000 - 10{,}000)/9\text{ years}) \times 3\text{ years}]\}\\ &= 15{,}000.\end{aligned}$$

27 A is correct. Gain or loss on the sale = Sale proceeds – Carrying amount. Rearranging this equation, Sale proceeds = Carrying amount + Gain or loss on sale. Thus, Sale price = (12 million – 2 million) + (–3.2 million) = 6.8 million.

28 C is correct. The carrying amount of the asset on the balance sheet is reduced by the amount of the impairment loss, and the impairment loss is reported on the income statement.

29 A is correct. The gain or loss on the sale of long-lived assets is computed as the sales proceeds minus the carrying amount of the asset at the time of sale. This is true under the cost and revaluation models of reporting long-lived assets. In the absence of impairment losses, under the cost model, the carrying amount will equal historical cost net of accumulated depreciation.

30 B is correct. IFRS do not require acquisition dates to be disclosed.

31 A is correct. IFRS do not require fair value of intangible assets to be disclosed.

32 C is correct. Under US GAAP, companies are required to disclose the estimated amortization expense for the next five fiscal years. Under US GAAP, there is no reversal of impairment losses. Disclosure of the useful lives—finite or indefinite and additional related details—is required under IFRS.

33 B is correct. Investment property earns rent. Investment property and property, plant, and equipment are tangible and long-lived.

34 C is correct. When a company uses the fair value model to value investment property, changes in the fair value of the property are reported in the income statement—not in other comprehensive income.

35 A is correct. Investment property earns rent. Inventory is held for resale, and property, plant, and equipment are used in the production of goods and services.

36 C is correct. A company will change from the fair value model to either the cost model or revaluation model when the company transfers investment property to property, plant, and equipment.

37 A is correct. Under both the revaluation model for property, plant, and equipment and the fair model for investment property, the asset's fair value must be able to be measured reliably. Under the fair value model, net income is affected by all changes in the asset's fair value. Under the revaluation model, any increase in an asset's value to the extent that it reverses a previous revaluation decrease will be recognized on the income statement and increase net income.

38 A is correct. Under IFRS, when using the cost model for its investment properties, a company must disclose useful lives. The method for determining fair value, as well as reconciliation between beginning and ending carrying amounts of investment property, is a required disclosure when the fair value model is used.

39 C is correct. Expensing rather than capitalising an investment in long-term assets will result in higher expenses and lower net income and net profit margin in the current year. Future years' incomes will not include depreciation expense related to these expenditures. Consequently, year-to-year growth in profitability will be higher. If the expenses had been capitalised, the carrying amount of the assets would have been higher and the 2009 total asset turnover would have been lower.

40 C is correct. In 2010, switching to an accelerated depreciation method would increase depreciation expense and decrease income before taxes, taxes payable, and net income. Cash flow from operating activities would increase because of the resulting tax savings.

41 B is correct. 2009 net income and net profit margin are lower because of the impairment loss. Consequently, net profit margins in subsequent years are likely to be higher. An impairment loss suggests that insufficient depreciation expense was recognized in prior years, and net income was overstated in prior years. The impairment loss is a non-cash item and will not affect operating cash flows.

42 A is correct. The estimated average remaining useful life is 20.75 years.

$$\begin{aligned}\text{Estimate of remaining useful life} &= \text{Net plant and equipment} \div \text{Annual depreciation expense}\\ \text{Net plant and equipment} &= \text{Gross P \& E} - \text{Accumulated depreciation}\\ &= €6000 - €1850 = €4150\\ \text{Estimate of remaining useful life} &= \text{Net P \& E} \div \text{Depreciation expense}\\ &= €4150 \div €200 = 20.75\end{aligned}$$

43 C is correct. The decision to capitalise the costs of the new computer system results in higher cash flow from operating activities; the expenditure is reported as an outflow of investing activities. The company allocates the capitalised amount over the asset's useful life as depreciation or amortisation expense rather than expensing it in the year of expenditure. Net income and total assets are higher in the current fiscal year.

44 B is correct. Alpha's fixed asset turnover will be lower because the capitalised interest will appear on the balance sheet as part of the asset being constructed. Therefore, fixed assets will be higher and the fixed asset turnover ratio (total revenue/average net fixed assets) will be lower than if it had expensed these costs. Capitalised interest appears on the balance sheet as part of the asset being constructed instead of being reported as interest expense in the period incurred. However, the interest coverage ratio should be based on interest payments, not interest expense (earnings before interest and taxes/interest payments), and should be unchanged. To provide a true picture of a company's interest coverage, the entire amount of interest expenditure, both the capitalised portion and the expensed portion, should be used in calculating interest coverage ratios.

45 A is correct. Accelerated depreciation will result in an improving, not declining, net profit margin over time, because the amount of depreciation expense declines each year. Under straight-line depreciation, the amount of depreciation expense will remain the same each year. Under the units-of-production method, the amount of depreciation expense reported each year varies with the number of units produced.

46 B is correct. The estimated average total useful life of a company's assets is calculated by adding the estimates of the average remaining useful life and the average age of the assets. The average age of the assets is estimated by dividing accumulated depreciation by depreciation expense. The average remaining useful life of the asset base is estimated by dividing net property, plant, and equipment by annual depreciation expense.

47 C is correct. The impairment loss is a non-cash charge and will not affect cash flow from operating activities. The debt to total assets and fixed asset turnover ratios will increase, because the impairment loss will reduce the carrying amount of fixed assets and therefore total assets.

48 A is correct. In an asset revaluation, the carrying amount of the assets increases. The increase in the asset's carrying amount bypasses the income statement and is reported as other comprehensive income and appears in equity under the heading of revaluation surplus. Therefore, shareholders' equity will increase but net income will not be affected, so return on equity will decline. Return on assets and debt to capital ratios will also decrease.

Income Taxes

by Elbie Louw, PhD, CFA, CIPM, and Michael A. Broihahn, CPA, CIA, CFA

Elbie Louw, PhD, CFA, CIPM (South Africa). Michael A. Broihahn, CPA, CIA, CFA, is at Barry University (USA).

LEARNING OUTCOMES

Mastery	*The candidate should be able to:*
☐	**a.** describe the differences between accounting profit and taxable income and define key terms, including deferred tax assets, deferred tax liabilities, valuation allowance, taxes payable, and income tax expense;
☐	**b.** explain how deferred tax liabilities and assets are created and the factors that determine how a company's deferred tax liabilities and assets should be treated for the purposes of financial analysis;
☐	**c.** calculate the tax base of a company's assets and liabilities;
☐	**d.** calculate income tax expense, income taxes payable, deferred tax assets, and deferred tax liabilities, and calculate and interpret the adjustment to the financial statements related to a change in the income tax rate;
☐	**e.** evaluate the effect of tax rate changes on a company's financial statements and ratios;
☐	**f.** identify and contrast temporary versus permanent differences in pre-tax accounting income and taxable income;
☐	**g.** describe the valuation allowance for deferred tax assets—when it is required and what effect it has on financial statements;
☐	**h.** explain recognition and measurement of current and deferred tax items;
☐	**i.** analyze disclosures relating to deferred tax items and the effective tax rate reconciliation and explain how information included in these disclosures affects a company's financial statements and financial ratios;
☐	**j.** identify the key provisions of and differences between income tax accounting under International Financial Reporting Standards (IFRS) and US generally accepted accounting principles (GAAP).

Note: Changes in accounting standards as well as new rulings and/or pronouncements issued after the publication of the readings on financial reporting and analysis may cause some of the information in these readings to become dated. Candidates are *not* responsible for anything that occurs after the readings were published. In addition, candidates are expected to be familiar with the analytical frameworks contained in the readings, as well as the implications of alternative accounting methods for financial analysis and valuation discussed in the readings. Candidates are also responsible for the content of accounting standards, but not for the actual reference numbers. Finally, candidates should be aware that certain ratios may be defined and calculated differently. When alternative ratio definitions exist and no specific definition is given, candidates should use the ratio definitions emphasized in the readings.

1 INTRODUCTION

For those companies reporting under International Financial Reporting Standards (IFRS), IAS 12 [Income Taxes] covers accounting for a company's income taxes and the reporting of deferred taxes. For those companies reporting under United States generally accepted accounting principles (US GAAP), FASB ASC Topic 740 [Income Taxes] is the primary source for information on accounting for income taxes. Although IFRS and US GAAP follow similar conventions on many income tax issues, there are some key differences that will be discussed in the reading.

Differences between how and when transactions are recognized for financial reporting purposes relative to tax reporting can give rise to differences in tax expense and related tax assets and liabilities. To reconcile these differences, companies that report under either IFRS or US GAAP create a provision on the balance sheet called deferred tax assets or deferred tax liabilities, depending on the nature of the situation.

Deferred tax assets or liabilities usually arise when accounting standards and tax authorities recognize the timing of revenues and expenses at different times. Because timing differences such as these will eventually reverse over time, they are called "temporary differences." Deferred tax assets represent taxes that have been recognized for tax reporting purposes (or often the carrying forward of losses from previous periods) but have not yet been recognized on the income statement prepared for financial reporting purposes. Deferred tax liabilities represent tax expense that has appeared on the income statement for financial reporting purposes, but has not yet become payable under tax regulations.

This reading provides a primer on the basics of income tax accounting and reporting. The reading is organized as follows. Sections 2 and 3 describe the differences between taxable income and accounting profit. Sections 4 and 5 explain the determination of tax base, which relates to the valuation of assets and liabilities for tax purposes. Sections 6 and 7 discuss several types of timing differences between the recognition of taxable and accounting profit. Section 8 examines unused tax losses and tax credits. Section 9 describes the recognition and measurement of current and deferred tax. Section 10 discusses the disclosure and presentation of income tax information on companies' financial statements and illustrates its practical implications for financial analysis. Section 11 provides an overview of the similarities and differences for income-tax reporting between IFRS and US GAAP. A summary of the key points and practice problems in the CFA Institute multiple-choice format conclude the reading.

2 DIFFERENCES BETWEEN ACCOUNTING PROFIT AND TAXABLE INCOME

a describe the differences between accounting profit and taxable income and define key terms, including deferred tax assets, deferred tax liabilities, valuation allowance, taxes payable, and income tax expense;

A company's **accounting profit** is reported on its income statement in accordance with prevailing accounting standards. Accounting profit (also referred to as income before taxes or pretax income) does not include a provision for income tax expense.[1] A company's **taxable income** is the portion of its income that is subject to income taxes under the tax laws of its jurisdiction. Because of different guidelines for how income is reported on a company's financial statements and how it is measured for income tax purposes, accounting profit and taxable income may differ.

---

[1] As defined under IAS 12, paragraph 5.

A company's taxable income is the basis for its **income tax payable** (a liability) or recoverable (an asset), which is calculated on the basis of the company's tax rate and appears on its balance sheet. A company's **tax expense**, or tax benefit in the case of a recovery, appears on its income statement and is an aggregate of its income tax payable (or recoverable in the case of a tax benefit) and any changes in deferred tax assets and liabilities.

When a company's taxable income is greater than its accounting profit, then its income taxes payable will be higher than what would have otherwise been the case had the income taxes been determined based on accounting profit. **Deferred tax assets**, which appear on the balance sheet, arise when an excess amount is paid for income taxes (taxable income higher than accounting profit) and the company expects to recover the difference during the course of future operations. Actual income taxes payable will thus exceed the financial accounting income tax expense (which is reported on the income statement and is determined based on accounting profit). Related to deferred tax assets is a **valuation allowance**, which is a reserve created against deferred tax assets. The valuation allowance is based on the likelihood of realizing the deferred tax assets in future accounting periods. **Deferred tax liabilities**, which also appear on the balance sheet, arise when a deficit amount is paid for income taxes and the company expects to eliminate the deficit over the course of future operations. In this case, financial accounting income tax expense exceeds income taxes payable.

Income tax paid in a period is the actual amount paid for income taxes (not a provision, but the actual cash outflow). The income tax paid may be less than the income tax expense because of payments in prior periods or refunds received in the current period. Income tax paid reduces the income tax payable, which is carried on the balance sheet as a liability.

The **tax base** of an asset or liability is the amount at which the asset or liability is valued for tax purposes, whereas the **carrying amount** is the amount at which the asset or liability is valued according to accounting principles.[2] Differences between the tax base and the carrying amount also result in differences between accounting profit and taxable income. These differences can carry through to future periods. For example, a **tax loss carry forward** occurs when a company experiences a loss in the current period that may be used to reduce future taxable income. The company's tax expense on its income statement must not only reflect the taxes payable based on taxable income, but also the effect of these differences.

CURRENT AND DEFERRED TAX ASSETS AND LIABILITIES

3

b explain how deferred tax liabilities and assets are created and the factors that determine how a company's deferred tax liabilities and assets should be treated for the purposes of financial analysis;

d calculate income tax expense, income taxes payable, deferred tax assets, and deferred tax liabilities, and calculate and interpret the adjustment to the financial statements related to a change in the income tax rate;

---

[2] The terms "tax base" and "tax basis" are interchangeable. "Tax basis" is more commonly used in the United States. Similarly, "carrying amount" and "book value" refer to the same concept.

A company's current tax liability is the amount payable in taxes and is based on current taxable income. If the company expects to receive a refund for some portion previously paid in taxes, the amount recoverable is referred to as a current tax asset. The current tax liability or asset may, however, differ from what the liability would have been if it was based on accounting profit rather than taxable income for the period. Differences in accounting profit and taxable income are the result of the application of different rules. Such differences between accounting profit and taxable income can occur in several ways, including:

- Revenues and expenses may be recognized in one period for accounting purposes and a different period for tax purposes;
- Specific revenues and expenses may be either recognized for accounting purposes and not for tax purposes; or not recognized for accounting purposes but recognized for tax purposes;
- The carrying amount and tax base of assets and/or liabilities may differ;
- The deductibility of gains and losses of assets and liabilities may vary for accounting and income tax purposes;
- Subject to tax rules, tax losses of prior years might be used to reduce taxable income in later years, resulting in differences in accounting and taxable income (tax loss carryforward); and
- Adjustments of reported financial data from prior years might not be recognized equally for accounting and tax purposes or might be recognized in different periods.

3.1 Deferred Tax Assets and Liabilities

Deferred tax assets represent taxes that have been paid (or often the carrying forward of losses from previous periods) but have not yet been recognized on the income statement. Deferred tax liabilities occur when financial accounting income tax expense is greater than regulatory income tax expense. Deferred tax assets and liabilities usually arise when accounting standards and tax authorities recognize the timing of taxes due at different times; for example, when a company uses accelerated depreciation when reporting to the tax authority (to increase expense and lower tax payments in the early years) but uses the straight-line method on the financial statements. Although not similar in treatment on a year-to-year basis (e.g., depreciation of 5 percent on a straight-line basis may be permitted for accounting purposes whereas 10 percent is allowed for tax purposes) over the life of the asset, both approaches allow for the total cost of the asset to be depreciated (or amortized). Because these timing differences will eventually reverse or self-correct over the course of the asset's depreciable life, they are called "temporary differences."

Any deferred tax asset or liability is based on temporary differences that result in an excess or a deficit amount paid for taxes, which the company expects to recover from future operations. Because taxes will be recoverable or payable at a future date, it is only a temporary difference and a deferred tax asset or liability is created. Changes in the deferred tax asset or liability on the balance sheet reflect the difference between the amounts recognized in the previous period and the current period. The changes in deferred tax assets and liabilities are added to income tax payable to determine the company's income tax expense (or credit) as it is reported on the income statement.

At the end of each fiscal year, deferred tax assets and liabilities are recalculated by comparing the tax bases and carrying amounts of the balance sheet items. Identified temporary differences should be assessed on whether the difference will result in future economic benefits. For example, Pinto Construction (a hypothetical company) depreciates equipment on a straight-line basis of 10 percent per year. The tax authorities allow depreciation of 15 percent per year. At the end of the fiscal year, the carrying amount of the equipment for accounting purposes would be greater than the tax base of the equipment thus resulting in a temporary difference. A deferred tax item may only be created if it is not doubtful that the company will realize economic benefits in the future. In our example, the equipment is used in the core business of Pinto Construction. If the company is a going concern and stable, there should be no doubt that future economic benefits will result from the equipment and it would be appropriate to create the deferred tax item.

Should it be doubtful that future economic benefits will be realized from a temporary difference (such as Pinto Construction being under liquidation), the temporary difference will not lead to the creation of a deferred tax asset or liability. If a deferred tax asset or liability resulted in the past, but the criteria of economic benefits is not met on the current balance sheet date, then, under IFRS, an existing deferred tax asset or liability related to the item will be reversed. Under US GAAP, a valuation allowance is established. In assessing future economic benefits, much is left to the discretion of the auditor in assessing the temporary differences and the issue of future economic benefits.

EXAMPLE 1

The following information pertains to a hypothetical company, Reston Partners:

Reston Partners Consolidated Income Statement

Period Ending 31 March (£ Millions)	Year 3	Year 2	Year 1
Revenue	£40,000	£30,000	£25,000
Other net gains	2,000	0	0
Changes in inventories of finished goods and work in progress	400	180	200
Raw materials and consumables used	(5,700)	(4,000)	(8,000)
Depreciation expense	(2,000)	(2,000)	(2,000)
Other expenses	(6,000)	(5,900)	(4,500)
Interest expense	(2,000)	(3,000)	(6,000)
Profit before tax	£26,700	£15,280	£4,700

The financial performance and accounting profit of Reston Partners on this income statement is based on accounting principles appropriate for the jurisdiction in which Reston Partners operates. The principles used to calculate accounting profit (profit before tax in the example above) may differ from the principles applied for tax purposes (the calculation of taxable income). For illustrative purposes, however, assume that all income and expenses on the income statement are treated identically for tax and accounting purposes *except* depreciation.

The depreciation is related to equipment owned by Reston Partners. For simplicity, assume that the equipment was purchased at the beginning of the Year 1. Depreciation should thus be calculated and expensed for the full year. Assume that accounting standards permit equipment to be depreciated on a straight-line basis over a 10-year period, whereas the tax standards in the jurisdiction specify that equipment should be depreciated on a straight-line basis over a 7-year period. For simplicity, assume a salvage value of £0 at the end of the equipment's useful life. Both methods will result in the full depreciation of the asset over the respective tax or accounting life.

The equipment was originally purchased for £20,000. In accordance with accounting standards, over the next 10 years the company will recognize annual depreciation of £2,000 (£20,000 ÷ 10) as an expense on its income statement and for the determination of accounting profit. For tax purposes, however, the company will recognize £2,857 (£20,000 ÷ 7) in depreciation each year. Each fiscal year the depreciation expense related to the use of the equipment will, therefore, differ for tax and accounting purposes (tax base vs. carrying amount), resulting in a difference between accounting profit and taxable income.

The previous income statement reflects accounting profit (depreciation at £2,000 per year). The following table shows the taxable income for each fiscal year.

Taxable Income (£ Millions)	**Year 3**	**Year 2**	**Year 1**
Revenue	£40,000	£30,000	£25,000
Other net gains	2,000	0	0
Changes in inventories of finished goods and work in progress	400	180	200
Raw materials and consumables used	(5,700)	(4,000)	(8,000)
Depreciation expense	(2,857)	(2,857)	(2,857)
Other expenses	(6,000)	(5,900)	(4,500)
Interest expense	(2,000)	(3,000)	(6,000)
Taxable income	£25,843	£14,423	£3,843

The carrying amount and tax base for the equipment is as follows:

(£ Millions)	**Year 3**	**Year 2**	**Year 1**
Equipment value for accounting purposes (*carrying amount*) (depreciation of £2,000/year)	£14,000	£16,000	£18,000
Equipment value for tax purposes (*tax base*) (depreciation of £2,857/year)	£11,429	£14,286	£17,143
Difference	£2,571	£1,714	£857

At each balance sheet date, the tax base and carrying amount of all assets and liabilities must be determined. The income tax payable by Reston Partners will be based on the taxable income of each fiscal year. If a tax rate of 30 percent is assumed, then the income taxes payable for Year 1, Year 2, and Year 3 are £1,153 (30% × 3,843), £4,327 (30% × 14,423), and £7,753 (30% × 25,843).

Remember, though, that if the tax obligation is calculated based on accounting profits, it will differ because of the differences between the tax base and the carrying amount of equipment. The difference in each fiscal year is reflected in the table above. In each fiscal year the carrying amount of the equipment exceeds its tax base. For tax purposes, therefore, the asset tax base is less than its carrying value under financial accounting principles. The difference results in a deferred tax liability.

(£ Millions)	**Year 3**	**Year 2**	**Year 1**
Deferred tax liability	£771	£514	£257

(Difference between tax base and carrying amount) × tax rate

Year 1: £(18,000 – 17,143) × 30% = 257

Year 2: £(16,000 – 14,286) × 30% = 514

Year 3: £(14,000 – 11,429) × 30% = 771

The comparison of the tax base and carrying amount of equipment shows what the deferred tax liability should be on a particular balance sheet date. In each fiscal year, only the change in the deferred tax liability should be included in the calculation of the income tax expense reported on the income statement prepared for accounting purposes.

On the income statement, the company's income tax expense will be the sum of change in the deferred tax liability and the income tax payable.

(£ Millions)	Year 3	Year 2	Year 1
Income tax payable (based on tax accounting)	£7,753	£4,327	£1,153
Change in deferred tax liability	257	257	257
Income tax (based on financial accounting)	£8,010	£4,584	£1,410

Note that because the different treatment of depreciation is a temporary difference, the income tax on the income statement is 30 percent of the accounting profit, although only a part is income tax payable and the rest is a deferred tax liability.

The consolidated income statement of Reston Partners including income tax is presented as follows:

Reston Partners Consolidated Income Statement

Period Ending 31 March (£ Millions)	Year 3	Year 2	Year 1
Revenue	£40,000	£30,000	£25,000
Other net gains	2,000	0	0
Changes in inventories of finished goods and work in progress	400	180	200
Raw materials and consumables used	(5,700)	(4,000)	(8,000)
Depreciation expense	(2,000)	(2,000)	(2,000)
Other expenses	(6,000)	(5,900)	(4,500)
Interest expense	(2,000)	(3,000)	(6,000)
Profit before tax	£26,700	£15,280	£4,700
Income tax	(8,010)	(4,584)	(1,410)
Profit after tax	£18,690	£10,696	£3,290

Any amount paid to the tax authorities will reduce the liability for income tax payable and be reflected on the statement of cash flows of the company.

DETERMINING THE TAX BASE OF ASSETS AND LIABILITIES

4

c calculate the tax base of a company's assets and liabilities;

As mentioned in Sections 2 and 3, temporary differences arise from a difference in the tax base and carrying amount of assets and liabilities. The tax base of an asset or liability is the amount attributed to the asset or liability for tax purposes, whereas the carrying amount is based on accounting principles. Such a difference is considered temporary if it is expected that the taxes will be recovered or payable at a future date.

4.1 Determining the Tax Base of an Asset

The tax base of an asset is the amount that will be deductible for tax purposes in future periods as the economic benefits become realized and the company recovers the carrying amount of the asset.

For example, our previously mentioned Reston Partners (from Example 1) depreciates equipment on a straight-line basis at a rate of 10 percent per year. The tax authorities allow depreciation of approximately 15 percent per year. At the end of the fiscal year, the carrying amount of equipment for accounting purposes is greater than the asset tax base thus resulting in a temporary difference.

EXAMPLE 2

Determining the Tax Base of an Asset

The following information pertains to Entiguan Sports, a hypothetical developer of products used to treat sports-related injuries. (The treatment of items for accounting and tax purposes is based on hypothetical accounting and tax standards and is not specific to a particular jurisdiction.) Calculate the tax base and carrying amount for each item.

1 *Dividends receivable*: On its balance sheet, Entiguan Sports reports dividends of €1 million receivable from a subsidiary. Assume that dividends are not taxable.

2 *Development costs*: Entiguan Sports capitalized development costs of €3 million during the year. Entiguan amortized €500,000 of this amount during the year. For tax purposes amortization of 25 percent per year is allowed.

3 *Research costs*: Entiguan incurred €500,000 in research costs, which were all expensed in the current fiscal year for financial reporting purposes. Assume that applicable tax legislation requires research costs to be expensed over a four-year period rather than all in one year.

4 *Accounts receivable*: Included on the income statement of Entiguan Sports is a provision for doubtful debt of €125,000. The accounts receivable amount reflected on the balance sheet, after taking the provision into account, amounts to €1,500,000. The tax authorities allow a deduction of 25 percent of the gross amount for doubtful debt.

Solutions:

	Carrying Amount (€)	Tax Base (€)	Temporary Difference (€)
1. Dividends receivable	1,000,000	1,000,000	0
2. Development costs	2,500,000	2,250,000	250,000
3. Research costs	0	375,000	(375,000)
4. Accounts receivable	1,500,000	1,218,750	281,250

Comments:

1 *Dividends receivable*: Although the dividends received are economic benefits from the subsidiary, we are assuming that dividends are not taxable. Therefore, the carrying amount equals the tax base for dividends receivable.

2 *Development costs*: First, we assume that development costs will generate economic benefits for Entiguan Sports. Therefore, it may be included as an asset on the balance sheet for the purposes of this example. Second, the amortization allowed by the tax authorities exceeds the amortization accounted for based on accounting rules. Therefore, the carrying amount of the asset exceeds its tax base. The carrying amount is (€3,000,000 – €500,000) = €2,500,000 whereas the tax base is [€3,000,000 – (25% × €3,000,000)] = €2,250,000.

3 *Research costs*: We assume that research costs will result in future economic benefits for the company. If this were not the case, creation of a deferred tax asset or liability would not be allowed. The tax base of research costs exceeds their carrying amount. The carrying amount is €0 because the full amount has been expensed for financial reporting purposes in the year in which it was incurred. Therefore, there would not have been a balance sheet item "Research costs" for tax purposes, and only a proportion may be deducted in the current fiscal year. The tax base of the asset is (€500,000 – €500,000/4) = €375,000.

4 *Accounts receivable*: The economic benefits that should have been received from accounts receivable have already been included in revenues included in the calculation of the taxable income when the sales occurred. Because the receipt of a portion of the accounts receivable is doubtful, the provision is allowed. The provision, based on tax legislation, results in a greater amount allowed in the current fiscal year than would be the case under accounting principles. This results in the tax base of accounts receivable being lower than its carrying amount. Note that the example specifically states that the balance sheet amount for accounts receivable after the provision for accounting purposes amounts to €1,500,000. Therefore, accounts receivable before any provision was €1,500,000 + €125,000 = €1,625,000. The tax base is calculated as (€1,500,000 + €125,000) – [25% × (€1,500,000 + €125,000)] = €1,218,750.

4.2 Determining the Tax Base of a Liability

The tax base of a liability is the carrying amount of the liability less any amounts that will be deductible for tax purposes in the future. With respect to payments from customers received in advance of providing the goods and services, the tax base of such a liability is the carrying amount less any amount of the revenue that will not be taxable in future. Keep in mind the following fundamental principle: In general, a company will recognize a deferred tax asset or liability when recovery/settlement of the carrying amount will affect future tax payments by either increasing or reducing the taxable profit. Remember, an analyst is not only evaluating the difference between the carrying amount and the tax base, but the relevance of that difference on future profits and losses and thus by implication future taxes.

IFRS offers specific guidelines with regard to revenue received in advance: IAS 12 states that the tax base is the carrying amount less any amount of the revenue that will not be taxed at a future date. Under US GAAP, an analysis of the tax base would result in a similar outcome. The tax legislation within the jurisdiction will determine the amount recognized on the income statement and whether the liability (revenue received in advance) will have a tax base greater than zero. This will depend on how tax legislation recognizes revenue received in advance.

EXAMPLE 3

Determining the Tax Base of a Liability

The following information pertains to the hypothetical company Entiguan Sports for the fiscal year -end. The treatment of items for accounting and tax purposes is based on fictitious accounting and tax standards and is not specific to a particular jurisdiction. Calculate the tax base and carrying amount for each item.

1. *Donations*: Entiguan Sports made donations of €100,000 in the current fiscal year. The donations were expensed for financial reporting purposes, but are not tax deductible based on applicable tax legislation.
2. *Interest received in advance*: Entiguan Sports received in advance interest of €300,000. The interest is taxed because tax authorities recognize the interest to accrue to the company (part of taxable income) on the date of receipt.
3. *Rent received in advance*: Entiguan recognized €10 million for rent received in advance from a lessee for an unused warehouse building. Rent received in advance is deferred for accounting purposes but taxed on a cash basis.
4. *Loan*: Entiguan Sports secured a long-term loan for €550,000 in the current fiscal year. Interest is charged at 13.5 percent per annum and is payable at the end of each fiscal year.

Solutions:

	Carrying Amount (€)	Tax Base (€)	Temporary Difference (€)
1. Donations	0	0	0
2. Interest received in advance	300,000	0	(300,000)
3. Rent received in advance	10,000,000	0	(10,000,000)
4. Loan (capital)	0	0	0
Interest paid	0	0	0

Comments:

1. *Donations*: The amount of €100,000 was immediately expensed on Entiguan's income statement; therefore, the carrying amount is €0. Tax legislation does not allow donations to be deducted for tax purposes, so the tax base of the donations equals the carrying amount. Note that while the carrying amount and tax base are the same, the difference in the treatment of donations for accounting and tax purposes (expensed for accounting purposes, but not deductible for tax purposes) represents a permanent difference (a difference that will not be reversed in future). Permanent and temporary differences are elaborated on in Sections 6 and 7 and it will refer to this particular case with an expanded explanation.
2. *Interest received in advance*: Based on the information provided, for tax purposes, interest is deemed to accrue to the company on the date of receipt. For tax purposes, it is thus irrelevant whether it is for the current or a future accounting period; it must be included in taxable income in the financial year received. Interest received in advance is, for accounting purposes though, included in the financial period in which it is deemed to have been earned. For this reason, the interest income received in advance

is a balance sheet liability. It was not included on the income statement because the income relates to a future financial year. Because the full €300,000 is included in taxable income in the current fiscal year, the tax base is €300,000 − 300,000 = €0. Note that although interest received in advance and rent received in advance are both taxed, the timing depends on how the particular item is treated in tax legislation.

3 *Rent received in advance*: The result is similar to interest received in advance. The carrying amount of rent received in advance would be €10,000,000 while the tax base is €0.

4 *Loan*: Repayment of the loan has no tax implications. The repayment of the capital amount does not constitute an income or expense. The interest paid is included as an expense in the calculation of taxable income as well as accounting income. Therefore, the tax base and carrying amount is €0. For clarity, the interest paid that would be included on the income statement for the year amounts to 13.5% × €550,000 = €74,250 if the loan was acquired at the beginning of the current fiscal year.

CHANGES IN INCOME TAX RATES

5

d calculate income tax expense, income taxes payable, deferred tax assets, and deferred tax liabilities, and calculate and interpret the adjustment to the financial statements related to a change in the income tax rate;

e evaluate the effect of tax rate changes on a company's financial statements and ratios;

The measurement of deferred tax assets and liabilities is based on current tax law. But if there are subsequent changes in tax laws or new income tax rates, existing deferred tax assets and liabilities must be adjusted for the effects of these changes. The resulting effects of the changes are also included in determining accounting profit in the period of change.

When income tax rates change, the deferred tax assets and liabilities are adjusted to the new tax rate. If income tax rates increase, deferred taxes (that is, the deferred tax assets and liabilities) will also increase. Likewise, if income tax rates decrease, deferred taxes will decrease. A decrease in tax rates decreases deferred tax liabilities, which reduces future tax payments to the taxing authorities. A decrease in tax rates will also decrease deferred tax assets, which reduces their value toward the offset of future tax payments to the taxing authorities.

To illustrate the effect of a change in tax rate, consider Example 1 again. In that illustration, the timing difference that led to the recognition of a deferred tax liability for Reston Partners was attributable to differences in the method of depreciation and the related effects on the accounting carrying value and the asset tax base. The relevant information is restated below.

The carrying amount and tax base for the equipment is:

(£ Millions)	Year 3	Year 2	Year 1
Equipment value for accounting purposes (*carrying amount*) (depreciation of £2,000/year)	£14,000	£16,000	£18,000
Equipment value for tax purposes (*tax base*) (depreciation of £2,857/year)	£11,429	£14,286	£17,143
Difference	£2,571	£1,714	£857

At a 30 percent income tax rate, the deferred tax liability was then determined as follows:

(£ Millions)	Year 3	Year 2	Year 1
Deferred tax liability	£771	£514	£257
(Difference between tax base and carrying amount)			
Year 1: £(18,000 – 17,143) × 30% = £257			
Year 2: £(16,000 – 14,286) × 30% = £514			
Year 3: £(14,000 – 11,429) × 30% = £771			

For this illustration, assume that the taxing authority has changed the income tax rate to 25 percent for Year 3. Although the difference between the carrying amount and the tax base of the depreciable asset are the same, the deferred tax liability for 2017 will be £643 (instead of £771 or a reduction of £128 in the liability). 2017: £(14,000 – 11,429) × 25% = £643.

Reston Partners' provision for income tax expense is also affected by the change in tax rates. Taxable income for Year 3 will now be taxed at a rate of 25 percent. The benefit of the Year 3 accelerated depreciation tax shield is now only £214 (£857 × 25%) instead of the previous £257 (a reduction of £43). In addition, the reduction in the beginning carrying value of the deferred tax liability for Year 3 (the year of change) further reduces the income tax expense for Year 3. The reduction in income tax expense attributable to the change in tax rate is £86. Year 3: (30% – 25%) × £1,714 = £86. Note that these two components together account for the reduction in the deferred tax liability (£43 + £86 = £129).

As may be seen from this discussion, changes in the income tax rate have an effect on a company's deferred tax asset and liability carrying values as well as an effect on the measurement of income tax expense in the year of change. The analyst must thus note that proposed changes in tax law can have a quantifiable effect on these accounts (and any related financial ratios that are derived from them) if the proposed changes are subsequently enacted into law.

6

TEMPORARY AND PERMANENT DIFFERENCES BETWEEN TAXABLE AND ACCOUNTING PROFIT

f identify and contrast temporary versus permanent differences in pre-tax accounting income and taxable income;

Temporary differences arise from a difference between the tax base and the carrying amount of assets and liabilities. The creation of a deferred tax asset or liability from a temporary difference is only possible if the difference reverses itself at some future date and to such an extent that the balance sheet item is expected to create future economic benefits for the company. IFRS and US GAAP both prescribe the balance sheet liability method for recognition of deferred tax. This balance sheet method focuses on the recognition of a deferred tax asset or liability should there be a temporary difference between the carrying amount and tax base of balance sheet items.[3]

Permanent differences are differences between tax and financial reporting of revenue (expenses) that *will not* be reversed at some future date. Because they will not be reversed at a future date, these differences do not give rise to deferred tax. These items typically include

- Income or expense items not allowed by tax legislation, and
- Tax credits for some expenditures that directly reduce taxes.

Because no deferred tax item is created for permanent differences, all permanent differences result in a difference between the company's effective tax rate and statutory tax rate. The effective tax rate is also influenced by different statutory taxes should an entity conduct business in more than one tax jurisdiction. The formula for the reported effective tax rate is thus equal to:

$$\text{Reported effective tax rate} = \text{Income tax expense} \div \text{Pretax income (accounting profit)}$$

The net change in deferred tax during a reporting period is the difference between the balance of the deferred tax asset or liability for the current period and the balance of the previous period.

6.1 Taxable Temporary Differences

Temporary differences are further divided into two categories, namely taxable temporary differences and deductible temporary differences. **Taxable temporary differences** are temporary differences that result in a taxable amount in a future period when determining the taxable profit as the balance sheet item is recovered or settled. Taxable temporary differences result in a deferred tax liability when the carrying amount of an asset exceeds its tax base and, in the case of a liability, when the tax base of the liability exceeds its carrying amount.

Under US GAAP, a deferred tax asset or liability is not recognized for unamortizable goodwill. Under IFRS, a deferred tax account is not recognized for goodwill arising in a business combination. Since goodwill is a residual, the recognition of a deferred tax liability would increase the carrying amount of goodwill. Discounting deferred tax assets or liabilities is generally not allowed for temporary differences related to business combinations as it is for other temporary differences.

IFRS provides an exemption (that is, deferred tax is not provided on the temporary difference) for the initial recognition of an asset or liability in a transaction that: a) is not a business combination (e.g., joint ventures, branches and unconsolidated investments); and b) affects neither accounting profit nor taxable profit at the time of the transaction. US GAAP does not provide an exemption for these circumstances.

---

[3] Previously, IAS 12 required recognition of deferred tax based on the deferred method (also known as the income statement method), which focused on timing differences. Timing differences are differences in the recognition of income and expenses for accounting and tax purposes that originate in one period and will reverse in a future period. Given the definition of timing differences, all timing differences are temporary differences, such as the different treatment of depreciation for tax and accounting purposes (although the timing is different with regard to the allowed depreciation for tax and accounting purposes, the asset will eventually be fully depreciated).

As a simple example of a temporary difference with no recognition of deferred tax liability, assume that a holding company of various leisure related businesses and holiday resorts buys an interest in a hotel in the current financial year. The goodwill related to the transaction will be recognized on the financial statements, but the related tax liability will not, as it relates to the initial recognition of goodwill.

6.2 Deductible Temporary Differences

Deductible temporary differences are temporary differences that result in a reduction or deduction of taxable income in a future period when the balance sheet item is recovered or settled. Deductible temporary differences result in a deferred tax asset when the tax base of an asset exceeds its carrying amount and, in the case of a liability, when the carrying amount of the liability exceeds its tax base. The recognition of a deferred tax asset is only allowed to the extent there is a reasonable expectation of future profits against which the asset or liability (that gave rise to the deferred tax asset) can be recovered or settled.

To determine the probability of sufficient future profits for utilization, one must consider the following: 1) Sufficient taxable temporary differences must exist that are related to the same tax authority and the same taxable entity; and 2) The taxable temporary differences that are expected to reverse in the same periods as expected for the reversal of the deductible temporary differences.

As with deferred tax liabilities, IFRS states that deferred tax assets should not be recognized in cases that would arise from the initial recognition of an asset or liability in transactions that are not a business combination and when, at the time of the transaction, there is no impact on either accounting or taxable profit. Subsequent to initial recognition under IFRS and US GAAP, any deferred tax assets that arise from investments in subsidiaries, branches, associates, and interests in joint ventures are recognized as a deferred tax asset.

IFRS and US GAAP allow the creation of a deferred tax asset in the case of tax losses and tax credits. These two unique situations will be further elaborated on in Section 9. IAS 12 *does not* allow the creation of a deferred tax asset arising from negative goodwill. Negative goodwill arises when the amount that an entity pays for an interest in a business is less than the net fair market value of the portion of assets and liabilities of the acquired company, based on the interest of the entity.

6.3 Examples of Taxable and Deductible Temporary Differences

Exhibit 1 summarizes how differences between the tax bases and carrying amounts of assets and liabilities give rise to deferred tax assets or deferred tax liabilities.

Exhibit 1 Treatment of Temporary Differences

Balance Sheet Item	Carrying Amount vs. Tax Base	Results in Deferred Tax Asset/Liability
Asset	Carrying amount > tax base	Deferred tax liability
Asset	Carrying amount < tax base	Deferred tax asset
Liability	Carrying amount > tax base	Deferred tax asset
Liability	Carrying amount < tax base	Deferred tax liability

EXAMPLE 4

Taxable and Deductible Temporary Differences

Examples 2 and 3 illustrated how to calculate the tax base of assets and liabilities, respectively. Based on the information provided in Examples 2 and 3, indicate whether the difference in the tax base and carrying amount of the assets and liabilities are temporary or permanent differences and whether a deferred tax asset or liability will be recognized based on the difference identified.

Solution to Example 2:

	Carrying Amount (€)	Tax Base (€)	Temporary Difference (€)	*Will Result in Deferred Tax Asset/Liability*
1. Dividends receivable	1,000,000	1,000,000	0	*N/A*
2. Development costs	2,500,000	2,250,000	250,000	*Deferred tax liability*
3. Research costs	0	375,000	(375,000)	*Deferred tax asset*
4. Accounts receivable	1,500,000	1,218,750	281,250	*Deferred tax liability*

Example 2 included comments on the calculation of the carrying amount and tax base of the assets.

1 *Dividends receivable*: As a result of non-taxability, the carrying amount equals the tax base of dividends receivable. This constitutes a permanent difference and will not result in the recognition of any deferred tax asset or liability. A temporary difference constitutes a difference that will, at some future date, be reversed. Although the timing of recognition is different for tax and accounting purposes, in the end the full carrying amount will be expensed/recognized as income. A permanent difference will never be reversed. Based on tax legislation, dividends from a subsidiary are not recognized as income. Therefore, no amount will be reflected as dividend income when calculating the taxable income, and the tax base of dividends receivable must be the total amount received, namely €1,000,000. The taxable income and accounting profit will permanently differ with the amount of dividends receivable, even on future financial statements as an effect on the retained earnings reflected on the balance sheet.

2 *Development costs*: The difference between the carrying amount and tax base is a temporary difference that, in the future, will reverse. In this fiscal year, it will result in a deferred tax liability.

3 *Research costs*: The difference between the carrying amount and tax base is a temporary difference that results in a deferred tax asset. Remember the explanation in Section 3 for deferred tax assets—a deferred tax asset arises because of an excess amount paid for taxes (when taxable income is greater than accounting profit), which is expected to be recovered from future operations. Based on accounting principles, the full amount was deducted resulting in a lower accounting profit, while the taxable income by implication, should be greater because of the lower amount expensed.

4 *Accounts receivable*: The difference between the carrying amount and tax base of the asset is a temporary difference that will result in a deferred tax liability.

Solution to Example 3:

	Carrying Amount (€)	Tax Base (€)	Temporary Difference (€)	*Will Result in Deferred Tax Asset/Liability*
1. Donations	0	0	0	*N/A*
2. Interest received in advance	300,000	0	(300,000)	*Deferred tax asset*
3. Rent received in advance	10,000,000	0	(10,000,000)	*Deferred tax asset*
4. Loan (capital)	550,000	550,000	0	*N/A*
Interest paid	0	0	0	*N/A*

Example 3 included extensive comments on the calculation of the carrying amount and tax base of the liabilities.

1. *Donations*: It was assumed that tax legislation does not allow donations to be deducted for tax purposes. No temporary difference results from donations, and thus a deferred tax asset or liability will not be recognized. This constitutes a permanent difference.
2. *Interest received in advance*: Interest received in advance results in a temporary difference that gives rise to a deferred tax asset. A deferred tax asset arises because of an excess amount paid for taxes (when taxable income is greater than accounting profit), which is expected to be recovered from future operations.
3. *Rent received in advance*: The difference between the carrying amount and tax base is a temporary difference that leads to the recognition of a deferred tax asset.
4. *Loan*: There are no temporary differences as a result of the loan or interest paid, and thus no deferred tax item is recognized.

7

EXCEPTIONS TO THE USUAL RULES FOR TEMPORARY DIFFERENCES

f identify and contrast temporary versus permanent differences in pre-tax accounting income and taxable income;

In some situations the carrying amount and tax base of a balance sheet item may vary at initial recognition. For example, a company may deduct a government grant from the initial carrying amount of an asset or liability that appears on the balance sheet. For tax purposes, such grants may not be deducted when determining the tax base of the balance sheet item. In such circumstances, the carrying amount of the asset or liability will be lower than its tax base. Differences in the tax base of an asset or liability as a result of the circumstances described above may not be recognized as deferred tax assets or liabilities.

For example, a government may offer grants to Small, Medium, and Micro Enterprises (SMME) in an attempt to assist these entrepreneurs in their endeavors that contribute to the country's GDP and job creation. Assume that a particular grant is offered for infrastructure needs (office furniture, property, plant, and equipment, etc.). In these circumstances, although the carrying amount will be lower than the tax base of the asset, the related deferred tax may not be recognized. As mentioned earlier, deferred tax assets and liabilities should not be recognized in cases that would arise from the initial recognition of an asset or liability in transactions that are not a business combination and when, at the time of the transaction, there is no impact on either accounting or taxable profit.

A deferred tax liability will also not be recognized at the initial recognition of goodwill. Although goodwill may be treated differently across tax jurisdictions, which may lead to differences in the carrying amount and tax base of goodwill, IAS 12 does not allow the recognition of such a deferred tax liability. Any impairment that an entity should, for accounting purposes, impose on goodwill will again result in a temporary difference between its carrying amount and tax base. Any impairment that an entity should, for accounting purposes, impose on goodwill and if part of the goodwill is related to the initial recognition, that part of the difference in tax base and carrying amount should not result in any deferred taxation because the initial deferred tax liability was not recognized. Any future differences between the carrying amount and tax base as a result of amortization and the deductibility of a portion of goodwill constitute a temporary difference for which provision should be made.

7.1 Business Combinations and Deferred Taxes

The fair value of assets and liabilities acquired in a business combination is determined on the acquisition date and may differ from the previous carrying amount. It is highly probable that the values of acquired intangible assets, including goodwill, would differ from their carrying amounts. This temporary difference will affect deferred taxes as well as the amount of goodwill recognized as a result of the acquisition.

7.2 Investments in Subsidiaries, Branches, Associates and Interests in Joint Ventures

Investments in subsidiaries, branches, associates and interests in joint ventures may lead to temporary differences on the consolidated versus the parent's financial statements. The related deferred tax liabilities as a result of temporary differences will be recognized unless both of the following criterion are satisfied:

- The parent is in a position to control the timing of the future reversal of the temporary difference, and
- It is probable that the temporary difference will not reverse in the future.

With respect to deferred tax assets related to subsidiaries, branches, and associates and interests, deferred tax assets will only be recognized if the following criteria are satisfied:

- The temporary difference will reverse in the future, and
- Sufficient taxable profits exist against which the temporary difference can be used.

UNUSED TAX LOSSES AND TAX CREDITS

8

h explain recognition and measurement of current and deferred tax items;

IAS 12 allows the recognition of unused tax losses and tax credits only to the extent that it is probable that in the future there will be taxable income against which the unused tax losses and credits can be applied. Under US GAAP, a deferred tax asset is recognized in full but is then reduced by a valuation allowance if it is more likely than not that some or all of the deferred tax asset will not be realized. The same requirements for creation of a deferred tax asset as a result of deductible temporary differences also apply to unused tax losses and tax credits. The existence of tax losses may indicate that the entity cannot reasonably be expected to generate sufficient future taxable income. All other things held constant, the greater the history of tax losses, the greater the concern regarding the company's ability to generate future taxable profits.

Should there be concerns about the company's future profitability, then the deferred tax asset may not be recognized until it is realized. When assessing the probability that sufficient taxable profit will be generated in the future, the following criteria can serve as a guide:

- If there is uncertainty as to the probability of future taxable profits, a deferred tax asset as a result of unused tax losses or tax credits is only recognized to the extent of the available taxable temporary differences;
- Assess the probability that the entity will in fact generate future taxable profits before the unused tax losses and/or credits expire pursuant to tax rules regarding the carry forward of the unused tax losses;
- Verify that the above is with the same tax authority and based on the same taxable entity;
- Determine whether the past tax losses were a result of specific circumstances that are unlikely to be repeated; and
- Discover if tax planning opportunities are available to the entity that will result in future profits. These may include changes in tax legislation that is phased in over more than one financial period to the benefit of the entity.

It is imperative that the timing of taxable and deductible temporary differences also be considered before creating a deferred tax asset based on unused tax credits.

9

RECOGNITION AND MEASUREMENT OF CURRENT AND DEFERRED TAX

g describe the valuation allowance for deferred tax assets—when it is required and what effect it has on financial statements;

h explain recognition and measurement of current and deferred tax items;

Current taxes payable or recoverable from tax authorities are based on the applicable tax rates at the balance sheet date. Deferred taxes should be measured at the tax rate that is expected to apply when the asset is realized or the liability settled. With respect to the income tax for a current or prior period not yet paid, it is recognized as a tax liability until paid. Any amount paid in excess of any tax obligation is recognized as an asset. The income tax paid in excess or owed to tax authorities is separate from deferred taxes on the company's balance sheet.

When measuring deferred taxes in a jurisdiction, there are different forms of taxation such as income tax, capital gains tax (any capital gains made), or secondary tax on companies (tax payable on the dividends that a company declares) and possibly different tax bases for a balance sheet item (as in the case of government grants influencing the tax base of an asset such as property). In assessing which tax laws should apply, it is dependent on how the related asset or liability will be settled. It would be prudent to use the tax rate and tax base that is consistent with how it is expected the tax base will be recovered or settled.

Although deferred tax assets and liabilities are related to temporary differences expected to be recovered or settled at some future date, neither are discounted to present value in determining the amounts to be booked. Both must be adjusted for changes in tax rates.

Deferred taxes as well as income taxes should always be recognized on the income statement of an entity unless it pertains to:

- Taxes or deferred taxes charged directly to equity, or
- A possible provision for deferred taxes relates to a business combination.

The carrying amount of the deferred tax assets and liabilities should also be assessed. The carrying amounts may change even though there may have been no change in temporary differences during the period evaluated. This can result from:

- Changes in tax rates;
- Reassessments of the recoverability of deferred tax assets; or
- Changes in the expectations for how an asset will be recovered and what influences the deferred tax asset or liability.

All unrecognized deferred tax assets and liabilities must be reassessed at the balance sheet date and measured against the criteria of probable future economic benefits. If such a deferred asset is likely to be recovered, it may be appropriate to recognize the related deferred tax asset.

Different jurisdictions have different requirements for determining tax obligations that can range from different forms of taxation to different tax rates based on taxable income. When comparing financial statements of entities that conduct business in different jurisdictions subject to different tax legislation, the analyst should be cautious in reaching conclusions because of the potentially complex tax rules that may apply.

9.1 Recognition of a Valuation Allowance

Deferred tax assets must be assessed at each balance sheet date. If there is any doubt whether the deferral will be recovered, then the carrying amount should be reduced to the expected recoverable amount. Should circumstances subsequently change and suggest the future will lead to recovery of the deferral, the reduction may be reversed.

Under US GAAP, deferred tax assets are reduced by creating a valuation allowance. Establishing a valuation allowance reduces the deferred tax asset and income in the period in which the allowance is established. Should circumstances change to such an extent that a deferred tax asset valuation allowance may be reduced, the reversal will increase the deferred tax asset and operating income. Because of the subjective judgment involved, an analyst should carefully scrutinize any such changes.

9.2 Recognition of Current and Deferred Tax Charged Directly to Equity

In general, IFRS and US GAAP require that the recognition of deferred tax liabilities and current income tax should be treated similarly to the asset or liability that gave rise to the deferred tax liability or income tax based on accounting treatment. Should an item that gives rise to a deferred tax liability be taken directly to equity, the same should hold true for the resulting deferred tax.

The following are examples of such items:

- Revaluation of property, plant, and equipment (revaluations are not permissible under US GAAP);
- Long-term investments at fair value;

- Changes in accounting policies;
- Errors corrected against the opening balance of retained earnings;
- Initial recognition of an equity component related to complex financial instruments; and
- Exchange rate differences arising from the currency translation procedures for foreign operations.

Whenever it is determined that a deferred tax liability will not be reversed, an adjustment should be made to the liability. The deferred tax liability will be reduced and the amount by which it is reduced should be taken directly to equity. Any deferred taxes related to a business combination must also be recognized in equity.

Depending on the items that gave rise to the deferred tax liabilities, an analyst should exercise judgment regarding whether the taxes should be included with deferred tax liabilities or whether it should be taken directly to equity. It may be more appropriate simply to ignore deferred taxes.

EXAMPLE 5

Taxes Charged Directly to Equity

The following information pertains to Khaleej Company (a hypothetical company). A building owned by Khaleej Company was originally purchased for €1,000,000 on 1 January 20x1. For accounting purposes, buildings are depreciated at 5 percent a year on a straight-line basis, and depreciation for tax purposes is 10 percent a year on a straight-line basis. On the first day of 20x3, the building is revalued at €1,200,000. It is estimated that the remaining useful life of the building from the date of revaluation is 20 years. *Important*: For tax purposes the revaluation of the building is not recognized.

Based on the information provided, the following illustrates the difference in treatment of the building for accounting and tax purposes.

	Carrying Amount of Building	Tax Base of Building
Balance on 1 January 20x1	€1,000,000	€1,000,000
Depreciation 20x1	(50,000)	(100,000)
Balance on 31 December 20x1	€950,000	€900,000
Depreciation 20x2	(50,000)	(100,000)
Balance on 31 December 20x2	€900,000	€800,000
Revaluation on 1 January 20x3	300,000	n/a
Balance on 1 January 20x3	€1,200,000	€800,000
Depreciation 20x3	(60,000)	(100,000)
Balance on 31 December 20x3	€1,140,000	€700,000
Accumulated depreciation		
Balance on 1 January 20x1	€0	€0
Depreciation 20x1	50,000	100,000
Balance on 31 December 20x1	€50,000	€100,000
Depreciation 20x2	50,000	100,000
Balance on 31 December 20x2	€100,000	€200,000
Revaluation at 1 January 20x3	(100,000)	n/a
Balance on 1 January 20x3	€0	€200,000
Depreciation 20x3	60,000	100,000
Balance on 30 November 20x3	€60,000	€300,000

	Carrying Amount	Tax Base
On 31 December 20x1	€950,000	€900,000
On 31 December 20x2	€900,000	€800,000
On 31 December 20x3	€1,140,000	€700,000

31 December 20x1: On 31 December 20x1, different treatments for depreciation expense result in a temporary difference that gives rise to a deferred tax liability. The difference in the tax base and carrying amount of the building was a result of different depreciation amounts for tax and accounting purposes. Depreciation appears on the income statement. For this reason the deferred tax liability will also be reflected on the income statement. If we assume that the applicable tax rate in 20x1 was 40 percent, then the resulting deferred tax liability will be 40% × (€950,000 – €900,000) = €20,000.

31 December 20x2: As of 31 December 20x2, the carrying amount of the building remains greater than the tax base. The temporary difference again gives rise to a deferred tax liability. Again, assuming the applicable tax rate to be 40 percent, the deferred tax liability from the building is 40% × (€900,000 – €800,000) = €40,000.

31 December 20x3: On 31 December 20x3, the carrying amount of the building again exceeds the tax base. This is not the result of disposals or additions, but is a result of the revaluation at the beginning of the 20x3 fiscal year and the different rates of depreciation. The deferred tax liability would seem to be 40% × (€1,140,000 – €700,000) = €176,000, *but* the treatment is different than it was for the 20x1 and 20x2. In 20x3, revaluation of the building gave rise to a balance sheet equity account, namely "Revaluation Surplus" in the amount of €300,000, which is not recognized for tax purposes.

The deferred tax liability would usually have been calculated as follows:

	20x3	20x2	20x1
Deferred tax liability (closing balance at end of fiscal year)	€176,000	€40,000	€20,000
(Difference between tax base and carrying amount)			
20x1: €(950,000 – 900,000) × 40% = 20,000			
20x2: €(900,000 – 800,000) × 40% = 40,000			
20x3: €(1,140,000 – 700,000) × 40% = 176,000			

The change in the deferred tax liability in 20x1 is €20,000, in 20x2: €20,000 (€40,000 – €20,000) and, it would seem, in 20x3: €136,000 (€176,000 – €40,000). In 20x3, although it would seem that the balance for deferred tax liability should be €176,000, the revaluation is not recognized for tax purposes. Only the portion of the difference between the tax base and carrying amount that is not a result of the revaluation is recognized as giving rise to a deferred tax liability.

The effect of the revaluation surplus and the associated tax effects are accounted for in a direct adjustment to equity. The revaluation surplus is reduced by the tax provision associated with the excess of the fair value over the carry value and it affects retained earnings (€300,000 × 40% = €120,000).

The deferred tax liability that should be reflected on the balance sheet is thus not €176,000 but only €56,000 (€176,000 – €120,000). Given the balance of deferred tax liability at the beginning of the 20x3 fiscal year in the amount of €40,000, the change in the deferred tax liability is only €56,000 – €40,000 = €16,000.

In the future, at the end of each year, an amount equal to the depreciation as a result of the revaluation minus the deferred tax effect will be transferred from the revaluation reserve to retained earnings. In 20x3 this will amount to a portion of depreciation resulting from the revaluation, €15,000 (€300,000 ÷ 20), minus the deferred tax effect of €6,000 (€15,000 × 40%), thus €9,000.

10

PRESENTATION AND DISCLOSURE

i. analyze disclosures relating to deferred tax items and the effective tax rate reconciliation and explain how information included in these disclosures affects a company's financial statements and financial ratios;

We will discuss the presentation and disclosure of income tax related information by way of example. The Consolidated Statements of Operations (Income Statements) and Consolidated Balance Sheets for Micron Technology (MU), a global technology company based in the US, are provided in Exhibits 2 and 3, respectively. Exhibit 4 provides the income tax note disclosures for MU for the 2015, 2016, and 2017 fiscal years.

MU's income tax provision (i.e., income tax expense) for fiscal year 2017 is $114 million (see Exhibit 2). The income tax note disclosure in Exhibit 4 reconciles how the income tax provision was determined beginning with MU's reported income before taxes (shown in Exhibit 4 as $5,196 million for fiscal year 2017). The note disclosure then denotes the income tax provision for 2017 that is current ($153 million), which is then offset by the deferred tax benefit for foreign taxes ($39 million), for a net income tax provision of $114 million. Exhibit 4 further shows a reconciliation of how the income tax provision was derived from the US federal statutory rate. Many public companies comply with this required disclosure by displaying the information in percentage terms, but MU has elected to provide the disclosure in absolute dollar amounts. From this knowledge, for 2017 we can see that the dollar amount shown for US federal income tax provision at the statutory rate ($1,819 million) was determined by multiplying MU's income before taxes by the 35 percent US federal statutory rate ($5,196 × 0.35 = $1,819).

In addition, the note disclosure in Exhibit 4 provides detailed information about the derivation of the deferred tax assets ($766 million for 2017) and deferred tax liabilities ($17 million for 2017). These deferred tax assets are shown separately on MU's consolidated balance sheet for fiscal year 2017 with noncurrent assets (see Exhibit 3), while the deferred tax liabilities are included in other noncurrent liabilities (also see Exhibit 3).

Exhibit 2 Micron Technology, Inc. Consolidated Statements of Operations (Amounts in US$ Millions except Per Share)

For the Year Ended	31 Aug. 2017	1 Sept. 2016	3 Sept. 2015
Net sales	20,322	$12,399	$16,192
Cost of goods sold	11,886	9,894	10,977
Gross margin	8,436	2,505	5,215
Selling, general and administrative	743	659	719

Exhibit 4 Micron Technology, Inc. Income Taxes Note to the Consolidated Financial Statements

Income (loss) before taxes and the income tax (provision) benefit consisted of the following:

(in US$ Millions)	2017	2016	2015
Income (loss) before income taxes, net income (loss) attributable to noncontrolling interests, and equity in net income (loss) of equity method investees			
Foreign	$5,252	$(353)	$2,431
US	(56)	72	178
	$5,196	$(281)	$2,609
Income tax (provision) benefit:			
Current:			
Foreign	$(152)	$(27)	$(93)
State	(1)	(1)	(1)
US federal	—	—	6
	(153)	(28)	(88)
Deferred:			

Exhibit 4 (Continued)

(in US$ Millions)	2017	2016	2015
US federal	—	39	15
State	—	2	1
Foreign	39	(32)	(85)
	39	9	(69)
Income tax (provision)	$(114)	$(19)	$(157)

The company's income tax (provision) computed using the US federal statutory rate and the company's income tax (provision) benefit is reconciled as follows:

(US$ Millions)	2017	2016	2015
US federal income tax (provision) benefit at statutory rate	$(1,819)	$98	$(913)
Foreign tax rate differential	1,571	(300)	515
Change in valuation allowance	64	63	260
Change in unrecognized tax benefits	12	52	(118)
Tax credits	66	48	53
Noncontrolling investment transactions	—	—	57
Other	(8)	20	(11)
Income tax (provision) benefit	(114)	$(19)	$(157)

State taxes reflect investment tax credits of $233 million as at 31 August 2017. Deferred income taxes reflect the net tax effects of temporary differences between the bases of assets and liabilities for financial reporting and income tax purposes. The company's deferred tax assets and liabilities consist of the following as of the end of the periods shown below:

(US$ Millions)	2017	2016
Deferred tax assets:		
Net operating loss and tax credit carryforwards	$3,426	$3,014
Accrued salaries, wages, and benefits	211	142
Other accrued liabilities	59	76
Other	86	65
Gross deferred assets	3,782	3,297
Less valuation allowance	(2,321)	(2,107)
Deferred tax assets, net of valuation allowance	1,461	1,190
Deferred tax liabilities:		
Debt discount	(145)	(170)
Property, plant, and equipment	(300)	(135)
Unremitted earnings on certain subsidiaries	(123)	(121)
Product and process technology	(85)	(81)
Other	(59)	(28)
Deferred tax liabilities	(712)	(535)
Net deferred tax assets	$749	$655
Reported as:		

(continued)

Exhibit 4 (Continued)

(US$ Millions)	2017	2016
Current deferred tax assets (included in other current assets)	$—	$—
Deferred tax assets	766	657
Current deferred tax liabilities (included in accounts payable and accrued expenses)	—	—
Deferred tax liabilities (included in other noncurrent liabilities)	(17)	(2)
Net deferred tax assets	$749	$655

The company has a valuation allowance against substantially all of its US net deferred tax assets. As of 31 August 2017, the company had aggregate US tax net operating loss carryforwards of $3.88 billion and unused US tax credit carryforwards of $416 million. The company also has unused state tax net operating loss carryforwards of $1.95 billion and unused state tax credits of $233 million. The net operating loss carryforwards and the tax credit carryforwards expire between 2018 to 2037.

The changes in valuation allowance of $64 million and $63 million in 2017 and 2016, respectively, are primarily a result of uncertainties of realizing certain US and foreign net operating losses and certain tax credit carryforwards.

Provision has been made for deferred taxes on undistributed earnings of non-US subsidiaries to the extent that dividend payments from such companies are expected to result in additional tax liability. Remaining undistributed earnings of $12.91 billion as of 31 August 2017 have been indefinitely reinvested. Determination of the amount of unrecognized deferred tax liability on these unremitted earnings is not practicable.

EXAMPLE 6

Financial Analysis Example

Use the financial statement information and disclosures provided by MU in Exhibits 2, 3, and 4 to answer the following questions:

1. MU discloses a valuation allowance of $2,321 million (see Exhibit 4) against gross deferred assets of $3,782 million in 2017. Does the existence of this valuation allowance have any implications concerning MU's future earnings prospects?
2. How would MU's deferred tax assets and deferred tax liabilities be affected if the federal statutory tax rate was changed to 21 percent?
3. How would reported earnings have been affected if MU were not using a valuation allowance?
4. How would MU's $3.88 billion in net operating loss carryforwards in 2017 (see Exhibit 4) affect the valuation that an acquiring company would be willing to offer?
5. Under what circumstances should the analyst consider MU's deferred tax liability as debt or as equity? Under what circumstances should the analyst exclude MU's deferred tax liability from both debt and equity when calculating the debt-to-equity ratio?

Solution to 1:

According to Exhibit 4, MU's deferred tax assets expire gradually until 2037 (2018 to 2037 for the net operating loss carryforwards and the tax credit carryforwards).

Because the company is still relatively young, it is likely that most of these expirations occur toward the end of that period. Because cumulative US tax net operating loss carryforwards total $3.88 billion, the valuation allowance could imply that MU is not reasonably expected to earn $3.88 billion over the next 20 years. However, as we can see in Exhibit 2, MU earned a profit for 2017 and 2015, thereby showing that the allowance could be adjusted downward if the company continues to generate profits in the future, and making it more likely than not that the deferred tax asset would be recognized.

Solution to 2:

MU's total deferred tax assets exceed total deferred tax liabilities by $749 million. A change in the federal statutory tax rate to 21 percent from the current rate of 35 percent would make these net deferred assets less valuable. Also, because it is possible that the deferred tax asset valuation allowance could be adjusted downward in the future (see discussion to solution 1), the impact could be far greater in magnitude.

Solution to 3:

The disclosure in Exhibit 4 shows that the increase in the valuation allowance increased the income tax provision as reported on the income statement by $64 million in 2017. Additional potential reductions in the valuation allowance could similarly reduce reported income taxes (actual income taxes would not be affected by a valuation allowance established for financial reporting) in future years (see discussion to solution 1).

Solution to 4:

If an acquiring company is profitable, it may be able to use MU's tax loss carryforwards to offset its own tax liabilities. The value to an acquirer would be the present value of the carryforwards, based on the acquirer's tax rate and expected timing of realization. The higher the acquiring company's tax rate, and the more profitable the acquirer, the sooner it would be able to benefit. Therefore, an acquirer with a high current tax rate would theoretically be willing to pay more than an acquirer with a lower tax rate.

Solution to 5:

The analyst should classify the deferred tax liability as debt if the liability is expected to reverse with subsequent tax payment. If the liability is not expected to reverse, there is no expectation of a cash outflow and the liability should be treated as equity. By way of example, future company losses may preclude the payment of any income taxes, or changes in tax laws could result in taxes that are never paid. The deferred tax liability should be excluded from both debt and equity when both the amounts and timing of tax payments resulting from the reversals of temporary differences are uncertain.

11

COMPARISON OF IFRS AND US GAAP

j identify the key provisions of and differences between income tax accounting under International Financial Reporting Standards (IFRS) and US generally accepted accounting principles (GAAP).

As mentioned earlier, though IFRS and US GAAP follow similar conventions on many tax issues, there are some notable differences. Exhibit 5 summarizes many of the key similarities and differences between IFRS and US GAAP. Though both frameworks require a provision for deferred taxes, there are differences in the methodologies.

Exhibit 5 Deferred Income Tax Issues IFRS and US GAAP Methodology Similarities and Differences

IFRS	US GAAP
Introduction	
The objective in accounting for income taxes is to recognize the amount of taxes +currently payable or refundable and deferred taxes. Income tax expense is the current tax expense (or recovery) plus the period change in deferred taxes (net of tax arising from a business combination or recorded outside profit or loss).	Similar to IFRS.
Unpaid taxes for current and prior periods are recognized as a liability, and an asset is recognised if the amount already paid exceeds the amount due. A prior tax loss benefit used to recover previous period current tax is also an asset.	The approach to calculating current taxes is similar to IFRS with some exceptions, such as the treatment of taxes on the elimination of intercompany profits.
In general, deferred taxes are recognized using an asset and liability approach which focuses on temporary differences arising between the tax base of an asset or liability and its carrying amount in the statement of financial position. Deferred taxes are recognized for the future tax consequences of events that have been recognized in an entity's financial statements or tax returns.	US GAAP also follows an asset and liability approach to calculating deferred taxes, although there are some differences in the application relative to IFRS.
Deferred taxes are not recognized for:	Deferred taxes are not recognized for:
■ The initial recognition of goodwill	■ Goodwill for which amortization is not deductible for tax purposes
■ The initial recognition of an asset or liability in a non-business combination transaction and where accounting profit or taxable profit (tax loss) is not affected	■ Unlike IFRS, US GAAP does not have a similar exception
■ Taxable temporary differences from investments in subsidiaries/branches/ associates, and interests in joint ventures in which the parent etc. is able to control the timing of the reversal of the temporary difference, and it is probable that the temporary difference will not reverse in the foreseeable future	■ An excess of the amount for the financial reporting over the tax basis of an investment in a foreign subsidiary or a foreign corporate joint venture that is essentially permanent in duration, unless it becomes apparent that those temporary differences will reverse in the foreseeable future. Unlike IFRS, this exception does not apply to domestic subsidiaries and corporate joint venture and investments in equity investees.
	Unlike IFRS, recognition of deferred taxes is prohibited for differences that are remeasured from the local currency into the functional currency using historical exchange rates and that result from changes in exchange rates or indexing for tax purposes.

Exhibit 5 (Continued)

IFRS	US GAAP
Deferred taxes should be recognized for the difference between the carrying amount determined by using the historical exchange rate and the relevant tax base, which may have been affected by exchange rate changes or tax indexing.	
Recognition and measurement	
Current tax liabilities and assets for the current and prior periods are measured at amounts expected to be paid to (recovered from) the taxation authorities based on tax rates (and tax laws) that have been enacted or substantially enacted by the end of the reporting period. Deferred tax assets are measured at the tax rates that are expected to apply when the asset is realized or the liability is settled, based on tax rates (and tax laws) that have been enacted or substantively enacted by the end of the reporting period.	Similar to IFRS. Measurement of current and deferred tax assets and liabilities is based on enacted tax law. Deferred tax assets and liabilities are measured using enacted tax rate(s) expected to apply to taxable income in periods in which deferred tax is expected to be settled or realized. Unlike IFRS, use of substantially enacted tax rates is not permitted.
Deferred tax assets are recognized to the extent that it is probable (more likely than not) that taxable profit will be available to utilize the deductible temporary difference or carryforward of unused tax losses or tax credits. End of reporting period reviews may reduce the carrying amount if sufficient taxable profit is no longer probable such as to allow the utilization benefit of all or part of that deferred tax asset, and any such reduction is reversed if it subsequently becomes probable again.	Unlike IFRS, deferred tax assets are recognized in full and reduced by a valuation allowance if it is more likely than not that some portion or all of the deferred tax assets will not be realized.
Current and deferred taxes are recognized outside profit or loss if the tax relates to items that are recognized, in the same or a different period, in other comprehensive income (OCI), or directly to equity.	Similar to IFRS, the tax effects of certain items occurring during the year are charged or credited directly to OCI or to related components of shareholders' equity.
Deferred tax assets and liabilities are not discounted.	Similar to IFRS.
Presentation and disclosure	
Deferred tax assets and liabilities are offset if the entity has a legally enforceable right to offset current tax assets against current tax liabilities and the deferred tax assets and deferred tax liabilities relate to income taxes levied by the same taxing authority on either the same taxable entity, or different taxable entities that intend either to settle current tax assets and liabilities on a net basis or to simultaneously realize/settle the asset/liability.	All deferred taxes are offset and presented as a single amount.

(continued)

Exhibit 5 (Continued)

IFRS	US GAAP
Deferred tax assets and liabilities are presented as separate line items in the statement of financial position. If a classified statement of financial position is used, deferred taxes are classified as noncurrent.	Deferred tax assets and deferred tax liabilities are presented as noncurrent in a classified statement of financial position, which aligns with IFRS.
All entities must disclose an explanation of the relationship between tax expense and accounting profit using either or both of the following formats: ■ A numerical reconciliation between tax expense (income) and the product of accounting profit multiplied by the applicable tax rate(s) including disclosure of the basis on which the applicable rate is computed. ■ A numerical reconciliation between the average effective tax rate and the applicable tax rate, including disclosure of the basis on which the applicable tax rate is computed.	Public companies must disclose a reconciliation using percentages or dollar amounts of the reported amount of income tax expense attributable to continuing operations for the year to that amount of income tax expense that would result from applying domestic federal statutory tax rates to pretax income from continuing operations. Nonpublic enterprises must disclose the nature of significant reconciling items but may omit a numerical reconciliation.

SUMMARY

Income taxes are a significant category of expense for profitable companies. Analyzing income tax expenses is often difficult for the analyst because there are many permanent and temporary timing differences between the accounting that is used for income tax reporting and the accounting that is used for financial reporting on company financial statements. The financial statements and notes to the financial statements of a company provide important information that the analyst needs to assess financial performance and to compare a company's financial performance with other companies. Key concepts in this reading are as follows:

- Differences between the recognition of revenue and expenses for tax and accounting purposes may result in taxable income differing from accounting profit. The discrepancy is a result of different treatments of certain income and expenditure items.
- The tax base of an asset is the amount that will be deductible for tax purposes as an expense in the calculation of taxable income as the company expenses the tax basis of the asset. If the economic benefit will not be taxable, the tax base of the asset will be equal to the carrying amount of the asset.
- The tax base of a liability is the carrying amount of the liability less any amounts that will be deductible for tax purposes in the future. With respect to revenue received in advance, the tax base of such a liability is the carrying amount less any amount of the revenue that will not be taxable in the future.
- Temporary differences arise from recognition of differences in the tax base and carrying amount of assets and liabilities. The creation of a deferred tax asset or liability as a result of a temporary difference will only be allowed if the difference reverses itself at some future date and to the extent that it is expected that the balance sheet item will create future economic benefits for the company.

- Permanent differences result in a difference in tax and financial reporting of revenue (expenses) that will not be reversed at some future date. Because it will not be reversed at a future date, these differences do not constitute temporary differences and do not give rise to a deferred tax asset or liability.
- Current taxes payable or recoverable are based on the applicable tax rates on the balance sheet date of an entity; in contrast, deferred taxes should be measured at the tax rate that is expected to apply when the asset is realized or the liability settled.
- All unrecognized deferred tax assets and liabilities must be reassessed on the appropriate balance sheet date and measured against their probable future economic benefit.
- Deferred tax assets must be assessed for their prospective recoverability. If it is probable that they will not be recovered at all or partly, the carrying amount should be reduced. Under US GAAP, this is done through the use of a valuation allowance.

PRACTICE PROBLEMS

1. Using the straight-line method of depreciation for reporting purposes and accelerated depreciation for tax purposes would *most likely* result in a:
   - **A** valuation allowance.
   - **B** deferred tax asset.
   - **C** temporary difference.
2. In early 2018 Sanborn Company must pay the tax authority €37,000 on the income it earned in 2017. This amount was recorded on the company's 31 December 2017 financial statements as:
   - **A** taxes payable.
   - **B** income tax expense.
   - **C** a deferred tax liability.
3. Income tax expense reported on a company's income statement equals taxes payable, plus the net increase in:
   - **A** deferred tax assets and deferred tax liabilities.
   - **B** deferred tax assets, less the net increase in deferred tax liabilities.
   - **C** deferred tax liabilities, less the net increase in deferred tax assets.
4. Analysts should treat deferred tax liabilities that are expected to reverse as:
   - **A** equity.
   - **B** liabilities.
   - **C** neither liabilities nor equity.
5. Deferred tax liabilities should be treated as equity when:
   - **A** they are not expected to reverse.
   - **B** the timing of tax payments is uncertain.
   - **C** the amount of tax payments is uncertain.
6. When both the timing and amount of tax payments are uncertain, analysts should treat deferred tax liabilities as:
   - **A** equity.
   - **B** liabilities.
   - **C** neither liabilities nor equity.
7. When accounting standards require recognition of an expense that is not permitted under tax laws, the result is a:
   - **A** deferred tax liability.
   - **B** temporary difference.
   - **C** permanent difference.
8. When certain expenditures result in tax credits that directly reduce taxes, the company will *most likely* record:
   - **A** a deferred tax asset.
   - **B** a deferred tax liability.
   - **C** no deferred tax asset or liability.

© 2019 CFA Institute. All rights reserved.

9 When accounting standards require an asset to be expensed immediately but tax rules require the item to be capitalized and amortized, the company will *most likely* record:

A a deferred tax asset.

B a deferred tax liability.

C no deferred tax asset or liability.

10 A company incurs a capital expenditure that may be amortized over five years for accounting purposes, but over four years for tax purposes. The company will *most likely* record:

A a deferred tax asset.

B a deferred tax liability.

C no deferred tax asset or liability.

11 A company receives advance payments from customers that are immediately taxable but will not be recognized for accounting purposes until the company fulfills its obligation. The company will *most likely* record:

A a deferred tax asset.

B a deferred tax liability.

C no deferred tax asset or liability.

The following information relates to Questions 12–14

Note I
Income Taxes

The components of earnings before income taxes are as follows ($ thousands):

	Year 3	Year 2	Year 1
Earnings before income taxes:			
United States	$88,157	$75,658	$59,973
Foreign	116,704	113,509	94,760
Total	$204,861	$189,167	$154,733

The components of the provision for income taxes are as follows ($ thousands):

	Year 3	Year 2	Year 1
Income taxes			
Current:			
Federal	$30,632	$22,031	$18,959
Foreign	28,140	27,961	22,263
	$58,772	$49,992	$41,222
Deferred:			
Federal	($4,752)	$5,138	$2,336
Foreign	124	1,730	621

(continued)

	Year 3	Year 2	Year 1
	(4,628)	6,868	2,957
Total	$54,144	$56,860	$44,179

12 In Year 3, the company's US GAAP income statement recorded a provision for income taxes *closest* to:

A $30,632.

B $54,144.

C $58,772.

13 The company's effective tax rate was *highest* in:

A Year 1.

B Year 2.

C Year 3.

14 Compared to the company's effective tax rate on US income, its effective tax rate on foreign income was:

A lower in each year presented.

B higher in each year presented.

C higher in some periods and lower in others.

---

15 Zimt AG presents its financial statements in accordance with US GAAP. In Year 3, Zimt discloses a valuation allowance of $1,101 against total deferred tax assets of $19,201. In Year 2, Zimt disclosed a valuation allowance of $1,325 against total deferred tax assets of $17,325. The change in the valuation allowance *most likely* indicates that Zimt's:

A deferred tax liabilities were reduced in Year 3.

B expectations of future earning power has increased.

C expectations of future earning power has decreased.

16 Cinnamon, Inc. recorded a total deferred tax asset in Year 3 of $12,301, offset by a $12,301 valuation allowance. Cinnamon *most likely*:

A fully utilized the deferred tax asset in Year 3.

B has an equal amount of deferred tax assets and deferred tax liabilities.

C expects not to earn any taxable income before the deferred tax asset expires.

The following information relates to Questions 17–19

The tax effects of temporary differences that give rise to deferred tax assets and liabilities are as follows ($ thousands):

	Year 3	Year 2
Deferred tax assets:		
Accrued expenses	$8,613	$7,927
Tax credit and net operating loss carryforwards	2,288	2,554

	Year 3	Year 2
LIFO and inventory reserves	5,286	4,327
Other	2,664	2,109
Deferred tax assets	18,851	16,917
Valuation allowance	(1,245)	(1,360)
Net deferred tax assets	$17,606	$15,557
Deferred tax liabilities:		
Depreciation and amortization	$(27,338)	$(29,313)
Compensation and retirement plans	(3,831)	(8,963)
Other	(1,470)	(764)
Deferred tax liabilities	(32,639)	(39,040)
Net deferred tax liability	($15,033)	($23,483)

17 A reduction in the statutory tax rate would *most likely* benefit the company's:

A income statement and balance sheet.

B income statement but not the balance sheet.

C balance sheet but not the income statement.

18 If the valuation allowance had been the same in Year 3 as it was in Year 2, the company would have reported $115 *higher*:

A net income.

B deferred tax assets.

C income tax expense.

19 Compared to the provision for income taxes in Year 3, the company's cash tax payments were:

A lower.

B higher.

C the same.

The following information relates to Questions 20–22

A company's provision for income taxes resulted in effective tax rates attributable to loss from continuing operations before cumulative effect of change in accounting principles that varied from the statutory federal income tax rate of 34 percent, as summarized in the table below.

Year Ended 30 June	Year 3	Year 2	Year 1
Expected federal income tax expense (benefit) from continuing operations at 34 percent	($112,000)	$768,000	$685,000
Expenses not deductible for income tax purposes	357,000	32,000	51,000
State income taxes, net of federal benefit	132,000	22,000	100,000

(continued)

Year Ended 30 June	Year 3	Year 2	Year 1
Change in valuation allowance for deferred tax assets	(150,000)	(766,000)	(754,000)
Income tax expense	$227,000	$56,000	$82,000

20 In Year 3, the company's net income (loss) was *closest* to:

A ($217,000).

B ($329,000).

C ($556,000).

21 The $357,000 adjustment in Year 3 *most likely* resulted in:

A an increase in deferred tax assets.

B an increase in deferred tax liabilities.

C no change to deferred tax assets and liabilities.

22 Over the three years presented, changes in the valuation allowance for deferred tax assets were *most likely* indicative of:

A decreased prospect for future profitability.

B increased prospects for future profitability.

C assets being carried at a higher value than their tax base.

SOLUTIONS

1. C is correct. Because the differences between tax and financial accounting will correct over time, the resulting deferred tax liability, for which the expense was charged to the income statement but the tax authority has not yet been paid, will be a temporary difference. A valuation allowance would only arise if there was doubt over the company's ability to earn sufficient income in the future to require paying the tax.
2. A is correct. The taxes a company must pay in the immediate future are taxes payable.
3. C is correct. Higher reported tax expense relative to taxes paid will increase the deferred tax liability, whereas lower reported tax expense relative to taxes paid increases the deferred tax asset.
4. B is correct. If the liability is expected to reverse (and thus require a cash tax payment) the deferred tax represents a future liability.
5. A is correct. If the liability will not reverse, there will be no required tax payment in the future and the "liability" should be treated as equity.
6. C is correct. The deferred tax liability should be excluded from both debt and equity when both the amounts and timing of tax payments resulting from the reversals of temporary differences are uncertain.
7. C is correct. Accounting items that are not deductible for tax purposes will not be reversed and thus result in permanent differences.
8. C is correct. Tax credits that directly reduce taxes are a permanent difference, and permanent differences do not give rise to deferred tax.
9. A is correct. The capitalization will result in an asset with a positive tax base and zero carrying value. The amortization means the difference is temporary. Because there is a temporary difference on an asset resulting in a higher tax base than carrying value, a deferred tax asset is created.
10. B is correct. The difference is temporary, and the tax base will be lower (because of more rapid amortization) than the carrying value of the asset. The result will be a deferred tax liability.
11. A is correct. The advances represent a liability for the company. The carrying value of the liability exceeds the tax base (which is now zero). A deferred tax asset arises when the carrying value of a liability exceeds its tax base.
12. B is correct. The income tax provision in Year 3 was $54,144, consisting of $58,772 in current income taxes, of which $4,628 were deferred.
13. B is correct. The effective tax rate of 30.1 percent ($56,860/$189,167) was higher than the effective rates in Year 2 and Year 3.
14. A is correct. In Year 3 the effective tax rate on foreign operations was 24.2 percent [($28,140 + $124)/$116,704] and the effective US tax rate was [($30,632 – $4,752)/$88,157] = 29.4 percent. In Year 2 the effective tax rate on foreign operations was 26.2 percent and the US rate was 35.9 percent. In Year 1 the foreign rate was 24.1 percent and the US rate was 35.5 percent.
15. B is correct. The valuation allowance is taken against deferred tax assets to represent uncertainty that future taxable income will be sufficient to fully utilize the assets. By decreasing the allowance, Zimt is signaling greater likelihood that future earnings will be offset by the deferred tax asset.

16 C is correct. The valuation allowance is taken when the company will "more likely than not" fail to earn sufficient income to offset the deferred tax asset. Because the valuation allowance equals the asset, by extension the company expects *no* taxable income prior to the expiration of the deferred tax assets.

17 A is correct. A lower tax rate would increase net income on the income statement, and because the company has a net deferred tax liability, the net liability position on the balance sheet would also improve (be smaller).

18 C is correct. The reduction in the valuation allowance resulted in a corresponding reduction in the income tax provision.

19 B is correct. The net deferred tax liability was smaller in Year 3 than it was in Year 2, indicating that in addition to meeting the tax payments provided for in Year 3 the company also paid taxes that had been deferred in prior periods.

20 C is correct. The income tax provision at the statutory rate of 34 percent is a benefit of $112,000, suggesting that the pre-tax income was a loss of $112,000/0.34 = ($329,412). The income tax provision was $227,000. ($329,412) – $227,000 = ($556,412).

21 C is correct. Accounting expenses that are not deductible for tax purposes result in a permanent difference, and thus do not give rise to deferred taxes.

22 B is correct. Over the three-year period, changes in the valuation allowance reduced cumulative income taxes by $1,670,000. The reductions to the valuation allowance were a result of the company being "more likely than not" to earn sufficient taxable income to offset the deferred tax assets.

Non-Current (Long-Term) Liabilities

by Elizabeth A. Gordon, PhD, MBA, CPA, and Elaine Henry, PhD, CFA

Elizabeth A. Gordon, PhD, MBA, CPA, is at Temple University (USA). Elaine Henry, PhD, CFA, is at Stevens Institute of Technology (USA).

LEARNING OUTCOMES

Mastery	*The candidate should be able to:*
☐	**a.** determine the initial recognition, initial measurement and subsequent measurement of bonds;
☐	**b.** describe the effective interest method and calculate interest expense, amortisation of bond discounts/premiums, and interest payments;
☐	**c.** explain the derecognition of debt;
☐	**d.** describe the role of debt covenants in protecting creditors;
☐	**e.** describe the financial statement presentation of and disclosures relating to debt;
☐	**f.** explain motivations for leasing assets instead of purchasing them;
☐	**g.** explain the financial reporting of leases from a lessee's perspective;
☐	**h.** explain the financial reporting of leases from a lessor's perspective;
☐	**i.** compare the presentation and disclosure of defined contribution and defined benefit pension plans;
☐	**j.** calculate and interpret leverage and coverage ratios.

Note: Changes in accounting standards as well as new rulings and/or pronouncements issued after the publication of the readings on financial reporting and analysis may cause some of the information in these readings to become dated. Candidates are *not* responsible for anything that occurs after the readings were published. In addition, candidates are expected to be familiar with the analytical frameworks contained in the readings, as well as the implications of alternative accounting methods for financial analysis and valuation discussed in the readings. Candidates are also responsible for the content of accounting standards, but not for the actual reference numbers. Finally, candidates should be aware that certain ratios may be defined and calculated differently. When alternative ratio definitions exist and no specific definition is given, candidates should use the ratio definitions emphasized in the readings.

1 INTRODUCTION

A non-current liability (long-term liability) broadly represents a probable sacrifice of economic benefits in periods generally greater than one year in the future. Common types of **non-current liabilities** reported in a company's financial statements include long-term debt (e.g., bonds payable, long-term notes payable), leases, pension liabilities, and deferred tax liabilities. This reading focuses on bonds payable, leases, and pension liabilities.

This reading is organised as follows. Section 2 introduces bonds and the accounting for their issuance. Section 3 discusses the recording of interest expense and interest payments as well as the amortisation of discount or premium. Section 4 describes fair value accounting for bonds, an alternative to the amortised cost approach. Section 5 discusses the repayment of principal when bonds are redeemed or reach maturity, which requires derecognition from the financial statements. Section 6 covers debt covenants. Section 7 describes the financial statement presentation and disclosures about debt financings. Section 8 discusses leases, including the benefits of leasing and accounting for leases by both lessees and lessors. Section 9 introduces pension accounting and the resulting non-current liabilities. Section 10 discusses the use of leverage and coverage ratios in evaluating solvency. Section 11 concludes and summarises the reading.

2 BONDS PAYABLE & ACCOUNTING FOR BOND ISSUANCE

a determine the initial recognition, initial measurement and subsequent measurement of bonds

This section discusses accounting for bonds payable—a common form of long-term debt. In some contexts (e.g., some government debt obligations), the word "bond" is used only for a debt security with a maturity of 10 years or longer; "note" refers to a debt security with a maturity between 2 and 10 years; and "bill" refers to a debt security with a maturity of less than 2 years. In this reading, we use the terms bond and note interchangeably because the accounting treatments of bonds payable and long-term notes payable are similar. In the following sections, we discuss bond issuance (initial recognition and measurement); bond amortisation, interest expense, and interest payments; market rates and fair value (subsequent measurement); repayment of bonds, including retirements and redemptions (derecognition); and other issues concerning disclosures related to debt. We also discuss debt covenants.

2.1 Accounting for Bond Issuance

Bonds are contractual promises made by a company (or other borrowing entity) to pay cash in the future to its lenders (i.e., bondholders) in exchange for receiving cash in the present. The terms of a bond contract are contained in a document called an indenture. The cash or sales proceeds received by a company when it issues bonds is based on the value (price) of the bonds at the time of issue; the price at the time of issue is determined as the present value of the future cash payments promised by the company in the bond agreement.

Ordinarily, bonds contain promises of two types of future cash payments: 1) the face value of the bonds, and 2) periodic interest payments. The **face value** of the bonds is the amount of cash payable by the company to the bondholders when the bonds mature. The face value is also referred to as the principal, par value, stated value, or maturity value. The date of maturity of the bonds (the date on which the face value is paid to bondholders) is stated in the bond contract and typically is a number of years in the future. Periodic interest payments are made based on the interest rate promised in the bond contract applied to the bonds' face value. The interest rate promised in the contract, which is the rate used to calculate the periodic interest payments, is referred to as the **coupon rate**, nominal rate, or stated rate. Similarly, the periodic interest payment is referred to as the coupon payment or simply the coupon. For fixed rate bonds (the primary focus of our discussion here), the coupon rate remains unchanged throughout the life of the bonds. The frequency with which interest payments are made is also stated in the bond contract. For example, bonds paying interest semi-annually will make two interest payments per year.[1]

The future cash payments are discounted to the present to arrive at the market value of the bonds. The **market rate of interest** is the rate demanded by purchasers of the bonds given the risks associated with future cash payment obligations of the particular bond issue. The market rate of interest at the time of issue often differs from the coupon rate because of interest rate fluctuations that occur between the time the issuer establishes the coupon rate and the day the bonds are actually available to investors. If the market rate of interest when the bonds are issued equals the coupon rate, the market value (price) of the bonds will equal the face value of the bonds. Thus, ignoring

issuance costs, the issuing company will receive sales proceeds (cash) equal to the face value of the bonds. When a bond is issued at a price equal to its face value, the bond is said to have been issued at par.

If the coupon rate when the bonds are issued is higher than the market rate, the market value of the bonds—and thus the amount of cash the company receives—will be higher than the face value of the bonds. In other words, the bonds will sell at a premium to face value because they are offering an attractive coupon rate compared to current market rates. If the coupon rate is lower than the market rate, the market value and thus the sale proceeds from the bonds will be less than the face value of the bonds; the bond will sell at a discount to face value. The market rate at the time of issuance is the **effective interest rate** or borrowing rate that the company incurs on the debt. The effective interest rate is the discount rate that equates the present value of the two types of promised future cash payments to their selling price. For the issuing company, interest expense reported for the bonds in the financial statements is based on the effective interest rate.

On the issuing company's statement of cash flows, the cash received (sales proceeds) from issuing bonds is reported as a financing cash inflow. On the issuing company's balance sheet at the time of issue, bonds payable normally are measured and reported at the sales proceeds. In other words, the bonds payable are initially reported at the face value of the bonds minus any discount, or plus any premium.

Using a three-step approach, the following two examples illustrate accounting for bonds issued at face value and then accounting for bonds issued at a discount to face value. Accounting for bonds issued at a premium involves steps similar to the steps followed in the examples below. For simplicity, these examples assume a flat interest rate yield curve (i.e., that the market rate of interest is the same for each period). More-precise bond valuations use the interest rate applicable to each time period in which a payment of interest or principal occurs.

---

[1] Interest rates are stated on an annual basis regardless of the frequency of payment.

EXAMPLE 1

Bonds Issued at Face Value

Debond Corp. (a hypothetical company) issues £1,000,000 worth of five-year bonds, dated 1 January 2018, when the market interest rate on bonds of comparable risk and terms is 5 percent per annum. The bonds pay 5 percent interest annually on 31 December. What are the sales proceeds of the bonds when issued, and how is the issuance reflected in the financial statements?

Solution:

Calculating the value of the bonds at issuance and thus the sales proceeds involves three steps: 1) identifying key features of the bonds and the market interest rate, 2) determining future cash outflows, and 3) discounting the future cash flows to the present.

First, identify key features of the bonds and the market interest rate necessary to determine sales proceeds:

Face value (principal):	£1,000,000	
Time to maturity:	5 years	
Coupon rate:	5%	
Market rate at issuance:	5%	
Frequency of interest payments:	annual	
Interest payment:	£50,000	Each annual interest payment is the face value times the coupon rate (£1,000,000 × 5%). If interest is paid other than annually, adjust the interest rate to match the interest payment period (e.g., divide the annual coupon rate by two for semi-annual interest payments).

Second, determine future cash outflows. Debond will pay bondholders £1,000,000 when the bonds mature in five years. On 31 December of each year until the bonds mature, Debond will make an interest payment of £50,000.

Third, sum the present value[2] of the future payments of interest and principal to obtain the value of the bonds and thus the sales proceeds from issuing the bonds. In this example, the sum is £1,000,000 = (£216,474 + £783,526).

Date	Interest Payment	Present Value at Market Rate (5%)	Face Value Payment	Present Value at Market Rate (5%)	Total Present Value
31 December 2018	£50,000	£47,619			
31 December 2019	50,000	45,352			
31 December 2020	50,000	43,192			
31 December 2021	50,000	41,135			
31 December 2022	50,000	39,176	£1,000,000	£783,526	
Total		£216,474		£783,526	£1,000,000
					Sales Proceeds

---

[2] Alternative ways to calculate the present value include 1) to treat the five annual interest payments as an annuity and use the formula for finding the present value of an annuity and then add the present value of the principal payment, or 2) to use a financial calculator to calculate the total present value.

The sales proceeds of the bonds when issued are £1,000,000. There is no discount or premium because these bonds are issued at face value. The issuance is reflected on the balance sheet as an increase of cash and an increase in a long-term liability, bonds payable, of £1,000,000. The issuance is reflected in the statement of cash flows as a financing cash inflow of £1,000,000.

The price of bonds is often expressed as a percentage of face value. For example, the price of bonds issued at par, as in Example 1, is 100 (i.e., 100 percent of face value). In Example 2, in which bonds are issued at a discount, the price is 95.79 (i.e., 95.79 percent of face value).

EXAMPLE 2

Bonds Issued at a Discount

Debond Corp. issues £1,000,000 worth of five-year bonds, dated 1 January 2018, when the market interest rate on bonds of comparable risk and terms is 6 percent. The bonds pay 5 percent interest annually on 31 December. What are the sales proceeds of the bonds when issued, and how is the issuance reflected in the financial statements?

Solution:

The key features of the bonds and the market interest rate are:

Face value (principal):	£1,000,000	
Time to maturity:	5 years	
Coupon rate:	5%	
Market rate at issuance:	6%	
Frequency of interest payments:	annual	
Interest payment:	£50,000	Each annual interest payment is the face value times the coupon rate (£1,000,000 × 5%).

The future cash outflows (interest payments and face value payment), the present value of the future cash outflows, and the total present value are:

Date	Interest Payment	Present Value at Market Rate (6%)	Face Value Payment	Present Value at Market Rate (6%)	Total Present Value
31 December 2018	£50,000	£47,170			
31 December 2019	50,000	44,500			
31 December 2020	50,000	41,981			
31 December 2021	50,000	39,605			
31 December 2022	50,000	37,363	£1,000,000	£747,258	
Total		£210,618		£747,258	£957,876
					Sales Proceeds

The sales proceeds of the bonds when issued are £957,876. The bonds sell at a discount of £42,124 = (£1,000,000 − £957,876) because the market rate when the bonds are issued (6 percent) is greater than the bonds' coupon rate (5 percent). The issuance is reflected on the balance sheet as an increase of cash and an increase in a long-term liability, bonds payable, of £957,876. The bonds payable is composed of the face value of £1,000,000 minus a discount of £42,124. The issuance is reflected in the statement of cash flows as a financing cash inflow of £957,876.

In Example 2, the bonds were issued at a discount to face value because the bonds' coupon rate of 5 percent was less than the market rate. Bonds are issued at a premium to face value when the bonds' coupon rate exceeds the market rate.

Bonds issued with a coupon rate of zero (zero-coupon bonds) are issued at a discount to face value if the market rate is greater than zero. If the market rate is zero or negative, zero-coupon bonds will be issued at par or at premium, respectively. The value of zero-coupon bonds is based on the present value of the principal payment only because there are no periodic interest payments.

Such issuance costs as printing, legal fees, commissions, and other types of charges are costs incurred when bonds are issued. Under International Financial Reporting Standards (IFRS), all debt issuance costs are included in the measurement of the liability, bonds payable. Under US generally accepted accounting principles (US GAAP), companies generally used to show these debt issuance costs as an asset (a deferred charge), which was amortised on a straight-line basis to the relevant expense (e.g., legal fees) over the life of the bonds. Under US GAAP, debt issuance costs are deducted from the related debt liability. Companies reporting under US GAAP may still report debt issuance costs for lines of credit as an asset because the SEC indicated that it would not object to this treatment. Under IFRS and US GAAP, cash outflows related to bond issuance costs are included in the financing section of the statement of cash flows, usually netted against bond proceeds.

3

ACCOUNTING FOR BOND AMORTISATION, INTEREST EXPENSE, AND INTEREST PAYMENTS

a determine the initial recognition, initial measurement and subsequent measurement of bonds

b describe the effective interest method and calculate interest expense, amortisation of bond discounts/premiums, and interest payments

In this section, we discuss accounting and reporting for bonds after they are issued. Most companies maintain the historical cost (sales proceeds) of the bonds after issuance, and they amortise any discount or premium over the life of the bond. The amount reported on the balance sheet for bonds is thus the historical cost plus or minus the cumulative amortisation, which is referred to as amortised cost. Companies also have the option to report the bonds at their current fair values.

The rationale for reporting the bonds at amortised historical cost is the company's intention to retain the debt until it matures. Therefore, changes in the underlying economic value of the debt are not relevant from the issuing company's perspective. From an investor's perspective, however, analysis of a company's underlying economic liabilities and solvency is more difficult when debt is reported at amortised historical cost. The rest of this section illustrates accounting and reporting of bonds at amortised historical cost. Section 2.3 discusses the alternative of reporting bonds at fair value.

Companies initially report bonds as a liability on their balance sheet at the amount of the sales proceeds net of issuance costs under both IFRS and US GAAP. The amount at which bonds are reported on the company's balance sheet is referred to as the carrying amount, carrying value, book value, or net book value. If the bonds are issued at par, the initial carrying amount will be identical to the face value, and usually the carrying amount will not change over the life of the bonds.[3] For bonds issued at face value, the amount of periodic interest *expense* will be the same as the amount of periodic interest *payment* to bondholders.

If, however, the market rate differs from the bonds' coupon rate at issuance such that the bonds are issued at a premium or discount, the premium or discount is amortised systematically over the life of the bonds as a component of interest expense. For bonds issued at a premium to face value, the carrying amount of the bonds is initially greater than the face value. As the premium is amortised, the carrying amount (amortised cost) of the bonds will decrease to the face value. The reported interest expense will be less than the coupon payment. For bonds issued at a discount to face value, the carrying amount of the bonds is initially less than the face value. As the discount is amortised, the carrying amount (amortised cost) of the bonds will increase to the face value. The reported interest expense will be higher than the coupon payment.

The accounting treatment for bonds issued at a discount reflects the fact that the company essentially paid some of its borrowing costs at issuance by selling its bonds at a discount. Rather than there being an actual cash transfer in the future, this "payment" was made in the form of accepting less than the face value for the bonds at the date of issuance. The remaining borrowing cost occurs as a cash interest payment to investors each period. The total interest expense reflects both components of the borrowing cost: the periodic interest payments plus the amortisation of the discount. The accounting treatment for bonds issued at a premium reflects the fact that the company essentially received a reduction on its borrowing costs at issuance by selling its bonds at a premium. Rather than there being an actual reduced cash transfer in the future, this "reduction" was made in the form of receiving more than face value for the bonds at the date of issuance. The total interest expense reflects both components of the borrowing cost: the periodic interest payments less the amortisation of the premium. When the bonds mature, the carrying amount will be equal to the face value regardless of whether the bonds were issued at face value, a discount, or a premium.

Two methods for amortising the premium or discount of bonds that were issued at a price other than par are the effective interest rate method and the straight-line method. The effective interest rate method is required under IFRS and preferred under US GAAP because it better reflects the economic substance of the transaction. The effective interest rate method applies the market rate in effect when the bonds were issued (historical market rate or effective interest rate) to the current amortised cost (carrying amount) of the bonds to obtain interest expense for the period. The difference between the interest expense (based on the effective interest rate and amortised cost) and the interest payment (based on the coupon rate and face value) is the **amortisation** of the discount or premium. The straight-line method of amortisation evenly amortises the premium or discount over the life of the bond, similar to straight-line depreciation on long-lived assets. Under either method, as the bond approaches maturity, the amortised cost approaches face value.

Example 3 illustrates both methods of amortisation for bonds issued at a discount. Example 4 shows amortisation for bonds issued at a premium.

---

[3] If a company reports debt at fair value, rather than amortised cost, the carrying value may change.

EXAMPLE 3

Amortising a Bond Discount

Debond Corp. issues £1,000,000 face value of five-year bonds, dated 1 January 2017, when the market interest rate is 6 percent. The sales proceeds are £957,876. The bonds pay 5 percent interest annually on 31 December.

1 What is the interest *payment* on the bonds each year?

2 What amount of interest *expense* on the bonds would be reported in 2017 and 2018 using the effective interest rate method?

3 Determine the reported value of the bonds (i.e., the carrying amount) at 31 December 2017 and 2018, assuming the effective interest rate method is used to amortise the discount.

4 What amount of interest expense on the bonds would be reported under the straight-line method of amortising the discount?

Solution to 1:

The interest payment equals £50,000 annually (£1,000,000 × 5%).

Solution to 2:

The sales proceeds of £957,876 are less than the face value of £1,000,000; the bonds were issued at a discount of £42,124. The bonds are initially reported as a long-term liability, bonds payable, of £957,876, which comprises the face value of £1,000,000 minus a discount of £42,124. The discount is amortised over time, ultimately, increasing the carrying amount (amortised cost) to face value.

Under the effective interest rate method, interest expense on the bonds is calculated as the bonds' carrying amount times the market rate in effect when the bonds are issued (effective interest rate). For 2017, interest expense is £57,473 = (£957,876 × 6%). The amount of the discount amortised in 2017 is the difference between the interest expense of £57,473 and the interest payment of £50,000 (i.e., £7,473). The bonds' carrying amount increases by the discount amortisation; at 31 December 2017, the bonds' carrying amount is £965,349 (beginning balance of £957,876 plus £7,473 discount amortisation). At this point, the carrying amount reflects a remaining unamortised discount of £34,651 (£42,124 discount at issuance minus £7,473 amortised).

For 2018, interest expense is £57,921 = (£965,349 × 6%), the carrying amount of the bonds on 1 January 2018 times the effective interest rate. The amount of the discount amortised in 2018 is the difference between the interest expense of £57,921 and the interest payment of £50,000 (i.e., £7,921). At 31 December 2018, the bonds' carrying amount is £973,270 (beginning balance of £965,349 plus £7,921 discount amortisation).

The following table illustrates interest expense, discount amortisation, and carrying amount (amortised cost) over the life of the bonds.

Year	Carrying Amount (beginning of year)	Interest Expense (at effective interest rate of 6%)	Interest Payment (at coupon rate of 5%)	Amortisation of Discount	Carrying Amount (end of year)
	(a)	(b)	(c)	(d)	(e)
2017	£957,876	£57,473	£50,000	£7,473	£965,349
2018	965,349	57,921	50,000	7,921	973,270
2019	973,270	58,396	50,000	8,396	981,666

Year	Carrying Amount (beginning of year)	Interest Expense (at effective interest rate of 6%)	Interest Payment (at coupon rate of 5%)	Amortisation of Discount	Carrying Amount (end of year)
2020	981,666	58,900	50,000	8,900	990,566
2021	990,566	59,434	50,000	9,434	1,000,000
Total		£292,124	£250,000	£42,124	

Solution to 3:

The carrying amounts of the bonds at 31 December 2017 and 2018 are £965,349 and £973,270, respectively. Observe that the carrying amount of the bonds issued at a discount increases over the life of the bonds. At maturity, 31 December 2021, the carrying amount of the bonds equals the face value of the bonds. The carrying amount of the bonds will be reduced to zero when the principal payment is made.

Solution to 4:

Under the straight-line method, the discount (or premium) is evenly amortised over the life of the bonds. In this example, the £42,124 discount would be amortised by £8,424.80 (£42,124 divided by 5 years) each year under the straight-line method. So, the annual interest expense under the straight-line method would be £58,424.80 (£50,000 plus £8,424.80).

The accounting and reporting for zero-coupon bonds is similar to the example above except that no interest payments are made; thus, the amount of interest expense each year is the same as the amount of the discount amortisation for the year.

EXAMPLE 4

Amortising a Bond Premium

Prembond Corp. issues £1,000,000 face value of five-year bonds, dated 1 January 2017, when the market interest rate is 4 percent. The sales proceeds are £1,044,518. The bonds pay 5 percent interest annually on 31 December.

1. What is the interest *payment* on the bonds each year?
2. What amount of interest *expense* on the bonds would be reported in 2017 and 2018 using the effective interest rate method?
3. Determine the reported value of the bonds (i.e., the carrying amount) at 31 December 2017 and 2018, assuming the effective interest rate method is used to amortise the premium.
4. What amount of interest expense on the bonds would be reported under the straight-line method of amortising the premium?

Solution to 1:

The interest payment equals £50,000 annually (£1,000,000 × 5%).

Solution to 2:

The sales proceeds of £1,044,518 are more than the face value of £1,000,000; the bonds were issued at a premium of £44,518. The bonds are initially reported as a long-term liability, bonds payable, of £1,044,518, which comprises the face value of £1,000,000 plus a premium of £44,518. The premium is amortised over time, ultimately decreasing the carrying amount (amortised cost) to face value.

Under the effective interest rate method, interest expense on the bonds is calculated as the bonds' carrying amount times the market rate in effect when the bonds are issued (effective interest rate). For 2017, interest expense is £41,781 = (£1,044,518 × 4%). The amount of the premium amortised in 2017 is the difference between the interest expense of £41,781 and the interest payment of £50,000 (i.e., £8,219). The bonds' carrying amount decreases by the premium amortisation; at 31 December 2017, the bonds' carrying amount is £1,036,299 (beginning balance of £1,044,518 less £8,219 premium amortisation). At this point, the carrying amount reflects a remaining unamortised premium of £36,299 (£44,518 premium at issuance minus £8,219 amortised).

For 2018, interest expense is £41,452 = (£1,036,299 × 4%). The amount of the premium amortised in 2011 is the difference between the interest expense of £41,452 and the interest payment of £50,000 (i.e., £8,548). At 31 December 2018, the bonds' carrying amount is £1,027,751 (beginning balance of £1,036,299 less £8,548 premium amortisation).

The following table illustrates interest expense, premium amortisation, and carrying amount (amortised cost) over the life of the bonds.

Year	Carrying Amount (beginning of year)	Interest Expense (at effective interest rate of 4%)	Interest Payment (at coupon rate of 5%)	Amortisation of Premium	Carrying Amount (end of year)
	(a)	(b)	(c)	(d)	(e)
2017	£1,044,518	£41,781	£50,000	£8,219	£1,036,299
2018	1,036,299	41,452	50,000	8,548	1,027,751
2019	1,027,751	41,110	50,000	8,890	1,018,861
2020	1,018,861	40,754	50,000	9,246	1,009,615
2021	1,009,615	40,385	50,000	9,615	1,000,000
Total				£44,518	

Solution to 3:

The carrying amounts of the bonds at 31 December 2017 and 2018 are £1,036,299 and £1,027,751, respectively. Observe that the carrying amount of the bonds issued at a premium decreases over the life of the bonds. At maturity, 31 December 2021, the carrying amount of the bonds equals the face value of the bonds. The carrying amount of the bonds will be reduced to zero when the principal payment is made.

Solution to 4:

Under the straight-line method, the premium is evenly amortised over the life of the bonds. In this example, the £44,518 premium would be amortised by £8,903.64 (£44,518 divided by 5 years) each year under the straight-line method. So, the annual interest expense under the straight-line method would be £41,096.36 (£50,000 less £8,903.64).

The reporting of interest payments on the statement of cash flows can differ under IFRS and US GAAP. Under IFRS, interest payments on bonds can be included as an outflow in either the operating section or the financing section of the statement of cash flows. US GAAP requires interest payments on bonds to be included as an operating cash outflow. (Some financial statement users consider the placement of interest payments in the operating section to be inconsistent with the placement of bond issue proceeds in the financing section of the statement of cash flows.) Typically, cash interest paid is not shown directly on the statement of cash flows, but companies are required to disclose interest paid separately.

Amortisation of a discount (premium) is a non-cash item and thus, apart from its effect on pretax income, has no effect on cash flow. In the section of the statement of cash flows that reconciles net income to operating cash flow, amortisation of a discount (premium) is added back to (subtracted from) net income.

ACCOUNTING FOR BONDS AT FAIR VALUE

4

a determine the initial recognition, initial measurement and subsequent measurement of bonds

Reporting bonds at amortised historical costs (historical cost plus or minus the cumulative amortisation) reflects the market rate at the time the bonds were *issued* (i.e., historical market rate or effective interest rate). As market interest rates change, the bonds' carrying amount diverges from the bonds' fair market value. When market interest rates decline, the fair value of a bond with a fixed coupon rate increases. As a result, a company's economic liabilities may be higher than its reported debt based on amortised historical cost. Conversely, when market interest rates increase, the fair value of a bond with a fixed coupon rate decreases and the company's economic liability may be lower than its reported debt. Using financial statement amounts based on amortised cost may underestimate (or overestimate) a company's debt-to-total-capital ratio and similar leverage ratios.

Companies have the option to report financial liabilities at fair value. Financial liabilities reported at fair value are designated as financial liabilities at fair value through profit or loss under IFRS, or, equivalently under US GAAP, as liabilities under the fair value option. Even if a company does not opt to report financial liabilities at fair value, the availability of fair value information in the financial statements has increased. IFRS and US GAAP require fair value disclosures in the financial statements unless the carrying amount approximates fair value or the fair value cannot be reliably measured.[4]

A company electing to measure a liability at fair value will report decreases in the liability's fair value as income and increases in the liability's fair value as losses. Because changes in a liability's fair value can result from changes in market rates and/or changes in the credit quality of the issuing company, accounting standards require companies to present separately the portion of the change resulting from changes in their own credit risk. Specifically, the company will report the portion of the change in value attributable to changes in their credit risk in other comprehensive income. Only the portion of the change in value not attributable to changes in their credit risk will be recognised in profit or loss.[5]

As of the end of 2018, few companies have selected the option to report financial liabilities at fair value. Those that have are primarily companies in the financial sector. Reporting standards for financial investments and derivatives already required these companies to report a significant portion of their assets at fair values. Measuring financial liabilities at other than fair value, when financial assets are measured at fair value, results in earnings volatility. This volatility is the result of using different bases of measurement for financial assets and financial liabilities. Furthermore, when a liability is related to a specific asset, using different measurement bases creates an accounting mismatch. Goldman Sachs elected to account for some financial liabilities at fair value under the fair value option. In its fiscal year 2017 10-K filing (page 136), Goldman explains this choice:

---

[4] IFRS (IAS 32, IFRS 7, IFRS 9) and US GAAP (FASB ASC 820 and 825).

[5] IFRS 9, US GAAP (FASB ASC 825 and ASU 2016-01).

> "The primary reasons for electing the fair value option are to:
>
> - Reflect economic events in earnings on a timely basis;
> - Mitigate volatility in earnings from using different measurement attributes (e.g., transfers of financial instruments owned accounted for as financings are recorded at fair value, whereas the related secured financing would be recorded on an accrual basis absent electing the fair value option); and
> - Address simplification and cost-benefit considerations (e.g., accounting for hybrid financial instruments at fair value in their entirety versus bifurcation of embedded derivatives and hedge accounting for debt hosts)."

Most companies, as required under IFRS and US GAAP, disclose the fair values of financial liabilities. The primary exception to the disclosure occurs when fair value cannot be reliably measured. Example 5 illustrates ING Group's fair value disclosures, including the fair values of long-term debt.

EXAMPLE 5

Fair Value Disclosures of Debt and Financial Instruments

ING Group 2017 Form 20-F

ING Group [Condensed] Balance Sheet as of 31 December 2017 and 2016 [Liabilities Only]

Amounts in billions of euros	2017	2016
Deposits from banks	36.8	32.0
Customer deposits	539.8	522.9
Financial liabilities at fair value through profit or loss	87.2	99.0
Other liabilities	18.9	20.1
Debt securities in issue/subordinated loans	112.1	120.4
Total liabilities	**794.8**	**794.4**

The following are excerpts from the footnotes to ING Group's financial statements.

Excerpt from Note 1 Accounting Policies

> **Financial assets and liabilities at fair value through profit or loss**
>
> … Financial liabilities at fair value through profit or loss comprise the following sub-categories: trading liabilities, non-trading derivatives, and other financial liabilities designated at fair value through profit or loss by management. Trading liabilities include equity securities, debt securities, funds on deposit, and derivatives.
>
> A financial asset or financial liability is classified at fair value through profit or loss if acquired principally for the purpose of selling in the short term or if designated by management as such.

Management will designate a financial asset or a financial liability as such only if this eliminates a measurement inconsistency or if the related assets and liabilities are managed on a fair value basis....

Financial liabilities at amortised cost

Financial liabilities at amortised cost include the following subcategories: preference shares classified as debt, debt securities in issue, subordinated loans, and deposits from banks and customer deposits.

Financial liabilities at amortised cost are recognised initially at their issue proceeds (fair value of consideration received) net of transaction costs incurred. Liabilities in this category are subsequently stated at amortised cost; any difference between proceeds, net of transaction costs, and the redemption value is recognised in the statement of profit or loss over the period of the liability using the effective interest method....

Excerpt from Note 16 Debt securities in issue

Debt securities in issue relate to debentures and other issued debt securities with either fixed interest rates or interest rates based on floating interest rate levels, such as certificates of deposit and accepted bills issued by ING Group, except for subordinated items. Debt securities in issue do not include debt securities presented as Financial liabilities at fair value through profit or loss.

Excerpt from Note 37 Fair value of assets and liabilities

Fair Value of Financial Liabilities as of 31 December 2017 and 2016

	Estimated Fair Value		Statement of Financial Position Value	
Amounts in millions of euros	**2017**	**2016**	**2017**	**2016**
Financial liabilities				
Deposits from banks	36,868	32,352	36,821	31,964
Customer deposits	540,547	523,850	539,828	522,908
Financial liabilities at fair value through profit or loss				
• trading liabilities	73,596	83,167	73,596	83,167
• non-trading derivatives	2,331	3,541	2,331	3,541
• designated as at fair value through profit or loss	11,215	12,266	11,215	12,266
Other liabilities	14,488	15,247	14,488	15,247
Debt securities in issue	96,736	103,559	96,086	103,234
Subordinated loans	16,457	17,253	15,968	17,223
	792,238	**791,235**	**790,333**	**789,550**

Use the condensed balance sheet and excerpts from the notes to ING Group's financial statements shown above to address the following questions:

1 As of 31 December 2017, what proportion of the amount of liabilities on ING Group's balance sheet is reported at fair value through profit or loss?

2 As of 31 December 2017 and 2016, what is the percent difference between the carrying amount and fair value of the debt securities that are shown on ING Group's balance sheet at amortised cost?

Solution to 1:

Of ING Group's total €794.8 billion liabilities, 11 percent (=€87.2 billion/€794.8 billion) are reported at fair value through profit or loss.

Solution to 2:

ING's debt securities that are shown on the balance sheet at amortised cost appear in the line labeled "Debt securities in issue". Note 1 states that "Debt securities in issue" are reported at amortised cost. Note 16 indicates that this line item relates to debentures and other issued debt securities, and thus we exclude subordinated loans and deposits from banks and customer deposits in this case (there are no preference shares classified as debt listed in the Note 37 excerpt).

According to the above excerpt from Note 37, in each year the fair value of ING's debt securities is slightly higher than its carrying amount. The difference is 0.7% [= (96,736/96,086) – 1] on 31 December 2017 and 0.3% [= (103,559/103,234) – 1] on 31 December 2016.

5 DERECOGNITION OF DEBT

c explain the derecognition of debt

Once bonds are issued, a company may leave the bonds outstanding until maturity or redeem the bonds before maturity either by calling the bonds (if the bond issue includes a call provision) or by purchasing the bonds in the open market. If the bonds remain outstanding until the maturity date, the company pays bondholders the face value of the bonds at maturity. The discount or premium on the bonds would be fully amortised at maturity; the carrying amount would equal face value. Upon repayment, the bonds payable account is reduced by the carrying amount at maturity (face value) of the bonds, and cash is reduced by an equal amount. Repayment of the bonds appears in the statement of cash flows as a financing cash outflow.

If a company decides to redeem bonds before maturity and thus extinguish the liability early, the bonds payable account is reduced by the carrying amount of the redeemed bonds. The difference between the cash required to redeem the bonds and the carrying amount of the bonds is a gain or loss on the extinguishment of debt. Under IFRS, debt issuance costs are included in the measurement of the liability and are thus part of its carrying amount. Under US GAAP, debt issuance costs are accounted for separately from bonds payable and are amortised over the life of the bonds. Any unamortised debt issuance costs must be written off at the time of redemption and included in the gain or loss on debt extinguishment.

For example, a company reporting under IFRS has a £10 million bond issuance with a carrying amount equal to its face value and five years remaining until maturity. The company redeems the bonds at a call price of 103. The redemption cost is

£10.3 million (= £10 million × 103%). The company's loss on redemption would be £300 thousand (£10 million carrying amount minus £10.3 million cash paid to redeem the callable bonds).

A gain or loss on the extinguishment of debt is reported on the income statement, in a separate line item, when the amount is material. A company typically discloses further detail about the extinguishment in the management discussion and analysis (MD&A) and/or notes to the financial statements.[6] In addition, in a statement of cash flows prepared using the indirect method, net income is adjusted to remove any gain or loss on the extinguishment of debt from operating cash flows and the cash paid to redeem the bonds is classified as cash used for financing activities. (Recall that the indirect method of the statement of cash flows begins with net income and makes necessary adjustments to arrive at cash from operations, including removal of gains or losses from non-operating activities.)

To illustrate the financial statement impact of the extinguishment of debt, consider the notes payable repurchase in Example 6 below.

EXAMPLE 6

Debt Extinguishment Disclosure

The following excerpts are from the 2018 annual report of Monte Rock Inc. (a hypothetical company). In its statement of cash flows, the company uses the indirect method to reconcile net income with net cash (used in) provided by operations.

***Excerpt from* Consolidated Statements of Income**
For the years ended 31 December 2018, 2017, and 2016

	2018	2017	2016
Revenues:			
⋮	⋮	⋮	⋮
Total revenues	104,908,900	112,416,800	96,879,000

Total operating expenses	100,279,900	96,140,600	71,018,900
Income from operations	4,629,000	16,276,200	25,860,100
Other income (expense):			
⋮	⋮	⋮	⋮
Gain on debt extinguishment	2,345,000	—	—
⋮	⋮	⋮	⋮
Total other income (expense), net	11,236,100	(14,257,000)	(7,085,800)
Net income	$15,865,100	$2,019,200	$18,774,300

---

[6] We use the term MD&A generally to refer to any management commentary provided on a company's financial condition, changes in financial condition, and results of operations. In the United States, the Securities and Exchange Commission (SEC) requires a management discussion and analysis for companies listed on US public markets. Reporting requirements for such a commentary as the SEC-required MD&A vary across exchanges, but some are similar to the SEC requirements. The IASB issued an IFRS Practice Statement, "Management Commentary," in December 2010 to guide all companies reporting under IFRS.

Excerpt from **Consolidated Statements of Cash Flows**
For the years ended 31 December 2018, 2017, and 2016

	2018	2017	2016
CASH FLOWS FROM OPERATING ACTIVITIES:			
Net Income	$15,865,100	$2,019,200	$18,774,300
Adjustments to reconcile net income to net cash (used in) provided by operating activities:			
⋮	⋮	⋮	⋮
Gain on debt extinguishment	(2,345,000)	—	—
⋮	⋮	⋮	⋮
Total adjustments	(16,636,000)	38,842,400	19,815,800
Net cash (used in) provided by operating activities	(770,900)	40,861,600	38,590,100
⋮	⋮	⋮	⋮
CASH FLOWS FROM FINANCING ACTIVITIES:			
Payments for debt financing costs	(294,000)	(1,526,500)	(1,481,500)
⋮	⋮	⋮	⋮
Purchase of debt securities	(2,155,000)	—	(5,000,000)
⋮	⋮	⋮	⋮
Payments of unsecured debt	—	(31,402,960)	(1,356,000)

Excerpt from **NOTE 8: BONDS PAYABLE**

On December 12, 2014, the Company issued $25 million of unsecured bonds… Interest on the bonds is equal to Libor plus 4%, payable quarterly in arrears. … During the 4th quarter of 2018, the Company repurchased the unsecured bonds with a face value of $4.5 million and realized a $2.3 million gain.

1 The balance in bonds payable was reduced at redemption by:

A $2,155,000.

B $2,345,000.

C $4,500,000.

2 How much cash did the Company pay to redeem the bonds?

A $2,155,000

B $2,345,000

C $4,500,000

Solution to 1:

C is correct. The bonds payable is reduced at redemption by the carrying amount of the bonds redeemed. The cash paid to extinguish the bonds plus the gain on redemption equals the carrying amount of the bonds. The carrying amount of the bonds was $4,500,000. In this case, the carrying amount equals the face value. The company recognised a gain of $2,345,000 when it extinguished the debt of $4,500,000 by paying only $2,155,000.

Solution to 2:

A is correct. As shown in the Statement of Cash flow, the company paid $2,155,000 to redeem the bonds. The company recognised a gain of $2,345,000 when it extinguished the debt of $4,500,000 by paying only $2,155,000.

DEBT COVENANTS

6

d describe the role of debt covenants in protecting creditors

Borrowing agreements (the bond indenture) often include restrictions called covenants that protect creditors by restricting activities of the borrower. Debt covenants benefit borrowers to the extent that they lower the risk to the creditors and thus reduce the cost of borrowing. Affirmative covenants restrict the borrower's activities by requiring certain actions. For instance, covenants may require that the borrower maintain certain ratios above a specified amount or perform regular maintenance on real assets used as collateral. Negative covenants require that the borrower not take certain actions. These covenants may restrict the borrower's ability to invest, pay dividends, or make other operating and strategic decisions that might adversely affect the company's ability to pay interest and principal.

Common covenants include limitations on how borrowed monies can be used, maintenance of collateral pledged as security (if any), restrictions on future borrowings, and requirements that limit dividends. Covenants may also specify minimum acceptable levels of financial ratios, such as debt-to-equity ratio, current ratio, or interest coverage.

When a company violates a debt covenant, it is a breach of contract. Depending on the severity of the breach and the terms of the contract, lenders may choose to waive the covenant, be entitled to a penalty payment or higher interest rate, renegotiate, or call for payment of the debt. Bond contracts typically require that the decision to call for immediate repayment be made, on behalf of all the bondholders, by holders of some minimum percentage of the principal amount of the bond issue.

Example 7 illustrates common disclosures related to debt covenants included in financial statement disclosures (notes to the financial statements).

EXAMPLE 7

The following excerpts are from the 2017 Form 20-F filing of TORM plc, a tanker company which describes itself as one of the world's largest carriers of refined oil products. TORM plc was established in 2016 following the restructuring of TORM A/S.

Illustration of Debt Covenant Disclosures

The following excerpt is from the Risk Factors section of TORM's fiscal year 2017 Form 20-F.

> Our current debt facilities impose restrictions on our financial and operational flexibility. Our debt facilities impose, and any future debt facility may impose, covenants and other operating and financial restrictions on our ability to, among other things, pay dividends, charter-in vessels, incur additional debt, sell vessels or refrain from procuring the timely release of arrested vessels. Our debt facilities require us to maintain various financial ratios, including a specified

> minimum liquidity requirement, a minimum equity requirement and a collateral maintenance requirement. Our ability to comply with these restrictions and covenants is dependent on our future performance and our ability to operate our fleet and may be affected by events beyond our control, including fluctuating vessel values. We may therefore need to seek permission from our lenders in order to engage in certain corporate actions.
>
> Failure to comply with the covenants and financial and operational restrictions under our debt facilities may lead to an event of default under those agreements. An event of default may lead to an acceleration of the repayment of debt. In addition, any default or acceleration under our existing debt facilities or agreements governing our other existing or future indebtedness is likely to lead to an acceleration of the repayment of debt under any other debt instruments that contain cross-acceleration or cross-default provisions. If all or a part of our indebtedness is accelerated, we may not be able to repay that indebtedness or borrow sufficient funds to refinance that debt, which could have a material adverse effect on our future performance, results of operations, cash flows and financial position and could lead to bankruptcy or other insolvency proceedings.
>
> … As of December 31, 2017, we were in compliance with the financial covenants contained in our debt facilities.

The following excerpt is from the Liquidity and Capital Resources section in TORM's fiscal year 2017 Form 20-F.

> The DSF [Danish Ship Finance] Facility contains, among others, the following financial and other covenants:
>
> - Loan-to-value. If at any time the aggregate market value of the vessels and the value of any additional security is less than 133% of the loan amount less amounts on credit in the deposit accounts and reserve account and the value of any additional security, the borrower and guarantors shall, within 30 days of a written request, post additional security or prepay the loan to reduce the excess to zero.
> - Free Liquidity. Minimum unencumbered cash and cash equivalents … of the higher of $75 million and 5% of our total debt, of which $40 million is required to be unencumbered cash and cash equivalents.
> - Equity Ratio. The ratio of market value adjusted shareholders' equity to total market value adjusted assets shall be at least 25%.
> - Dividends. We are restricted from making any distributions, including payment of dividends and repayments of shareholders loans, except ….

1 Which of the covenants described in the above excerpts are affirmative covenants?

2 Based on the excerpt above, what are the potential consequences of breaching the loan covenants?

Solution to 1:

Examples of affirmative covenants in the above excerpts are from TORM's disclosure about the DSF Facility and include: the requirement for TORM to maintain a loan-to-value relationship such that the assets securing the loan (the vessels) are 133% of the loan amount; the requirement for TORM to maintain "free liquidity" (i.e., a minimum level of cash and cash equivalents); and the requirement that the equity ratio be at least 25%. These covenants require the issuer to do something. The dividend covenant requiring that TORM not take certain actions (i.e., not pay dividends unless certain conditions are met) is a negative covenant. In addition, the excerpt from Risk Factors describes other negative covenants in TORM's debt facilities including restrictions on chartering-in vessels, incurring additional debt, or selling vessels.

Solution to 2:

A breach of a loan covenant by TORM—an event of default—may result in the entire amount of its debt becoming due.

PRESENTATION AND DISCLOSURE OF LONG-TERM DEBT

7

e describe the financial statement presentation of and disclosures relating to debt

The non-current (long-term) liabilities section of the balance sheet usually includes a single line item of the total amount of a company's long-term debt due after one year, with the portion of long-term debt due in the next twelve months shown as a current liability. Notes to the financial statements provide more information on the types and nature of a company's debt. These note disclosures can be used to determine the amount and timing of future cash outflows. The notes generally include stated and effective interest rates, maturity dates, restrictions imposed by creditors (covenants), and collateral pledged (if any). The amount of scheduled debt repayments for the next five years also is shown in the notes.

Example 8 contains an excerpt from the 2017 Form 10-K of Johnson & Johnson (J&J), a US manufacturer of health care products.

EXAMPLE 8

Illustration of Long-Term Debt Disclosures

Exhibit 1 is an excerpt from Note 7 of Johnson & Johnson's 2017 annual report that illustrates financial statement disclosures for long-term debt, including type and nature of long-term debt, carrying amounts, effective interest rates, and required payments over the next five years. Johnson & Johnson reports its debt at amortised cost.

Exhibit 1 Johnson & Johnson Borrowings

The components of long-term debt are as follows:

(Dollars in Millions)	2017	Effective Rate %	2016	Effective Rate %
5.55% Debentures due 2017	$—	—	$1,000	5.55
1.125% Notes due 2017	—	—	699	1.15
5.15% Debentures due 2018	900	5.18	899	5.18
1.65% Notes due 2018	597	1.70	600	1.70

(continued)

Exhibit 1 (Continued)

4.75% Notes due 2019 (1B Euro 1.1947)[2]/(1B Euro 1.0449)[3]	1,192	5.83	1,041	5.83
1.875% Notes due 2019	496	1.93	499	1.93
0.89% Notes due 2019	300	1.75	299	1.20
1.125% Notes due 2019	699	1.13	699	1.13
3% Zero Coupon Convertible Subordinated Debentures due 2020	60	3.00	84	3.00
2.95% Debentures due 2020	547	3.15	546	3.15

Subtotal	**32,174**	**3.19**[1]	**24,146**	**3.33**[1]
Less current portion	1,499		1,704	
Total long-term debt	**$30,675**		**$22,442**	

(1) Weighted average effective rate.
(2) Translation rate at December 31, 2017.
(3) Translation rate at January 1, 2017.

"Fair value of the long-term debt was estimated using market prices, which were corroborated by quoted broker prices and significant other observable inputs.

"The Company has access to substantial sources of funds at numerous banks worldwide. In September 2017, the Company secured a new 364-day Credit Facility. Total credit available to the Company approximates $10 billion, which expires on September 13, 2018. Interest charged on borrowings under the credit line agreements is based on either bids provided by banks, the prime rate or London Interbank Offered Rates (Libor), plus applicable margins. Commitment fees under the agreements are not material… Throughout 2017, the Company continued to have access to liquidity through the commercial paper market. Short-term borrowings and the current portion of long-term debt amounted to approximately $3.9 billion at the end of 2017, of which $2.3 billion was borrowed under the Commercial Paper Program, $1.5 billion is the current portion of the long term debt, and the remainder principally represents local borrowing by international subsidiaries. …"

Aggregate maturities of long-term obligations commencing in 2018 are (dollars in millions):

2018	2019	2020	2021	2022	After 2022
$1,499	2,752	1,105	1,797	2,189	22,832

Use the information in Exhibit 1 to answer the following questions:

1. Why are the effective interest rates unchanged from 2016 to 2017 for most of the borrowings listed?

2 Why does the carrying amount of the "1.125% Notes due 2019" remain the same in 2016 and 2017?

3 Why is the carrying amount of the "4.75% Notes due 2019" higher in 2017 than in 2016?

Solution to 1:

The effective rate typically refers to the market rate at which the bonds are issued and typically does not change from year to year.

Solution to 2:

The carrying amount of the "1.125% Notes due 2019" remains the same because the effective interest rate at which the debentures were issued (1.13%) is approximately the same as the coupon rate indicating that the notes were issued approximately at par. Thus, there would be no amortization of a premium or discount to affect the carrying amount of the notes, and assuming no repurchases, the carrying amount would not change.

Solution to 3:

The notes are denominated in Euros, with a face value of €1 billion. The dollar/euro translation exchange rate at the end of 2017 was higher than the exchange rate at the end of 2016 (1.1947 versus 1.0449). That increase explains part of the increase in carrying value. In addition, the effective interest rate of 5.83% is higher than the 4.75% coupon rate – implying that the notes were issued at a discount. Thus, the increase in the carrying amount of the notes also reflects the amortisation of the issuance discount.

In this reading, we focus on accounting for simple debt contracts. Debt contracts can take on additional features, which lead to more complexity. For instance, convertible debt and debt with warrants are more complex instruments that have both debt and equity features. Convertible debt gives the debt holder the option to exchange the debt for equity. Bonds issued with warrants give holders the right to purchase shares of the issuer's common stock at a specific price, similar to stock options. Issuance of bonds with warrants is more common by non-US companies. Example 9 provides an example of a financial statement disclosure of bonds with warrants.

EXAMPLE 9

Financial Statement Disclosure of Bonds with Warrants

The following describes a company's issuance of convertible bonds with warrants.

> On 1 February 2018, the Company issued convertible bonds with stock warrants due 2024 with an aggregate principal amount of RMB 30 billion (the "Bonds with Warrants"). The Bonds with Warrants with fixed interest rate of 0.8% per annum and interest payable annually, were issued at par value of RMB 100. Each lot of the Bonds with Warrants, comprising ten Bonds with Warrants are entitled to warrants (the "Warrants") to subscribe 50.5 shares of the Company during the 5 trading days prior to 3 March 2020 at an initial exercise price of RMB 19.68 per share, subject to adjustment for, amongst other things, cash dividends, subdivision or consolidation of shares,

> bonus issues, rights issues, capital distribution, change of control and other events which have a dilutive effect on the issued share capital of the Company.

If all warrants were exercised, how many shares would be subscribed for?

Solution:

1,515,000,000 shares would be subscribed for [aggregate principal amount divided by par value of a lot times shares subscribed per lot = (RMB 30,000,000,000/RMB 100 × 10) × 50.5 shares].

In addition to disclosures in the notes to the financial statements, an MD&A commonly provides other information about a company's capital resources, including debt financing and off-balance-sheet financing. In the MD&A, management often provides a qualitative discussion on any material trends, favorable or unfavorable, in capital resources and indicates any expected material changes in their mix and relative cost. Additional quantitative information is typically provided, including schedules summarising a company's contractual obligations (e.g., bond payables) and other commitments (e.g., lines of credit and guarantees) in total and over the next five years.

8 LEASES

f explain motivations for leasing assets instead of purchasing them

A **lease** is a contract that conveys the right to use an asset for a period of time in exchange for consideration. The party who uses the asset and pays the consideration is the **lessee**, and the party who owns the asset, grants the right to use the asset, and receives consideration is the **lessor**. For a contract to be a lease, it must

a identify a specific underlying asset,

b give the customer the right to obtain largely all of the economic benefits from the asset over the contract term, and

c give the customer, not the supplier, the ability to direct how and for what objective the underlying asset is used.

For example, a contract between a customer and a trucking company is a lease if the contract identifies a specific truck, allows the customer exclusive use of it during the contract term, and lets the customer direct its use. However, if the customer contracts with a trucking company to ship goods for a fee, the contract would not be a lease, because a specific truck is not identified nor does the customer obtain largely all of the economic benefits from the truck over the contract term.

Leasing is a way to obtain the benefits of the asset without purchasing it outright. From the perspective of a lessee, it is a form of financing that resembles acquiring an asset with a note payable. From the perspective of a lessor, a lease is a form of investment and can also be an effective selling strategy, because customers generally prefer to pay in installments.

8.1 Examples of Leases

Leasing is among the most prevalent forms of financing. In 2014, the International Accounting Standards Board found that more than 14,000 publicly listed companies were lessees and they owed over $3.3 trillion in future lease payments in aggregate.[7] The following exhibit illustrates several examples of these arrangements.

Lessee	Lease Disclosure Excerpt
Alibaba	"The Company entered into operating lease agreements primarily for shops and malls, offices, warehouses, and land."
Copa Airlines	"The Company leases some aircraft under long-term lease agreements with an average duration of 10 years. Other leased assets include real estate, airport and terminal facilities, sales offices, maintenance facilities, and general offices."
Facebook	"We have entered into various non-cancelable operating lease agreements for certain of our offices, data center, land, colocations, and equipment."
Standard Bank	"The group leases various offices, branch space, and ATM space."

Sources: Companies' 2020 and 2019 annual reports.

Lessors are often banks, although there are some large independent leasing companies, such as AerCap Holdings N.V., which describes itself as "the global leader in aircraft leasing, . . . leasing aircraft to customers in every major geographical region. As of December 31, 2019, [it] owned 939 aircraft."[8]

8.2 Advantages of Leasing

There are several advantages to leasing an asset compared with purchasing it:

- Less cash is needed up front. Leases typically require little, if any, down payment.
- Cost effectiveness: Leases are a form of secured borrowing; in the event of nonpayment, the lessor simply repossesses the leased asset. As a result, the effective interest rate for a lease is typically lower than what the lessee would pay on an unsecured loan or bond.
- Convenience and lower risks associated with asset ownership, such as obsolescence.

From the perspective of a lessor, leasing has advantages over selling outright, which include earning interest income over the lease term and increasing the market for its product by offering customers the ability to use or control an asset while paying smaller amounts over time.

8.3 Lease Classification as Finance or Operating

Leases can resemble either the purchase of an asset or a rental contract. For example, a 10-year lease of an automobile with a 10-year useful life for monthly payments that, in aggregate, are equal to the fair value of the automobile is effectively a debt-financed purchase of that automobile. In contrast, a 1-year lease of a machine with a 20-year useful life resembles a rental contract. A lease that resembles a purchase is classified as a **finance lease**. All other leases are **operating leases**.

---

[7] IFRS, "IASB Shines Light on Leases by Bringing Them onto the Balance Sheet" (13 January 2016). www.ifrs.org/news-and-events/2016/01/iasb-shines-light-on-leases-by-bringing-them-onto-the-balance-sheet.

[8] AerCap Holdings N.V. annual report for the fiscal year ended 31 December 31 2019 on Form 20-F.

More specifically, a lease is a finance lease if *any* of the following five criteria are met. These criteria are the same for the International Financial Reporting Standards (IFRS) and US generally accepted accounting principles (GAAP). If none of the criteria are met, the lease is an operating lease. The same criteria are used for both lessees and lessors in classifying the lease.

1. The lease transfers ownership of the underlying asset to the lessee.
2. The lessee has an option to purchase the underlying asset and is reasonably certain it will do so.
3. The lease term is for a major part of the asset's useful life.
4. The present value of the sum of the lease payments equals or exceeds substantially all of the fair value of the asset.
5. The underlying asset has no alternative use to the lessor.

EXAMPLE 10

Lease Identification and Classification

1. Company C enters a contract with Company D that requires Company C to pay ¥100 million at the end of each of the next two years to Company D for exclusive use of a specific machine over that time period. The present value of the payments is ¥186 million. At the end of the contract, Company C will return the machine to Company D. The contract does not contain a purchase option. The machine can be used in many applications by many types of customers. The remaining useful life of the machine is four years, and its fair value is ¥190 million. This contract is:
   - **A** not a lease.
   - **B** an operating lease.
   - **C** a finance lease.
2. If the fair value of the machine in Question 1 was ¥300 million, would the classification of the contract change?
   - **A** No
   - **B** Yes, from an operating lease to a finance lease
   - **C** Yes, from a finance lease to an operating lease

Solution to 1:

C is correct. This contract is a lease because a specific asset is identified, Company C will exclusively use it, and Company C will have the ability to direct its use. The contract is a finance lease because one of the five criteria is met: The present value of the lease payments equals substantially all of the fair value (186/190 = 98%).

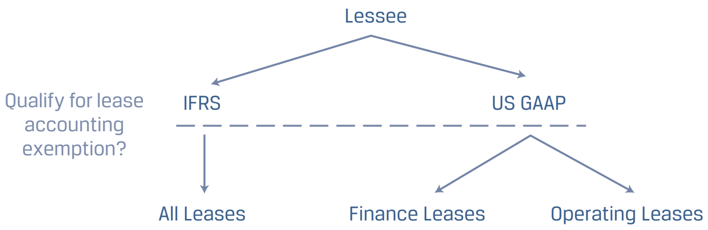
Solution to 2:

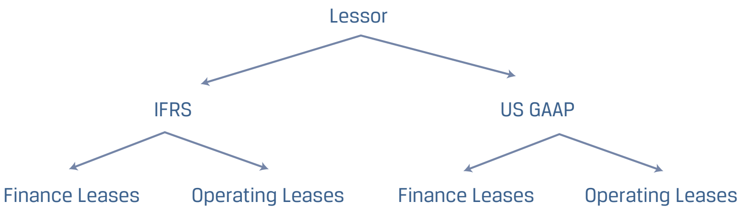
C is correct. This change would result in the lease not meeting any of the five criteria for a finance lease. If a lease does not meet any of the five criteria, it is an operating lease.

8.4 Financial Reporting of Leases

The financial reporting of a lease depends on whether the party is the lessee or lessor, whether the party reports with IFRS or US GAAP, and the classification of the lease as finance or operating. Additionally, for lessees, there are lease accounting exemptions for certain lease contracts: If its term is 12 months or less (IFRS and US GAAP) or it is for a “low-value asset,” up to $5,000 in sales price (IFRS only), then the lessee can elect to simply expense the lease payments on a straight-line basis. These exemptions are not available to lessors. The following diagram illustrates the different permutations for lease accounting.

Lease Classifications for Lessee and Lessor:





Fortunately, lessor accounting under both IFRS and US GAAP is substantially identical, and the differences in treatment for lessees are modest.

8.5 Lessee Accounting—IFRS

g explain the financial reporting of leases from a lessee’s perspective

Under IFRS, there is a single accounting model for both finance and operating leases for lessees. At lease inception, the lessee records a lease payable liability and a “right-of-use” (ROU) asset on its balance sheet, both equal to the present value of future lease payments. The discount rate used in the present value calculation is either the rate implicit in the lease or an estimated secured borrowing rate.

The lease liability is subsequently reduced by each lease payment using the effective interest method. Each lease payment is composed of interest expense, which is the product of the lease liability and the discount rate, and principal repayment, which is the difference between the interest expense and lease payment.

The ROU asset is subsequently amortized, often on a straight-line basis, over the lease term. So, although the lease liability and ROU asset begin with the same carrying value on the balance sheet, they typically diverge in subsequent periods because the principal repayment that reduces the lease liability and the amortization expense that reduces the ROU asset are calculated differently.

The following list shows how the transaction affects the financial statements:

1. The lease liability net of principal repayments and the ROU asset net of accumulated amortization are reported on the balance sheet.
2. Interest expense on the lease liability and the amortization expense related to the ROU asset are reported separately on the income statement.

3 The principal repayment component of the lease payment is reported as a cash outflow under financing activities on the statement of cash flows, and depending on the lessee's reporting policies, interest expense is reported under either operating or financing activities on the statement of cash flows.

EXAMPLE 11

Lessee Accounting—IFRS

Proton Enterprises, a hypothetical manufacturer based in Germany, is offered the following terms to lease a machine: five-year lease with an implied interest rate of 10% and an annual lease payment of EUR100,000 per year payable at the end of each year. The present value of the machinery is therefore EUR379,079 (in Microsoft Excel, the formula is =PV(10%,5,-100,000). The asset will be amortized over the five-year lease term on a straight-line basis. Proton reports under IFRS.

What would be the impact of this lease on Proton's:

1 balance sheet at the beginning of the year?

2 income statement during the following year?

3 statement of cash flows during the following year?

Solution to 1:

Proton would report a EUR379,079 lease liability and ROU asset.

Solution to 2:

Interest expense and amortization expense are reported on the income statement. In Year 2, interest expense is EUR31,699 and amortization expense is EUR 75,816, as illustrated in the following tables:

	Lease Payment	Interest Expense (10% × Lease Liability)	Principal Repayment (Payment – Interest)	Lease Liability
	FO.1	FO.2	FO.3	FO.4
Year 0				379,079
Year 1	100,000	37,908	62,092	316,987
Year 2	100,000	31,699	68,301	248,685
Year 3	100,000	24,869	75,131	173,554
Year 4	100,000	17,355	82,645	90,909
Year 5	100,000	9,091	90,909	0
Total	500,000	120,921	379,079	

	Amortization Expense	ROU Asset
	Straight-Line F.1	F.2
Year 0		379,079
Year 1	75,816	303,263
Year 2	75,816	227,447
Year 3	75,816	151,631
Year 4	75,816	75,816

	Amortization Expense	ROU Asset
Year 5	75,816	0
Total	379,079	

Note: Totals may not sum due to rounding.

Solution to 3:

Principal repayments are reported as a cash outflow under financing activities on the statement of cash flows, and depending on Proton's reporting policies, interest expense is reported under operating or financing activities on the statement of cash flows. From the previous tables, Year 2 principal repayment is EUR68,301 and interest expense is EUR31,699, for a total of EUR100,000.

8.6 Lessee Accounting—US GAAP

Under US GAAP, there are two accounting models for lessees: one for finance leases and another for operating leases. The finance lease accounting model is identical to the lessee accounting model for IFRS. The operating lease accounting model is different.

At operating lease inception, the lessee records a lease payable liability and a corresponding right-of-use asset on its balance sheet that are subsequently reduced by the principal repayment component of the lease payment and amortization, respectively, in the same manner that an IFRS lessee would.

The key difference between an operating lease and a finance lease is how the amortization of the ROU asset is calculated. For an operating lease, the lessee's ROU asset amortization expense is the lease payment minus the interest expense. The implication is that the total expense reported on the income statement (interest plus amortization) will equal the lease payment and that the lease liability and the ROU asset will always equal each other because the principal repayment and amortization are calculated in an identical manner.

The following list shows how the transaction appears on the financial statements:

a The lease liability net of principal repayments and the ROU asset net of accumulated amortization are reported on the balance sheet.

b Interest expense on the lease liability and the amortization expense related to the ROU asset are reported as a single line titled "lease expense" as an operating expense on the income statement. The interest and amortization components are *not* reported separately, nor are they grouped with other types of interest and amortization expense (e.g., interest on a bond, amortization of an intangible asset).

c The entire lease payment is reported as a cash outflow under operating activities on the statement of cash flows. The interest and principal repayment components are *not* reported separately.

EXAMPLE 12

Lessee Accounting—Operating Lease under US GAAP

If Proton Enterprises classified the lease of the machinery from Example 11 as an operating lease:

1 how would its financial statements differ, if at all?

2 how would the classification, all else equal, affect EBITDA margin, total asset turnover, and cash flow per share?

Solution to 1:

The first step is to construct the lease liability and ROU asset amortization tables under an operating lease scenario. The lease liability amortization is the same as the finance lease columns FO.1–FO.4 in Example 11.

	Amortization Expense	ROU Asset	Lease Expense
	(Lease Payment – Interest)		(Amortization + Interest)
	0.1	0.2	0.3
Year 0		379,079	
Year 1	62,092	316,987	100,000
Year 2	68,301	248,685	100,000
Year 3	75,131	173,554	100,000
Year 4	82,645	90,909	100,000
Year 5	90,909	0	100,000
Total	379,078		500,000

Now we can compare the financial statement impacts under both finance and operating lease scenarios.

Balance Sheet	Year 1	Year 2	Year 3	Year 4	Year 5
Finance lease:					
ROU asset, net: F.2	303,263	227,447	151,631	75,816	0
Lease liability, net: FO.4	316,987	248,685	173,554	90,909	0
Operating lease:					
ROU asset, net: O.2	316,987	248,685	173,554	90,909	0
Lease liability, net: FO.4	316,987	248,685	173,554	90,909	0

The ROU asset is lower in each period under a finance lease because the amortization expense is higher.

Income Statement	Year 1	Year 2	Year 3	Year 4	Year 5
Finance lease:					
Amortization: F.1	75,816	75,816	75,816	75,816	75,816
Interest: FO.2	37,908	31,699	24,869	17,355	9,091
Total	113,724	107,515	100,685	93,171	84,907

Income Statement	Year 1	Year 2	Year 3	Year 4	Year 5
Operating lease:					
Lease expense: O.3	100,000	100,000	100,000	100,000	100,000

Total expense is higher for a finance lease in Years 1–3 but lower in Years 4 and 5. The largest difference is classification; amortization and interest are presented separately for a finance lease, whereas operating lease expense is an operating expense.

Statement of Cash Flows	Year 1	Year 2	Year 3	Year 4	Year 5
Finance lease:					
Cash flow from operating activities	(37,908)	(31,699)	(24,869)	(17,355)	(9,091)
Cash flow from financing activities	(62,902)	(68,301)	(75,131)	(82,645)	(90,909)
Total	(100,000)	(100,000)	(100,000)	(100,000)	(100,000)
Operating lease:					
Cash flows from operating activities	(100,000)	(100,000)	(100,000)	(100,000)	(100,000)

The difference on the statement of cash flows is only in classification, because in both cases the total cash outflow is equal to the lease payment.

Solution to 2:

The following table shows how the classification affects the indicated financial ratios.

Ratio	Formula	Impact of Using an Operating Lease Instead of a Finance Lease
EBITDA margin	$\frac{\text{EBITDA}}{\text{Total revenues}}$	Lower: Lease expense is classified as an operating expense rather than interest and amortization.
Asset turnover	$\frac{\text{Total revenues}}{\text{Total assets}}$	Lower: Total assets are higher under an operating lease because the ROU asset is amortized at a slower pace in Years 1–3.
Cash flow per share	$\frac{\text{Cash flow from operations}}{\text{Shares outstanding}}$	Lower: Cash flow from operations is lower because the entire lease payment is included in operating activities versus solely interest expense for a finance lease.

8.7 Lessor Accounting

h explain the financial reporting of leases from a lessor's perspective

The accounting for lessors is substantially identical under IFRS and US GAAP. Under both accounting standards, lessors classify leases as finance or operating leases, which determines the financial reporting. Although lessors under US GAAP recognize finance leases as either "sales-type" or "direct financing," the distinction is immaterial from an analyst's perspective.

At finance lease inception, the lessor recognizes a lease receivable asset equal to the present value of future lease payments and de-recognizes the leased asset, simultaneously recognizing any difference as a gain or loss. The discount rate used in the present value calculation is the rate implicit in the lease.

The lease receivable is subsequently reduced by each lease payment using the effective interest method. Each lease payment is composed of interest income, which is the product of the lease receivable and the discount rate, and principal proceeds, which equals the difference between the interest income and cash receipt.

The following list shows how the transaction affects the financial statements:

1 Lease receivable net of principal proceeds is reported on the balance sheet.
2 Interest income is reported on the income statement. If leasing is a primary business activity for the entity, as it commonly is for financial institutions and independent leasing companies, it is reported as revenue.
3 The entire cash receipt is reported under operating activities on the statement of cash flows.

The accounting treatment for an operating lease is different in that, because the contract is essentially a rental agreement, the lessor keeps the leased asset on its books and recognizes lease revenue on a straight-line basis. Interest revenue is not recognized because the transaction is not considered a financing.

The following list shows how the transaction affects the financial statements:

1 The balance sheet is not affected. The lessor continues to recognize the leased asset at cost net of accumulated depreciation.
2 Lease revenue is recognized on a straight-line basis on the income statement. Depreciation expense continues to be recognized.
3 The entire cash receipt is reported under operating activities on the statement of cash flows. This is the same as a finance lease.

EXAMPLE 13

Lessor Accounting

Let's examine Proton's machine lease from Examples 11 and 12 from the perspective of the lessor. Assume that the carrying value of the asset immediately prior to the lease is EUR350,000, accumulated depreciation is zero, and the lessor elects to depreciate it on a straight-line basis over five years.

How are the lessor's financial statements affected by the classification of the lease as a finance or operating lease?

Solution

The difference on the balance sheet is material, because a finance lease requires the lessor to de-recognize the asset and recognize a lease receivable, whereas an operating lease lessor continues to recognize the asset and depreciate it over its useful life. In this case, where the present value of the lease payments is well above the carrying value of the asset, the finance lease classification results in a significant increase in assets.

Balance Sheet	Year 1	Year 2	Year 3	Year 4	Year 5
Finance lease:					
Lease receivable, net	316,987	248,685	173,554	90,909	0
Operating lease:					
Property, plant, and equipment, net	280,000	210,000	140,000	70,000	0

The difference on the income statement is also material, because a finance lease lessor recognizes interest revenue under the effective interest method whereas the operating lease lessor recognizes straight-line lease revenue.

Income Statement	Year 1	Year 2	Year 3	Year 4	Year 5
Finance lease:					
Interest revenue	37,908	31,699	24,869	17,355	9,091
Operating lease:					
Lease revenue	100,000	100,000	100,000	100,000	100,000

The statement of cash flows, however, is no different for the lessor under a finance or operating lease: The entire cash inflow from the lease payment is recognized under operating activities.

Statement of Cash Flows	Year 1	Year 2	Year 3	Year 4	Year 5
Finance lease:					
Cash flows from operating activities	100,000	100,000	100,000	100,000	100,000
Operating lease:					
Cash flows from operating activities	100,000	100,000	100,000	100,000	100,000

INTRODUCTION TO PENSIONS AND OTHER POST-EMPLOYMENT BENEFITS

9

i. compare the presentation and disclosure of defined contribution and defined benefit pension plans

Pensions and other post-employment benefits give rise to non-current liabilities reported by many companies. Companies may offer various types of benefits to their employees following retirement, such as pension plans, health care plans, medical insurance, and life insurance. Pension plans often are the most significant post-employment benefits provided to retired employees.

The accounting and reporting for pension plans depends on the type of pension plan offered. Two common types of pension plans are **defined contribution pension plans** and **defined benefit pension plans**. Under a defined-contribution plan, a company contributes an agreed-upon (defined) amount into the plan. The agreed-upon amount is the pension expense. The amount the company contributes to the plan is treated as an operating cash outflow. The only impact on assets and liabilities is a decrease in cash, although if some portion of the agreed-upon amount has not been paid by fiscal year-end, a liability would be recognised on the balance sheet. Because the amount of the contribution is defined and the company has no further obligation once the contribution has been made, accounting for a defined-contribution plan is fairly straightforward.

Accounting for a defined-benefit plan is more complicated. Under a defined-benefit plan, a company makes promises of future benefits to be paid to the employee during retirement. For example, a company could promise an employee annual pension payments equal to 70 percent of his final salary at retirement until death. Estimating the eventual amount of the obligation arising from that promise requires the company to make many assumptions, such as the employee's expected salary at retirement and the number of years the employee is expected to live beyond retirement. The company estimates the future amounts to be paid and discounts the future estimated amounts to a present value (using a rate reflective of a high-quality corporate bond yield) to determine the pension obligation. The discount rate used to determine the pension obligation significantly affects the amount of the pension obligation. The pension obligation is allocated over the employee's employment as part of pension expense.

Most defined-benefit pension plans are funded through a separate legal entity, typically a pension trust fund. A company makes payments into the pension fund, and retirees are paid from the fund. The payments that a company makes into the fund are invested until they are needed to pay the retirees. If the fair value of the fund's assets is higher than the present value of the estimated pension obligation, the plan has a surplus and the company's balance sheet will reflect a net pension asset.[9] Conversely, if the present value of the estimated pension obligation exceeds the fund's assets, the plan has a deficit and the company's balance sheet will reflect a net pension liability.[10] Thus, a company reports either a net pension asset or a net pension liability. Each period, the change in the net pension asset or liability is recognised either in profit or loss or in other comprehensive income.

Under IFRS, the change in the net pension asset or liability each period is viewed as having three general components. Two of the components of this change are recognised as pension expense in profit and loss: (1) employees' service costs, and (2) the net interest expense or income accrued on the beginning net pension asset or liability. The service cost during the period for an employee is the present value of the increase in the pension benefit earned by the employee as a result of providing one more year of service. The service cost also includes past service costs, which are changes in the present value of the estimated pension obligation related to employees' service in prior periods, such as might arise from changes in the plan. The net interest expense or income represents the change in value of the net defined benefit pension asset or liability and is calculated as the net pension asset or liability multiplied by the discount rate used in estimating the present value of the pension obligation. The third component of the change in the net pension asset or liability during a period —"remeasurements"— is recognised in other comprehensive income. Remeasurements are not amortised into profit or loss over time.

Remeasurements include (a) actuarial gains and losses and (b) the actual return on plan assets less any return included in the net interest expense or income. Actuarial gains and losses can occur when changes are made to the assumptions on which a company bases its estimated pension obligation (e.g., employee turnover, mortality rates, retirement ages, compensation increases). The actual return on plan assets includes interest, dividends and other income derived from the plan assets, including realized and unrealized gains or losses. The actual return typically differs from the amount included in the net interest expense or income, which is calculated using a rate reflective of a high-quality corporate bond yield; plan assets are typically allocated across various asset classes, including equity as well as bonds.

---

[9] The amount of any reported net pension asset is capped at the amount of any expected future economic benefits to the company from the plan; this cap is referred to as the asset ceiling.

[10] The description of accounting for pensions presented in this reading corresponds to the June 2011 version of IAS 19 *Employee Benefits*, which took effect on 1 January 2013. Both IFRS and US GAAP require companies to present the amount of net pension liability or asset on the balance sheet.

Under US GAAP, the change in net pension asset or liability each period is viewed as having five components, some of which are recognised in profit and loss in the period incurred and some of which are recognised in other comprehensive income and amortised into profit and loss over time. The three components recognised in profit and loss in the period incurred are (1) employees' service costs for the period, (2) interest expense accrued on the beginning pension obligation, and (3) expected return on plan assets, which is a reduction in the amount of expense recognised. The other two components are past service costs and actuarial gains and losses. Past service costs are recognised in other comprehensive income in the period in which they arise and then subsequently amortised into pension expense over the future service period of the employees covered by the plan. Actuarial gains and losses are typically also recognised in other comprehensive income in the period in which they occur and then amortised into pension expense over time. In effect, this treatment allows companies to "smooth" the effects on pension expense over time for these latter two components. US GAAP does permit companies to immediately recognize actuarial gains and losses in profit and loss.

Similar to other forms of employee compensation for a manufacturing company, the pension expense related to production employees is added to inventory and expensed through cost of sales (cost of goods sold). For employees not involved directly in the production process, the pension expense is included with salaries and other administrative expenses. Therefore, pension expense is not directly reported on the income statement. Rather, extensive disclosures are included in the notes to the financial statements.

Example 14 presents excerpts from the balance sheet and pension-related disclosures in BT Group plc's Annual Report for the year ended 31 March 2018.

EXAMPLE 14

BT Group plc: Excerpt from Balance Sheets

Below is an excerpt of BT Group plc's balance sheet from the annual report for the year ended 31 March 2018. BT reports under IFRS.

Non-current liabilities, GBP million	Mar. 31, 2018	Mar. 31, 2017	Mar. 31, 2016
Loans and other borrowings	11,994	10,081	11,025
Derivative financial instruments	787	869	863
Retirement benefit obligations	6,371	9,088	6,382
Other payables	1,326	1,298	1,106
Deferred tax liabilities	1,340	1,240	1,262
Provisions	452	536	565
Non-current liabilities	22,270	23,112	21,203

Pension-Related Disclosures

The following are excerpts of pension-related disclosures from BT Group plc's 2018 Annual Report.

Extract from Note 3 "Summary of Significant Accounting Policies"

Retirement benefits

The group's net obligation in respect of defined benefit pension plans is the present value of the defined benefit obligation less the fair value of the plan assets.

The calculation of the obligation is performed by a qualified actuary using the projected unit credit method and key actuarial assumptions at the balance sheet date.

The income statement expense is allocated between an operating charge and net finance income or expense. The operating charge reflects the increase in the defined benefit obligation resulting from the pension benefit earned by active employees in the current period, the costs of administering the plans and any past service costs/credits such as those arising from curtailments or settlements. The net finance income or expense reflects the interest on the net retirement benefit obligations recognised in the group balance sheet, based on the discount rate at the start of the year. Actuarial gains and losses are recognised in full in the period in which they occur and are presented in the group statement of comprehensive income.

The group also operates defined contribution pension plans and the income statement expense represents the contributions payable for the year.

Extract from Note 20 "Retirement Benefit Plans"
Information on Defined Benefit Pension Plans

£m	2018	2017	2016
Present value of liabilities	**57,327**	60,200	50,350
Fair value of plan assets	**50,956**	51,112	43,968

Use information in the excerpts to answer the following questions:

1. What type(s) of pension plans does BT have?
2. What proportion of BT's total non-current liabilities are related to its retirement benefit obligations?
3. Describe how BT's retirement benefit obligation is calculated.

Solution to 1:

Note 3 "Summary of Significant Accounting Policies" indicates that the company has both defined contribution and defined benefit pension plans.

Solution to 2:

Retirement benefit obligations represent 29%, 39%, and 30% of BT's total non-current liabilities for the years 2018, 2017, and 2016. Using 2018 to illustrate, £6,371/£22,270 = 29%. (£ million)

Solution to 3:

Note 3 "Summary of Significant Accounting Policies" indicates that BT's Retirement benefit obligation is calculated as the present value of the defined benefit obligation minus the fair value of the plan assets.

Using data from Note 20 "Retirement Benefit Plans" the retirement benefit obligation for each year can be calculated. Using 2018 to illustrate, £57,327 - £50,956 = £6,371 (£ million).

EVALUATING SOLVENCY: LEVERAGE AND COVERAGE RATIOS

10

j calculate and interpret leverage and coverage ratios

Solvency refers to a company's ability to meet its long-term debt obligations, including both principal and interest payments. In evaluating a company's solvency, ratio analyses can provide information about the relative amount of debt in the company's capital structure and the adequacy of earnings and cash flow to cover interest expense and other fixed charges (such as lease or rental payments) as they come due. Ratios are useful to evaluate a company's performance over time compared to the performance of other companies and industry norms. Ratio analysis has the advantage of allowing the comparison of companies regardless of their size and reporting currency.

The two primary types of solvency ratios are leverage ratios and coverage ratios. Leverage ratios focus on the balance sheet and measure the extent to which a company uses liabilities rather than equity to finance its assets. Coverage ratios focus on the income statement and cash flows and measure the ability of a company to cover its debt-related payments.

Exhibit 2 describes the two types of commonly used solvency ratios. The first three leverage ratios use total debt in the numerator.[11] The *debt-to-assets ratio* expresses the percentage of total assets financed with debt. Generally, the higher the ratio, the higher the financial risk and thus the weaker the solvency. The *debt-to-capital ratio* measures the percentage of a company's total capital (debt plus equity) financed through debt. The *debt-to-equity ratio* measures the amount of debt financing relative to equity financing. A *debt-to-equity ratio* of 1.0 indicates equal amounts of debt and equity, which is the same as a debt-to-capital ratio of 50 percent. Interpretations of these ratios are similar. Higher debt-to-capital or debt-to-equity ratios imply weaker solvency. A caveat must be made when comparing debt ratios of companies in different countries. Within certain countries, companies historically have obtained more capital from debt than equity financing, so debt ratios tend to be higher for companies in these countries.

Exhibit 2 Definitions of Commonly Used Solvency Ratios

Solvency Ratios	Numerator	Denominator
Leverage ratios		
Debt-to-assets ratio	Total debt[a]	Total assets
Debt-to-capital ratio	Total debt[a]	Total debt[a] + Total shareholders' equity

(continued)

---

[11] For calculations in this reading, total debt is the sum of interest-bearing short-term and long-term debt, excluding non-interest-bearing liabilities, such as accrued expenses, accounts payable, and deferred income taxes. This definition of total debt differs from other definitions that are more inclusive (e.g., all liabilities) or more restrictive (e.g., long-term debt only). If the use of different definitions of total debt materially changes conclusions about a company's solvency, the reasons for the discrepancies should be further investigated.

Exhibit 2 (Continued)

Solvency Ratios	Numerator	Denominator
Leverage ratios		
Debt-to-equity ratio	Total debt[a]	Total shareholders' equity
Financial leverage ratio	Average total assets	Average shareholders' equity
Coverage ratios		
Interest coverage ratio	EBIT[b]	Interest payments
Fixed charge coverage ratio	EBIT[b] + lease payments	Interest payments + lease payments

[a] In this reading, debt is defined as the sum of interest-bearing short-term and long-term debt.
[b] EBIT is earnings before interest and taxes.

The *financial leverage ratio* (also called the 'leverage ratio' or 'equity multiplier') measures the amount of total assets supported by one money unit of equity. For example, a value of 4 for this ratio means that each €1 of equity supports €4 of total assets. The higher the financial leverage ratio, the more leveraged the company in the sense of using debt and other liabilities to finance assets. This ratio often is defined in terms of average total assets and average total equity and plays an important role in the DuPont decomposition of return on equity.[12]

The *interest coverage ratio* measures the number of times a company's EBIT could cover its interest payments. A higher interest coverage ratio indicates stronger solvency, offering greater assurance that the company can service its debt from operating earnings. The *fixed charge coverage ratio* relates fixed financing charges, or obligations, to the cash flow generated by the company. It measures the number of times a company's earnings (before interest, taxes, and lease payments) can cover the company's interest and lease payments.

Example 15 demonstrates the use of solvency ratios in evaluating the creditworthiness of a company.

EXAMPLE 15

Evaluating Solvency Ratios

A credit analyst is evaluating and comparing the solvency of two companies—BT Group plc (BT) and Telefonica S A (Telefonica). The following data are gathered from the companies' fiscal 2017 annual reports (line item titles may vary between the two companies):

	BT Group plc (£ millions)		Telefonica S A (€ millions)	
	31-Mar-18	31-Mar-17	31-Dec-17	31-Dec-16
Short-term borrowings	2,281	2,632	9,414	14,749
Long-term debt	11,994	10,081	46,332	45,612
Total shareholders' equity	10,304	8,335	26,618	28,385

---

[12] The basic DuPont decomposition is: Return on Equity = Net income/Average shareholders' equity = (Sales/Average total assets) × (Net income/Sales) × (Average total assets/Average shareholders' equity).

	BT Group plc (£ millions)		Telefonica S A (€ millions)	
	31-Mar-18	31-Mar-17	31-Dec-17	31-Dec-16
Total assets	42,759	42,372	115,066	123,641
EBIT*	3,381	3,167	6,791	5,469
Interest expense	776	817	3,363	4,476

* Operating profit (or operating income) is used as a proxy for EBIT for both companies.

Use the above information to answer the following questions:

1 With regard to leverage ratios of BT and Telefonica:

- **A** What are each company's debt-to-assets, debt-to-capital, and debt-to-equity ratios for 2017 and 2016?
- **B** Comment on any changes in the calculated leverage ratios from year-to-year for each company.
- **C** Comment on the calculated leverage ratios of BT Group plc compared to Telefonica SA.

2 With regard to coverage ratios of BT and Telefonica:

- **A** What is each company's interest coverage ratio for 2017 and 2016?
- **B** Comment on any changes in the interest coverage ratio from year to year for each company.
- **C** Comment on the interest coverage ratio of BT Group plc compared to Telefonica SA.

Solution to 1:

A The debt-to-assets, debt-to-capital, and debt-to-equity ratios are as follows, with supporting calculations from each company's most recent year demonstrated below.

	BT Group plc		Telefonica S A	
	31-Mar-18	31-Mar-17	31-Dec-17	31-Dec-16
Debt-to-assets	33.4%	30.0%	48.4%	48.8%
Debt-to-capital	58.1%	60.4%	67.7%	68.0%
Debt-to-equity	1.39	1.53	2.09	2.13

	BT Group plc	Telefonica S A
	31-Mar-18	*31-Dec-17*
Debt-to-assets	*33.4% = (2,281 + 11,994)/42,759*	*48.4% = (9,414 + 46,332)/115,066*
Debt-to-capital	*58.1% = (2,281 + 11,994)/(2,281 + 11,994 + 10,304)*	*67.7% = (9,414 + 46,332)/(9,414 + 46,332 + 26,618)*
Debt-to-equity	*1.39 = (2,281 + 11,994)/10,304*	*2.09 = (9,414 + 46,332)/26,618*

B BT's debt-to-assets ratio increased, while its debt-to-capital and debt-to-equity ratios both decreased. The decrease in BT's debt-to-capital and debt-to-equity ratios resulted primarily from the company's increase in total equity and indicate stronger solvency. In addition, we observe that BT decreased its short-term borrowings and increased its long-term debt.

Telefonica's leverage ratios appear fairly similar, albeit slightly lower, for 2017 compared to 2016. Similar to BT, it appears that Telefonica shifted away from short borrowings to long-term debt in 2017.

C In both years, all three of BT's leverage ratios were lower than Telefonica's. Based on these ratios, this may imply higher solvency of BT relative to Telefonica.

Solution to 2:

A The interest coverage ratios are as follows, with supporting calculations from each company's most recent year demonstrated below.

	BT Group plc		Telefonica S A	
	31-Mar-18	**31-Mar-17**	**31-Dec-17**	**31-Dec-16**
Interest coverage ratio	4.36	3.88	2.02	1.22

	BT Group plc	**Telefonica S A**
	31-Mar-18	***31-Dec-17***
Interest coverage ratio	*4.36 = 3,381/776*	*2.02 = 6,791/3,363*

B Both companies' interest coverage ratios increased from 2017 to 2018, indicating an improvement in solvency, consistent with the conclusions drawn from the companies' ratios in question 1. Both companies have sufficient operating earnings to cover interest payments.

C BT's ability to cover interest payments is greater than Telefonica's, although both companies have sufficient operating earnings to service its interest payments. This comparison indicates that BT has greater financial strength than Telefonica, which is also consistent with the conclusions drawn from a comparison of the companies' ratios in question 1.

SUMMARY

Non-current liabilities arise from different sources of financing and different types of creditors. Bonds are a common source of financing from debt markets. Key points in accounting and reporting of non-current liabilities include the following:

- The sales proceeds of a bond issue are determined by discounting future cash payments using the market rate of interest at the time of issuance (effective interest rate). The reported interest expense on bonds is based on the effective interest rate.
- Future cash payments on bonds usually include periodic interest payments (made at the stated interest rate or coupon rate) and the principal amount at maturity.

- When the market rate of interest equals the coupon rate for the bonds, the bonds will sell at par (i.e., at a price equal to the face value). When the market rate of interest is higher than the bonds' coupon rate, the bonds will sell at a discount. When the market rate of interest is lower than the bonds' coupon rate, the bonds will sell at a premium.
- An issuer amortises any issuance discount or premium on bonds over the life of the bonds.
- If a company redeems bonds before maturity, it reports a gain or loss on debt extinguishment computed as the net carrying amount of the bonds (including bond issuance costs under IFRS) less the amount required to redeem the bonds.
- Debt covenants impose restrictions on borrowers, such as limitations on future borrowing or requirements to maintain a minimum debt-to-equity ratio.
- The carrying amount of bonds is typically the amortised historical cost, which can differ from their fair value.
- Companies are required to disclose the fair value of financial liabilities, including debt. Although permitted to do so, few companies opt to report debt at fair values on the balance sheet.
- A lease is a contract in which a lessor grants the lessee the exclusive right to use a specific underlying asset for a period of time in exchange for payments.
- Leasing is a common arrangement because it has several advantages over purchasing an asset outright: less upfront cash commitment, generally low interest rates, and lower risks associated with ownership such as obsolescence.
- Leases are classified as operating or finance leases. Finance leases resemble an asset purchase or sale while operating leases resemble a rental agreement.
- US GAAP and IFRS share the same accounting treatment for lessors but differ for lessees. IFRS has a single accounting model for both operating leases and finance lease lessees, while US GAAP has an accounting model for each.
- Lessees reporting under IFRS and finance lease lessees reporting under US GAAP
  - Recognize a lease liability and corresponding right-of-use asset on the balance sheet, equal to the present value of lease payments. The liability is subsequently reduced using the effective interest method and the right-of-use asset is amortized. Interest expense and amortization expense are shown separately on the income statement. The statement of cash flows shows the entire lease payment.
- Operating lease lessees reporting under US GAAP
  - Recognize a lease liability and corresponding right-of-use asset on the balance sheet, equal to the present value of lease payments. The liability is subsequently reduced using the effective interest method, but the amortization of the right-of-use asset is the lease payment less the interest expense. Interest expense and amortization expense are shown together as a single operating expense on the income statement.
- Finance lease lessors (IFRS and US GAAP)
  - Recognize a lease receivable asset equal to the present value of future lease payments and de-recognize the leased asset, simultaneously recognizing any difference as a gain or loss. The lease receivable is subsequently reduced by each lease payment using the effective interest method. Interest income is reported on the income statement, typically as revenue, and the entire cash receipt is reported under operating activities on the statement of cash flows.
- Operating lease lessors (IFRS and US GAAP)

  - The balance sheet is not affected: the lessor continues to recognize the underlying asset and depreciate it. Lease revenue is recognized on a straight-line basis on the income statement and the entire cash receipt is reported under operating activities on the statement of cash flows.
- Two types of pension plans are defined contribution plans and defined benefits plans. In a defined contribution plan, the amount of contribution into the plan is specified (i.e., defined) and the amount of pension that is ultimately paid by the plan (received by the retiree) depends on the performance of the plan's assets. In a defined benefit plan, the amount of pension that is ultimately paid by the plan (received by the retiree) is defined, usually according to a benefit formula.
- Under a defined contribution pension plan, the cash payment made into the plan is recognised as pension expense.
- Under both IFRS and US GAAP, companies must report the difference between the defined benefit pension obligation and the pension assets as an asset or liability on the balance sheet. An underfunded defined benefit pension plan is shown as a non-current liability.
- Under IFRS, the change in the defined benefit plan net asset or liability is recognised as a cost of the period, with two components of the change (service cost and net interest expense or income) recognised in profit and loss and one component (remeasurements) of the change recognised in other comprehensive income.
- Under US GAAP, the change in the defined benefit plan net asset or liability is also recognised as a cost of the period with three components of the change (current service costs, interest expense on the beginning pension obligation, and expected return on plan assets) recognised in profit and loss and two components (past service costs and actuarial gains and losses) typically recognised in other comprehensive income.
- Solvency refers to a company's ability to meet its long-term debt obligations.
- In evaluating solvency, leverage ratios focus on the balance sheet and measure the amount of debt financing relative to equity financing.
- In evaluating solvency, coverage ratios focus on the income statement and cash flows and measure the ability of a company to cover its interest payments.

PRACTICE PROBLEMS

1 A company issues €1 million of bonds at face value. When the bonds are issued, the company will record a:

A cash inflow from investing activities.

B cash inflow from financing activities.

C cash inflow from operating activities.

2 At the time of issue of 4.50% coupon bonds, the effective interest rate was 5.00%. The bonds were *most likely* issued at:

A par.

B a discount.

C a premium.

3 Oil Exploration LLC paid $45,000 in printing, legal fees, commissions, and other costs associated with its recent bond issue. It is *most likely* to record these costs on its financial statements as:

A an asset under US GAAP and reduction of the carrying value of the debt under IFRS.

B a liability under US GAAP and reduction of the carrying value of the debt under IFRS.

C a cash outflow from investing activities under both US GAAP and IFRS.

4 A company issues $1,000,000 face value of 10-year bonds on 1 January 2015 when the market interest rate on bonds of comparable risk and terms is 5%. The bonds pay 6% interest annually on 31 December. At the time of issue, the bonds payable reflected on the balance sheet is *closest* to:

A $926,399.

B $1,000,000.

C $1,077,217.

5 Midland Brands issues three-year bonds dated 1 January 2015 with a face value of $5,000,000. The market interest rate on bonds of comparable risk and term is 3%. If the bonds pay 2.5% annually on 31 December, bonds payable when issued are most likely reported as *closest* to:

A $4,929,285.

B $5,000,000.

C $5,071,401.

6 A firm issues a bond with a coupon rate of 5.00% when the market interest rate is 5.50% on bonds of comparable risk and terms. One year later, the market interest rate increases to 6.00%. Based on this information, the effective interest rate is:

A 5.00%.

B 5.50%.

C 6.00%.

7 On 1 January 2010, Elegant Fragrances Company issues £1,000,000 face value, five-year bonds with annual interest payments of £55,000 to be paid each 31 December. The market interest rate is 6.0 percent. Using the effective interest rate method of amortisation, Elegant Fragrances is *most likely* to record:

© 2021 CFA Institute. All rights reserved.

A an interest expense of £55,000 on its 2010 income statement.

B a liability of £982,674 on the 31 December 2010 balance sheet.

C a £58,736 cash outflow from operating activity on the 2010 statement of cash flows.

8 Consolidated Enterprises issues €10 million face value, five-year bonds with a coupon rate of 6.5 percent. At the time of issuance, the market interest rate is 6.0 percent. Using the effective interest rate method of amortisation, the carrying value after one year will be *closest* to:

A €10.17 million.

B €10.21 million.

C €10.28 million.

9 A company issues €10,000,000 face value of 10-year bonds dated 1 January 2015 when the market interest rate on bonds of comparable risk and terms is 6%. The bonds pay 7% interest annually on 31 December. Based on the effective interest rate method, the interest expense on 31 December 2015 is *closest* to:

A €644,161.

B €700,000.

C €751,521.

10 A company issues $30,000,000 face value of five-year bonds dated 1 January 2015 when the market interest rate on bonds of comparable risk and terms is 5%. The bonds pay 4% interest annually on 31 December. Based on the effective interest rate method, the carrying amount of the bonds on 31 December 2015 is *closest* to:

A $28,466,099.

B $28,800,000.

C $28,936,215.

11 Lesp Industries issues five-year bonds dated 1 January 2015 with a face value of $2,000, 000 and 3% coupon rate paid annually on 31 December. The market interest rate on bonds of comparable risk and term is 4%. The sales proceeds of the bonds are $1,910,964. Under the effective interest rate method, the interest expense in 2017 is *closest* to:

A $77,096.

B $77,780.

C $77,807.

12 For a bond issued at a premium, using the effective interest rate method, the:

A carrying amount increases each year.

B amortization of the premium increases each year.

C premium is evenly amortized over the life of the bond.

13 Comte Industries issues $3,000,000 worth of three-year bonds dated 1 January 2015. The bonds pay interest of 5.5% annually on 31 December. The market interest rate on bonds of comparable risk and term is 5%. The sales proceeds of the bonds are $3,040,849. Under the straight-line method, the interest expense in the first year is *closest* to:

A $150,000.

B $151,384.

C $152,042.

14 The management of Bank EZ repurchases its own bonds in the open market. They pay €6.5 million for bonds with a face value of €10.0 million and a carrying value of €9.8 million. The bank will *most likely* report:

A other comprehensive income of €3.3 million.

B other comprehensive income of €3.5 million.

C a gain of €3.3 million on the income statement.

15 A company redeems $1,000,000 face value bonds with a carrying value of $990,000. If the call price is 104 the company will:

A reduce bonds payable by $1,000,000.

B recognize a loss on the extinguishment of debt of $50,000.

C recognize a gain on the extinguishment of debt of $10,000.

16 Innovative Inventions, Inc. needs to raise €10 million. If the company chooses to issue zero-coupon bonds, its debt-to-equity ratio will *most likely*:

A rise as the maturity date approaches.

B decline as the maturity date approaches.

C remain constant throughout the life of the bond.

17 Fairmont Golf issued fixed rate debt when interest rates were 6 percent. Rates have since risen to 7 percent. Using only the carrying amount (based on historical cost) reported on the balance sheet to analyze the company's financial position would *most likely* cause an analyst to:

A overestimate Fairmont's economic liabilities.

B underestimate Fairmont's economic liabilities.

C underestimate Fairmont's interest coverage ratio.

18 Which of the following is an example of an affirmative debt covenant? The borrower is:

A prohibited from entering into mergers.

B prevented from issuing excessive additional debt.

C required to perform regular maintenance on equipment pledged as collateral.

19 Debt covenants are *least likely* to place restrictions on the issuer's ability to:

A pay dividends.

B issue additional debt.

C issue additional equity.

20 Regarding a company's debt obligations, which of the following is *most likely* presented on the balance sheet?

A Effective interest rate

B Maturity dates for debt obligations

C The portion of long-term debt due in the next 12 months

21 Beginning with fiscal year 2019, for leases with a term longer than one year, lessees report a right-to-use asset and a lease liability on the balance sheet:

A only for finance leases.

B only for operating leases.

C for both finance and operating leases.

22 For a lessor, the leased asset appears on the balance sheet and continues to be depreciated when the lease is classified as:

A a finance lease.

B a sales-type lease.

C an operating lease.

23 Under US GAAP, a lessor's reported revenues at lease inception will be *highest* if the lease is classified as:

A a sales-type lease.

B an operating lease.

C a direct financing lease.

24 Under both IFRS and US GAAP, a lessor in an operating lease recognizes:

A selling profit at lease inception.

B a lease asset comprising the lease receivable and relevant residual value at lease inception.

C lease receipts as income and related costs, including depreciation, as expenses over the lease term.

25 Compared with a finance lease, an operating lease:

A is similar to renting an asset.

B is equivalent to the purchase of an asset.

C term is for the majority of the economic life of the leased asset.

26 Under US GAAP, a lessee's accounting for a long-term finance lease after inception will include:

A recognizing a single lease expense.

B recording depreciation expense on the right-of-use asset.

C increasing the balance of the lease liability by a portion of the lease payment.

27 A company enters into a finance lease agreement to acquire the use of an asset for three years with lease payments of €19,000,000 starting next year. The leased asset has a fair market value of €49,000,000 and the present value of the lease payments is €47,250,188. Based on this information, the value of the lease liability reported on the company's balance sheet at lease inception is *closest* to:

A €47,250,188.

B €49,000,000.

C €57,000,000.

28 The following presents selected financial information for a company:

	$ Millions
Short-term borrowing	4,231
Current portion of long-term interest-bearing debt	29
Long-term interest-bearing debt	925
Average shareholders' equity	18,752
Average total assets	45,981

The financial leverage ratio is *closest* to:

A 0.113

B 0.277

C 2.452

29 An analyst evaluating three industrial companies calculates the following ratios:

	Company A	Company B	Company C
Debt-to-Equity	23.5%	22.5%	52.5%
Interest Coverage	15.6	49.5	45.5

The company with both the lowest financial leverage and the greatest ability to meet interest payments is:

A Company A.

B Company B.

C Company C.

30 An analyst evaluating a company's solvency gathers the following information:

	$ Millions
Short-term interest-bearing debt	1,258
Long-term interest-bearing debt	321
Total shareholder's equity	4,285
Total assets	8,750
EBIT	2,504
Interest payments	52

The company's debt-to-assets ratio is *closest* to:

A 0.18.

B 0.27.

C 0.37.

31 Penben Corporation has a defined benefit pension plan. At 31 December, its pension obligation is €10 million and pension assets are €9 million. Under either IFRS or US GAAP, the reporting on the balance sheet would be *closest* to which of the following?

A €10 million is shown as a liability, and €9 million appears as an asset.

B €1 million is shown as a net pension obligation.

C Pension assets and obligations are not required to be shown on the balance sheet but only disclosed in footnotes.

32 The following information is associated with a company that offers its employees a defined benefit plan:

Fair value of fund's assets	$1,500,000,000
Estimated pension obligations	$2,600,000,000
Present value of estimated pension obligations	$1,200,000,000

Based on this information, the company's balance sheet will present a net pension:

A asset of $300,000,000.

B asset of $1,400,000,000.

C liability of $1,100,000,000.

SOLUTIONS

1. B is correct. The company receives €1 million in cash from investors at the time the bonds are issued, which is recorded as a financing activity.
2. B is correct. The effective interest rate is greater than the coupon rate and the bonds will be issued at a discount.
3. A is correct. Under US GAAP, expenses incurred when issuing bonds are generally recorded as an asset and amortised to the related expense (legal, etc.) over the life of the bonds. Under IFRS, they are included in the measurement of the liability. The related cash flows are financing activities.
4. C is correct. The bonds will be issued at a premium because the coupon rate is higher than the market interest rate. The future cash outflows, the present value of the cash outflows, and the total present value are as follows:

Date	Interest Payment ($)	Present Value at Market Rate 5% ($)		Present Value at Market Rate 5% ($)	Total Present Value ($)
31 December 2015	60,000.00	57,142.86			
31 December 2016	60,000.00	54,421.77			
31 December 2017	60,000.00	51,830.26			
31 December 2018	60,000.00	49,362.15			
31 December 2019	60,000.00	47,011.57			
31 December 2020	60,000.00	44,772.92			
31 December 2021	60,000.00	42,640.88			
31 December 2022	60,000.00	40,610.36			
31 December 2023	60,000.00	38,676.53			
31 December 2024	60,000.00	36,834.80	1,000,000.00	613,913.25	
		463,304.10		613,913.25	1,077,217.35
					Sales Proceeds

The following illustrates the keystrokes for many financial calculators to calculate sales proceeds of $1,077,217.35:

Calculator Notation	Numerical Value for This Problem
N	10
% *i* or I/Y	5
FV	$1,000,000.00
PMT	$60,000.00
PV compute	X

Thus, the sales proceeds are reported on the balance sheet as an increase in long-term liability, bonds payable of $1,077,217.

5. A is correct. The bonds payable reported at issue is equal to the sales proceeds. The interest payments and future value of the bond must be discounted at the market interest rate of 3% to determine the sales proceeds.

Date	Interest Payment	Present Value at Market Rate (3%)	Face Value Payment	Present Value at Market Rate (3%)	Total Present Value
31 December 2015	$125,000.00	$121,359.22			
31 December 2016	$125,000.00	$117,824.49			
31 December 2017	$125,000.00	$114,392.71	$5,000,000.00	$4,575,708.30	
Total		$353,576.42		$4,575,708.30	$4,929,284.72

The following illustrates the keystrokes for many financial calculators to calculate sales proceeds of $4,929,284.72:

Calculator Notation	Numerical Value for This Problem
N	3
% *i* or I/Y	3.0
FV	$5,000,000.00
PMT	$125,000.00
PV compute	X

6 B is correct. The market interest rate at the time of issuance is the effective interest rate that the company incurs on the debt. The effective interest rate is the discount rate that equates the present value of the coupon payments and face value to their selling price. Consequently, the effective interest rate is 5.50%.

7 B is correct. The bonds will be issued at a discount because the market interest rate is higher than the stated rate. Discounting the future payments to their present value indicates that at the time of issue, the company will record £978,938 as both a liability and a cash inflow from financing activities. Interest expense in 2010 is £58,736 (£978,938 times 6.0 percent). During the year, the company will pay cash of £55,000 related to the interest payment, but interest expense on the income statement will also reflect £3,736 related to amortisation of the initial discount (£58,736 interest expense less the £55,000 interest payment). Thus, the value of the liability at 31 December 2010 will reflect the initial value (£978,938) plus the amortised discount (£3,736), for a total of £982,674. The cash outflow of £55,000 may be presented as either an operating or financing activity under IFRS.

8 A is correct. The coupon rate on the bonds is higher than the market rate, which indicates that the bonds will be issued at a premium. Taking the present value of each payment indicates an issue date value of €10,210,618. The interest expense is determined by multiplying the carrying amount at the beginning of the period (€10,210,618) by the market interest rate at the time of issue (6.0 percent) for an interest expense of €612,637. The value after one year will equal the beginning value less the amount of the premium amortised to date, which is the difference between the amount paid (€650,000) and the expense accrued (€612,637) or €37,363. €10,210,618 – €37,363 = €10,173,255 or €10.17 million.

9 A is correct. The future cash outflows, the present value of the cash outflows, and the total present value are as follows:

Date	Interest Payment (€)	Present Value at Market Rate 6% (€)		Present Value at Market Rate 6% (€)	Total Present Value (€)
31 December 2015	700,000.00	660,377.36			
31 December 2016	700,000.00	622,997.51			
31 December 2017	700,000.00	587,733.50			
31 December 2018	700,000.00	554,465.56			
31 December 2019	700,000.00	523,080.72			
31 December 2020	700,000.00	493,472.38			
31 December 2021	700,000.00	465,539.98			
31 December 2022	700,000.00	439,188.66			
31 December 2023	700,000.00	414,328.92			
31 December 2024	700,000.00	390,876.34	10,000,000.00	5,583,947.77	
		5,152,060.94		5,583,947.77	10,736,008.71
					Sales Proceeds

The following illustrates the keystrokes for many financial calculators to calculate sales proceeds of €10,736,008.71:

Calculator Notation	Numerical Value for This Problem
N	10
% *i* or I/Y	6
FV	$10,000,000.00
PMT	$700,000.00
PV compute	X

The interest expense is calculated by multiplying the carrying amount at the beginning of the year by the effective interest rate at issuance. As a result, the interest expense at 31 December 2015 is €644,161 (€10,736,008.71 × 6%).

10 C is correct. The future cash outflows, the present value of the cash outflows, and the total present value are as follows:

Date	Interest Payment ($)	Present Value at Market Rate 5% ($)		Present Value at Market Rate 5% ($)	Total Present Value ($)
31 December 2015	1,200,000	1,142,857.14			
31 December 2016	1,200,000	1,088,435.37			
31 December 2017	1,200,000	1,036,605.12			
31 December 2018	1,200,000	987,242.97			
31 December 2019	1,200,000	940,231.40	30,000,000	23,505,785.00	
		5,195,372.00		23,505,785.00	28,701,157.00
					Sales Proceeds

The following illustrates the keystrokes for many financial calculators to calculate sales proceeds of $28,701,157.00:

Calculator Notation	Numerical Value for This Problem
N	5
% *i* or I/Y	5
FV	$30,000,000.00
PMT	$1,200,000.00
PV compute	X

The following table illustrates interest expense, premium amortization, and carrying amount (amortized cost) for 2015.

Year	Carrying Amount (beginning of year)	Interest Expense (at effective interest rate of 5%)	Interest Payment (at coupon rate of 4%)	Amortization of Discount	Carrying Amount (end of year)
2015	$28,701,157.00	$1,435,057.85	$1,200,000.00	$235,057.85	$28,936,214.85

The carrying amount at the end of the year is found by adding the amortization of the discount to the carrying amount at the beginning of the year. As a result, the carrying amount on 31 December 2015 is $28,936,215.

Alternatively, the following illustrates the keystrokes for many financial calculators to calculate the carrying value at the end of first year of $28,936, 215:

Calculator Notation	Numerical Value for This Problem
N	4
% *i* or I/Y	5
FV	$30,000,000.00
PMT	$1,200,000.00
PV compute	X

11 B is correct. The interest expense for a given year is equal to the carrying amount at the beginning of the year times the effective interest of 4%. Under the effective interest rate method, the difference between the interest expense and the interest payment (based on the coupon rate and face value) is the discount amortized in the period, which increases the carrying amount annually. For 2017, the interest expense is the beginning carrying amount ($1,944,499) times the effective interest of 4%.

Year	Carrying Amount (beginning)	Interest Expense (at effective interest of 4%)	Interest Payment (at coupon rate of 3%)	Amortization of Discount	Carrying Amount (end of year)
2015	$1,910,964	$76,439	$60,000.00	$16,439	$1,927,403
2016	$1,927,403	$77,096	$60,000.00	$17,096	$1,944,499
2017	$1,944,499	$77,780	$60,000.00	$17,780	$1,962,279

12 B is correct. The amortization of the premium equals the interest payment minus the interest expense. The interest payment is constant and the interest expense decreases as the carrying amount decreases. As a result, the amortization of the premium increases each year.

13 B is correct. Under the straight-line method, the bond premium is amortized equally over the life of the bond. The annual interest payment is \$165,000 (\$3,000,000 × 5.5%) and annual amortization of the premium under the straight-line method is \$13,616 [(\$3,040,849 – \$3,000,000)/3)]. The interest expense is the interest payment less the amortization of the premium (\$165,000 – \$13,616 = \$151,384).

14 C is correct. A gain of €3.3 million (carrying amount less amount paid) will be reported on the income statement.

15 B is correct. If a company decides to redeem a bond before maturity, bonds payable is reduced by the carrying amount of the debt. The difference between the cash required to redeem the bonds and the carrying amount of the bonds is a gain or loss on the extinguishment of debt. Because the call price is 104 and the face value is \$1,000,000, the redemption cost is 104% of \$1,000,000 or \$1,040,000. The company's loss on redemption would be \$50,000 (\$990,000 carrying amount of debt minus \$1,040,000 cash paid to redeem the callable bonds).

16 A is correct. The value of the liability for zero-coupon bonds increases as the discount is amortised over time. Furthermore, the amortised interest will reduce earnings at an increasing rate over time as the value of the liability increases. Higher relative debt and lower relative equity (through retained earnings) will cause the debt-to-equity ratio to increase as the zero-coupon bonds approach maturity.

17 A is correct. When interest rates rise, bonds decline in value. Thus, the carrying amount of the bonds being carried on the balance sheet is higher than the market value. The company could repurchase the bonds for less than the carrying amount, so the economic liabilities are overestimated. Because the bonds are issued at a fixed rate, there is no effect on interest coverage.

18 C is correct. Affirmative covenants require certain actions of the borrower. Requiring the company to perform regular maintenance on equipment pledged as collateral is an example of an affirmative covenant because it requires the company to do something. Negative covenants require that the borrower not take certain actions. Prohibiting the borrower from entering into mergers and preventing the borrower from issuing excessive additional debt are examples of negative covenants.

19 C is correct. Covenants protect debtholders from excessive risk taking, typically by limiting the issuer's ability to use cash or by limiting the overall levels of debt relative to income and equity. Issuing additional equity would increase the company's ability to meet its obligations, so debtholders would not restrict that ability.

20 C is correct. The non-current liabilities section of the balance sheet usually includes a single line item of the total amount of a company's long-term debt due after 1 year, and the current liabilities section shows the portion of a company's long-term debt due in the next 12 months. Notes to the financial statements generally present the stated and effective interest rates and maturity dates for a company's debt obligations

21 C is correct. Beginning with fiscal year 2019, lessees report a right-of-use asset and a lease liability for all leases longer than one year. An exception under IFRS exists for leases when the underlying asset is of low value.

22 C is correct. When a lease is classified as an operating lease, the underlying asset remains on the lessor's balance sheet. The lessor will record a depreciation expense that reduces the asset's value over time.

23 A is correct. A sales-type lease treats the lease as a sale of the asset, and revenue is recorded at the time of sale equal to the value of the leased asset. Under a direct financing lease, only interest income is reported as earned. Under an operating lease, revenue from lease receipts is reported when collected.

24 C is correct. Lessor accounting for an operating lease under US GAAP is similar to that under IFRS: Over the lease term, the lessor recognizes lease receipts as income and recognizes related costs, including depreciation of the leased asset, as expenses. Under IFRS, at inception of a finance lease—not an operating lease—the lessor derecognizes the underlying leased asset and recognizes a lease asset comprising the lease receivable and relevant residual value. Further, an IFRS-reporting lessor will recognize selling profit at the beginning of all leases that are not classified as operating leases. In contrast, a US GAAP–reporting lessor will recognize selling profit only on sales-type leases at the beginning of the lease term.

25 A is correct. An operating lease is an agreement that allows the lessee to use an asset for a period of time. Thus, an operating lease is similar to renting an asset, whereas a finance lease is equivalent to the purchase of an asset by the lessee that is directly financed by the lessor.

26 B is correct. A lessee's accounting for a long-term finance lease under US GAAP and after lease inception includes recording depreciation expense on the right-of-use asset, recognizing interest expense on the lease liability, and reducing the balance of the lease liability for the portion of the lease payments that represents repayment of the lease liability. A lessee's accounting for an operating lease under US GAAP and after lease inception will recognize a single lease expense, which is a straight-line allocation of the cost of the lease over its term.

27 A is correct. Under the revised reporting standards under IFRS and US GAAP, a lessee must recognize an asset and a lease liability at inception of each of its leases (with an exception for short-term leases). The lessee reports a "right-of-use" (ROU) asset and a lease liability, calculated essentially as the present value of fixed lease payments, on its balance sheet. Thus, at lease inception, the company will record a lease liability on the balance sheet of €47,250,188.

28 C is correct. The financial leverage ratio is calculated as follows:

$$\frac{\text{Average total assets}}{\text{Average shareholder's equity}} = \frac{\$45{,}981\text{ million}}{\$18{,}752\text{ million}} = \$2.452\text{ million}$$

29 B is correct. Company B has the lowest debt-to-equity ratio, indicating the lowest financial leverage, and the highest interest coverage ratio, indicating the greatest number of times that EBIT covers interest payments.

30 A is correct because the debt-to-assets (total debt)/(total assets) ratio is (1,258 + 321)/(8,750) = 1,579/8,750 = 0.18

31 B is correct. The company will report a net pension obligation of €1 million equal to the pension obligation (€10 million) less the plan assets (€9 million).

32 A is correct. A company that offers a defined benefit plan makes payments into a pension fund and the retirees are paid from the fund. The payments that a company makes into the fund are invested until they are needed to pay retirees. If the fair value of the fund's assets is higher than the present value of the estimated pension obligation, the plan has a surplus and the company's balance sheet will reflect a net pension asset. Because the fair value of the fund's assets is $1,500,000,000 and the present value of estimated pension obligations is $1,200,000,000, the company will present a net pension asset of $300,000,000 on its balance sheet.

FINANCIAL STATEMENT ANALYSIS

STUDY SESSION

8

Financial Statement Analysis (4)

This study session introduces the concept of financial reporting quality. The session examines the financial reporting quality differences that may exist between companies and the means for identifying them. Warning signs of poor or low quality reporting are covered. The application of financial analysis techniques to evaluate a company's past and projected performance, assess credit risk, and screen for potential equity investments follows. Common adjustments to reported financials to facilitate cross-company comparisons conclude the session.

READING ASSIGNMENTS

Reading 25	Financial Reporting Quality by Jack T. Ciesielski, CPA, CFA, Elaine Henry, PhD, CFA, and Thomas I. Selling, PhD, CPA
Reading 26	Applications of Financial Statement Analysis by Thomas R. Robinson, PhD, CFA, J. Hennie van Greuning, DCom, CFA, Elaine Henry, PhD, CFA, and Michael A. Broihahn, CPA, CIA, CFA

Note: Changes in accounting standards as well as new rulings and/or pronouncements issued after the publication of the readings on financial reporting and analysis may cause some of the information in these readings to become dated. Candidates are *not* responsible for anything that occurs after the readings were published. In addition, candidates are expected to be familiar with the analytical frameworks contained in the readings, as well as the implications of alternative accounting methods for financial analysis and valuation discussed in the readings. Candidates are also responsible for the content of accounting standards, but not for the actual reference numbers. Finally, candidates should be aware that certain ratios may be defined and calculated differently. When alternative ratio definitions exist and no specific definition is given, candidates should use the ratio definitions emphasized in the readings.

Financial Reporting Quality

by Jack T. Ciesielski, CPA, CFA, Elaine Henry, PhD, CFA, and
Thomas I. Selling, PhD, CPA

Jack T. Ciesielski, CPA, CFA, is at R.G. Associates, Inc., former publisher of The Analyst's Accounting Observer (USA). Elaine Henry, PhD, CFA, is at Stevens Institute of Technology (USA). Thomas I. Selling, PhD, CPA, is at the Cox School of Business, Southern Methodist University (USA).

LEARNING OUTCOMES

Mastery	*The candidate should be able to:*
☐	**a.** compare and contrast financial reporting quality with the quality of reported results (including quality of earnings, cash flow, and balance sheet items);
☐	**b.** describe a spectrum for assessing financial reporting quality;
☐	**c.** explain the difference between conservative and aggressive accounting;
☐	**d.** describe motivations that might cause management to issue financial reports that are not high quality;
☐	**e.** describe conditions that are conducive to issuing low-quality, or even fraudulent, financial reports;
☐	**f.** describe mechanisms that discipline financial reporting quality and the potential limitations of those mechanisms;
☐	**g.** describe presentation choices, including non-GAAP measures, that could be used to influence an analyst's opinion;
☐	**h.** describe accounting methods (choices and estimates) that could be used to manage earnings, cash flow, and balance sheet items;
☐	**i.** describe accounting warning signs and methods for detecting manipulation of information in financial reports.

Note: Changes in accounting standards as well as new rulings and/or pronouncements issued after the publication of the readings on financial reporting and analysis may cause some of the information in these readings to become dated. Candidates are *not* responsible for anything that occurs after the readings were published. In addition, candidates are expected to be familiar with the analytical frameworks contained in the readings, as well as the implications of alternative accounting methods for financial analysis and valuation discussed in the readings. Candidates are also responsible for the content of accounting standards, but not for the actual reference numbers. Finally, candidates should be aware that certain ratios may be defined and calculated differently. When alternative ratio definitions exist and no specific definition is given, candidates should use the ratio definitions emphasized in the readings.

1 INTRODUCTION & CONCEPTUAL OVERVIEW

a compare and contrast financial reporting quality with the quality of reported results (including quality of earnings, cash flow, and balance sheet items);

b describe a spectrum for assessing financial reporting quality;

Ideally, analysts would always have access to financial reports that are based on sound financial reporting standards, such as those from the International Accounting Standards Board (IASB) and the Financial Accounting Standards Board (FASB), and are free from manipulation. But, in practice, the quality of financial reports can vary greatly. High-quality financial reporting provides information that is useful to analysts in assessing a company's performance and prospects. Low-quality financial reporting contains inaccurate, misleading, or incomplete information.

Extreme lapses in financial reporting quality have given rise to high-profile scandals that resulted not only in investor losses but also in reduced confidence in the financial system. Financial statement users who were able to accurately assess financial reporting quality were better positioned to avoid losses. These lapses illustrate the challenges analysts face as well as the potential costs of failing to recognize practices that result in misleading or inaccurate financial reports.[1] Examples of misreporting can provide an analyst with insight into various signals that may indicate poor-quality financial reports.

This reading addresses *financial reporting quality*, which pertains to the quality of information in financial reports, including disclosures in notes. High-quality reporting provides decision-useful information, which is relevant and faithfully represents the economic reality of the company's activities during the reporting period as well as the company's financial condition at the end of the period. A separate but interrelated attribute of quality is *quality of reported results* or *earnings quality*, which pertains to the earnings and cash generated by the company's actual economic activities and the resulting financial condition. The term "earnings quality" is commonly used in practice and will be used broadly to encompass the quality of earnings, cash flow, and/or balance sheet items. High-quality earnings result from activities that a company will likely be able to sustain in the future and provide a sufficient return on the company's investment. The concepts of earnings quality and financial reporting quality are interrelated because a correct assessment of earnings quality is possible only when there is some basic level of financial reporting quality. Beyond this basic level, as the quality of reporting increases, the ability of financial statement users to correctly assess earnings quality and to develop expectations for future performance arguably also increases.

Sections 1–5 provide a conceptual overview of reporting quality. Sections 6 and 7 discuss motivations that might cause, and conditions that might enable, management to issue financial reports that are not high quality and mechanisms that aim to provide discipline to financial reporting quality. Sections 8–12 describe choices made by management that can affect financial reporting quality—presentation choices, accounting methods, and estimates—as well as warning signs of poor-quality financial reporting.

---

[1] In this reading, the examples of misleading or inaccurate financial reports occurred in prior years—*not* because there are no current examples of questionable financial reporting, but rather because it has been conclusively resolved that misreporting occurred in the historical examples.

1.1 Conceptual Overview

As indicated in the introduction, financial reporting quality and results or earnings quality are interrelated attributes of quality. Exhibit 1 illustrates this interrelationship and its implications.

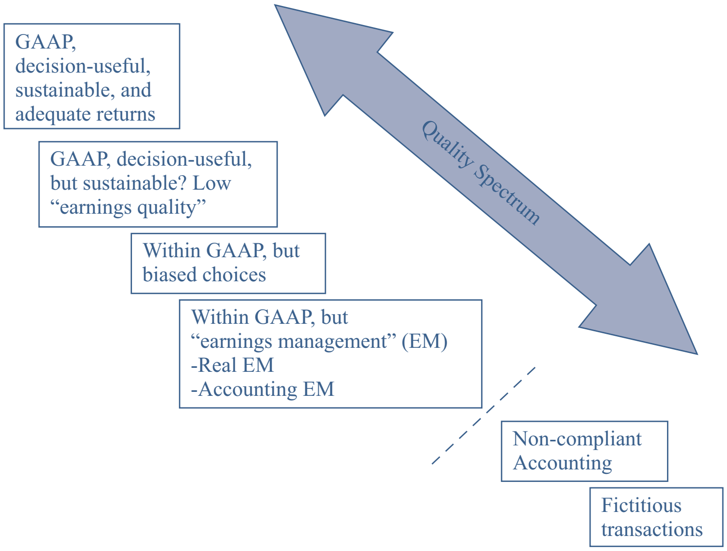
Exhibit 1 Relationships between Financial Reporting Quality and Earnings Quality

		Financial Reporting Quality	
		Low	**High**
Earnings (Results) Quality	High	LOW financial reporting quality impedes assessment of earnings quality and impedes valuation.	HIGH financial reporting quality enables assessment. HIGH earnings quality increases company value.
	Low		HIGH financial reporting quality enables assessment. LOW earnings quality decreases company value.

As can be seen in Exhibit 1, if financial reporting quality is low, the information provided is of little use in assessing the company's performance, and thus in making investment and other decisions.

Financial reporting quality varies across companies. High-quality reports contain information that is relevant, complete, neutral, and free from error. The lowest-quality reports contain information that is pure fabrication. Earnings (results) quality can range from high and sustainable to low and unsustainable. Providers of resources prefer high and sustainable earnings. Combining the two measures of quality—financial reporting and earnings—the overall quality of financial reports from a user perspective can be thought of as spanning a continuum from the highest to the lowest. Exhibit 2 presents a quality spectrum that provides a basis for evaluating better versus poorer quality reports. This spectrum ranges from reports that are of high financial reporting quality and reflect high and sustainable earnings quality to reports that are not useful because of poor financial reporting quality.

Exhibit 2 Quality Spectrum of Financial Reports



GAAP, decision-useful, sustainable, and adequate returns
GAAP, decision-useful, but sustainable? Low "earnings quality"
Within GAAP, but biased choices
Within GAAP, but "earnings management" (EM) -Real EM -Accounting EM
Non-compliant Accounting
Fictitious transactions
Quality Spectrum

2 GAAP, DECISION USEFUL FINANCIAL REPORTING

b describe a spectrum for assessing financial reporting quality;

At the top of the spectrum, labeled in Exhibit 2 as "GAAP, decision-useful, sustainable, and adequate returns," are high-quality reports that provide useful information about high-quality earnings.

- High-quality financial reports conform to the generally accepted accounting principles (GAAP) of the jurisdiction, such as International Financial Reporting Standards (IFRS), US GAAP, or other home-country GAAP. The exhibit uses the term GAAP to refer generically to the accounting standards accepted in a company's jurisdiction.
- In addition to conforming to GAAP, high-quality financial reports also embody the characteristics of decision-useful information such as those defined in the *Conceptual Framework*.[2] Recall that the fundamental characteristics of useful information are relevance and faithful representation. Relevant information is defined as information that can affect a decision and encompasses the notion of materiality. (Information is considered material if "omitting it or misstating it

---

[2] The characteristics of decision-useful information are identical under IFRS and US GAAP. In September 2010, the IASB adopted the *Conceptual Framework for Financial Reporting* in place of the *Framework for the Preparation and Presentation of Financial Statements* (1989). The *Conceptual Framework* represents the partial completion of a joint convergence project between the IASB and FASB on an updated framework. The *Conceptual Framework* (2010) contains two updated chapters: "The Objective of Financial Reporting" and "Qualitative Characteristics of Useful Financial Information." The remainder of the material in the *Conceptual Framework* is from the *Framework* (1989) and will be updated as the project is completed. Also in September 2010, the FASB issued Concepts Statement 8, "Conceptual Framework for Financial Reporting," to replace Concepts Statements 1 and 2.

could influence decisions that users make on the basis of the financial information of a specific reporting entity."[3]) Faithful representation of economic events is complete, neutral, and free from error.

The *Conceptual Framework* also enumerates enhancing characteristics of useful information: comparability, verifiability, timeliness, and understandability. Of course, the desirable characteristics for financial information require trade-offs. For example, financial reports must balance the aim of providing information that is produced quickly enough to be timely and thus relevant, and yet not so quickly that errors occur. Financial reports must balance the aim of providing information that is complete but not so exhaustive that immaterial information is included. High-quality information results when these and other tradeoffs are made in an unbiased, skillful manner.

- High-quality earnings indicate an adequate level of return on investment and derive from activities that a company will likely be able to sustain in the future. An adequate level of return on investment exceeds the cost of the investment and also equals or exceeds the expected return. Sustainable activities and sustainable earnings are those expected to recur in the future. Sustainable earnings that provide a high return on investment contribute to higher valuation of a company and its securities.

2.1 GAAP, Decision-Useful, but Sustainable?

The next level down in Exhibit 2, "GAAP, decision-useful, but sustainable?" refers to circumstances in which high-quality reporting provides useful information, but that information reflects results or earnings that are not sustainable (lower earnings quality). The earnings may not be sustainable because the company cannot expect earnings that generate the same level of return on investment in the future or because the earnings, although replicable, will not generate sufficient return on investment to sustain the company. Earnings quality is low in both cases. Reporting can be high quality even when the economic reality being depicted is not of high quality. For example, consider a company that generates a loss, or earnings that do not provide an adequate return on investment, or earnings that resulted from non-recurring activities. The relatively undesirable economic reality could nonetheless be depicted in financial reporting that provides high-quality, decision-useful information.

Exhibit 3 presents an excerpt from the fiscal year 2014 first-quarter results of Toyota Motor Corporation, a Japanese automobile company. As highlighted by a *Wall Street Journal* article,[4] the company sold fewer cars but reported an 88% increase in operating profits compared with the prior year, primarily because of the change in exchange rates. The weaker yen benefited Toyota both because the company manufactures more cars in Japan (compared with its competitors) and because the company sells a significant number of cars outside of Japan. Exchange rate weakening is a less sustainable source of profits than manufacturing and selling cars. In summary, this example is a case of high-quality financial reporting coupled with lower earnings quality.

---

[3] Text from conceptual frameworks referenced in Note 4.

[4] Back (2013).

Exhibit 3 Excerpt from Toyota Motor Corporation's Consolidated Financial Results for FY2014 First Quarter Ending 30 June 2013

Consolidated vehicle unit sales in Japan and overseas decreased by 37 thousand units, or 1.6%, to 2,232 thousand units in FY2014 first quarter (the three months ended June 30, 2013) compared with FY2013 first quarter (the three months ended June 30, 2012). Vehicle unit sales in Japan decreased by 51 thousand units, or 8.8%, to 526 thousand units in FY2014 first quarter compared with FY2013 first quarter. Meanwhile, overseas vehicle unit sales increased by 14 thousand units, or 0.8%, to 1,706 thousand units in FY2014 first quarter compared with FY2013 first quarter.

As for the results of operations, net revenues increased by 753.7 billion yen, or 13.7%, to 6,255.3 billion yen in FY2014 first quarter compared with FY2013 first quarter, and operating income increased by 310.2 billion yen, or 87.9%, to 663.3 billion yen in FY2014 first quarter compared with FY2013 first quarter. The factors contributing to an increase in operating income were the effects of changes in exchange rates of 260.0 billion yen, cost reduction efforts of 70.0 billion yen, marketing efforts of 30.0 billion yen and other factors of 10.2 billion yen. On the other hand, the factors contributing to a decrease in operating income were the increase in expenses and others of 60.0 billion yen.

3 BIASED ACCOUNTING CHOICES

b describe a spectrum for assessing financial reporting quality;

c explain the difference between conservative and aggressive accounting;

The next level down in the spectrum in Exhibit 2 is "Within GAAP, but biased choices." Biased choices result in financial reports that do not faithfully represent the economic substance of what is being reported. The problem with bias in financial reporting, as with other deficiencies in reporting quality, is that it impedes an investor's ability to correctly assess a company's past performance, to accurately forecast future performance, and thus to appropriately value the company.

Choices are deemed to be "aggressive" if they increase a company's reported performance and financial position in the period under review. The choice can increase the amount of revenues, earnings, and/or operating cash flow reported for the period, or decrease expenses, and/or reduce the level of debt reported on the balance sheet. Aggressive choices may lead to a reduction in the company's reported performance and in its financial position in later periods. In contrast, choices are deemed "conservative" if they decrease a company's performance and financial position in the reporting period. This can include lowering the reported revenues, earnings, and/or operating cash flow reported or increasing expenses, or recording a higher level of debt on the balance sheet. Conservative choices may lead to a rise in the company's reported performance and financial position in later periods.

Another type of bias is understatement of earnings volatility, so-called earnings "smoothing". Earnings smoothing can result from conservative choices to understate earnings in periods when a company's operations are performing well, building up (often hidden) reserves that allow aggressive choices in periods when its operations are struggling.

Biased choices can be made not only in the context of reported amounts but also in the context of how information is presented. For example, companies can disclose information transparently, which facilitates analysis, or they can disclose it in a manner that aims to obscure unfavorable and/or emphasize favorable information.

EXAMPLE 1

Quality of Financial Reports

PACCAR Inc. designs, manufactures, and distributes trucks and related aftermarket parts that are sold worldwide under the Kenworth, Peterbilt, and DAF nameplates. In 2013, the US SEC charged PACCAR for various accounting deficiencies that "clouded their financial reporting to investors in the midst of the financial crisis." The SEC complaint cites the company's 2009 segment reporting. Exhibit 4A presents an excerpt from the notes to PACCAR's financial statements, and Exhibit 4B presents an excerpt from the management's discussion and analysis (MD&A) of PACCAR's annual report.

Exhibit 4A Excerpt from Notes to PACCAR's 2009 Financial Statements

S. SEGMENT AND RELATED INFORMATION

PACCAR operates in two principal segments, Truck and Financial Services. The Truck segment includes the manufacture of trucks and the distribution of related aftermarket parts, both of which are sold through a network of independent dealers... The Financial Services segment is composed of finance and leasing products and services provided to truck customers and dealers … Included in All Other is PACCAR's industrial winch manufacturing business. Also within this category are other sales, income and expenses not attributable to a reportable segment, including a portion of corporate expense.

Business Segment Data ($ millions)

	2009	2008	2007
Income before Income Taxes			
Truck	$25.9	$1,156.5	$1,352.8
All other	42.2	6.0	32.0
	68.1	1,162.5	1,384.8
Financial services	84.6	216.9	284.1
Investment income	22.3	84.6	95.4
	$175.0	$1,464.0	$1,764.3

Exhibit 4B Excerpt from MD&A of PACCAR's 2009 Annual Report

Net sales and revenues and gross margins for truck units and aftermarket parts are provided below. The aftermarket parts gross margin includes direct revenues and costs, but excludes certain truck segment costs.

(continued)

Exhibit 4B (Continued)

	2009	2008	% Change
Net Sales and Revenues			
Trucks	$5,103.30	$11,281.30	–55
Aftermarket parts	1,890.70	2,266.10	–17
	$6,994.00	$13,547.40	–48
Gross Margin			
Trucks	–$46.6	$1,141.70	–104
Aftermarket parts	625.7	795.20	–21
	$579.1	$1,936.90	–70

1 Based on the segment data excerpted from the notes to the financial statements, was PACCAR's truck segment profitable in 2009?

2 Based on the data about the truck's gross margin presented in the MD&A, was PACCAR's truck segment profitable in 2009?

3 What is the main difference between the note presentation and the MD&A presentation?

4 The SEC complaint stated that "PACCAR failed to report the operating results of its aftermarket parts business separately from its truck sales business as required under segment reporting requirements, which are in place to ensure that investors gain the same insight into a company as its executives." Is the PACCAR situation an example of issues with financial reporting quality, earnings quality, or both?

Solution to 1:

Yes, the segment data presented in the note to the financial statements indicates that the Truck segment earned $25.9 million in 2009.

Solution to 2:

No, the segment data presented in the MD&A indicates that the Truck segment had a negative gross margin.

Solution to 3:

The main difference between the note presentation and the MD&A presentation is that the aftermarket parts business is combined with the trucks business in the notes but separated in the MD&A. Although the data are not exactly comparable in the two disclosures (because the note shows income before taxes and the MD&A shows gross profit), the two disclosures present a different picture of PACCAR's profits from truck sales.

Solution to 4:

The PACCAR situation appears to be an example of issues with both financial reporting quality and earnings quality. The substantial decrease in truck sales and the negative gross margin reflect poor earnings quality. The failure to disclose clear segment information is an instance of poor financial reporting quality.

While choices exist within GAAP for the presentation of a desired economic picture, non-GAAP reporting adds yet another dimension of management discretion. Non-GAAP reporting of financial metrics not in compliance with generally accepted accounting principles such as US GAAP and IFRS includes both financial metrics and operating metrics.[5] Non-GAAP financial metrics relate directly to the financial statements. A common non-GAAP financial metric is "non-GAAP earnings," which are created by companies "that adjust standards-compliant earnings to *exclude items required* by accounting standards or to *include items not permitted* by accounting standards" (Ciesielski and Henry, 2017). In contrast, non-GAAP operating metrics do not relate directly to the financial statements and include metrics that are typically industry-driven, such as subscriber numbers, active users, and occupancy rates.

Non-GAAP financial reporting has become increasingly common, presenting challenges to analysts. An important challenge is that non-GAAP financial reporting diminishes comparability across financial statements. The adjustments that companies make to create non-GAAP earnings, for example, are generally ad hoc and thus differ significantly. When evaluating non-GAAP metrics, investors must decide the extent to which specific adjustments should be incorporated into their analyses and forecasts.[6]

Another challenge arises from differences in terminology. Non-GAAP earnings are sometimes referred to as underlying earnings, adjusted earnings, recurring earnings, core earnings, or similar. Exhibit 5 provides an example from Jaguar Land Rover Automotive plc (JLR), a subsidiary of Tata Motors Ltd. The company prepares its financial reports under IFRS. The exhibit is an excerpt from JLR's 2016/17 annual report and uses the term "alternative performance measures". Exhibit 6 is from Tata Motors Ltd's Form 6-K filed with the US SEC, containing supplemental information regarding JLR and using the term "non-IFRS Financial Measures". The information in the two exhibits is essentially identical, but the terminology and formatting differ.

Exhibit 5

JLR's 2016/17 Annual Report: Footnote 3 [Excerpt]

3) ALTERNATIVE PERFORMANCE MEASURES

Many companies use alternative performance measures (APMs) to provide helpful additional information for users of their financial statements, telling a clearer story of how the business has performed over the period... These measures exclude certain items that are included in comparable statutory measures….

Reconciliations between these alternative performance measures and statutory reported measures are shown below.

EBIT AND EBITDA (£m)

Year ended 31 March	2017
EBITDA	**2,955**
Depreciation and amortisation	–1,656
Share of profit/(loss) of equity accounted investments	159
EBIT	**1,458**

(continued)

---

[5] The term "non-GAAP" refers generally to all metrics that are non-compliant with generally accepted accounting principles and thus includes "non-IFRS" metrics.

[6] A survey of non-GAAP earnings in the S&P 500 is presented in Ciesielski and Henry (2017). Some observers even recommend that investors shift their focus from a company's earnings to a company's "strategic assets" and the contribution of these assets to its competitive edge (Gu and Lev, 2017).

Exhibit 5 (Continued)

Year ended 31 March	2017
Foreign exchange (loss)/gain on derivatives	–11
Unrealised gain/(loss) on commodities	148
Foreign exchange loss on loans	–101
Finance income	33
Finance expense (net)	–68
Exceptional item	151
Profit before tax	**1,610**

Exhibit 6

Tata Motors Ltd. SEC Form 6-K [Excerpt]

Non-IFRS Financial Measures

This Report includes references to certain non-IFRS measures, including EBITDA, EBIT … [These measures] and related ratios should not be considered in isolation and are not measures of JLR's financial performance or liquidity under IFRS and should not be considered as an alternative to profit or loss for the period or any other performance measures derived in accordance with IFRS or as an alternative to cash flow from operating, investing or financing activities or any other measure of JLR's liquidity derived in accordance with IFRS. … In addition, EBITDA, EBIT… as defined, may not be comparable to other similarly titled measures used by other companies.

Exhibit 1 to Form 6-K Supplemental Information Regarding the Jaguar and Land Rover Business of Tata Motors Limited [Excerpt]

The reconciliation of JLR's EBIT and EBITDA to profit for the period line item is:

Fiscal year ended March 31, 2017	£m
Profit for the period	1,272
Add back taxation	338
Add/(less) back exceptional charge/(credit)	–151
Add back/(less) foreign exchange (gains)/loss – financing	101
Add back/(less) foreign exchange (gains)/loss – derivatives	11
Add back/(less) unrealized commodity losses/(gains) – unrealized derivatives	–148
Less finance income	–33
Add back finance expense (net)	68
EBIT	**1,458**
Add back depreciation and amortization	1,656

Exhibit 1 (Continued)

Fiscal year ended March 31, 2017	£m
Add/(less) back share of loss/(profit) from equity accounted investees	–159
EBITDA	**2,955**

Management emphasis on non-GAAP financial measures to deflect attention from less-than-desirable GAAP financial results is an example of an aggressive presentation choice. Since 2003, if a company uses a non-GAAP financial measure[7] in an SEC filing, it is required to display the most directly comparable GAAP measure with equal prominence and to provide a reconciliation between the non-GAAP measure and the equivalent GAAP measure. In other words, a company is not allowed to give more prominence to a non-GAAP financial measure in an SEC filing.

Similarly, the IFRS Practice Statement "Management Commentary," issued December 2010, requires disclosures when non-IFRS measures are included in financial reports:

> If information from the financial statements has been adjusted for inclusion in management commentary, that fact should be disclosed. If financial performance measures that are not required or defined by IFRSs are included within management commentary, those measures should be defined and explained, including an explanation of the relevance of the measure to users. When financial performance measures are derived or drawn from the financial statements, those measures should be reconciled to measures presented in the financial statements that have been prepared in accordance with IFRSs. (Page 17)

The reconciliation between as-reported measures (GAAP financial measures presented in the financial statements) and as-adjusted measures (non-GAAP financial measures presented in places other than the financial statements) can provide important information.

The European Securities and Markets Authority (ESMA) published guidelines in October 2015 *(ESMA Guidelines on Alternative Performance Measures)* covering such points as the definition of APMs, reconciliation to GAAP, explanation of the metrics' relevance, and consistency over time. We discuss ESMA in more detail later in this reading.

EXAMPLE 2

Presentation of Non-GAAP Financial Measures

Convatec Group PLC (Convatec), a global medical products manufacturer, raised $1.8 billion via an initial public offering (IPO) on the London Stock Exchange in 2016. The company had been purchased by private equity firms from Bristol-Myers Squibb in 2008 for $4.1 billion. Exhibit 7 presents excerpts from the company's regulatory filing at the London Stock Exchange announcing its full year 2016 results.

---

[7] Non-domestic private issuers can file financial statements prepared in accordance with IFRS without reconciliation to US GAAP. The SEC recognizes US GAAP and IFRS as GAAP.

Exhibit 7 Excerpt from ConvaTec's Press Release for Full Year 2016 Results

Headline: "Strong results, delivering on strategy"

CEO Review [Excerpt]

At constant currency, revenue grew 4% to $1,688 million and adjusted EBITDA was $508 million, up 6.5% at constant currency...

[Footnote] Constant currency growth 'CER' is calculated by restating 2016 results using 2015 foreign exchange rates for the relevant period.

Consolidated Statement of Profit or Loss for the year ended 31 December 2016 ($ m)

	2016	2015
Revenue	1,688.3	1,650.4
Cost of goods sold	–821.0	–799.9
Gross profit	867.3	850.5
Selling and distribution expenses	–357.0	–346.7
General and administrative expenses	–318.2	–233.1
Research and development expenses	–38.1	–40.3
Operating profit	154.0	230.4
Finance costs	–271.4	–303.6
Other expense, net	–8.4	–37.1
Loss before income taxes	–125.8	–110.3
Income tax (expense) benefit	–77.0	16.9
Net loss	–202.8	–93.4

Non-IFRS Financial Information [Excerpt]

This release contains certain financial measures that are not defined or recognised under IFRS. These measures are referred to as "Adjusted" measures... These measures are not measurements of financial performance or liquidity under IFRS and should not replace measures of liquidity or operating profit that are derived in accordance with IFRS.

Reconciliation to adjusted earnings [Excerpt]

2016	Reported	(a)	(b)	(c)	(d)	(e)	(f)	(g)	Adjusted
Revenue	1,688.3	—	—	—	—	—	—	—	1,688.3
…									
Operating profit	**154.0**	**155.1**	**30.9**	**11.7**	**0.8**	**—**	**90.2**	**29.5**	**472.2**
…									
(Loss) profit before income taxes	–125.8	155.1	30.9	11.7	0.8	37.6	90.2	29.5	230.0

2016	Reported	(a)	(b)	(c)	(d)	(e)	(f)	(g)	Adjusted
Income tax expense(h)	–77.0								–51.2
Net (loss) profit	–202.8								178.8

(a) Represents an adjustment to exclude (i) acquisition-related amortisation expense … (ii) accelerated depreciation …related to the closure of certain manufacturing facilities, and (iii) impairment charges and assets write offs related to property, plant and equipment and intangible assets ….

(b) Represents restructuring costs and other related costs …

(c) Represents remediation costs which include regulatory compliance costs related to FDA activities, IT enhancement costs, and professional service fees associated with activities that were undertaken in respect of the Group's compliance function and to strengthen its control environment within finance.

(d) Represents costs primarily related to (i) corporate development activities and (ii) a settlement of ordinary course multi-year patent-related litigations in 2015 ….

(e) Represents adjustments to exclude (i) loss on extinguishment of debt and write off of deferred financing fees … and (ii) foreign exchange related transactions.

(f) Represents an adjustment to exclude (i) share-based compensation expense … arising from pre-IPO employee equity grants and (ii) pre-IPO ownership structure related costs, including management fees to Nordic Capital and Avista (refer to Note 6 Related Party Transactions for further information).

(g) Represents IPO related costs, primary advisory fees.

(h) Adjusted income tax expense/benefit is income tax (expense) benefit net of tax adjustments.

Adjusted EBITDA [Excerpt]

Adjusted EBITDA is defined as Adjusted EBIT…further adjusted to exclude (i) software and R&D amortisation, (ii) depreciation and (iii) post-IPO share-based compensation.

The following table reconciles the Group's Adjusted EBIT to Adjusted EBITDA.

	2016 ($m)
Adjusted EBIT	472.2
Software and R&D amortization	6.7
Depreciation	27.9
Post-IPO share-based compensation	0.8
Adjusted EBITDA	507.6

1 Based on the information provided, explain the differences between the following two disclosures contained in Convatec's press release:

- **A** The CEO Review of 2016 results, at the beginning of the release, states that "revenue grew 4% to $1,688 million."
- **B** Convatec's Consolidated Statement of Profit or Loss shows 2016 revenues of $1,688.3 million and 2015 revenues of $1,650.4 million.

2 Based on the information provided, explain the differences between the following two disclosures contained in Convatecs's earnings release:

- **A** The CEO Review of 2016 results states that "adjusted EBITDA was $508 million, up 6.5% at constant currency."
- **B** Convatec's Consolidated Statement of Profit or Loss shows 2016 net loss of $202.8 million and 2015 net loss of $93.4 million.

Solution to 1:

The amount of revenue reported on the company's income statement conforms to International Financial Reporting Standards (IFRS). Using the amounts from the income statement, the company's total revenue increased by 2.3 % (= \$1,688.3/\$1,650.4 − 1). The revenue growth rate of 4% in the CEO review is a non-IFRS measure, calculated on a "constant currency" basis, which the footnote describes as a comparison using 2016 revenues restated at 2015 foreign exchange rates.

Solution to 2:

The amounts reported on the company's income statement conform to IFRS. Using amounts from the income statement, the company reported a loss in 2016 of \$202.8 million, which was more than twice as large a loss as the \$93.4 million loss reported in 2015. Also referring to the income statement, the company reported 2016 operating profit (referred to elsewhere as EBIT) of \$154.0 million, a decline of 33.2% from the \$230.4 million operating profit reported in 2016.

In contrast, the "Adjusted EBITDA" amount highlighted in the CEO Review is neither defined nor recognized under IFRS. It is a non-IFRS measure. To create the Adjusted EBITDA, the company first begins with EBIT (called Operating profit in excerpts II and III) of \$154.0 and creates Adjusted EBIT (\$472.2 million) by adding back 8 different expenses that IFRS requires the company to recognize. These adjustments are listed beneath the first tabular reconciliation in Items a through g. After developing Adjusted EBIT, the company creates Adjusted EBITDA (\$507.6 million) by adding back a further 3 different expenses that IFRS requires the company to recognize.

Overall, there are three key differences between Disclosures A and B: (1) Most importantly, disclosure A refers to a non-IFRS metric rather than an IFRS-compliant metric; (2) Disclosure A refers to operating profit, which was positive, rather than to net income, which was negative; and (3) Disclosure A highlights a positive economic outcome—i.e., an increase, on a currency adjusted basis. An analyst should be aware of the alternative means by which earnings announcements can paint a positive picture of companies' results.

Often, poor reporting quality occurs simultaneously with poor earnings quality; for example, aggressive accounting choices are made to obscure poor performance. It is also possible, of course, for poor reporting quality to occur with high-quality earnings. Although a company with good performance would not require aggressive accounting choices to obscure poor performance, it might nonetheless produce poor-quality reports for other reasons. A company with good performance might be unable to produce high-quality reports because of inadequate internal systems.

Another scenario in which poor reporting quality might occur simultaneously with high quality earnings is that a company with good performance might deliberately produce reports based on "conservative" rather than aggressive accounting choices—that is, choices that make current performance look worse. One motivation might be to avoid unwanted political attention. Another motivation could arise in a period in which management had already exceeded targets before the end of the period and thus made conservative accounting choices that would delay reporting profits until the following period (so-called "hidden reserves"). Similar motivations might also contribute to accounting choices that create the appearance that the trajectory of future results would appear more attractive. For example, a company might make choices to accelerate losses in the first year of an acquisition or the first year of a new CEO's tenure so that the trajectory of future results would appear more attractive.

Overall, *unbiased* financial reporting is the ideal. Some investors may prefer conservative choices rather than aggressive ones, however, because a positive surprise is easier to tolerate than a negative surprise. Biased reporting, whether conservative or aggressive, adversely affects a user's ability to assess a company.

The quality spectrum considers the more intuitive situation in which less-than-desired underlying economics are the central motivation for poor reporting quality. In addition, it is necessary to have some degree of reporting quality in order to evaluate earnings quality. Proceeding down the spectrum, therefore, the concepts of reporting quality and earnings quality become progressively less distinguishable.

3.1 Within GAAP, but "Earnings Management"

The next level down on the spectrum in Exhibit 2 is labeled "Within GAAP, but 'earnings management.'" The term "earnings management" is defined here as making intentional choices that create biased financial reports.[8] The distinction between earnings management and biased choices is subtle and, primarily, a matter of intent. Earnings management represents "deliberate actions to influence reported earnings and their interpretation" (Ronen and Yaari, 2008). Earnings can be "managed" upward (increased) by taking *real* actions, such as deferring research and development (R&D) expenses into the next reporting period. Alternatively, earnings can be increased by *accounting* choices, such as changing accounting estimates. For example, the amount of estimated product returns, bad debt expense, or asset impairment could be decreased to create higher earnings. Because it is difficult to determine intent, we include earnings management under the biased choices discussion.

DEPARTURES FROM GAAP

4

b describe a spectrum for assessing financial reporting quality;

The next levels down on the spectrum in Exhibit 2 mark departures from GAAP. Financial reporting that departs from GAAP can generally be considered low quality. In such situations, earnings quality is likely difficult or impossible to assess because comparisons with earlier periods and/or other entities cannot be made. An example of improper accounting was Enron (accounting issues revealed in 2001), whose inappropriate use of off-balance-sheet structures and other complex transactions resulted in vastly understated indebtedness as well as overstated profits and operating cash flow. Another notorious example of improper accounting was WorldCom (accounting issues discovered in 2002), a company that by improperly capitalizing certain expenditures dramatically understated its expenses and thus overstated its profits. More recently, New Century Financial (accounting issues revealed in 2007) issued billions of dollars of subprime mortgages and improperly reserved only minimal amounts for loan repurchase losses. Each of these companies subsequently filed for bankruptcy.

---

[8] Various definitions have appeared in academic research. Closest to the discussion here is Schipper (1989), which uses the term "earnings management" to mean "'disclosure management' in the sense of a purposeful intervention in the external financial reporting process, with the intent of obtaining some private gain (as opposed to, say, merely facilitating the neutral operation of the process)."

In the 1980s, Polly Peck International (PPI) reported currency losses, incurred in the normal course of operations, directly through equity rather than in its profit and loss statements. In the 1990s, Sunbeam improperly reported revenues from "bill-and-hold" sales and also manipulated the timing of expenses in an effort to falsely portray outstanding performance of its then-new chief executive.

At the bottom of the quality spectrum, fabricated reports portray fictitious events, either to fraudulently obtain investments by misrepresenting the company's performance and/or to obscure fraudulent misappropriation of the company's assets. Examples of fraudulent reporting are unfortunately easy to find, although they were not necessarily easy to identify at the time. In the 1970s, Equity Funding Corp. created fictitious revenues and even fictitious policyholders. In the 1980s, Crazy Eddie's reported fictitious inventory as well as fictitious revenues supported by fake invoices. In 2004, Parmalat reported fictitious bank balances.

EXAMPLE 3

Spectrum for Assessing Quality of Financial Reports

Jake Lake, a financial analyst, has identified several items in the financial reports of several (hypothetical) companies. Describe each of these items in the context of the financial reporting quality spectrum.

1. ABC Co.'s 2018 earnings totaled \$233 million, including a \$100 million gain from selling one of its less profitable divisions. ABC's earnings for the prior three years totaled \$120 million, \$107 million, and \$111 million. The company's financial reports are extremely clear and detailed, and the company's earnings announcement highlights the one-time nature of the \$100 million gain.
2. DEF Co. discloses that in 2018, it changed the depreciable life of its equipment from 3 years to 15 years. Equipment represents a substantial component of the company's assets. The company's disclosures indicate that the change is permissible under the accounting standards of its jurisdiction but provide only limited explanation of the change.
3. GHI Co.'s R&D expenditures for the past five years have been approximately 3% of sales. In 2018, the company significantly reduced its R&D expenditures. Without the reduction in R&D expenditures, the company would have reported a loss. No explanation is disclosed.

Solution to 1:

ABC's 2018 total earnings quality can be viewed as low because nearly half of the earnings are derived from a non-sustainable activity, namely the sale of a division. ABC's 2018 quality of earnings from continuing operations may be high because the amounts are fairly consistent from year to year, although an analyst would undertake further analysis to confirm earnings quality. In general, a user of financial reports should look beyond the bottom-line net income. The description provided suggests that the company's reporting quality is high; the reports are clear and detailed, and the one-time nature of the \$100 million gain is highlighted.

Solution to 2:

DEF's accounting choice appears to be within permissible accounting standards, but its effect is to substantially lower depreciation expense and thus to increase earnings for the year. The quality of reported earnings is questionable. Although the new level of earnings may be sustainable, similar increases in earnings for future periods might not be achievable, because increasing earnings solely by changing accounting estimates is likely not sustainable. In addition, the description provided suggests that the company's reporting quality is low because it offers only a limited explanation for the change.

Solution to 3:

GHI's operational choice to reduce its R&D may reflect real earnings management because the change enabled the company to avoid reporting a loss. In addition, the description provided suggests that the company's reporting quality is low because it does not offer an explanation for the change.

DIFFERENTIATE BETWEEN CONSERVATIVE AND AGGRESSIVE ACCOUNTING

5

c explain the difference between conservative and aggressive accounting;

This section returns to the implications of conservative and aggressive accounting choices. As mentioned earlier, *unbiased* financial reporting is the ideal. But some investors may prefer or be perceived to prefer conservative rather than aggressive accounting choices because a positive surprise is acceptable. In contrast, management may make, or be perceived to make, aggressive accounting choices because they increase the company's reported performance and financial position.

Aggressive accounting choices in the period under review may decrease the company's reported performance and financial position in later periods, which creates a sustainability issue. Conservative choices do not typically create a sustainability issue because they decrease the company's reported performance and financial position, and may increase them in later periods. In terms of establishing expectations for the future, however, financial reporting that is relevant and faithfully representative is the most useful.

A common presumption is that financial reports are typically biased upward, but that is not always the case. Although accounting standards ideally promote unbiased financial reporting, some accounting standards may specifically require a conservative treatment of a transaction or an event. Also, managers may choose to take a conservative approach when applying standards. It is important that an analyst consider the possibility of conservative choices and their effects.

At its most extreme, conservatism follows accounting practices that "anticipate no profit, but anticipate all losses" (Bliss, 1924). But in general, conservatism means that revenues may be recognized once a verifiable and legally enforceable receivable has been generated and that losses need not be recognized until it becomes "probable" that an actual loss will be incurred. Conservatism is not an absolute but is characterized by degrees, such as "the accountant's tendency to require a higher degree of verification to recognize good news as gains than to recognize bad news as losses" (Basu, 1997). From this perspective, "verification" (e.g., physical existence of inventories, evidence of costs incurred or to be incurred, or establishment of rights and obligations on legal grounds) drives the degree of conservatism. For recognition of revenues, a higher degree of verification would be required than for expenses.

5.1 Conservatism in Accounting Standards

The *Conceptual Framework* supports neutrality of information: "A neutral depiction is without bias in the selection or presentation of financial information."[9] Neutrality—lack of upward or downward bias—is considered a desirable characteristic of financial reporting. Conservatism directly conflicts with the characteristic of neutrality because the asymmetric nature of conservatism leads to bias in measuring assets and liabilities—and ultimately, earnings.

Despite efforts to support neutrality in financial reporting, many conservatively biased standards remain. Standards across jurisdictions may differ on the extent of conservatism embedded within them. An analyst should be aware of the implications of accounting standards for the financial reports.

An example is the different treatment by IFRS and US GAAP of the impairment of long-lived assets.[10] Both IFRS and US GAAP specify an impairment analysis protocol that begins with an assessment of whether recent events indicate that the economic benefit from an individual or group of long-lived assets may be less than its carrying amount(s). From that point on, however, the two regimes diverge:

- Under IFRS, if the "recoverable amount" (the higher of fair value less costs to sell and value in use) is less than the carrying amount, then an impairment charge will be recorded.
- Under US GAAP, an impairment charge will be recorded only when the sum of the undiscounted future cash flows expected to be derived from the asset(s) is less than the carrying amount(s). If the undiscounted future cash flows are less than the carrying amount, the asset is written down to fair value.

To illustrate the difference in application, assume that a factory is the unit of account eligible for impairment testing. Its carrying amount is $10,000,000; "fair value" and "recoverable amount" are both $6,000,000; and the undiscounted future net cash flows associated with the factory total $10,000,000. Under IFRS, an impairment charge of $4,000,000 would be recorded; but under US GAAP, no impairment charge would be recognized.

Thus, on its face, IFRS would be regarded as more conservative than US GAAP because impairment losses would normally be recognized earlier under IFRS than under US GAAP. But, taking the analysis one step further, such a broad generalization may not hold up. For example, if an asset is impaired under both IFRS and US GAAP and the asset's value in use exceeds its fair value, the impairment loss under US GAAP will be greater. Also, IFRS permits the recognition of recoveries of the recoverable amount in subsequent periods if evidence indicates that the recoverable amount has subsequently increased. In contrast, US GAAP prohibits the subsequent write-up of an asset after an impairment charge has been taken; it would recognize the asset's increased value only when the asset is ultimately sold.

Common examples of conservatism in accounting standards include the following:

- *Research costs*. Because the future benefit of research costs is uncertain at the time the costs are incurred, both US GAAP and IFRS require immediate expensing instead of capitalization.

---

[9] IASB and FASB, *The Conceptual Framework for Financial Reporting* (2010): QC 14.

[10] See IAS 36 and FASB ASC Section 360-10-35.

- *Litigation losses*. When it becomes "probable" that a cost will be incurred, both US GAAP and IFRS require expense recognition, even though a legal liability may not be incurred until a future date.
- *Insurance recoverables*. Generally, a company that receives payment on an insurance claim may not recognize a receivable until the insurance company acknowledges the validity of the claimed amount.

Watts (2003) reviews empirical studies of conservatism, and identifies four potential benefits of conservatism:

- Given asymmetrical information, conservatism may protect the contracting parties with less information and greater risk. This protection is necessary because the contracting party may be at a disadvantage. For example, corporations that access debt markets have limited liability, and lenders thus have limited recourse to recover their losses from shareholders. As another example, executives who receive earnings-based bonuses might not be subject to having those bonuses "clawed back" if earnings are subsequently discovered to be overstated.
- Conservatism reduces the possibility of litigation and, by extension, litigation costs. Rarely, if ever, is a company sued because it understated good news or overstated bad news.
- Conservative rules may protect the interests of regulators and politicians by reducing the possibility that fault will be found with them if companies overstate earnings or assets.
- In many tax jurisdictions, financial and tax reporting rules are linked. For example, in Germany and Japan, only deductions taken against reported income can be deducted against taxable income. Hence, companies can reduce the present value of their tax payments by electing conservative accounting policies for certain types of events.

Analysts should consider possible conservative and aggressive biases and their consequences when examining financial reports. Current-period financial reports may be unbiased, upward biased through aggressive accounting choices, downward biased through conservative accounting choices, or biased through a combination of conservative and aggressive accounting choices.

5.2 Bias in the Application of Accounting Standards

Any application of accounting standards, whether the standard itself is neutral or not, often requires significant amounts of judgment. Characterizing the application of an accounting standard as conservative or aggressive is more a matter of intent rather than definition.

Careful analysis of disclosures, facts, and circumstances contributes to making an accurate inference of intent. Management seeking to manipulate earnings may take a longer view by sacrificing short-term profitability in order to ensure higher profits in later periods. One example of biased accounting in the guise of conservatism is the so-called "big bath" restructuring charges. Both US GAAP and IFRS provide for accrual of future costs associated with restructurings, and these costs are often associated with and presented along with asset impairments. But in some instances, companies use the accounting provisions to estimate "big" losses in the period under review so that performance in future periods will appear better. Having observed numerous instances of manipulative practices in the late 1990s, in which US companies set up opportunities to report higher profits in future periods that were not connected with performance in those periods, the SEC staff issued rules that narrowed the circumstances under which costs can be categorized as part of a "non-recurring" restructuring event and enhanced the transparency surrounding restructuring charges and asset impairments.[11]

A similar manifestation of "big bath" accounting is often referred to as "cookie jar reserve accounting." Both US GAAP and IFRS require accruals of estimates of future non-payments of loans. In his 1998 speech "The 'Numbers Game,'" SEC chair Arthur Levitt expressed the general concern that corporations were overstating loans and other forms of loss allowances for the purpose of smoothing income over time.[12] In 2003, the SEC issued interpretive guidance that essentially requires a company to provide a separate section in management's discussion and analysis (MD&A) titled "Critical Accounting Estimates."[13] If the effects of subjective estimates and judgments of highly uncertain matters are material to stakeholders (investors, customers, suppliers, and other users of the financial statements), disclosures of their nature and exposure to uncertainty should be made in the MD&A. This requirement is in addition to required disclosures in the notes to the financial statements.

6

CONTEXT FOR ASSESSING FINANCIAL REPORTING QUALITY: MOTIVATIONS AND CONDITIONS CONDUCIVE TO ISSUING LOW QUALITY FINANCIAL REPORTS

d describe motivations that might cause management to issue financial reports that are not high quality;

e describe conditions that are conducive to issuing low-quality, or even fraudulent, financial reports;

In assessing financial reporting quality, it is useful to consider whether a company's managers may be motivated to issue financial reports that are not high quality. If motivation exists, an analyst should consider whether the reporting environment is conducive to managers' misreporting. It is important to consider mechanisms within the reporting environment that discipline financial reporting quality, such as the regulatory regime.

[12] Arthur Levitt, "The 'Numbers Game,'" Remarks given at NYU Center for Law and Business (28 September 1998): www.sec.gov/news/speech/speecharchive/1998/spch220.txt.

[13] SEC, "Commission Guidance Regarding Management's Discussion and Analysis of Financial Condition and Results of Operations," Financial Reporting Release (FRR) No. 72 (2003): www.sec.gov/rules/interp/33-8350.htm.

6.1 Motivations

Managers may be motivated to issue financial reports that are not high quality to mask poor performance, such as loss of market share or lower profitability than competitors. Lewis (2012) stated, "A firm experiencing performance problems, particularly those it considers transient, may induce a response that inflates current earnings numbers in exchange for lower future earnings."

- Even when there is no need to mask poor performance, managers frequently have incentives to meet or beat market expectations as reflected in analysts' forecasts and/or management's own forecasts. Exceeding forecasts typically increases the stock price, if only temporarily. Additionally, exceeding forecasts can increase management compensation that is linked to increases in stock price or to reported earnings. Graham, Harvey, and Rajgopal (2005) found that the CFOs they surveyed view earnings as the most important financial metric to financial markets. Achieving (or exceeding) particular benchmarks, including prior-year earnings and analysts' forecasts, is very important. The authors examined a variety of motivations for why managers might "exercise accounting discretion to achieve some desirable earnings goal." Motivations to meet earnings benchmarks include equity market effects (for example, building credibility with market participants and positively affecting stock price) and trade effects (for example, enhancing reputation with customers and suppliers). Equity market effects are the most powerful incentives, but trade effects are important, particularly for smaller companies.
- Career concerns and incentive compensation may motivate accounting choices. For example, managers might be concerned that working for a company that performs poorly will limit their future career opportunities or that they will not receive a bonus based on exceeding a particular earnings target. In both cases, management might be motivated to make accounting choices to increase earnings. In a period of marginally poor performance, a manager might accelerate or inflate revenues and/or delay or under report expenses. Conversely, in a period of strong performance, a manager might delay revenue recognition or accelerate expense recognition to increase the probability of exceeding the next period's targets (i.e., to "bank" some earnings for the next period.) The surveyed managers indicated a greater concern with career implications of reported results than with incentive compensation implications.

Avoiding debt covenant violations can motivate managers to inflate earnings. Graham, Harvey, and Rajgopal's survey indicates that avoidance of bond covenant violation is important to highly leveraged and unprofitable companies but relatively unimportant overall.

6.2 Conditions Conducive to Issuing Low-Quality Financial Reports

As discussed, deviations from a neutral presentation of financial results could be driven by management choices or by a jurisdiction's financial reporting standards. Ultimately, a decision to issue low-quality, or even fraudulent, financial reports is made by an individual or individuals. Why individuals make such choices is not always immediately apparent. For example, why would the newly appointed CEO of Sunbeam, who already had a net worth of more than $100 million, commit accounting fraud by improperly reporting revenues from "bill-and-hold" sales and manipulating the timing of expenses, rather than admit to lower-than-expected financial results?

Typically, three conditions exist when low-quality financial reports are issued: opportunity, motivation, and rationalization. Opportunity can be the result of internal conditions, such as poor internal controls or an ineffective board of directors, or external conditions, such as accounting standards that provide scope for divergent choices or minimal consequences for an inappropriate choice. Motivation can result from pressure to meet some criteria for personal reasons, such as a bonus, or corporate reasons, such as concern about financing in the future. Rationalization is important because if an individual is concerned about a choice, he or she needs to be able to justify it to him- or herself.

Former Enron CFO Andrew Fastow, speaking at the 2013 Association of Certified Fraud Examiners Annual Fraud Conference, indicated that he knew at the time he was doing something wrong but followed procedure to justify his decision (Pavlo, 2013). He made sure to get management and board approval, as well as legal and accounting opinions, and to include appropriate disclosures. The incentive and corporate culture was to create earnings rather than focus on long-term value. Clearly, as reflected in his prison sentence, he did something that was not only wrong but illegal.

7

MECHANISMS THAT DISCIPLINE FINANCIAL REPORTING QUALITY

f describe mechanisms that discipline financial reporting quality and the potential limitations of those mechanisms;

Markets potentially discipline financial reporting quality. Companies and nations compete for capital, and the cost of capital is a function of perceived risk—including the risk that a company's financial statements will skew investors' expectations. Thus, in the absence of other conflicting economic incentives, a company seeking to minimize its long-term cost of capital should aim to provide high-quality financial reports. In addition to markets, other mechanisms that discipline financial reporting quality include market regulatory authorities, auditors, and private contracts.

7.1 Market Regulatory Authorities

Companies seeking to minimize the cost of capital should maximize reporting quality, but as discussed earlier, conflicting incentives often exist. For this reason, national regulations, and the regulators that establish and enforce rules, can play a significant role in financial reporting quality. Many of the world's securities regulators are members of the International Organization of Securities Commissions (IOSCO). IOSCO is recognized as the "global standard setter for the securities sector" although it does not actually set standards but rather establishes objectives and principles to guide securities and capital market regulation. IOSCO's membership includes more than 120 securities regulators and 80 other securities market participants, such as stock exchanges.[14]

One member of IOSCO is ESMA , an independent EU authority with a mission to "enhance the protection of investors and reinforce stable and well-functioning financial markets in the European Union."[15] ESMA organizes financial reporting enforcement activities through a forum consisting of European enforcers from European Economic Area countries. Direct supervision and enforcement activities are performed at the national level. For example, the Financial Conduct Authority (FCA) is the IOSCO member with primary responsibility for securities regulation in the United Kingdom. ESMA reported that European enforcers examined the interim and/or annual financial statements of 1,141 issuers in 2017, which in turn led to enforcement actions for 328 issuers with the following outcomes: 12 required reissuances of financial statements, 71 public corrective notes, and 245 required corrections in future financial statements.[16]

---

[14] Visit www.iosco.org for more information.

[15] Text from ESMA's mission statement on their website: www.esma.europa.eu.

Another member of IOSCO is the US regulatory authority, the Securities and Exchange Commission. The SEC is responsible for overseeing approximately 9,100 US public companies (along with investment advisers, broker/dealers, securities exchanges, and other entities) and reviews the disclosures of these companies at least once every three years with the aim of improving information available to investors and potentially uncovering possible violations of securities laws.[17] In 2017, the SEC reported that it had filed 754 total and 446 standalone enforcement actions, about 20% of which concerned issuer reporting/accounting and auditing.[18]

Examples of regulatory bodies in Asia include the Financial Services Agency in Japan, the China Securities Regulatory Commission, and the Securities and Exchange Board of India. Examples of regulatory bodies in South America include the Comisión Nacional de Valores in Argentina, Comissão de Valores Mobiliários in Brazil, and Superintendencia de Valores y Seguros in Chile. A full list of IOSCO members can be found on the organization's website.

Typical features of a regulatory regime that most directly affect financial reporting quality include the following:

- *Registration requirements*. Market regulators typically require publicly traded companies to register securities before offering the securities for sale to the public. A registration document typically contains current financial statements, other relevant information about the risks and prospects of the company issuing the securities, and information about the securities being offered.
- *Disclosure requirements*. Market regulators typically require publicly traded companies to make public periodic reports, including financial reports and management comments. Standard-setting bodies, such as the IASB and FASB, are typically private sector, self-regulated organizations with board members who are experienced accountants, auditors, users of financial statements, and academics. Regulatory authorities, such as the Accounting and Corporate Regulatory Authority in Singapore, the Securities and Exchange Commission in the United States, the Securities and Exchange Commission in Brazil, and the Financial Reporting Council in the United Kingdom, have the legal authority to enforce financial reporting requirements and exert other controls over entities that participate in the capital markets within their jurisdiction. In other words, *generally*, standard-setting bodies set the standards, and regulatory authorities recognize and enforce those standards. Without the recognition of standards by regulatory authorities, the private-sector standard-setting bodies would have no authority. Regulators often retain the legal authority to establish financial reporting standards in their jurisdiction and can overrule the private-sector standard-setting bodies.

[18] SEC, Securities and Exchange Commission Division of Enforcement Annual Report, "A Look Back at Fiscal Year 2017" www.sec.gov/report.

- *Auditing requirements*. Market regulators typically require companies' financial statements to be accompanied by an audit opinion attesting that the financial statements conform to the relevant set of accounting standards. Some regulators, such as the SEC in the United States, require an additional audit opinion attesting to the effectiveness of the company's internal controls over financial reporting.
- *Management commentaries*. Regulations typically require publicly traded companies' financial reports to include statements by management. For example, the FCA in the United Kingdom requires a management report containing "(1) a fair review of the issuer's business; and (2) a description of the principal risks and uncertainties facing the issuer" (Disclosure Guidance and Transparency Rules sourcebook.)
- *Responsibility statements*. Regulations typically require a statement from the person or persons responsible for the company's filings. Such statements require the responsible individuals to explicitly acknowledge responsibility and to attest to the correctness of the financial reports. Some regulators, such as the SEC in the United States, require formal certifications that carry specific legal penalties for false certifications.
- *Regulatory review of filings*. Regulators typically undertake a review process to ensure that the rules have been followed. The review process typically covers all initial registrations and a sample of subsequent periodic financial reports.
- *Enforcement mechanisms*. Regulators are granted various powers to enforce the securities market rules. Such powers can include assessing fines, suspending or permanently barring market participants, and bringing criminal prosecutions. Public announcements of disciplinary actions are also a type of enforcement mechanism.

In summary, market regulatory authorities play a central role in encouraging high-quality financial reporting.

7.2 Auditors

As noted, regulatory authorities typically require that publicly traded companies' financial statements be audited by an independent auditor. Private companies also obtain audit opinions for their financial statements, either voluntarily or because audit reports are required by an outside party, such as providers of debt or equity capital.

Audit opinions provide financial statement users with some assurance that the information complies with the relevant set of accounting standards and presents the company's information fairly. Exhibits 8, 9, 10, and 11 provide excerpts from the independent auditors' reports for GlaxoSmithKline plc, Alibaba Group Holding Limited, Apple Inc., and Tata Motors Limited, respectively. For each company, the auditor issued an unqualified opinion on the financial statements, indicating that the financial statements present fairly the company's performance in accordance with relevant standards. (Note: The term "unqualified opinion" means that the opinion did not include any qualifications or exceptions; the term is synonymous with the less formal term "clean opinion." Unqualified opinions are the most common.) Other items in the audit reports reflect the specific requirements of the company's regulatory regime. For example, the audit report for GlaxoSmithKline spans nine pages and includes opinions on the company's financial statements as well as the Strategic Report and the Directors' Report. This audit report also includes disclosures about "Key audit matters," in accordance with International Standards on Auditing (ISAs) issued by the International Auditing and Assurance Standards Board (IAASB) in 2015 and effective for periods ending on or after December 15, 2016.

The excerpts for Alibaba, Apple, and Tata Motors show the auditors' opinions on the companies' financial statements and additionally the SEC-required opinions on the effectiveness of the companies' internal controls because these companies are listed in the United States. For Alibaba, a single report includes both unqualified opinions: (i) the financial statements present fairly the financial position, results of operations, and cash flows… in conformity with US GAAP; and (ii) the company maintained effective control over financial reporting. For Apple, the first report includes the unqualified opinion on the financial statements, and the second report includes the unqualified opinion on the company's effective internal controls. For Tata Motors, the first report includes the unqualified opinion that the financial statements present the company's position and results fairly in accordance with IFRS. (The SEC permits non-US companies to report using US GAAP, IFRS as issued by the IASB, or home-country GAAP.) However, the second report includes an *adverse* opinion on the effectiveness of the company's internal controls: "In our opinion, because of the effect of the material weakness … the company has not maintained effective internal control." The report explains that the material weakness involved a third party's inappropriate access to the company's systems. The report further states that although the material weakness resulted in ineffective internal controls, it did not affect the audit opinion on the financial statements. Elsewhere in Tata Motors' annual report (not shown in the excerpt), the company discloses that the weakness did not result in a financial misstatement and that it has undertaken remedial measures.

Exhibit 8 Excerpts from Audit Opinion of PricewaterhouseCoopers LLP from the 2017 Annual Report *(pages 149–157)* of GlaxoSmithKline plc

In our opinion, GlaxoSmithKline plc's Group financial statements (the "financial statements"):

- give a true and fair view of the state of the Group's affairs as at 31 December 2017 and of its profit and cash flows for the year then ended;
- have been properly prepared in accordance with International Financial Reporting Standards ("IFRSs") as adopted by the European Union; and
- have been prepared in accordance with the requirements of the Companies Act 2006 and Article 4 of the IAS Regulation.

…

In our opinion, the Group financial statements have been properly prepared in accordance with IFRSs as issued by the IASB.

…

Key audit matters

Key audit matters are those matters that, in the auditors' professional judgement, were of most significance in the audit of the financial statements of the current period and include the most significant assessed risks of material misstatement (whether or not due to fraud) identified by the auditors, including those which had the greatest effect on: the overall audit strategy; the allocation of resources in the audit; and directing the efforts of the engagement team. These matters, and any comments we make on the results of our procedures thereon, were addressed in the context of our audit of the financial statements as a whole, and in forming our opinion thereon, and we do not provide a separate opinion on these matters. This is not a complete list of all risks identified by our audit.

…

(continued)

Exhibit 8 (Continued)

In our opinion, based on the work undertaken in the course of the audit, the information given in the Strategic Report and Directors' Report for the year ended 31 December 2017 is consistent with the financial statements and has been prepared in accordance with applicable legal requirements.

Exhibit 9 Excerpts from Audit Opinion of PricewaterhouseCoopers Hong Kong, SAR from the Annual Report ***(SEC Form 20-F, Pages F-2 and F-3)*** **of Alibaba Group Holding Limited for the year ended March 31, 2018**

In our opinion, the consolidated financial statements referred to above present fairly, in all material respects, the financial position of the Company as of March 31, 2017 and 2018, and the results of their operations and their cash flows for each of the three years in the period ended March 31, 2018 in conformity with accounting principles generally accepted in the United States of America. Also in our opinion, the Company maintained, in all material respects, effective internal control over financial reporting as of March 31, 2018, based on criteria established in Internal Control — Integrated Framework (2013) issued by the COSO.

Exhibit 10 Excerpt from Audit Opinion of Ernst & Young from the Annual Report (***SEC Form 10-K, pages 70 and 71*****) of Apple Inc. for the year ended September 30, 2017**

[From the Financial Statement Opinion]

We have audited the accompanying consolidated balance sheets of Apple Inc. as of September 30, 2017 and September 24, 2016, and the related consolidated statements of operations, comprehensive income, shareholders' equity and cash flows for each of the three years in the period ended September 30, 2017.

....

In our opinion, the financial statements referred to above present fairly, in all material respects, the consolidated financial position of Apple Inc. at September 30, 2017 and September 24, 2016, and the consolidated results of its operations and its cash flows for each of the three years in the period ended September 30, 2017, in conformity with U.S. generally accepted accounting principles.

...

We also have audited, in accordance with the standards of the Public Company Accounting Oversight Board (United States), Apple Inc.'s internal control over financial reporting as of September 30, 2017, based on criteria established in Internal Control – Integrated Framework issued by the Committee of Sponsoring Organizations of the Treadway Commission (2013 framework) and our report dated November 3, 2017 expressed an unqualified opinion thereon.

[From the Internal Controls Opinion]

We have audited Apple Inc.'s internal control over financial reporting as of September 30, 2017, based on criteria established in Internal Control – Integrated Framework issued by the Committee of Sponsoring Organizations of the Treadway Commission (2013 framework) ("the COSO criteria").

Exhibit 10 (Continued)

…

In our opinion, Apple Inc. maintained, in all material respects, effective internal control over financial reporting as of September 30, 2017, based on the COSO criteria.

We also have audited, in accordance with the standards of the Public Company Accounting Oversight Board (United States), the 2017 consolidated financial statements of Apple Inc. and our report dated November 3, 2017 expressed an unqualified opinion thereon.

Exhibit 11 Excerpt from Audit Opinion of KPMG Mumbai, India from the Annual Report (*SEC Form 20-F, pages F2 to F4*) of Tata Motors Limited for the year ended March 31, 2018

Opinion on the Consolidated Financial Statements

We have audited the accompanying consolidated balance sheet of Tata Motors Limited and its subsidiaries (the "Company") as of March 31, 2018, the related consolidated income statement, statement of comprehensive income, statement of cash flows, and statement of changes in equity for the year ended March 31, 2018, and the related notes and financial statement schedule 1 (collectively, the consolidated financial statements).

In our opinion, the consolidated financial statements present fairly, in all material respects, the financial position of the Company as of March 31, 2018, and the results of its operations and its cash flows for the year ended March 31, 2018, in conformity with the International Financial Reporting Standards as issued by the International Accounting Standards Board ("IFRS").

We also have audited, in accordance with the standards of the Public Company Accounting Oversight Board (United States) (PCAOB), the Company's internal control over financial reporting as of March 31, 2018, based on criteria established in *Internal Control – Integrated Framework (2013)* issued by the Committee of Sponsoring Organizations of the Treadway Commission, and our report dated July, 31, 2018 expressed an adverse opinion on the effectiveness of the Company's internal control over financial reporting.

…

Opinion on Internal Control Over Financial Reporting

We have audited Tata Motors Limited's and subsidiaries' (the Company) internal control over financial reporting as of March 31, 2018, based on criteria established in Internal Control – Integrated Framework (2013) issued by the Committee of Sponsoring Organizations of the Treadway Commission. In our opinion, because of the effect of the material weakness described below, on the achievement of the objectives of the control criteria, the Company has not maintained effective internal control over financial reporting as of March 31, 2018, based on criteria established in *Internal Control – Integrated Framework (2013)* issued by the Committee of Sponsoring Organizations of the Treadway Commission.

…

A material weakness is a deficiency, or a combination of deficiencies, in internal control over financial reporting, such that there is a reasonable possibility that a material misstatement of the company's annual or interim financial statements will not be prevented or detected on a timely basis. A material weakness related to inappropriate system access restrictions at a third party logistics provider

(continued)

Exhibit 11 (Continued)

has been identified and included in management's assessment. The material weakness was considered in determining the nature, timing, and extent of audit tests applied in our audit of the 2018 consolidated financial statements, and this report does not affect our report on those consolidated financial statements.

Although audit opinions provide discipline for financial reporting quality, inherent limitations exist. First, an audit opinion is based on a review of information prepared by the company. If a company deliberately intends to deceive its auditor, a review of information might not uncover misstatements. Second, an audit is based on sampling, and the sample might not reveal misstatements. Third, an "expectations gap" may exist between the auditor's role and the public's expectation of auditors. An audit is not typically intended to detect fraud; it is intended to provide assurance that the financial reports are fairly presented. Finally, the company being audited pays the audit fees, often established through a competitive process. This situation could provide an auditor with an incentive to show leniency to the company being audited, particularly if the auditor's firm provides additional services to the company.

7.3 Private Contracting

Aspects of private contracts, such as loan agreements or investment contracts, can serve as mechanisms to discipline financial reporting quality. Many parties that have a contractual arrangement with a company have an incentive to monitor that company's performance and to ensure that the company's financial reports are high quality. For example, loan agreements often contain loan covenants, which create specifically tailored financial reporting requirements that are legally binding for the issuer. As noted earlier, avoidance of debt covenant violation is a potential motivation for managers to inflate earnings. As another example, an investment contract could contain provisions giving investors the option to recover all or part of their investment if certain financial triggers occur. Such provisions could motivate the investee's managers to manipulate reported results to avoid the financial triggers.

Because the financial reports prepared by the investees or borrowers directly affect the contractual outcomes—potentially creating a motivation for misreporting—investors and lenders are motivated to monitor financial reports and to ensure that they are high quality.

EXAMPLE 4

Financial Reporting Manipulation: Motivations and Disciplining Mechanisms

For each of the following two scenarios, identify (1) factors that might motivate the company's managers to manipulate reported financial amounts and (2) applicable mechanisms that could discipline financial reporting quality.

1 ABC Co. is a private company. Bank NTBig has made a loan to ABC Co. ABC is required to maintain a minimum 2.0 interest coverage ratio. In its most recent financial reports, ABC reported earnings before interest and taxes of $1,200 and interest expense of $600. In the report's notes, the

company discloses that it changed the estimated useful life of its property, plant, and equipment during the year. Depreciation was approximately $150 lower as a result of this change in estimate.

2 DEF Co. is a publicly traded company. For the most recent quarter, the average of analysts' forecasts for earnings per share was $2.50. In its quarterly earnings announcement, DEF reported net income of $3,458,780. The number of common shares outstanding was 1,378,000. DEF's main product is a hardware device that includes a free two-year service contract in the selling price. Based on management estimates, the company allocates a portion of revenues to the hardware device, which it recognizes immediately, and a portion to the service contract, which it defers and recognizes over the two years of the contract. Based on the disclosures, a higher percentage of revenue was allocated to hardware than in the past, with an estimated after-tax impact on net income of $27,000.

Solution to 1:

The need to maintain a minimum interest coverage ratio of 2.0 might motivate ABC's managers to manipulate reported financial amounts. The company's coverage ratio based on the reported amounts is exactly equal to 2.0. If ABC's managers had not changed the estimated useful life of the property, plant, and equipment, the coverage ratio would have fallen below the required level.

EBIT, as reported	$1,200
Impact on depreciation expense of changed assumptions about useful life	150
EBIT, as adjusted	$1,050
Interest expense	$600
Coverage ratio, as reported	2.00
Coverage ratio, as adjusted	1.75

The potential disciplining mechanisms include the auditors, who will assess the reasonableness of the depreciable lives estimates. In addition, the lenders will carefully scrutinize the change in estimate because the company only barely achieved the minimum coverage ratio and would not have achieved the minimum without the change in accounting estimate.

Solution to 2:

The desire to meet or exceed the average of analysts' forecasts for earnings per share might motivate DEF Co.'s managers to manipulate reported financial amounts. As illustrated in the following calculations, the impact of allocating a greater portion of revenue to hardware enabled the company to exceed analysts' earnings per share forecasts by $0.01.

Net income, as reported	$3,458,780
Impact on gross profit of changed revenue recognition, net of tax	27,000
Net income, as adjusted	$3,431,780
Weighted average number of shares	1,378,000

(continued)

Earnings per share, as reported	$2.51
Earnings per share, as adjusted	$2.49

The potential disciplining mechanisms include the auditors, market regulators, financial analysts, and financial journalists.

8

DETECTION OF FINANCIAL REPORTING QUALITY ISSUES: INTRODUCTION & PRESENTATION CHOICES

g describe presentation choices, including non-GAAP measures, that could be used to influence an analyst's opinion;

h describe accounting methods (choices and estimates) that could be used to manage earnings, cash flow, and balance sheet items;

Choices in the application of accounting standards abound, which is perhaps one reason why accounting literature and texts are so voluminous. Compounding the complexity, measurement often depends on estimates of economic phenomena. Two estimates might be justifiable, but they may have significantly different effects on the company's financial statements. As discussed earlier, the choice of a particular estimate may depend on the motivations of the reporting company's managers. With many choices available, and the inherent flexibility of estimates in the accounting process, managers have many tools for managing and meeting analysts' expectations through financial reporting.

An understanding of the choices that companies make in financial reporting is fundamental to evaluating the overall quality—both financial reporting and earnings quality—of the reports produced. Choices exist both in how information is presented (financial reporting quality) and in how financial results are calculated (earnings quality). Choices in presentation (financial reporting quality) may be fairly transparent to investors. Choices in the calculation of financial results (earnings quality), however, are more difficult to discern because they can be deeply embedded in the construction of reported financial results.

The availability of accounting choices enables managers to affect the reporting of financial results. Some choices increase performance and financial position in the reporting period (aggressive choices), and others increase them in later periods (conservative choices). A manager that wants to increase performance and financial position in the reporting period could:

- Recognize revenue prematurely;
- Use non-recurring transactions to increase profits;
- Defer expenses to later periods;
- Measure and report assets at higher values; and/or
- Measure and report liabilities at lower values.

A manager that wants to increase performance and financial position in a later period could:

- Defer current income to a later period (save income for a "rainy day"); and/or
- Recognize future expenses in a current period, setting the table for improving future performance.

The following sections describe some of the potential choices for how information is presented and how accounting elements [assets, liabilities, owners' equity, revenue and gains (income), and expenses and losses] are recognized, measured, and reported. In addition to choices within GAAP, companies may prepare fraudulent reports. For example, these reports may include non-existent revenue or assets. These sections conclude with some of the warning signs that can indicate poor-quality financial reports.

8.1 Presentation Choices

The technology boom of the 1990s and the internet bubble of the early 2000s featured companies, popular with investors, that often shared the same characteristic: They could not generate enough current earnings to justify their stock prices using the traditional price-to-earnings ratio (P/E) approaches to valuation. Many investors chose to explain these apparent anomalies by rationalizing that the old focus on profits and traditional valuation approaches no longer applied to such companies. Strange new metrics for determining operating performance emerged. Website operators spoke of the "eyeballs" they had captured in a quarter, or the "stickiness" of their websites for web surfers' visits. Various versions of "pro forma earnings"—that is, "non-GAAP earnings measures"—became a financial reporting staple of the era.

Many technology companies were accomplished practitioners of pro forma reporting, but they were not the first to use it. In the early 1990s, downsizing of large companies was a commonplace event, and massive restructuring charges obscured the operating performance at many established companies. For example, as it learned to cope in a world that embraced the personal computer rather than mainframe computing, International Business Machines (IBM) reported massive restructuring charges in 1991, 1992, and 1993: $3.7 billion, $11.6 billion, and $8.9 billion, respectively. IBM was not alone. Sears incurred $2.7 billion of restructuring charges in 1993, and AT&T reported restructuring charges of $7.7 billion in 1995. These events were not isolated; restructuring charges were a standard quarterly reporting event. To counter perceptions that their operations were floundering, and supposedly to assist investors in evaluating operating performance, companies often sanitized earnings releases by excluding restructuring charges in pro forma measures of financial performance.

Accounting principles for reporting business combinations also played a role in boosting the popularity of pro forma earnings. Before 2001, acquisitions of one company by another often resulted in goodwill amortization charges that made subsequent earnings reports look weak. Complicating matters, there were two accounting methods for recording acquisitions: pooling-of-interests and purchase methods. The now-extinct pooling-of-interests treatment was difficult for companies to achieve because of the many restrictive criteria for its use, but it was greatly desired because it did not result in goodwill amortization charges. In the technology boom period, acquisitions were common and many were reported as purchases, with consequential goodwill amortization dragging down earnings for as long as 40 years under the then-existing rules. Acquisitive companies reporting under purchase accounting standards perceived themselves to be at a reporting disadvantage compared with companies able to apply pooling-of-interests. They responded by presenting earnings adjusted for the exclusion of amortization of intangible assets and goodwill.

Because investors try to make intercompany comparisons on a consistent basis, earnings before interest, taxes, depreciation, and amortization has become an extremely popular performance measure. EBITDA is widely viewed as eliminating noisy reporting signals. That noise may be introduced by different accounting methods among companies for depreciation, amortization of intangible assets, and restructuring charges.

Companies may construct and report their own version of EBITDA, sometimes referring to it as "adjusted EBITDA," by adding to the list of items to exclude from net income. Items that analysts might encounter include the following:

- Rental payments for operating leases, resulting in EBITDAR (earnings before interest, taxes, depreciation, amortization, and rentals);
- Equity-based compensation, usually justified on the grounds that it is a non-cash expense;
- Acquisition-related charges;
- Impairment charges for goodwill or other intangible assets;
- Impairment charges for long-lived assets;
- Litigation costs; and
- Loss/gain on debt extinguishments.

Among other incentives for the spread of non-GAAP earnings measures are loan covenants. Lenders may make demands on a borrowing company that require achieving and maintaining performance criteria that use GAAP net income as a starting point but arrive at a measure suitable to the lender. The company may use this measure as its preferred non-GAAP metric in earnings releases, and also when describing its liquidity or solvency situation in the management commentary (called management discussion and analysis in the United States).

As mentioned earlier, if a company uses a non-GAAP financial measure in an SEC filing, it must display the most directly comparable GAAP measure with equal prominence and provide a reconciliation between the two. Management must explain why it believes that the non-GAAP financial measure provides useful information regarding the company's financial condition and operations. Management must also disclose additional purposes, if material, for which it uses the non-GAAP financial measures.

Similarly, IFRS requires a definition and explanation of any non-IFRS measures included in financial reports, including why the measure is potentially relevant to users. Management must provide reconciliations of non-IFRS measures with IFRS measures. There is a concern that management may use non-GAAP measures to distract attention from GAAP measures.

The SEC intended that the definition of non-GAAP financial measures would capture all measures with the effect of depicting either:

- a measure of performance that differs from that presented in the financial statements, such as income or loss before taxes or net income or loss, as calculated in accordance with GAAP; or
- a measure of liquidity that differs from cash flow or cash flow from operations computed in accordance with GAAP.[19]

The SEC prohibits the exclusion of charges or liabilities requiring cash settlement from any non-GAAP liquidity measures, other than EBIT and EBITDA. Also prohibited is the calculation of a non-GAAP performance measure intended to eliminate or smooth items tagged as non-recurring, infrequent, or unusual when such items are very likely to occur again. The SEC views the period within two years of either before or after the reporting date as the relevant time frame for considering whether a charge or gain is a recurring item. Example 5 describes a case of misuse and misreporting of non-GAAP measures.

[19] SEC, "Final Rule: Conditions for Use of Non-GAAP Financial Measures," Securities and Exchange Commission (www.sec.gov/rules/final/33-8176.htm).

EXAMPLE 5

Misuse and Misreporting of Non-GAAP Measures

Groupon is an online discount merchant. In the company's initial S-1 registration statement in 2011, then-CEO Andrew Mason gave prospective investors an up-front warning in a section entitled "We don't measure ourselves in conventional ways", which described Groupon's adjusted consolidated segment operating income (adjusted CSOI) measure. Exhibit 12 provides excerpts from a section entitled "Non-GAAP Financial Measures," which offered a more detailed explanation. Exhibit 13, also from the initial registration statement, shows a reconciliation of CSOI to the most comparable US GAAP measure. In its review, the SEC took the position that online marketing expenses were a recurring cost of business. Groupon responded that the marketing costs were similar to acquisition costs, not recurring costs, and that "we'll ramp down marketing just as fast as we ramped it up, reducing the customer acquisition part of our marketing expenses" as time passes.[20]

Eventually, and after much negative publicity, Groupon changed its non-GAAP measure. Exhibit 14 shows an excerpt from the final prospectus filed in November, after the SEC's review. Use the three exhibits to answer the questions that follow.

Exhibit 12 Groupon's "Non-GAAP Financial Measures"

Disclosures from June S-1 Filing

Adjusted CSOI is operating income of our two segments, North America and International, adjusted for online marketing expense, acquisition-related costs and stock-based compensation expense. Online marketing expense primarily represents the cost to acquire new subscribers and is dictated by the amount of growth we wish to pursue. Acquisition-related costs are non-recurring non-cash items related to certain of our acquisitions. Stock-based compensation expense is a non-cash item. We consider Adjusted CSOI to be an important measure of the performance of our business as it excludes expenses that are non-cash or otherwise not indicative of future operating expenses. We believe it is important to view Adjusted CSOI as a complement to our entire consolidated statements of operations.

Our use of Adjusted CSOI has limitations as an analytical tool, and you should not consider this measure in isolation or as a substitute for analysis of our results as reported under GAAP. Some of these limitations are:

- Adjusted CSOI does not reflect the significant cash investments that we currently are making to acquire new subscribers;
- Adjusted CSOI does not reflect the potentially dilutive impact of issuing equity-based compensation to our management team and employees or in connection with acquisitions;
- Adjusted CSOI does not reflect any interest expense or the cash requirements necessary to service interest or principal payments on any indebtedness that we may incur;
- Adjusted CSOI does not reflect any foreign exchange gains and losses;

(continued)

---

[20] Correspondence between Groupon and SEC, filed in EDGAR on 16 September 2011.

Exhibit 12 (Continued)

- Adjusted CSOI does not reflect any tax payments that we might make, which would represent a reduction in cash available to us;
- Adjusted CSOI does not reflect changes in, or cash requirements for, our working capital needs; and
- Other companies, including companies in our industry, may calculate Adjusted CSOI differently or may use other financial measures to evaluate their profitability, which reduces the usefulness of it as a comparative measure.

Because of these limitations, Adjusted CSOI should not be considered as a measure of discretionary cash available to us to invest in the growth of our business. When evaluating our performance, you should consider Adjusted CSOI alongside other financial performance measures, including various cash flow metrics, net loss and our other GAAP results.

Exhibit 13 Groupon's "Adjusted CSOI"

Excerpt from June S-1 Filing

The following is a reconciliation of CSOI to the most comparable US GAAP measure, "loss from operations," for the years ended December 31, 2008, 2009, and 2010 and the three months ended March 31, 2010 and 2011:

	Year Ended December 31,			Three Months Ended March 31,	
(in $ thousands)	**2008**	**2009**	**2010**	**2010**	**2011**
(Loss) Income from operations	(1,632)	(1,077)	(420,344)	8,571	(117,148)
Adjustments:					
Online marketing	162	4,446	241,546	3,904	179,903
Stock-based compensation	24	115	36,168	116	18,864
Acquisition-related	—	—	203,183	—	—
Total adjustments	186	4,561	480,897	4,020	198,767
Adjusted CSOI	(1,446)	3,484	60,553	12,591	81,619

Exhibit 14 Groupon's "CSOI"

Excerpt from Revised S-1 Filing

The following is a reconciliation of CSOI to the most comparable US GAAP measure, "loss from operations," for the years ended December 31, 2008, 2009, and 2010 and the nine months ended September 30, 2010 and 2011:

Exhibit 14 (Continued)

	Year Ended December 31,			Nine Months Ended September 30,	
(in $ thousands)	**2008**	**2009**	**2010**	**2010**	**2011**
Loss from operations	(1,632)	(1,077)	(420,344)	(84,215)	(218,414)
Adjustments:					
Stock-based compensation	24	115	36,168	8,739	60,922
Acquisition-related	—	—	203,183	37,844	(4,793)
Total adjustments	24	115	239,351	46,583	56,129
CSOI	(1,608)	(962)	(180,993)	(37,632)	(162,285)

1. What cautions did Groupon include along with its description of the “Adjusted CSOI” metric?
2. Groupon excludes “online marketing” from “Adjusted CSOI.” How does the exclusion of this expense compare with the SEC’s limits on non-GAAP performance measures?
3. In the first quarter of 2011, what was the effect of excluding online marketing expenses on the calculation of “Adjusted CSOI”?
4. For 2010, how did results under the revised non-GAAP metric compare with the originally reported metric?

Solution to 1:

Groupon cautioned that the “Adjusted CSOI” metric should not be considered in isolation, should not be considered as a substitute for analysis using GAAP results, and “should not be considered a measure of discretionary cash flow.” The company lists numerous limitations, primarily citing items that adjusted CSOI did not reflect.

Solution to 2:

The SEC specifies that non-GAAP measures should not eliminate items tagged as non-recurring, infrequent, or unusual when such items may be very likely to occur again. Because the online marketing expense occurred in every period reported and is likely to occur again, exclusion of this item appears contrary to SEC requirements.

Solution to 3:

As shown in Exhibit 13, in the first quarter of 2011, the exclusion of the online marketing expense was enough to swing the company from a net loss under US GAAP reporting to a profit—at least, a profit as defined by adjusted CSOI. Using adjusted CSOI as a performance measure, the company showed results that were 35% higher for the first *quarter* of 2011 compared with the entire previous *year*.

Solution to 4:

As shown in Exhibit 14, the revised metric is now called "CSOI" and no longer refers to "Adjusted CSOI." For 2010, results under the revised non-GAAP metric, which includes online marketing costs, shows a loss of $180,993,000 instead of a profit of $60,553,000.

In the case described in Example 5, Groupon changed its reporting and corrected the non-GAAP metric that the SEC had identified as misleading. In other cases, the SEC has pursued enforcement actions against companies for reporting misleading non-GAAP information. One such action was brought in 2009 against SafeNet Inc., where the SEC charged the company with improperly classifying ordinary operating expenses as non-recurring. This related to the integration of an acquired company and exclusion of the expenses from non-GAAP earnings in order to exceed earnings targets. A second action was brought by the SEC in 2017 against MDC Partners Inc. ("MDCA") for improper reconciliation of a non-GAAP measure and for improperly displaying the non-GAAP measure with greater prominence in its earnings releases. The case was brought after the company agreed to follow the rules but then failed to do so, as evidenced by the remark in the SEC's action: "Despite agreeing to comply with non-GAAP financial measure disclosure rules in December 2012 correspondence with the [SEC's] Division of Corporation Finance, MDCA continued to violate those rules for six quarters …" Exhibit 15 presents the headline and sub-headings for one of MDC Partners' earnings announcements that was the subject of the enforcement action.

Exhibit 15 MDC Partners Inc. Press Release [Excerpt]

SEC Form 8-K filed 24 April 2014

This excerpt shows the headline, sub-heads, and lead sentence of the company's press release announcing periodic earnings.

MDC PARTNERS INC. REPORTS RECORD RESULTS FOR THE THREE MONTHS ENDED MARCH 31, 2014

ORGANIC REVENUE GROWTH OF 8.3%, EBITDA GROWTH OF 18.1% AND 90 BASIS POINTS OF MARGIN IMPROVEMENT

FREE CASH FLOW GROWTH OF 34.0%

INCREASED 2014 GUIDANCE IMPLIES YEAR-OVER-YEAR EBITDA GROWTH OF +13.5% TO +16.1%, MARGIN IMPROVEMENT OF 60 TO 70 BASIS POINTS, AND FREE CASH FLOW GROWTH OF +15.8% TO +20.2%

FIRST QUARTER HIGHLIGHTS:

- Revenue increased to $292.6 million from $265.6 million, an increase of 10.1%
- Organic revenue increased 8.3%
- EBITDA increased to $36.4 million from $30.8 million, an increase of 18.1%
- EBITDA margin increased 90 basis points to 12.5% from 11.6%
- Free Cash Flow increased to $20.6 million from $15.4 million, an increase of 34.0%
- Net New Business wins totaled $24.4 million

Exhibit 15 (Continued)

NEW YORK, NY (April 24, 2014) – MDC Partners Inc. (NASDAQ: MDCA; TSX: MDZ.A) today announced financial results for the three months ended March 31, 2014.

…

In general, management may choose to construct non-GAAP financial measures not only to help investors better understand the company's performance but also to paint a more flattering picture of its performance. In some cases, management may attempt to present non-GAAP measures in a way that diverts attention from the standards-compliant financial information that it is required to present.

ACCOUNTING CHOICES AND ESTIMATES AND HOW ACCOUNTING CHOICES AND ESTIMATES AFFECT EARNINGS AND BALANCE SHEETS

9

h describe accounting methods (choices and estimates) that could be used to manage earnings, cash flow, and balance sheet items;

Choices do not necessarily involve complex accounting standards. Something as simple as the shipping terms for goods delivered to customers can have a profound effect on the timing of revenue. On the last day of the first quarter, suppose a company ships $10,000 of goods to a customer on the terms "free on board (FOB) shipping point," arriving the next day. This shipping term means that the customer takes title to the goods, and bears the risk of loss, at the time the goods leave the seller's loading dock. Barring any issues with collectability of the receivable, or a likelihood of a return, the seller would be able to recognize revenue on the sale along with the associated profit. That revenue and profit would be recognized in the first quarter of the year. Change the point at which the goods' title transfers to the customer to "FOB destination" and the revenue pattern will be completely different. Under these terms, the title—and risk of loss—transfers to the customer when the goods arrive at their destination, which is the customer's address. The seller cannot recognize the sale and profit until the shipment arrives the following day, which is the start of a new accounting period.

A simple change in shipping terms can make the difference between revenue and profits in the reporting period or postponing them until the next period. Shipping terms can also influence management behavior. To "make the numbers," managers might push product out the door prematurely under FOB shipping point arrangements in order to reflect as much revenue as possible in the reporting period. Alternatively, in the case of an over-abundance of orders, the company could run the risk of exceeding analysts' consensus estimates by a large margin. Management might be uncomfortable with this situation because investors might extrapolate too much from one reporting period in which expectations were exceeded. Management might want to prevent investors from becoming too optimistic and, if possible, delay revenue recognition until the next quarter. This result could be accomplished by fulfilling customer orders by initiating delivery on the last day of the quarter, with shipping terms set as FOB destination. By doing so, title would transfer in the next accounting period. Another possibility in this scenario is that if the customers insisted on FOB shipping point terms, the selling company could simply delay shipment until after the close of the quarter.

This illustration also highlights a difficult distinction for investors to make. A company may use accounting as a tool to aggressively promote earnings growth—as in the example with the premature shipment of goods with FOB shipping point terms—but it may be aggressively managing the business flow by slacking off on shipping goods when business is "too good," as in the second example. In either case, a desired management outcome is obtained by a simple change in shipping terms. Yet, many investors might be inclined to say that the second example is a conservative kind of earnings management and accept it, even though it artificially masks the actual economic activity that occurred at the time.

9.1 How Accounting Choices and Estimates Affect Earnings and Balance Sheets

Assumptions about inventory cost flows provide another example of how accounting choices can affect financial reporting. Companies may assume that their purchases of inventory items are sold to customers on a first-in-first-out (FIFO) basis, with the result that the remaining inventory reflects the most recent costs. Alternatively, they may assume that their purchases of inventory items are sold to customers on a weighted-average cost basis. Example 6 makes the point that merely choosing a cost flow assumption can affect profitability.

EXAMPLE 6

Effect of Cost Flow Assumption

A company starts operations with no inventory at the beginning of a fiscal year and makes purchases of a good for resale five times during the period at increasing prices. Each purchase is for the same number of units of the good. The purchases, and the cost of goods available for sale, appear in the following table. Notice that the price per unit has increased by 140% by the end of the period.

	Units	Price	Cost
Purchase 1	5	$100	$500
Purchase 2	5	150	750
Purchase 3	5	180	900
Purchase 4	5	200	1,000
Purchase 5	5	240	1,200
Cost of goods available for sale			$4,350

During the period, the company sells, at $250 each, all of the goods purchased except for five of them. Although the ending inventory consists of five units, the cost attached to those units can vary greatly.

1 What are the ending inventory and cost of goods sold if the company uses the FIFO method of inventory costing?

2 What are the ending inventory and cost of goods sold if the company uses the weighted-average method of inventory costing?

3 Compare cost of goods sold and gross profit calculated under the two methods.

Solution to 1:

The ending inventory and cost of goods sold if the company uses the FIFO method of inventory costing are $1,200 and $3,150.

Solution to 2:

The ending inventory and cost of goods sold if the company uses the weighted-average method of inventory costing are $870 and $3,480.

Solution to 3:

The following table shows how the choice of inventory costing methods—FIFO versus weighted average—affects the cost of goods sold and gross profit.

Cost Flow Assumption	FIFO	Weighted Average
Cost of goods available for sale	$4,350	$4,350
Ending inventory (5 units)	(1,200)	(870)
Cost of goods sold	$3,150	$3,480
Sales	$5,000	$5,000
Cost of goods sold	3,150	3,480
Gross profit	$1,850	$1,520
Gross profit margin	37.0%	30.4%

Note: Average inventory cost is calculated as Cost of goods available for sale/Units purchased = $4,350/25 = $174. There are five units in ending inventory, yielding an inventory value of $870.

Depending on which cost flow assumption the company uses, the end-of-period inventory is either $870 (under the weighted-average method) or $1,200 (under FIFO). The choice of method results in a difference of $330 in gross profit and 6.6% in gross profit margin.

The previous example is simplified and extreme for purposes of illustration clarity, but the point is important: Management's choice among acceptable inventory assumptions and methods affects profit. The selection of an inventory costing method is a policy decision, and companies cannot arbitrarily switch from one method to another. The selection does matter to profitability, however, and it also matters to the balance sheet.

In periods of changing prices, the FIFO cost assumption will provide a more current picture of ending inventory value, because the most recent purchases will remain in inventory. The balance sheet will be more relevant to investors. Under the weighted-average cost assumption, however, the balance sheet will display a blend of old and new costs. During inflationary periods, the value of the inventory will be understated: The company will not be able to replenish its inventory at the value shown. At the same time, the weighted-average inventory cost method ensures that the more current costs are shown in cost of sales, making the income statement more relevant than under the FIFO assumption. Trade-offs exist, and investors should be aware of how accounting choices affect financial reports. High-quality financial reporting provides users with sufficient information to assess the effects of accounting choices.

Estimates abound in financial reporting because of the use of accrual accounting, which attempts to show the effects of all economic events on a company during a particular period. Accrual accounting stands in contrast to cash basis accounting, which shows only the cash transactions conducted by a company. Although a high degree of certainty exists with reporting only cash transactions, much information is hidden. For instance, a company with growing revenues that makes the majority of its sales on credit would be understating its revenues for each period if it reported only cash transactions. On an accrual basis, revenues reflect all transactions that occurred, whether they transacted on a cash basis or credit-extended basis. Estimates enter the process because some facts related to events occurring in a particular period might not yet be known. Estimates can be well grounded in reality and applied to present a complete picture of the events affecting a company, or they can be management tools for achieving a desired financial picture.

To illustrate how estimates can affect financial reporting, consider sales made on credit. A company sells $1,000,000 of merchandise on credit and records the sale just before year end. Under accrual accounting, that amount is included in revenues and accounts receivable. The company's managers know from experience that they will never collect every dollar of the accounts receivable. Past experience is that, on average, only 97% of accounts receivable is collected. The company would estimate an amount of the uncollectible accounts at the time the sales occur and record an uncollectible accounts expense of $30,000, lowering earnings. The other side of the entry would be to establish an allowance for uncollectible accounts of $30,000. This allowance would be a contra asset account, presented as an offset to accounts receivable. The accounts receivable, net of the allowance for uncollectible accounts, would be stated at $970,000, which is the amount of cash the company ultimately expects to receive. If cash-basis accounting had been used, no revenues or accounts receivable would have been reported even though sales of merchandise had occurred. Accrual accounting, which contains estimates about future events, provides a much fuller picture of what transpired in the period than pure cash-basis accounting.

Yet, accrual accounting poses temptations to managers to manage the numbers, rather than to manage the business. Suppose a company's managers realize that the company will not meet analysts' consensus estimates in a particular quarter, and further, their bonus pay is dependent on reaching specified earnings targets. By offering special payment terms, or discounts, the managers may induce customers to take delivery of products that they would normally not order, so they could ship the products on FOB shipping point terms and recognize the revenues in the current quarter. They could even be so bold as to ship the goods under those terms even if the customer did not order them, in the hope that the customer would keep them or, at worst, return them in the next accounting period. Their aim would be to move the product off the company's property with FOB shipping point terms.

To further improve earnings in order to meet the consensus estimates, the company's managers might revise their estimate of the uncollectible accounts. The company's collection history shows a typical non-collection rate of 3% of sales, but the managers might rationalize the use of a 2% non-collection rate. This change will reduce the allowance for uncollectible accounts and the expense reported for the period. The managers might be able to justify the reduction on the grounds that the sales occurred in a part of the country that was experiencing an improved economic outlook, or that the company's collection history had been biased by the inclusion of a prolonged period of economic downturn. Whatever the justification, it would be hard to prove that the new estimate was completely right or wrong until time had passed. Because proof of the reliability of estimates is rarely available at the time the estimate is recorded, managers have a readily available means for manipulating earnings at their discretion.

ConAgra Foods Inc. provides an example of how the allowance for uncollectible accounts may be manipulated to manage earnings.[21] A subsidiary, called United Agri-Products (UAP), engaged in several improper accounting practices, one of them being the understatement of uncollectible accounts expense for several years. Exhibit 16 presents an excerpt from the SEC's Accounting and Auditing Enforcement Release.

Exhibit 16 SEC's Accounting and Auditing Enforcement Release Regarding United Agri-Products

> … Generally, UAP's policy required that accounts which were past due between 90 days and one year should be reserved at 50%, and accounts over one year past due were to be reserved at 100%.
>
> … In FY 1999 and continuing through FY 2000, UAP had substantial bad debt problems. In FY 2000, certain former UAP senior executives were informed that UAP needed to record an additional $50 million of bad debt expense. Certain former UAP senior executives were aware that in FY 1999 the size of the bad debt at certain IOCs had been substantial enough that it could have negatively impacted those IOC's ability to achieve PBT (profits before taxes) targets. In addition, just prior to the end of UAP's FY 2000, the former UAP COO (chief operating officer), in the presence of other UAP employees, ordered that UAP's bad debt reserve be reduced by $7 million in order to assist the Company in meeting its PBT target for the fiscal year.
>
> … At the end of FY 2000, former UAP senior executives reported financial results to ConAgra which they knew, or were reckless in not knowing, overstated UAP's income before income taxes because UAP had failed to record sufficient bad debt expense. The misconduct with respect to bad debt expense caused ConAgra to overstate its reported income before income taxes by $7 million, or 1.13%, in FY 2000. At the Agricultural Products' segment level, the misconduct caused that segment's reported operating profit to be overstated by 5.05%.

Deferred-tax assets provide a similar example of choices in estimates affecting the earnings outcome. Deferred-tax assets may arise when a company reports a net operating loss under tax accounting rules. A company may record a deferred-tax asset based on the expectation that losses in the reporting period will offset expected future profits and reduce the company's future income tax liability. Accounting standards require that the deferred tax asset be reduced by a "valuation allowance" to account for the possibility that the company will be unable to generate enough profit to use all of the available tax benefits.[22]

Assume a company loses €1 billion in 2012, generating a net operating loss of the same amount for tax purposes. The company's income tax rate is 25%, and it will be able to apply the net operating loss to its taxable income for the next 10 years. The net operating loss results in a deferred tax asset with a nominal value of €250 million (25% × €1,000,000,000). Initial recognition would result in a deferred tax asset of €250 million and a credit to deferred tax expense of €250 million. The company must address the question of whether or not the €250 million will ever be completely applied to future income. It may be experiencing increased competition and other circumstances that resulted in the €1 billion loss, and it may be unreasonable to assume it will have taxable income against which to apply the loss. In fact, the company's managers might believe it is reasonable to assume only that it will survive for five years, and with marginal profitability. The €250 million deferred tax asset is thus overstated if no valuation allowance is recorded to offset it.

---

[21] Accounting and Auditing Enforcement Release No. 2542, "SEC v. James Charles Blue, Randy Cook, and Victor Campbell,) United States District Court for the District of Colorado, Civ. Action No. 07-CV-00095 REB-MEH (17 January 2007).

[22] See Accounting Standards Codification 740-10-30-16 to 25, "Establishment of a Valuation Allowance for Deferred Tax Assets."

The managers believe that only €100 million of the net operating losses will actually be applied to the company's taxable income. That belief implies that only €25 million of the tax benefits will ever be realized. The deferred tax assets reported on the balance sheet should not exceed this amount. The company should record a valuation allowance of €225 million, which would offset the deferred tax asset balance of €250 million, resulting in a net deferred tax asset balance of €25 million. There would also be a €225 million credit to the deferred tax provision. It is important to understand that the valuation allowance should be revised whenever facts and circumstances change.

The ultimate value of the deferred tax asset is driven by management's outlook for the future—and that outlook may be influenced by other factors. If the company needs to stay in compliance with debt covenants and needs every euro of value that can be justified by the outlook, its managers may take a more optimistic view of the future and keep the valuation allowance artificially low (in other words, the net deferred tax asset high).

PowerLinx Inc. provides an example of how over-optimism about the realizability of a deferred tax asset can lead to misstated financial reports. PowerLinx was a maker of security video cameras, underwater cameras, and accessories. Aside from fraudulently reporting 90% of its fiscal year 2000 revenue, PowerLinx had problems with valuation of its deferred tax assets. Exhibit 17 provides an excerpt from the SEC's Accounting and Auditing Enforcement Release with emphasis added.[23]

Exhibit 17 SEC's Accounting and Auditing Enforcement Release Regarding PowerLinx

PowerLinx improperly recorded on its fiscal year 2000 balance sheet a deferred tax asset of $1,439,322 without any valuation allowance. The tax asset was material, representing *almost forty percent of PowerLinx's total assets* of $3,841,944. PowerLinx also recorded deferred tax assets of $180,613, $72,907, and $44,921, respectively, in its financial statements for the first three quarters of 2000.

PowerLinx did not have a proper basis for recording the deferred tax assets. The company had accumulated significant losses in 2000 and had no historical operating basis from which to conclude that it would be profitable in future years. Underwater camera sales had declined significantly and the company had devoted most of its resources to developing its SecureView product. The sole basis for PowerLinx's "expectation" of future profitability was the purported $9 million backlog of SecureView orders, which management assumed would generate taxable income; however, this purported backlog, which predated Bauer's hiring, did not reflect actual demand for SecureView cameras and, consequently, was not a reasonable or reliable indicator of future profitability.

Another example of misstated financial results caused by improper reflection of the realizability of a deferred tax asset occurred with Hampton Roads Bankshares Inc. ("HRBS"), a commercial bank with deteriorating loan portfolio quality and commensurate losses in the years following the financial crisis. The company reported a deferred tax asset related to its loan losses; however, it did not establish a valuation allowance against its deferred tax asset. This decision was based on dubious projections indicating that the company would earn the necessary future taxable income "to fully utilize the [deferred tax asset] DTA over the applicable carry-forward period."[24] Over time, it became clear that the earnings projections were not realistic, and ultimately the company restated its financial results to include a valuation allowance against almost the entire deferred tax asset. Exhibit 18 presents an excerpt from the company's amended Form 10-Q/A containing the restatement.

[23] Accounting and Auditing Enforcement Release No. 2448, "In the Matter of Douglas R. Bauer, Respondent," SEC (27 June 2006): www.sec.gov/litigation/admin/2006/34-54049.pdf.

EXHIBIT 18 Hampton Roads Bankshares, Inc. Form 10-Q/A filed August 13, 2010 [Excerpt from footnotes]

NOTE B – RESTATEMENT OF CONSOLIDATED FINANCIAL STATEMENTS

Subsequent to filing the Company's annual report on Form 10-K for the year ended December 31, 2009 and its Form 10-Q for the three months ended March 31, 2010 the Company determined that a valuation allowance on its deferred tax assets should be recognized as of December 31, 2009. The Company decided to establish a valuation allowance against the deferred tax asset because it is uncertain when it will realize this asset.

Accordingly, the December 31, 2009 consolidated balance sheet and the March 31, 2010 consolidated financial statements have been restated to account for this determination. The effect of this change in the consolidated financial statements was as follows (in thousands, except per share amounts).

Consolidated Balance Sheet at March 31, 2010

	As Reported	Adjustment	As Restated
Deferred tax assets, net	$70,323	$(70,323)	—
Total assets	3,016,470	(70,323)	$2,946,147
Retained earnings deficit	(158,621)	(70,323)	(228,944)
Total shareholder's equity	156,509	(70,323)	86,186
Total Liabilities and shareholders' equity	3,016,470	(70,323)	2,946,147

Consolidated Balance Sheet at December 31, 2009

	As Reported	Adjustment	As Restated
Deferred tax assets, net	$56,380	$(55,983)	$397
Total assets	2,975,559	(55,983)	2,919,576
Retained earnings deficit	(132,465)	(55,983)	(188,488)

[24] Accounting and Auditing Enforcement Release No. 3600, "In the Matter of Hampton Roads Bankshares Inc., Respondent," SEC (5 December 2014) https://www.sec.gov/litigation/admin/2014/34-73750.pdf.

(Continued)

	As Reported	Adjustment	As Restated
Total shareholder's equity	180,996	(55,983)	125,013
Total Liabilities and shareholders' equity	2,975,559	(55,983)	2,919,576

Another example of how choices and estimates can affect reported results lies in the selection of a depreciation method for allocating the cost of long-lived assets to accounting periods subsequent to their acquisition. A company's managers may choose to depreciate long-lived assets (1) on a straight-line basis, with each year bearing the same amount of depreciation expense; (2) using an accelerated method, with greater depreciation expense recognition in the earlier part of an asset's life; or (3) using an activity-based depreciation method, which allocates depreciation expense based on units of use or production. Depreciation expense is affected by another set of choices and estimates regarding the salvage value of the assets being depreciated. A salvage value of zero will always increase depreciation expense under any method compared with the choice of a non-zero salvage value.

Assume a company invests $1,000,000 in manufacturing equipment and expects it to have a useful economic life of 10 years. During its expected life, the equipment will produce 400,000 units of product, or $2.50 depreciation expense per unit produced. When it is disposed of at the end of its expected life, the company's managers expect to realize no value for the equipment. The following table shows the differences in the three alternative methods of depreciation: straight-line, accelerated on a double-declining balance basis, and units-of-production method, with no salvage value assumed at the end of the equipment's life.

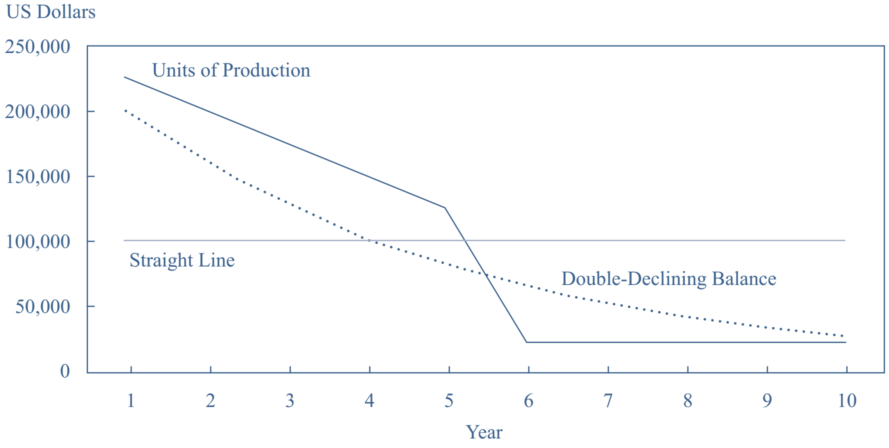
	Straight-Line Method	Double-Declining Balance Method			Units-of-Production Method		
Year	Depreciation Expense	Balance	Declining Balance Rate[1]	Depreciation Expense	Units Produced	Depreciation Rate/Unit	Depreciation Expense
1	$100,000	$1,000,000	20%	$200,000	90,000	$2.50	$225,000
2	100,000	800,000	20%	160,000	80,000	$2.50	200,000
3	100,000	640,000	20%	128,000	70,000	$2.50	175,000
4	100,000	512,000	20%	102,400	60,000	$2.50	150,000
5	100,000	409,600	20%	81,920	50,000	$2.50	125,000
6	100,000	327,680	20%	65,536	10,000	$2.50	25,000
7	100,000	262,144	20%	52,429	10,000	$2.50	25,000
8	100,000	209,715	20%	41,943	10,000	$2.50	25,000
9	100,000	167,772	20%	33,554	10,000	$2.50	25,000
10	100,000	134,218	20%	26,844	10,000	$2.50	25,000
Total	$1,000,000			$892,626	400,000		$1,000,000

[1] Declining balance rate of 20% calculated as 10-year life being equivalent to 10% annual depreciation rate, multiplied by 2 = 20%.

The straight-line method allocates the cost of the equipment evenly to all 10 years of the equipment's life. The double-declining balance method will have a higher allocation of cost to the earlier years of the equipment's life. As its name implies, the depreciation expense will decline in each succeeding year because it is based on a fixed rate applied to a declining balance. The rate used was double the straight-line rate, but it could have been any other rate that the company's managers believed was representative of the way the actual equipment depreciation occurred. Notice that the double-declining balance method also results in an incomplete depreciation of the machine at the end of 10 years; a balance of $107,374 (= $1,000,000 – $892,626) remains at the end of the expected life, which will result in a loss upon the retirement of the equipment if the company's expectation of zero salvage value turns out to be correct. Some companies may choose to depreciate the equipment to its expected salvage value, zero in this case, in its final year of use. Some companies may use a policy of switching to straight-line depreciation after the mid-life of its depreciable assets in order to fully depreciate them. That particular pattern is coincidentally displayed in the units-of-production example, in which the equipment is used most heavily in the earliest part of its useful life, and then levels off to much less utilization in the second half of the expected life.

Exhibit 19 shows the different expense allocation patterns of the methods over the same life. Each will affect earnings differently.

Exhibit 19 Expense Allocation Patterns of Different Depreciation Methods



The company's managers could justify any of these methods. Each might fairly represent the way the equipment will be consumed over its expected economic life, which is a subjective estimate itself. The choices of methods and lives can profoundly affect reported income. These choices are not proven right or wrong until far into the future—but managers must estimate their effects in the present.

Exhibit 20 shows the effects of the three different methods on operating profit and operating profit margins, assuming that the production output of the equipment generates revenues of $500,000 each year and $200,000 of cash operating expenses are incurred, leaving $300,000 of operating profit before depreciation expense.

Exhibit 20 Effects of Depreciation Methods on Operating Profit

	Straight Line		
Year	**Depreciation**	**Operating Profit**	**Operating Profit Margin**
1	$100,000	$200,000	40.0%
2	100,000	200,000	40.0%

10	134,218*	165,782	33.2%

	Units of Production		
Year	**Depreciation**	**Operating Profit**	**Operating Profit Margin**
1	$225,000	$75,000	15.0%
2	200,000	100,000	20.0%
3	175,000	125,000	25.0%
4	150,000	150,000	30.0%
5	125,000	175,000	35.0%
6	25,000	275,000	55.0%
7	25,000	275,000	55.0%
8	25,000	275,000	55.0%
9	25,000	275,000	55.0%
10	25,000	275,000	55.0%

* Includes $107,374 of undepreciated basis, treated as depreciation expense in final year of service.

The straight-line method shows consistent operating profit margins, and the other two methods show varying degrees of increasing operating profit margins as the depreciation expense decreases over time.

The example above shows the differences among alternative methods, but even more depreciation expense variation is possible by changing estimated lives and assumptions about salvage value. For instance, change the expected life assumption to 5 years from 10 and add an expectation that the equipment will have a 10% salvage value at the end of its expected life. Exhibit 21 shows the revised depreciation calculations. Notice that under the double-declining balance method, the depreciation rate is applied to the gross cost, unlike the other two methods. The straight-line method and the units-of-production method subtract the salvage value from the cost before depreciation expense is calculated. Also note that the assumption about the usage of the equipment is revised so that it is depreciated only to its salvage value of $100,000 by the end of its estimated life. The total depreciation under each method is $900,000.

Exhibit 21 Depreciation Calculations for Each Method in Changed Scenario

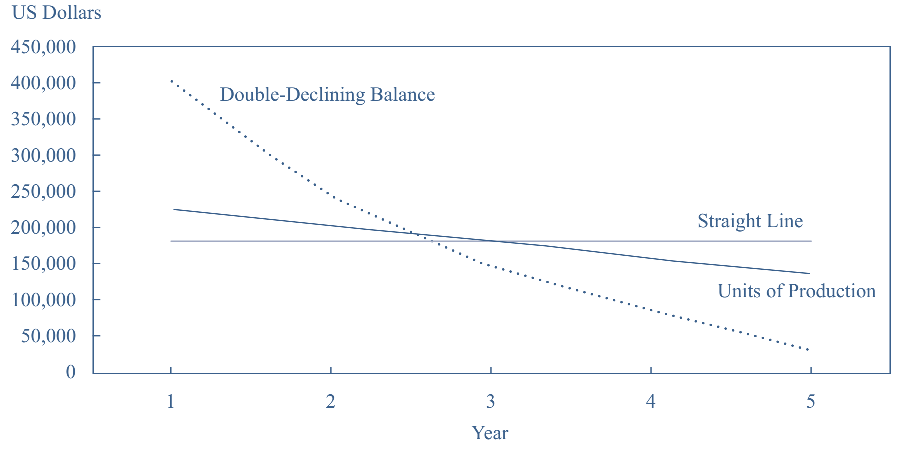
	Straight-Line Method	Double-Declining Balance Method			Units-of-Production Method		
Year	Depreciation Expense	Balance	Declining Balance Rate[1]	Depreciation Expense	Units Produced	Depreciation Rate/Unit	Depreciation Expense
1	**$180,000**	$1,000,000	40%	**$400,000**	100,000	$2.25	**$225,000**
2	**180,000**	600,000	40%	**240,000**	90,000	$2.25	**202,500**
3	**180,000**	360,000	40%	**144,000**	80,000	$2.25	**180,000**
4	**180,000**	216,000	40%	**86,400**	70,000	$2.25	**157,500**
5	**180,000**	129,600	40%	**29,600**[2]	60,000	$2.25	**135,000**
Total	**$900,000**			**$900,000**	400,000		**$900,000**

[1] Declining balance rate of 40% calculated as 5-year life being equivalent to 20% annual depreciation rate, multiplied by 2 = 40%.

[2] Depreciation calculated as $29,600 instead of 40% × $129,600. Rote application of the declining-balance rate would have resulted in $51,840 of expense, which would have depreciated the asset below salvage value.

Exhibit 22 shows the different expense allocation patterns of the methods over the five-year expected life, and assuming a 10% salvage value. Although each method is distinctly different in the timing of the cost allocation over time, the variation is less pronounced than over the longer life used in the previous example.

Exhibit 22 Expense Allocation Patterns of Depreciation Methods in Changed Scenario



One of the clearest examples of how choices affect both the balance sheet and income statement can be found in capitalization practices. In classifying a payment made, management must determine whether the payment will benefit only the current period—making it an expense—or whether it will benefit future periods, leading to classification as a cost to be capitalized as an asset. This management judgment embodies an implicit forecast of how the item acquired by the payment will be used, or not used, in the future.

That judgment can be biased by the powerful effect a capitalization policy can have on earnings. Every amount capitalized on the balance sheet as a building, an item of inventory, a deferred cost, or any "other asset" is an amount that does not get recognized as an expense in the reporting period.

A real-life example can be found in the case of WorldCom Inc., a telecom concern that grew rapidly in the late 1990s. Much of WorldCom's financial reporting was eventually found to be fraudulent. An important part of the misreporting centered on its treatment of what is known in the telecom industry as "line costs". These are the costs of carrying a voice call or data transmission from its starting point to its ending point, and they represented WorldCom's largest expense. WorldCom's chief financial officer decided to capitalize such costs instead of treating them as an operating expense. As a consequence, from the second quarter of 1999 through the first quarter of 2002, WorldCom increased its operating income by $7 billion. In three of the five quarters in which the improper line cost capitalization took place, WorldCom would have recognized pre-tax losses instead of profits.[25]

Similarly, acquisitions are an area in which managers must exercise judgment. An allocation of the purchase price must be made to all of the different assets acquired based on their fair values, and those fair values are not always objectively verifiable. Management may have to make its own estimate of fair values for assets acquired, and it may be biased towards a low estimate for the values of depreciable assets in order to depress future depreciation expense. Another benefit to keeping depreciable asset values low is that the amount of the purchase price that cannot be allocated to specific assets is classified as goodwill, which is neither depreciated nor amortized in future reporting periods.

---

[25] See Report of Investigation by the Special Investigative Committee of the Board of Directors of WorldCom, Inc., by Dennis R. Beresford, Nicholas deB. Katzenbach, & C.B. Rogers, Jr.PP 9-11: www.sec.gov/Archives/edgar/data/723527/000093176303001862/dex991.htm.

Goodwill reporting has choices of its own. Although goodwill has no effect on future earnings when unimpaired, annual testing of its fair value may reveal that the excess of price paid over the fair value of assets may not be recoverable, which should lead to a write-down of goodwill. The estimation process for the fair value of goodwill may depend heavily on projections of future performance. Those projections may be biased upward in order to avoid a goodwill write-down.

HOW CHOICES THAT AFFECT THE CASH FLOW STATEMENT

10

h describe accounting methods (choices and estimates) that could be used to manage earnings, cash flow, and balance sheet items;

The cash flow statement consists of three sections: the operating section, which shows the cash generated or used by operations; the investing section, which shows cash used for investments or provided by their disposal; and the financing section, which shows transactions attributable to financing activities.

The operating section is closely scrutinized by investors. Many of them consider it a reality check on reported earnings, on the grounds that earnings attributable to accrual accounting only and unsupported by actual cash flows may indicate earnings manipulation. Such investors believe that amounts shown for cash generated by operations is more insulated from managerial manipulation than the income statement. Cash generated by operations can be managed to an extent, however.

The operating section of the cash flow statement can be shown either under the direct method or the indirect method. Under the direct method, "entities are encouraged to report major classes of gross cash receipts and gross cash payments and their arithmetic sum—the net cash flow from operating activities."[26] In practice, companies rarely use the direct method. Instead, they use the indirect method, which shows a reconciliation of net income to cash provided by operations. The reconciliation shows the non-cash items affecting net income along with changes in working capital accounts affecting cash from operations. Exhibit 23 provides an example of the indirect presentation method.

Exhibit 23 Indirect Presentation Method

Cash Flows from Operating Activities ($ millions)	2018
Net income	$3,000
Adjustments to reconcile net income to net cash provided by operating activities:	
Provision for doubtful receivables	10
Provision for depreciation and amortization	1,000
Goodwill impairment charges	35
Share-based compensation expense	100
Provision for deferred income taxes	200
Changes in assets and liabilities:	

(continued)

---

[26] Accounting Standards Codification Section 230-10-45-25, "Reporting Operating, Investing, and Financing Activities." The direct method and indirect method are similar in IFRS, as addressed in IAS 7, Paragraph 18.

Exhibit 23 (Continued)

Cash Flows from Operating Activities ($ millions)	2018
Trade, notes and financing receivables related to sales	(2,000)
Inventories	(1,500)
Accounts payable	1,200
Accrued income taxes payable/receivable	(80)
Retirement benefits	90
Other	(250)
Net cash provided by operating activities	$1,805

Whether the indirect method or direct method is used, simple choices exist for managers to improve the *appearance* of cash flow provided by operations without actually improving it. One such choice is in the area of accounts payable management, shaded in Exhibit 23. Assume that the accounts payable balance is $5,200 million at the end of the period, an increase of $1,200 million from its previous year-end balance of $4,000 million. The $1,200 million increase in accounts payable matched increased expenses and/or assets but did not require cash. If the company's managers had further delayed paying creditors $500 million until the day *after* the balance sheet date, they could have increased the cash provided by operating activities by $500 million. If the managers believe that cash generated from operations is a metric of focus for investors, they can impress them with artificially strong cash flow by simply stretching the accounts payable credit period.

What might alert investors to such machinations? They need to examine the composition of the operations section of the cash flow statement—if they do not, then *nothing* will ever alert them. Studying changes in the working capital can reveal unusual patterns that may indicate manipulation of the cash provided by operations.

Another practice that might lead an investor to question the quality of cash provided by operations is to compare a company's cash generation with an industry-wide level or with the cash operating performance of one or more similar competitors. Cash generation performance can be measured several ways. One way is to compare the relationship between cash generated by operations and net income. Cash generated by operations in excess of net income signifies better quality of earnings, whereas a chronic excess of net income over cash generated by operations should be a cause for concern; it may signal the use of accounting methods to simply raise net income instead of depicting financial reality. Another way to measure cash generation performance is to compare cash generated by operations with debt service, capital expenditures, and dividends (if any). When there is a wide variance between the company's cash generation performance and that of its benchmarks, investors should seek an explanation and carefully examine the changes in working capital accounts.

Because investors may focus on cash from operations as an important metric, managers may resort to managing the working capital accounts as described in order to present the most favorable picture. But there are other ways to do this. A company may misclassify operating uses of cash into either the investing or financing sections of the cash flow statement, which enhances the appearance of cash generated by operating activities.

Dynegy Inc. provides an example of manipulation of cash from operations through clever construction of contracts and assistance from an unconsolidated special purpose entity named ABG Gas Supply LLC (ABG). In April 2001, Dynegy entered into a contract for the purchase of natural gas from ABG. According to the contract, Dynegy would purchase gas at *below-market* rates from ABG for nine months and sell it at the current market rate. The nine-month term coincided with Dynegy's 2001 year-end and would result in gains backed by cash flows. Dynegy also agreed to buy gas at *above-market* rates from ABG for the following 51 months and sell it at the current market rate. The contract was reported at its fair value at the end of fiscal year 2001. It had no effect on net income for the year. The earlier portion of the contract resulted in a gain, supported by $300 million of cash flow, but the latter portion of the contract resulted in non-cash losses that offset the profit. The mark-to-market rules required the recognition of both gains and losses from all parts of the contract, and hence the net effect on earnings was zero.

In April 2002, a *Wall Street Journal* article exposed the chicanery, thanks to leaked documents. The SEC required Dynegy to restate the cash flow statement by reclassifying $300 million from the operating section of the cash flow statement to the financing section, on the grounds that Dynegy had used ABG as a conduit to effectively borrow $300 million from Citigroup. The bank had extended credit to ABG, which it used to finance its losses on the contract (Lee, 2012).

Another area of flexibility in cash flow reporting is found in the area of interest capitalization, which creates differences between total interest payments and total interest costs.[27] Assume a company incurs total interest cost of $30,000, composed of $3,000 of discount amortization and $27,000 of interest payments. Of the $30,000, two-thirds of it ($20,000) is expensed; the remaining third ($10,000) is capitalized as plant assets. If the company uses the same interest expense/capitalization proportions to allocate the interest payments between operating and investing activities, then it will report $18,000 (2/3 × $27,000) as an operating outflow and $9,000 (1/3 × $27,000) as an investing outflow. The company might also choose to offset the entire $3,000 of non-cash discount amortization against the $20,000 treated as expense, resulting in an operating outflow as low as $17,000, or as much as $20,000 if it allocated all of the non-cash discount amortization to interest capitalized as investing activities. Similarly, the investing outflow could be as much as $10,000 or as little as $7,000, depending on the treatment of the non-cash discount amortization. There are choices within the choices, all in areas where investors believe choices do not even exist. Nurnberg and Largay (1998) note that companies apparently favor the method that reports the lowest operating outflow, presumably to maximize reported cash from operations.

Investors and analysts need to be aware that presentation choices permitted in IAS 7, "Statement of Cash Flows," offer flexibility in classification of certain items in the cash flow statement. This flexibility can drastically change the results in the operating section of the cash flow statement. An excerpt from IAS 7, Paragraphs 33 and 34, provides the background:

> 33. Interest paid and interest and dividends received are usually classified as operating cash flows for a financial institution. However, there is no consensus on the classification of these cash flows for other entities. Interest paid and interest and dividends received may be classified as operating cash flows because they enter into the determination of profit or loss. *Alternatively, interest paid and interest and dividends received may be classified as financing cash flows and investing cash flows respectively, because they are costs of obtaining financial resources or returns on investments.*
>
> 34. Dividends paid may be classified as a financing cash flow because they are a cost of obtaining financial resources. *Alternatively, dividends paid may be classified as a component of cash flows from operating activities in order to assist users to determine the ability of an entity to pay dividends out of operating cash flows.* [Emphasis added.]

---

[27] See Nurnberg and Largay (1998) and Nurnberg (2006).

By allowing a choice of operating or financing for the placement of interest and dividends received or paid, IAS 7 gives a company's managers the opportunities to select the presentation that gives the best-looking picture of operating performance. An example is Norse Energy Corp. ASA, a Norwegian gas explorer and producer, which changed its classifications of interest paid and interest received in 2007 (Gordon, Henry, Jorgensen, and Linthicum, 2017). Interest paid was switched to financing instead of decreasing cash generated from operations. Norse Energy also switched its classification of interest received to investing from operating cash flow. The net effect of these changes was to report positive, rather than negative, operating cash flows in both 2007 and 2008. With these simple changes, the company could also change the perception of its operations. The cash flow statement formerly presented the appearance of a company with operations that used more cash than it generated, and it possibly raised questions about the sustainability of operations. After the revision, the operating section of the cash flow statement depicted a much more viable operation.

Exhibit 24 shows the net effect of the reclassifications on Norse Energy's cash flows.

Exhibit 24 Reclassification of Cash Flows (amounts in $ millions)

	As Reported (following 2007 reclassification)		Adjustments, If No Reclassification*		Pro-forma (if no reclassification)	
	2008	2007	2008	2007	2008	2007
Operating	**$5.30**	**$2.80**	**($13.70)**	**($14.40)**	**($8.40)**	**($11.60)**
Investing	$0.90	($56.80)	($9.00)	($3.50)	($8.10)	($60.30)
Financing	($16.60)	$34.50	$22.70	$17.90	$6.10	$52.40
Total	($10.40)	($19.50)	$0	$0	($10.40)	($19.50)

* The adjustments reverse the addition of interest received to investing and instead add it to operating. The adjustments also reverse the deduction of interest paid from financing and instead subtract it from operating.

11 CHOICES THAT AFFECT FINANCIAL REPORTING

h describe accounting methods (choices and estimates) that could be used to manage earnings, cash flow, and balance sheet items;

Exhibit 25 summarizes some of the areas where choices can be made that affect financial reports.

Exhibit 25 Areas Where Choices and Estimates Affect Financial Reporting

Area of Choice/ Estimate	Analyst Concerns
Revenue recognition	■ How is revenue recognized: upon shipment or upon delivery of goods? ■ Is the company engaging in “channel stuffing”—the practice of overloading a distribution channel with more product than it is normally capable of selling? This can be accomplished by inducing customers to buy more through unusual discounts, the threat of near-term price increases, or both—or simply by shipping goods that were not ordered. These transactions may be corrected in a subsequent period and may result in restated results. Are accounts receivable relative to revenues abnormally high for relative to the company’s history or to its peers? If so, channel stuffing may have occurred. ■ Is there unusual activity in the allowance for sales returns relative to past history? ■ Does the company’s days sales outstanding show any collection issues that might indicate shipment of unneeded or unwanted goods to customers? ■ Does the company engage in “bill-and-hold” transactions? This is when a customer purchases goods but requests that they remain with the seller until a later date. This kind of transaction makes it possible for a seller to manufacture fictitious sales by declaring end-of-period inventory as “sold but held,” with a minimum of effort and phony documentation. ■ Does the company use rebates as part of its marketing approach? If so, how significantly do the estimates of rebate fulfillment affect net revenues, and have any unusual breaks with history occurred? ■ Does the company separate its revenue arrangements into multiple deliverables of goods or services? This area is one of great revenue recognition flexibility, and also one that provides little visibility to investors. They simply cannot examine a company’s arrangements and decide for themselves whether revenue has been properly allocated to different components of a contract. If a company uses multiple deliverable arrangements with its customers as a routine matter, investors might be more sensitive to revenue reporting risks. In seeking a comfort level, they might ask the following questions: Does the company explain adequately how it determines the different allocations of deliverables and how revenue is recognized on each one? Do deferred revenues result? If not, does it seem reasonable that there are no deferred revenues for this kind of arrangement? Are there unusual trends in revenues and receivables, particularly with regard to cash conversion? If an investor is not satisfied with the answers to these questions, he or she might be more comfortable with other investment choices.

(continued)

Exhibit 25 (Continued)

Area of Choice/ Estimate	Analyst Concerns
Long-lived assets: Depreciation policies	■ Do the estimated life spans of the associated assets make sense, or are they unusually low compared with others in the same industry? ■ Have there been changes in depreciable lives that have a positive effect on current earnings? ■ Do recent asset write-downs indicate that company policy on asset lives might need to be reconsidered?
Intangibles: Capitalization policies	■ Does the company capitalize expenditures related to intangibles, such as software? Does its balance sheet show any R&D capitalized as a result of acquisitions? Or, if the company is an IFRS filer, has it capitalized any internally generated development costs? ■ How do the company's capitalization policies compare with the competition? ■ Are amortization policies reasonable?
Allowance for doubtful accounts/ loan loss reserves	■ Are additions to such allowances lower or higher than in the past? ■ Does the collection experience justify any difference from historical provisioning? ■ Is there a possibility that any lowering of the allowance may be the result of industry difficulties along with the difficulty of meeting earnings expectations?
Inventory cost methods	■ Does the company use a costing method that produces fair reporting results in view of its environment? How do its inventory methods compare with others in its industry? Are there differences that will make comparisons uneven if there are unusual changes in inflation? ■ Does the company use reserves for obsolescence in its inventory valuation? If so, are they subject to unusual fluctuations that might indicate adjusting them to arrive at a specified earnings result? ■ If a company reports under US GAAP and uses last-in-first-out (LIFO) inventory accounting, does LIFO liquidation (the assumed sale of old, lower-cost layers of inventory) occur through inventory reduction programs? This inventory reduction may generate earnings without supporting cash flow, and management may intentionally reduce the layers to produce specific earnings benefits.

Exhibit 25 (Continued)

Area of Choice/ Estimate	Analyst Concerns
Tax asset valuation accounts	■ Tax assets, if present, must be stated at the value at which management expects to realize them, and an allowance must be set up to restate tax assets to the level expected to eventually be converted into cash. Determining the allowance involves an estimate of future operations and tax payments. Does the amount of the valuation allowance seem reasonable, overly optimistic, or overly pessimistic? ■ Are there contradictions between the management commentary and the allowance level, or the tax note and the allowance level? There cannot be an optimistic management commentary and a fully reserved tax asset, or vice versa. One of them has to be wrong. ■ Look for changes in the tax asset valuation account. It may be 100% reserved at first, and then "optimism" increases whenever an earnings boost is needed. Lowering the reserve decreases tax expense and increases net income.
Goodwill	■ Companies must annually assess goodwill balances for impairment on a qualitative basis. If further testing appears necessary, it is based on estimates of the fair value of the reporting units (US GAAP issuers), or cash-generating units (IFRS issuers), associated with goodwill balances. The tests are based on subjective estimates, including future cash flows and the employment of discount rates. ■ Do the disclosures on goodwill testing suggest that the exercise was skewed to avoid impairment charges?
Warranty reserves	■ Have additions to the reserves been reduced, perhaps to make earnings targets? Examine the trend in the charges of actual costs against the reserves: Do they support or contradict the warranty provisioning activity? Do the actual costs charged against the reserve give the analyst any indication about the quality of the products sold?
Related-party transactions	■ Is the company engaged in transactions that disproportionately benefit members of management? Does one company have control over another's destiny through supply contracts or other dealings? ■ Do extensive dealings take place with *non-public* companies that are under management control? If so, those companies could absorb losses (through supply arrangements that are unfavorable to them, for example) in order to make the public company's performance look good. This scenario may provide opportunities for an owner to cash out.

The most important lesson is that choices exist among accounting methods and estimates, and an analyst needs a working knowledge of them in order to understand whether management may have made choices to achieve a desired result.

12

WARNING SIGNS

i. describe accounting warning signs and methods for detecting manipulation of information in financial reports.

The choices management makes to achieve desired results leave a trail, like tracks in sand or snow. The evidence, or warning signs, of information manipulation in financial reports is directly linked to the basic means of manipulation: biased revenue recognition and biased expense recognition. The bias may relate to timing and/or location of recognition. An example of the timing issue is that a company may choose to defer expenses by capitalizing them. Regarding location, it may recognize a loss in other comprehensive income or directly through equity, rather than through the profit and loss statement. The alert investor or analyst should do the following to find warning signs.

1) Pay attention to revenue.

The single largest number on the income statement is revenue, and revenue recognition is a recurring source of accounting manipulation and even outright fraud. Answering the question, "Is revenue higher or lower than the previous comparable period?" is not sufficient. Many analytical procedures can be routinely performed to identify warning signals of malfeasance:

- *Examine the accounting policies note for a company's revenue recognition policies.*
  - Consider whether the policies make it easier to prematurely recognize revenue, such as recognizing revenue immediately upon shipment of goods, or if the company uses bill-and-hold arrangements whereby a sale is recognized before goods are actually shipped to the customer.
  - Barter transactions may exist, which can be difficult to value properly.
  - Rebate programs involve many estimates, including forecasts of the amount of rebates that will ultimately be incurred, which can have significant effects on revenue recognition.
  - Multiple-deliverable arrangements of goods and services are common, but clarity about the timing of revenue recognition for each item or service delivered is necessary for the investor to be comfortable with the reporting of revenues.

  Although none of these decisions necessarily violates accounting standards, each involves significant judgement and warrants close attention if other warning signs are present.
- *Look at revenue relationships.* Compare a company's revenue growth with its primary competitors or its industry peer group.
  - If a company's revenue growth is out of line with its competitors, its industry, or the economy, the investor or analyst needs to understand the reasons for the outperformance. It may be a result of superior management or products and services, but not all management is superior, nor are the products and services of their companies. Revenue quality might be suspect, and the investor should take additional analytical steps.
  - Compare accounts receivable with revenues over several years.

    - Examine the trend to determine whether receivables are increasing as a percentage of total revenues. If so, a company might be engaging in channel-stuffing activities, or worse, recording fictitious sales transactions.
    - Calculate receivables turnover for several years:
        - Examine the trend for unusual changes and seek an explanation if they exist.
        - Compare a company's days sales outstanding (DSO) or receivables turnover with that of relevant competitors or an industry peer group and determine whether the company is an outlier.

  An increase in DSO or decrease in receivables turnover could suggest that some revenues are recorded prematurely or are even fictitious, or that the allowance for doubtful accounts is insufficient.

  - Examine asset turnover. If a company's managers make poor asset allocation choices, revenues may not be sufficient to justify the investment. Be particularly alert when asset allocation choices involve acquisitions of entire companies. If post-acquisition revenue generation is weak, managers might reach for revenue growth anywhere it can be found. That reach for growth might result in accounting abuses.

    Revenues, divided by total assets, indicate the productivity of assets in generating revenues. If the company's asset turnover is continually declining, or lagging the asset turnover of competitors or the industry, it may portend future asset write-downs, particularly in the goodwill balances of acquisitive companies.

2) Pay attention to signals from inventories.

Although inventory is not a component of every company's asset base, its presence creates an opportunity for accounting manipulation.

- *Look at inventory relationships.* Because revenues involve items sold from inventory, the kind of examination an investor should perform on inventory is similar to that for revenues.
  - Compare growth in inventories with competitors and industry benchmarks. If a company's inventory growth is out of line with its peers, without any concurrent sales growth, then it may be simply the result of poor inventory management—an operational inefficiency that might affect an investor's view of a company. It may also signal obsolescence problems in the company's inventory that have not yet been recognized through markdowns to the inventory's net realizable value. Reported gross and net profits could be overstated because of overstated inventory.
  - Calculate the inventory turnover ratio. This ratio is the cost of sales divided by the average ending inventory. Declining inventory turnover could also suggest obsolescence problems that should be recognized.
  - Companies reporting under US GAAP may use LIFO inventory cost flow assumptions. When this assumption is part of the accounting policies, and a company operates in an inflationary environment, investors should note whether old, low-cost inventory costs have been passed through current earnings and artificially improved gross, operating, and net profits.

3) Pay attention to capitalization policies and deferred costs.

In a study of enforcement actions over a five-year period, the SEC found that improper revenue recognition was the most prevalent accounting issue.[28] Suppression of expenses was the next most prevalent problem noted. As the earlier discussion of WorldCom showed, improper capitalization practices can result in a significant misstatement of financial results.

- *Examine the company's accounting policy note for its capitalization policy for long-term assets, including interest costs, and for its handling of other deferred costs.* Compare the company's policy with the industry practice. If the company is the only one capitalizing certain costs while other industry participants treat them as expenses, a red flag is raised. If an outlier company of this type is encountered, it would be useful to cross-check such a company's asset turnover and profitability margins with others in its industry. An investor might expect such a company to be more profitable than its competitors, but the investor might also have lower confidence in the quality of the reported numbers.

4) Pay attention to the relationship of cash flow and net income.

Net income propels stock prices, but cash flow pays bills. Management can manipulate either one, but sooner or later, net income must be realized in cash if a company is to remain viable. When net income is higher than cash provided by operations, one possibility is that aggressive accrual accounting policies have shifted current expenses to later periods. Increasing earnings in the presence of declining cash generated by operations might signal accounting irregularities.

- *Construct a time series of cash generated by operations divided by net income.* If the ratio is consistently below 1.0 or has declined repeatedly, there may be problems in the company's accrual accounts.

5) Other potential warnings signs.

Other areas that might suggest the need for further analysis include the following:

- *Depreciation methods and useful lives.* As discussed earlier, selection of depreciation methods and useful lives can greatly influence profitability. An investor should compare a company's policies with those of its peers to determine whether it is particularly lenient in its effects on earnings. Investors should likewise compare the length of depreciable lives used by a company with those used by its peers.
- *Fourth-quarter surprises.* An investor should be suspicious of possible earnings management if a company routinely disappoints investors with poor earnings or overachieves in the fourth quarter of the year when no seasonality exists in the business. The company may be over- or under-reporting profits in the first three quarters of the year.
- *Presence of related-party transactions.* Related-party transactions often arise when a company's founders are still very active in managing the company, with much of their wealth tied to the company's fortunes. They may be more biased

---

[28] SEC, "Report Pursuant to Section 704 of the Sarbanes–Oxley Act of 2002" (www.sec.gov/news/studies/sox704report.pdf): 5–6.

in their view of a company's performance because it relates directly to their own wealth and reputations, and they may be able to transact business with the company in ways that may not be detected. For instance, they may purchase unsellable inventory from the company for disposal in another company of their own in order to avoid markdowns.

- *Non-operating income or one-time sales included in revenue.* To disguise weakening revenue growth, or just to enhance revenue growth, a company might classify non-operating income items into revenues or fail to clarify the nature of revenues. In the first quarter of 1997, Sunbeam Corporation included one-time disposal of product lines in sales without indicating that such non-recurring sales were included in revenues. This inclusion gave investors a false impression of the company's sustainable revenue-generating capability.
- *Classification of expenses as "non-recurring."* To make operating performance look more attractive, managers might carve out "special items" in the income statement. Particularly when these items appear period after period, equity investors might find their interests best served by not accepting the carve-out of serial "special items" and instead focusing on the net income line in evaluating performance over long periods.
- *Gross/operating margins out of line with competitors or industry.* This disparity is an ambivalent warning sign. It might signal superior management ability. But it might also signal the presence of accounting manipulations to add a veneer of superior management ability to the company's reputation. Only the compilation and examination of other warning signals will enable an investor or analyst to decide which signal is being given.

Warning signals are just that: signals, not indisputable declarations of accounting manipulation guilt. Investors and analysts need to evaluate them cohesively, not on an isolated basis. When an investor finds a number of these signals, the investee company should be viewed with caution or even discarded in favor of alternatives.

Furthermore, as discussed earlier, context is important in judging the value of warning signals. A few examples of facts and circumstances to be aware of are as follows.

- *Younger companies with an unblemished record of meeting growth projections.* It is plausible, especially for a younger company with new and popular product offerings, to generate above-average returns for a period of time. But, as demand dissipates, products mature, and competitors challenge for market share, management may seek to extend its recent record of rapid growth in sales and profitability by unconventional means. At this point, the "earnings games" begin: aggressive estimates, drawing down "cookie jar" reserves, selling assets for accounting gains, taking on excess leverage, or entering into financial transactions with no apparent business purpose other than financial statement "window dressing."
- *Management has adopted a minimalist approach to disclosure.* Confidence in accounting quality depends on disclosure. If management does not seem to take seriously its obligation to provide information, one needs to be concerned. For example, for a large company, management might claim that it has only one reportable segment, or its commentary might be similar from period to period. A plausible explanation for minimalist disclosure policies could be that management is protecting investors' interests by withholding valuable information from competitors. But, this is not necessarily the case. For example, after Sony Corporation acquired CBS Records and Columbia Pictures, it incurred substantial losses for a number of years. Yet, Sony chose to hide its negative trends and doubtful future prospects by aggregating the results within a much larger "Entertainment Division." In 1998, after Sony ultimately wrote off much

of the goodwill associated with these ill-fated acquisitions, the SEC sanctioned Sony and its CFO for failing to separately discuss them in MD&A in a balanced manner.[29]

- *Management fixation on earnings reports.* Beware of companies whose management appears to be fixated on reported earnings, sometimes to the detriment of attending to real drivers of value. Indicators of excessive earnings fixation include the aggressive use of non-GAAP measures of performance, special items, or non-recurring charges. Another indicator of earnings fixation is highly decentralized operations in which division managers' compensation packages are heavily weighted toward the attainment of reported earnings or non-GAAP measures of performance.

Company Culture

A company's culture is an intangible that investors should bear in mind when they are evaluating financial statements for the possibility of accounting manipulation. A management's highly competitive mentality may serve investors well when the company conducts business (assuming that actions taken are not unethical, illegal, or harmfully myopic), but that kind of thinking should not extend to communications with the owners of the company: the shareholders. That mentality can lead to the kind of accounting gamesmanship seen in the early part of the century. In examining financial statements for warning signs of manipulation, the investor should consider whether that mindset exists in the preparation of the financial statements.

One notable example of the mindset comes from one of the most recognized corporate names in the world, General Electric. In the mid-1980s, GE acquired Kidder Peabody, and it was ultimately determined that much of the earnings that Kidder had reported were bogus. As a consequence, GE would announce within two days that it would take a non-cash write-off of $350 million. Here is how former CEO/Chair Jack Welsh described the ensuing meeting with senior management in his memoir, *Straight from the Gut*:

> "The response of our business leaders to the crisis was typical of the GE *culture* [emphasis added]. Even though the books had closed on the quarter, many immediately offered to pitch in to cover the Kidder gap. Some said they could find an extra $10 million, $20 million, and even $30 million from their businesses to offset the surprise. Though it was too late, their willingness to help was a dramatic contrast to the excuses I had been hearing from the Kidder people." (p. 225)

It appears that the corporate governance apparatus fostered a GE culture that extended the concept of teamwork to the point of "sharing" profits to win one for the team as a whole, which is incompatible with the concept of neutral financial reporting. Although research is not conclusive on this question, it may also be worth considering that predisposition to earnings manipulation is more likely to be present when the CEO and board chair are one and the same, or when the audit committee of the board essentially serves at the pleasure of the CEO and lacks financial reporting sophistication. Finally, one could discuss whether the financial reporting environment today would reward or penalize a CEO who openly endorsed a view that he could legitimately exercise financial reporting discretion—albeit within limits—for the purpose of artificially smoothing earnings.

---

[29] Accounting and Auditing Enforcement Release No. 1061, "In the Matter of Sony Corporation and Sumio Sano, Respondents," SEC (5 August 1998).

Restructuring and/or impairment charges.

At times, a company's stock price has been observed to rise after it recognized a "big bath" charge to reported earnings. The conventional wisdom explaining the stock price rise is that accounting recognition signals something positive: that management is now ready to part with the lagging portion of a company, so as to redirect its attention and talents to more-profitable activities. Consequently, the earnings charge should be disregarded for being solely related to past events.

The analyst should also consider, however, that the events leading ultimately to the big bath on the financial statements did not happen overnight, even though the accounting for those events occurs at a subsequent point. Management may want to communicate that the accounting adjustments reflect the company's new path, but the restructuring charge also indicates that the old path of reported earnings was not real. In particular, expenses reported in prior years were very likely understated—even assuming that no improper financial statement manipulation had occurred. To extrapolate historical earnings trends, an analyst should consider making pro forma analytical adjustments to prior years' earnings to reflect a reasonable division of the latest period's restructuring and impairment charges.

Management has a merger and acquisition orientation.

Tyco International Ltd. acquired more than 700 companies from 1996 to 2002. Even assuming the best of intentions regarding financial reporting, a growth-at-any-cost corporate culture poses a severe challenge to operational and financial reporting controls. In Tyco's case, the SEC found that it consistently and fraudulently understated assets acquired (lowering future depreciation and amortization charges) and overstated liabilities assumed (avoiding expense recognition and potentially increasing earnings in future periods).[30]

SUMMARY

Financial reporting quality varies across companies. The ability to assess the quality of a company's financial reporting is an important skill for analysts. Indications of low-quality financial reporting can prompt an analyst to maintain heightened skepticism when reading a company's reports, to review disclosures critically when undertaking financial statement analysis, and to incorporate appropriate adjustments in assessments of past performance and forecasts of future performance.

- Financial reporting quality can be thought of as spanning a continuum from the highest (containing information that is relevant, correct, complete, and unbiased) to the lowest (containing information that is not just biased or incomplete but possibly pure fabrication).
- *Reporting quality*, the focus of this reading, pertains to the information disclosed. High-quality reporting represents the economic reality of the company's activities during the reporting period and the company's financial condition at the end of the period.

---

[30] Accounting and Auditing Enforcement Release No. 2414, "SEC Brings Settled Charges Against Tyco International Ltd. Alleging Billion Dollar Accounting Fraud," SEC (17 April 2006): www.sec.gov/litigation/litreleases/2006/lr19657.htm.

- *Results quality* (commonly referred to as earnings quality) pertains to the earnings and cash generated by the company's actual economic activities and the resulting financial condition, relative to expectations of current and future financial performance. Quality earnings are regarded as being sustainable, providing a sound platform for forecasts.
- An aspect of financial reporting quality is the degree to which accounting choices are conservative or aggressive. "Aggressive" typically refers to choices that aim to enhance the company's reported performance and financial position by inflating the amount of revenues, earnings, and/or operating cash flow reported in the period; or by decreasing expenses for the period and/or the amount of debt reported on the balance sheet.
- Conservatism in financial reports can result from either (1) accounting standards that specifically require a conservative treatment of a transaction or an event or (2) judgments made by managers when applying accounting standards that result in conservative results.
- Managers may be motivated to issue less-than-high-quality financial reports in order to mask poor performance, to boost the stock price, to increase personal compensation, and/or to avoid violation of debt covenants.
- Conditions that are conducive to the issuance of low-quality financial reports include a cultural environment that result in fewer or less transparent financial disclosures, book/tax conformity that shifts emphasis toward legal compliance and away from fair presentation, and limited capital markets regulation.
- Mechanisms that discipline financial reporting quality include the free market and incentives for companies to minimize cost of capital, auditors, contract provisions specifically tailored to penalize misreporting, and enforcement by regulatory entities.
- Pro forma earnings (also commonly referred to as non-GAAP or non-IFRS earnings) adjust earnings as reported on the income statement. Pro forma earnings that exclude negative items are a hallmark of aggressive presentation choices.
- Companies are required to make additional disclosures when presenting any non-GAAP or non-IFRS metric.
- Managers' considerable flexibility in choosing their companies' accounting policies and in formulating estimates provides opportunities for aggressive accounting.
- Examples of accounting choices that affect earnings and balance sheets include inventory cost flow assumptions, estimates of uncollectible accounts receivable, estimated realizability of deferred tax assets, depreciation method, estimated salvage value of depreciable assets, and estimated useful life of depreciable assets.
- Cash from operations is a metric of interest to investors that can be enhanced by operating choices, such as stretching accounts payable, and potentially by classification choices.

PRACTICE PROBLEMS

1 In contrast to earnings quality, financial reporting quality *most likely* pertains to:

A sustainable earnings.
B relevant information.
C adequate return on investment.

2 The information provided by a low-quality financial report will *most likely*:

A decrease company value.
B indicate earnings are not sustainable.
C impede the assessment of earnings quality.

3 To properly assess a company's past performance, an analyst requires:

A high earnings quality.
B high financial reporting quality.
C both high earnings quality and high financial reporting quality.

4 Low quality earnings *most likely* reflect:

A low-quality financial reporting.
B company activities which are unsustainable.
C information that does not faithfully represent company activities.

5 Earnings that result from non-recurring activities *most likely* indicate:

A lower-quality earnings.
B biased accounting choices.
C lower-quality financial reporting.

6 Which attribute of financial reports would *most likely* be evaluated as optimal in the financial reporting spectrum?

A Conservative accounting choices
B Sustainable and adequate returns
C Emphasized pro forma earnings measures

7 Financial reports of the lowest level of quality reflect:

A fictitious events.
B biased accounting choices.
C accounting that is non-compliant with GAAP.

8 When earnings are increased by deferring research and development (R&D) investments until the next reporting period, this choice is considered:

A non-compliant accounting.
B earnings management as a result of a real action.
C earnings management as a result of an accounting choice.

9 A high-quality financial report may reflect:

A earnings smoothing.
B low earnings quality.
C understatement of asset impairment.

© 2019 CFA Institute. All rights reserved.

10 If a particular accounting choice is considered aggressive in nature, then the financial performance for the reporting period would *most likely*:

A be neutral.

B exhibit an upward bias.

C exhibit a downward bias.

11 Which of the following is *most likely* to reflect conservative accounting choices?

A Decreased reported earnings in later periods

B Increased reported earnings in the period under review

C Increased debt reported on the balance sheet at the end of the current period

12 Which of the following is *most likely* to be considered a potential benefit of accounting conservatism?

A A reduction in litigation costs

B Less biased financial reporting

C An increase in current period reported performance

13 Which of the following statements *most likely* describes a situation that would motivate a manager to issue low-quality financial reports?

A The manager's compensation is tied to stock price performance.

B The manager has increased the market share of products significantly.

C The manager has brought the company's profitability to a level higher than competitors.

14 Which of the following concerns would *most likely* motivate a manager to make conservative accounting choices?

A Attention to future career opportunities

B Expected weakening in the business environment

C Debt covenant violation risk in the current period

15 Which of the following conditions *best* explains why a company's manager would obtain legal, accounting, and board level approval prior to issuing low-quality financial reports?

A Motivation

B Opportunity

C Rationalization

16 A company is experiencing a period of strong financial performance. In order to increase the likelihood of exceeding analysts' earnings forecasts in the next reporting period, the company would *most likely* undertake accounting choices for the period under review that:

A inflate reported revenue.

B delay expense recognition.

C accelerate expense recognition.

17 Which of the following situations represents a motivation, rather than an opportunity, to issue low-quality financial reports?

A Poor internal controls

B Search for a personal bonus

C Inattentive board of directors

18 Which of the following situations will *most likely* motivate managers to inflate reported earnings?

- **A** Possibility of bond covenant violation
- **B** Earnings in excess of analysts' forecasts
- **C** Earnings that are greater than the previous year

19 Which of the following *best* describes an opportunity for management to issue low-quality financial reports?

- **A** Ineffective board of directors
- **B** Pressure to achieve some performance level
- **C** Corporate concerns about financing in the future

20 An audit opinion of a company's financial reports is *most likely* intended to:

- **A** detect fraud.
- **B** reveal misstatements.
- **C** assure that financial information is presented fairly.

21 If a company uses a non-GAAP financial measure in an SEC filing, then the company must:

- **A** give more prominence to the non-GAAP measure if it is used in earnings releases.
- **B** provide a reconciliation of the non-GAAP measure and equivalent GAAP measure.
- **C** exclude charges requiring cash settlement from any non-GAAP liquidity measures.

22 A company wishing to increase earnings in the reporting period may choose to:

- **A** decrease the useful life of depreciable assets.
- **B** lower estimates of uncollectible accounts receivables.
- **C** classify a purchase as an expense rather than a capital expenditure.

23 Bias in revenue recognition would *least likely* be suspected if:

- **A** the firm engages in barter transactions.
- **B** reported revenue is higher than the previous quarter.
- **C** revenue is recognized before goods are shipped to customers.

24 Which technique *most likely* increases the cash flow provided by operations?

- **A** Stretching the accounts payable credit period
- **B** Applying all non-cash discount amortization against interest capitalized
- **C** Shifting classification of interest paid from financing to operating cash flows

25 Which of the following is an indication that a company may be recognizing revenue prematurely? Relative to its competitors, the company's:

- **A** asset turnover is decreasing.
- **B** receivables turnover is increasing.
- **C** days sales outstanding is increasing.

26 Which of the following would *most likely* signal that a company may be using aggressive accrual accounting policies to shift current expenses to later periods? Over the last five-year period, the ratio of cash flow to net income has:

- **A** increased each year.
- **B** decreased each year.
- **C** fluctuated from year to year.

27 An analyst reviewing a firm with a large reported restructuring charge to earnings should:

A view expenses reported in prior years as overstated.

B disregard it because it is solely related to past events.

C consider making pro forma adjustments to prior years' earnings.

SOLUTIONS

1 B is correct. Financial reporting quality pertains to the quality of information in financial reports. High-quality financial reporting provides decision-useful information, which is relevant and faithfully represents the economic reality of the company's activities. Earnings of high quality are sustainable and provide an adequate level of return. Highest-quality financial reports reflect both high financial reporting quality and high earnings quality.

2 C is correct. Financial reporting quality pertains to the quality of the information contained in financial reports. High-quality financial reports provide decision-useful information that faithfully represents the economic reality of the company. Low-quality financial reports impede assessment of earnings quality. Financial reporting quality is distinguishable from earnings quality, which pertains to the earnings and cash generated by the company's actual economic activities and the resulting financial condition. Low-quality earnings are not sustainable and decrease company value.

3 B is correct. Financial reporting quality pertains to the quality of the information contained in financial reports. If financial reporting quality is low, the information provided is of little use in assessing the company's performance. Financial reporting quality is distinguishable from earnings quality, which pertains to the earnings and cash generated by the company's actual economic activities and the resulting financial condition.

4 B is correct. Earnings quality pertains to the earnings and cash generated by the company's actual economic activities and the resulting financial condition. Low-quality earnings are likely not sustainable over time because the company does not expect to generate the same level of earnings in the future or because earnings will not generate sufficient return on investment to sustain the company. Earnings that are not sustainable decrease company value. Earnings quality is distinguishable from financial reporting quality, which pertains to the quality of the information contained in financial reports.

5 A is correct. Earnings that result from non-recurring activities are unsustainable. Unsustainable earnings are an example of lower-quality earnings. Recognizing earnings that result from non-recurring activities is neither a biased accounting choice nor indicative of lower quality financial reporting because it faithfully represents economic events.

6 B is correct. At the top of the quality spectrum of financial reports are reports that conform to GAAP, are decision useful, and have earnings that are sustainable and offer adequate returns. In other words, these reports have both high financial reporting quality and high earnings quality.

7 A is correct. Financial reports span a quality continuum from high to low based on decision-usefulness and earnings quality (see Exhibit 2 of the reading). The lowest-quality reports portray fictitious events, which may misrepresent the company's performance and/or obscure fraudulent misappropriation of the company's assets.

8 B is correct. Deferring research and development (R&D) investments into the next reporting period is an example of earnings management by taking a *real* action.

9 B is correct. High-quality financial reports offer useful information, meaning information that is relevant and faithfully represents actual performance. Although low earnings quality may not be desirable, if the reported earnings

are representative of actual performance, they are consistent with high-quality financial reporting. Highest-quality financial reports reflect both high financial reporting quality and high earnings quality.

10 B is correct. Aggressive accounting choices aim to enhance the company's reported performance by inflating the amount of revenues, earnings, and/or operating cash flow reported in the period. Consequently, the financial performance for that period would most likely exhibit an upward bias.

11 C is correct. Accounting choices are considered conservative if they decrease the company's reported performance and financial position in the period under review. Conservative choices may increase the amount of debt reported on the balance sheet. They may decrease the revenues, earnings, and/or operating cash flow reported for the period and increase those amounts in later periods.

12 A is correct. Conservatism reduces the possibility of litigation and, by extension, litigation costs. Rarely, if ever, is a company sued because it understated good news or overstated bad news. Accounting conservatism is a type of bias in financial reporting that decreases a company's reported performance. Conservatism directly conflicts with the characteristic of neutrality.

13 A is correct. Managers often have incentives to meet or beat market expectations, particularly if management compensation is linked to increases in stock prices or to reported earnings.

14 B is correct. Managers may be motivated to understate earnings in the reporting period and increase the probability of meeting or exceeding the next period's earnings target.

15 C is correct. Typically, conditions of opportunity, motivation, and rationalization exist when individuals issue low-quality financial reports. Rationalization occurs when an individual is concerned about a choice and needs to be able to justify it to herself or himself. If the manager is concerned about a choice in a financial report, she or he may ask for other opinions to convince herself or himself that it is okay.

16 C is correct. In a period of strong financial performance, managers may pursue accounting choices that increase the probability of exceeding earnings forecasts for the next period. By accelerating expense recognition or delaying revenue recognition, managers may inflate earnings in the next period and increase the likelihood of exceeding targets.

17 B is correct. Motivation can result from pressure to meet some criteria for personal reasons, such as a bonus, or corporate reasons, such as concern about future financing. Poor internal controls and an inattentive board of directors offer opportunities to issue low-quality financial reports.

18 A is correct. The possibility of bond covenant violations may motivate managers to inflate earnings in the reporting period. In so doing, the company may be able to avoid the consequences associated with violating bond covenants.

19 A is correct. Opportunities to issue low-quality financial reports include internal conditions, such as an ineffective board of directors, and external conditions, such as accounting standards that provide scope for divergent choices. Pressure to achieve a certain level of performance and corporate concerns about future financing are examples of motivations to issue low-quality financial reports. Typically, three conditions exist when low-quality financial reports are issued: opportunity, motivation, and rationalization.

20 C is correct. An audit is intended to provide assurance that the company's financial reports are presented fairly, thus providing discipline regarding financial reporting quality. Regulatory agencies usually require that the financial

statements of publicly traded companies be audited by an independent auditor to provide assurance that the financial statements conform to accounting standards. Privately held companies may also choose to obtain audit opinions either voluntarily or because an outside party requires it. An audit is not typically intended to detect fraud. An audit is based on sampling and it is possible that the sample might not reveal misstatements.

21 B is correct. If a company uses a non-GAAP financial measure in an SEC filing, it is required to provide the most directly comparable GAAP measure with equivalent prominence in the filing. In addition, the company is required to provide a reconciliation between the non-GAAP measure and the equivalent GAAP measure. Similarly, IFRS require that any non-IFRS measures included in financial reports must be defined and their potential relevance explained. The non-IFRS measures must be reconciled with IFRS measures.

22 B is correct. If a company wants to increase reported earnings, the company's managers may reduce the allowance for uncollected accounts and the related expense reported for the period. Decreasing the useful life of depreciable assets would increase depreciation expense and decrease earnings in the reporting period. Classifying a purchase as an expense, rather than capital expenditure, would decrease earnings in the reporting period. The use of accrual accounting may result in estimates in financial reports, because all facts associated with events may not be known at the time of recognition. These estimates can be grounded in reality or managed by the company to present a desired financial picture.

23 B is correct. Bias in revenue recognition can lead to manipulation of information presented in financial reports. Addressing the question as to whether revenue is higher or lower than the previous period is not sufficient to determine if there is bias in revenue recognition. Additional analytical procedures must be performed to identify warning signals of accounting malfeasance. Barter transactions are difficult to value properly and may result in bias in revenue recognition. Policies that make it easier to prematurely recognize revenue, such as before goods are shipped to customers, may be a warning sign of accounting malfeasance.

24 A is correct. Managers can temporarily show a higher cash flow from operations by stretching the accounts payable credit period. In other words, the managers delay payments until the next accounting period. Applying all non-cash discount amortization against interest capitalized causes reported interest expenses and operating cash outflow to be higher, resulting in a lower cash flow provided by operations. Shifting the classification of interest paid from financing to operating cash flows lowers the cash flow provided by operations.

25 C is correct. If a company's days sales outstanding (DSO) is increasing relative to competitors, this may be a signal that revenues are being recorded prematurely or are even fictitious. There are numerous analytical procedures that can be performed to provide evidence of manipulation of information in financial reporting. These warning signs are often linked to bias associated with revenue recognition and expense recognition policies.

26 B is correct. If the ratio of cash flow to net income for a company is consistently below 1 or has declined repeatedly over time, this may be a signal of manipulation of information in financial reports through aggressive accrual accounting policies. When net income is consistently higher than cash provided by operations, one possible explanation is that the company may be using aggressive accrual accounting policies to shift current expenses to later periods.

27 C is correct. To extrapolate historical earnings trends, an analyst should consider making pro forma analytical adjustments of prior years' earnings to reflect in those prior years a reasonable share of the current period's restructuring and impairment charges.

Applications of Financial Statement Analysis

by Thomas R. Robinson, PhD, CFA, J. Hennie van Greuning, DCom, CFA, Elaine Henry, PhD, CFA, and Michael A. Broihahn, CPA, CIA, CFA

Thomas R. Robinson, PhD, CFA, is at AACSB International (USA). J. Hennie van Greuning, DCom, CFA, is at BIBD (Brunei). Elaine Henry, PhD, CFA, is at Stevens Institute of Technology (USA). Michael A. Broihahn, CPA, CIA, CFA, is at Barry University (USA).

LEARNING OUTCOMES

Mastery	*The candidate should be able to:*
☐	**a.** evaluate a company's past financial performance and explain how a company's strategy is reflected in past financial performance;
☐	**b.** demonstrate how to forecast a company's future net income and cash flow;
☐	**c.** describe the role of financial statement analysis in assessing the credit quality of a potential debt investment;
☐	**d.** describe the use of financial statement analysis in screening for potential equity investments;
☐	**e.** explain appropriate analyst adjustments to a company's financial statements to facilitate comparison with another company.

Note: Changes in accounting standards as well as new rulings and/or pronouncements issued after the publication of the readings on financial reporting and analysis may cause some of the information in these readings to become dated. Candidates are *not* responsible for anything that occurs after the readings were published. In addition, candidates are expected to be familiar with the analytical frameworks contained in the readings, as well as the implications of alternative accounting methods for financial analysis and valuation discussed in the readings. Candidates are also responsible for the content of accounting standards, but not for the actual reference numbers. Finally, candidates should be aware that certain ratios may be defined and calculated differently. When alternative ratio definitions exist and no specific definition is given, candidates should use the ratio definitions emphasized in the readings.

1 INTRODUCTION & EVALUATING PAST FINANCIAL PERFORMANCE

a evaluate a company's past financial performance and explain how a company's strategy is reflected in past financial performance;

This reading presents several important applications of financial statement analysis. Among the issues we will address are the following:

- What are the key questions to address in evaluating a company's past financial performance?
- How can an analyst approach forecasting a company's future net income and cash flow?
- How can financial statement analysis be used to evaluate the credit quality of a potential fixed-income investment?
- How can financial statement analysis be used to screen for potential equity investments?
- How can differences in accounting methods affect financial ratio comparisons between companies, and what are some adjustments analysts make to reported financials to facilitate comparability among companies?

The reading "Financial Statement Analysis: An Introduction" described a framework for conducting financial statement analysis. Consistent with that framework, prior to undertaking any analysis, an analyst should explore the purpose and context of the analysis. The purpose and context guide further decisions about the approach, the tools, the data sources, and the format in which to report results of the analysis, and also suggest which aspects of the analysis are most important. Having identified the purpose and context, the analyst should then be able to formulate the key questions that the analysis must address. The questions will suggest the data the analyst needs to collect to objectively address the questions. The analyst then processes and analyzes the data to answer these questions. Conclusions and decisions based on the analysis are communicated in a format appropriate to the context, and follow-up is undertaken as required. Although this reading will not formally present applications as a series of steps, the process just described is generally applicable.

Section 1.1 of this reading describes the use of financial statement analysis to evaluate a company's past financial performance, and Sections 2 and 3 describe basic approaches to projecting a company's future financial performance. Section 4 presents the use of financial statement analysis in assessing the credit quality of a potential debt investment. Section 5 concludes the survey of applications by describing the use of financial statement analysis in screening for potential equity investments. Analysts often encounter situations in which they must make adjustments to a company's reported financial results to increase their accuracy or comparability with the financials of other companies. Sections 6–8 illustrate several common types of analyst adjustments. Section 9 presents a summary, and practice problems in the CFA Institute multiple-choice format conclude the reading.

1.1 Application: Evaluating Past Financial Performance

Analysts examine a company's past financial performance for a number of reasons. Cross-sectional analysis of financial performance facilitates understanding of the comparability of companies for a market-based valuation.[1] Analysis of a company's historical performance over time can provide a basis for a forward-looking analysis of the company. Both cross-sectional and trend analysis can provide information for evaluating the quality and performance of a company's management.

An evaluation of a company's past performance addresses not only *what* happened (i.e., how the company performed) but also *why* it happened—the causes behind the performance and how the performance reflects the company's strategy. Evaluative judgments assess whether the performance is better or worse than a relevant benchmark, such as the company's own historical performance, a competitor's performance, or market expectations. Some key analytical questions include the following:

- How and why have corporate measures of profitability, efficiency, liquidity, and solvency changed over the periods being analyzed?
- How do the level and trend in a company's profitability, efficiency, liquidity, and solvency compare with the corresponding results of other companies in the same industry? What factors explain any differences?
- What aspects of performance are critical for a company to successfully compete in its industry, and how did the company perform relative to those critical performance aspects?
- What are the company's business model and strategy, and how did they influence the company's performance as reflected in, for example, its sales growth, efficiency, and profitability?

Data available to answer these questions include the company's (and its competitors') financial statements, materials from the company's investor relations department, corporate press releases, and non-financial-statement regulatory filings, such as proxies. Useful data also include industry information (e.g., from industry surveys, trade publications, and government sources), consumer information (e.g., from consumer satisfaction surveys), and information that is gathered by the analyst firsthand (e.g., through on-site visits). Processing the data typically involves creating common-size financial statements, calculating financial ratios, and reviewing or calculating industry-specific metrics. Example 1 illustrates the effects of strategy on performance and the use of basic economic reasoning in interpreting results.

EXAMPLE 1

A Change in Products Reflected in Financial Performance

Apple Inc. is a company that has evolved and adapted over time. In its 1994 Prospectus filed with the US SEC, Apple identified itself as "one of the world's leading personal computer technology companies." At that time, most of its revenue was generated by computer sales. In the prospectus, however, Apple stated, "The Company's strategy is to expand its market share in the personal computing industry while developing and expanding into new related business such as Personal Interactive Electronics and Apple Business Systems." Over time, products other than computers became significant generators of revenue and profit.

---

[1] Pinto et al. (2010) describe market-based valuation as using price multiples—ratios of a stock's market price to some measure of value per share (e.g., price-to-earnings ratios). Although the valuation method may be used independently of an analysis of a company's past financial performance, such an analysis may provide reasons for differences in companies' price multiples.

In 2005, an article in *Barron's* said, "In the last year, the iPod has become Apple's best-selling product, bringing in a third of revenues for the Cupertino, Calif. firm . . . Little noticed by these iPod zealots, however is a looming threat . . . Wireless phone companies are teaming up with the music industry to make most mobile phones into music players" (*Barron's* 27 June 2005, p. 19). The threat noted by *Barron's* was not unnoticed or ignored by Apple.

In June 2007, Apple itself entered the mobile phone market with the launch of the original iPhone, followed in June 2008 by the second-generation iPhone 3G (a handheld device combining the features of a mobile phone, an iPod, and an internet connection device). Soon after, the company launched the iTunes App Store, which allows users to download third-party applications onto their iPhones. As noted in a 2009 *Business Week* article, Apple "is the world's largest music distributor, having passed Wal-Mart Stores in early 2008. Apple sells around 90% of song downloads and 75% of digital music players in the United States" (*Business Week*, 28 September 2009, p. 34). Product innovations continue as evidenced by the introduction of the iPad in January 2010.

In analyzing the historical performance of Apple in 2018, an analyst might refer to the information presented in Exhibit 1, which shows sales, profitability, sales by product line and product mix.

Exhibit 1 (dollars in millions)

Sales and Profitability	**2017**	**2016**	**2015**	**2014**	**2013**	**2012**	**2011**	**2010**
Sales	229,234	215,639	233,715	182,795	170,910	156,608	108,249	65,225
Cost of goods sold	141,048	131,376	140,089	112,258	106,606	87,846	64,431	39,541
Gross profit	88,186	84,263	93,626	70,537	64,304	68,762	43,818	25,684
Gross margin	38.5%	39.1%	40.1%	38.6%	37.6%	43.9%	40.5%	39.4%
Net sales by product								
Mac	25,850	22,831	25,471	24,079	21,483	23,221	21,783	17,480

Source: Apple 10-K filings.

Using the information provided, address the following:

1. How have sales and gross margin changed over time?
2. How has the company's product mix changed since the introduction of the iPad in 2010, and what might this change suggest for an analyst in evaluating Apple's profitability over time and its ability to maintain that profitability?

Solution to 1:

Since 2010 total sales have increased from $65 billion to $229 billion. This represents an annualized growth rate of almost 20%. There was only one year that did not have sales growth in dollars (2016). Gross margin has ranged from 37.6% to 43.9%. Gross margin increased from 2010, when the iPad was introduced, through 2012, when it reached its peak. Gross margin then declined in 2013 and trended upward through 2015. There were modest declines in gross margin after 2015.

Solution to 2:

When the iPad was introduced in 2010 it received a significant share of the product mix, rising to 17.7% in 2011, the first full year after introduction. The iPad's product mix share approached 20% share in 2012 and then declined slightly for two years before a larger decline down to a relatively stable product mix share of around 9%. This could be explained by reaching fairly widespread adoption. The iPhone also gained significant product mix share, rising steadily from 38.6% in 2010 to 66.3% in 2015. Share declined slightly since 2015 but still remains the largest of Apple's product segments at more than 60%. Sales of their original product, the Mac, have declined from more than 25% of sales to around 10%. Services have changed significantly but have shown a steady increase in recent years, most likely due to Apple's music and other media subscription plans. Initially a blockbuster product, the iPod is now included in "other," and this is the largest driver of the decline in that category over time.

Apple had a history of introducing new products every few years, but in recent years the company has not created new product categories. Instead the company has periodically introduced new models of iPads and iPhones. The recent decline in margins is attributable in part to the lack of new products and services and highlights the importance of product innovation to Apple in maintaining historically healthy margins.

In calculating and interpreting financial statement ratios, an analyst needs to be aware of the potential impact on the financial statements and related ratios of companies reporting under different accounting standards, such as international financial reporting standards (IFRS), US generally accepted accounting principles (US GAAP), or other home-country GAAP. Furthermore, even within a given set of accounting standards, companies still have discretion to choose among acceptable methods. A company also may make different assumptions and estimates even when applying the same method as another company. Therefore, making selected adjustments to a company's financial statement data may be useful to facilitate comparisons with other companies or with the industry overall. Examples of such analyst adjustments will be discussed in Sections 6–8.

Non-US companies that use any acceptable body of accounting standards (other than IFRS or US GAAP) and file with the US SEC (because their shares or depositary receipts based on their shares trade in the United States) are required to reconcile their net income and shareholders' equity accounts to US GAAP. Note that in 2007, the SEC eliminated the reconciliation requirement for non-US companies using IFRS and filing with the SEC, however companies may still voluntarily provide this information for comparison purposes.

In general, because the reconciliation data are no longer required by the SEC, we cannot always determine whether differences in net income, equity, and thus ROE also exist between IFRS and the companies' home-country GAAP (including US GAAP).

Comparison of the levels and trends in a company's performance provide information about *how* the company performed. The company's management presents its view about causes underlying its performance in the management commentary or management discussion and analysis (MD&A) section of its annual report and during periodic conference calls with analysts and investors. To gain additional understanding of the causes underlying a company's performance, an analyst can review industry information or seek information from additional sources, such as consumer surveys.

The results of an analysis of past performance provide a basis for reaching conclusions and making recommendations. For example, an analysis undertaken as the basis for a forward-looking study might conclude that a company's future performance is or is not likely to reflect continuation of recent historical trends. As another example, an analysis to support a market-based valuation of a company might focus on whether the company's profitability and growth outlook, which is better (worse) than the peer group median, justifies its relatively high (low) valuation. This analysis would consider market multiples, such as price-to-earnings ratio (P/E), price-to-book ratio, and total invested capital to EBITDA (earnings before interest, taxes, depreciation, and amortization).[2] As another example, an analysis undertaken as part of an evaluation of the management of two companies might result in conclusions about whether one company has grown as fast as another company, or as fast as the industry overall, and whether each company has maintained profitability while growing.

2

APPLICATION: PROJECTING FUTURE FINANCIAL PERFORMANCE AS AN INPUT TO MARKET BASED VALUATION

b demonstrate how to forecast a company's future net income and cash flow;

---

[2] **Total invested capital** is the sum of market value of common equity, book value of preferred equity, and face value of debt.

Projections of future financial performance are used in determining the value of a company or its equity component. Projections of future financial performance are also used in credit analysis—particularly in project finance or acquisition finance—to determine whether a company's cash flows will be adequate to pay the interest and principal on its debt and to evaluate whether a company will likely remain in compliance with its financial covenants.

Sources of data for analysts' projections include some or all of the following: the company's projections, the company's previous financial statements, industry structure and outlook, and macroeconomic forecasts.

Evaluating a company's past performance may provide a basis for forward-looking analyses. An evaluation of a company's business and economic environment and its history may persuade the analyst that historical information constitutes a valid basis for such analyses and that the analyst's projections may be based on the continuance of past trends, perhaps with some adjustments. Alternatively, in the case of a major acquisition or divestiture, for a start-up company, or for a company operating in a volatile industry, past performance may be less relevant to future performance.

Projections of a company's near-term performance may be used as an input to market-based valuation or relative valuation (i.e., valuation based on price multiples). Such projections may involve projecting next year's sales and using the common-size income statement to project major expense items or particular margins on sales (e.g., gross profit margin or operating profit margin). These calculations will then lead to the development of an income measure for a valuation calculation, such as net income, earnings per share (EPS) or EBITDA. More complex projections of a company's future performance involve developing a more detailed analysis of the components of performance for multiple periods—for example, projections of sales and gross margin by product line, projection of operating expenses based on historical patterns, and projection of interest expense based on requisite debt funding, interest rates, and applicable taxes. Furthermore, a projection should include sensitivity analyses applied to the major assumptions.

2.1 Projecting Performance: An Input to Market-Based Valuation

One application of financial statement analysis involves projecting a company's near-term performance as an input to market-based valuation. For example, an analyst might project a company's sales and profit margin to estimate EPS and then apply a projected P/E to establish a target price for the company's stock.

Analysts often take a top-down approach to projecting a company's sales.[3] First, industry sales are projected on the basis of their historical relationship with some macroeconomic indicator, such as growth in real gross domestic product (GDP). In researching the automobile industry, for example, the analyst may find that the industry's annual domestic unit car sales (number of cars sold in domestic markets) bears a relationship to annual changes in real GDP. Regression analysis is often used to establish the parameters of such relationships. Other factors in projecting sales may include consumer income or tastes, technological developments, and the availability of substitute products or services. After industry sales are projected, a company's market share is projected. Company-level market share projections may be based on historical market share and a forward-looking assessment of the company's competitive position. The company's sales are then estimated as its projected market share multiplied by projected total industry sales.

---

[3] The discussion in this paragraph is indebted to Benninga and Sarig (1997).

After developing a sales forecast for a company, an analyst can choose among various methods for forecasting income and cash flow. An analyst must decide on the level of detail to consider in developing forecasts. For example, separate forecasts may be made for individual expense items or for more aggregated expense items, such as total operating expenses. Rather than stating a forecast in terms of expenses, the forecast might be stated in terms of a forecasted profit margin (gross, operating, or net). The net profit margin, in contrast to the gross or operating profit margins, is affected by financial leverage and tax rates, which are subject to managerial and legal/regulatory revisions; therefore, historical data may sometimes be more relevant for projecting gross or operating profit margins than for projecting net profit margins. Whatever the margin used, the forecasted amount of profit for a given period is the product of the forecasted amount of sales and the forecast of the selected profit margin.

As Example 2 illustrates, for relatively mature companies operating in non-volatile product markets, historical information on operating profit margins can provide a useful starting point for forecasting future operating profits (at least over short forecasting horizons). Historical operating profit margins are typically less reliable for projecting future margins for a new or relatively volatile business or one with significant fixed costs (which can magnify the volatility of operating margins).

EXAMPLE 2

Using Historical Operating Profit Margins to Forecast Operating Profit

One approach to projecting operating profit is to determine a company's average operating profit margin over the previous several years and apply that margin to a forecast of the company's sales. Use the following information on three companies to answer Questions 1 and 2 below:

- Johnson & Johnson (JNJ). This US health care conglomerate, founded in 1887, had 2017 sales of around $76.5 billion from its three main businesses: pharmaceuticals, medical devices and diagnostics, and consumer products.
- BHP Billiton (BHP). This company, with group headquarters in Australia and secondary headquarters in London, is the world's largest natural resources company, reporting revenue of approximately US$38.3 billion for the fiscal year ended June 2017. The company mines, processes, and markets coal, copper, nickel, iron, bauxite, and silver and also has substantial petroleum operations.
- Baidu. This Chinese company, which was established in 2000 and went public on NASDAQ in 2005, is the leading Chinese language search engine. The company's revenues for 2017 were 84.8 billion renminbi (RMB), an increase of 20 percent from 2016 and almost 4 times revenue in 2012.

1. For each of the three companies, state and justify whether the suggested forecasting method (applying the average operating profit over the previous several years to a forecast of sales) would be a reasonable starting point for projecting future operating profit.
2. Assume that the 2017 forecast of sales was perfect and, therefore, equal to the realized sales by the company in 2017. Compare the forecast of 2017 operating profit, using an average of the previous five years' operating profit margins, with the actual 2017 operating profit reported by the company given the following additional information:

- JNJ: For the five years prior to 2017, JNJ's average operating profit margin was approximately 25.6 percent. The company's actual operating profit for 2017 was $18.2 billion.
- BHP: For the four years prior to the year ending June 2017, BHP's average operating profit margin was approximately 24.0 percent. The company's actual operating profit for the year ended June 2017 was US$11.8 billion.
- Baidu: Over the four years prior to 2017, Baidu's average operating profit margin was approximately 28.5 percent. The company's actual operating profit for 2017 was RMB15.7 billion.

Using the additional information given, state and justify whether actual results support the usefulness of the stable operating margin assumption.

Solution to 1:

JNJ. Because JNJ is an established company with diversified operations in relatively stable businesses, the suggested approach to projecting the company's operating profit would be a reasonable starting point.

BHP. Because commodity prices tend to be volatile and the mining industry is relatively capital intensive, the suggested approach to projecting BHP's operating profit would probably not be a useful starting point.

Baidu. Compared to the other two companies, Baidu has a more limited operating history and remains in a period of rapid growth. These aspects about the company suggests that the broad approach to projecting operating profit would not be a useful starting point for Baidu.

Solution to 2:

JNJ. JNJ's actual operating profit margin for 2017 was 23.8 percent ($18.2 billion divided by sales of $76.5 billion), which is a little less than company's five-year average operating profit margin of approximately 25.6 percent.

BHP. BHP's actual operating profit margin for the year ended June 2017 was 30.8 percent ($11.8 billion divided by sales of $38.3 billion). If the company's average profit margin of 24.0 percent had been applied to perfectly forecasted sales, the forecasted operating profit would have been approximately US$9.2 billion, around 22 percent lower than actual operating profit.

Baidu. Baidu's actual operating profit margin for 2017 was 18.5 percent (RMB15.7 billion divided by sales of RMB84.8 billion). If the average profit margin of 28.5 percent had been applied to perfectly forecasted sales, the forecasted operating profit would have been approximately RMB24.2 billion, or around 54 percent higher than Baidu's actual operating profit.

Although prior years' profit margins can provide a useful starting point in projections for companies with relatively stable business, the underlying data should, nonetheless, be examined to identify items that are not likely to occur again in the following year(s). Such non-recurring (i.e., transitory) items should be removed from computations of any profit amount or profit margin that will be used in projections. Example 3 illustrates this principle.

EXAMPLE 3

Issues in Forecasting

Following are excerpts from the 2017 annual report of Textron, a global aircraft, defense and industrial company.

Textron Consolidated Statements of Operations for each of the years in the three-year period ended December 31

(In millions, except per share data)	2017	2016	2015
Revenues			
Manufacturing revenues	$14,129	$13,710	$13,340
Finance revenues	69	78	83
Total revenues	14,198	13,788	13,423
Costs, expenses and other			
Cost of sales	11,795	11,311	10,979
Selling and administrative expense	1,337	1,304	1,304
Interest expense	174	174	169
Special charges	130	123	—
Total costs, expenses and other	13,436	12,912	12,452
Income from continuing operations before income taxes	762	876	971
Income tax expense	456	33	273
Income from continuing operations	306	843	698
Income (loss) from discontinued operations, net of income taxes*	1	119	(1)
Net income	307	962	697

Footnotes:
2017 Note 12 Special Charges

(Continued)

> In 2016, we initiated a plan to restructure and realign our businesses by implementing headcount reductions, facility consolidations and other actions in order to improve overall operating efficiency across Textron. Under this plan, Textron Systems discontinued production of its sensor-fuzed weapon product within its Weapons and Sensors operating unit, we combined our Jacobsen business with the Textron Specialized Vehicles business by consolidating facilities and general and administrative functions, and we reduced headcount at Textron Aviation, as well as other businesses and corporate functions. In December 2017, we decided to take additional restructuring actions to further consolidate operating facilities and streamline product lines, primarily within the Bell, Textron Systems and Industrial segments, which resulted in additional special charges of $45 million in the fourth quarter of 2017. We recorded total special charges of $213 million since the inception of the 2016 plan, which included $97 million of severance costs, $84 million of asset impairments and $32 million in contract terminations and other costs. Of these amounts, $83 million was incurred at Textron Systems, $63 million at Textron Aviation, $38 million at Industrial, $28 million at Bell and $1 million at Corporate. The total headcount reduction under this plan is expected to be approximately 2,100 positions, representing 5% of our workforce. In connection with the acquisition of Arctic Cat, as discussed in Note 2, we initiated a restructuring plan in the first quarter of 2017 to integrate this business into our Textron Specialized Vehicles business within the Industrial segment and reduce operating redundancies and maximize efficiencies. Under the Arctic Cat plan, we recorded restructuring charges of $28 million in 2017, which included $19 million of severance costs, largely related to change-of-control provisions, and $9 million of contract termination and other costs. In addition, we recorded $12 million of acquisition-related integration and transaction costs in 2017.

2016 Financial Statement General Footnote

> *Income from discontinued operations, net of income taxes for the year ended December 31, 2016 primarily includes the settlement of a U.S. federal income tax audit. See Note 13 to the Consolidated Financial Statements for additional information.

2016 Note 13 Income Taxes

> The provision for income taxes for 2016 included a benefit of $319 million to reflect the settlement with the U.S. Internal Revenue Service Office of Appeals for our 1998 to 2008 tax years, which resulted in a $206 million benefit attributable to continuing operations and $113 million attributable to discontinued operations.

Source: Textron annual reports.

Discussion:

Results of discontinued operations and restructuring charges should generally not be included when assessing past performance or when forecasting future net income. For purposes of evaluating the company's ongoing operating and net profit margins the special charges related to restructuring and the special tax benefit related to discontinued operations should be removed. For example, the company's operating margin for 2017 including special charges would be 5.4% (\$762 million/\$14,198 million). Excluding special charges, the operating margin would be 6.3% (\$762 million + \$130 million)/\$14,198 million. Similarly, the net profit margin would be determined by eliminating the income from discontinued operations, particularly for 2016.

In general, when earnings projections are used as a foundation for market-based valuations, an analyst will make appropriate allowance for transitory components of past earnings. Occasionally, an analyst will observe that a company takes special charges virtually every year. In such cases, they are not transitory and should not be removed in evaluating past and future margins.

3

PROJECTING MULTIPLE-PERIOD PERFORMANCE

b demonstrate how to forecast a company's future net income and cash flow;

Projections of future financial performance over multiple periods are needed in valuation models that estimate the value of a company or its equity by discounting future cash flows. The value of a company or its equity developed in this way can then be compared with its current market price as a basis for investment decisions.

Projections of future performance are also used for credit analysis. These projections are important in assessing a borrower's ability to repay interest and principal of debt obligations. Investment recommendations depend on the needs and objectives of the client and on an evaluation of the risk of the investment relative to its expected return—both of which are a function of the terms of the debt obligation itself as well as financial market conditions. Terms of the debt obligation include amount, interest rate, maturity, financial covenants, and collateral.

Example 4 presents an elementary illustration of net income and cash flow forecasting to illustrate a format for analysis and some basic principles. In Example 4, assumptions are shown first; then, the period-by-period abbreviated financial statement resulting from the assumptions is shown.

Depending on the use of the forecast, an analyst may choose to compute further, more specific cash flow metrics. For example, free cash flow to equity, which is used in discounted cash flow approaches to equity valuation, can be estimated as net income adjusted for noncash items, minus investment in net working capital and in net fixed assets, plus net borrowing.

EXAMPLE 4

Basic Example of Financial Forecasting

Assume a company is formed with \$100 of equity capital, all of which is immediately invested in working capital. Assumptions are as follows:

Variable	Assumption
First-year sales	$100
Sales growth	10% per year
Cost of goods sold/Sales	20%
Operating expense/Sales	70%
Interest income rate	5%
Tax rate	30%
Working capital as percent of sales	90%
Dividends	Non-dividend paying

Based on this information, forecast the company's net income and cash flow for five years.

Solution:

Exhibit 2 shows the net income forecasts in Line 7 and cash flow forecasts ("Change in cash") in Line 18.

Exhibit 2 Basic Financial Forecasting

	Time Period					
	0	1	2	3	4	5
(1) Sales		100.0	110.0	121.0	133.1	146.4
(2) Cost of goods sold		(20.0)	(22.0)	(24.2)	(26.6)	(29.3)
(3) Operating expenses		(70.0)	(77.0)	(84.7)	(93.2)	(102.5)
(4) Interest income		0.0	0.9	0.8	0.8	0.7
(5) Income before tax		10.0	11.9	12.9	14.1	15.3
(6) Taxes		(3.0)	(3.6)	(3.9)	(4.2)	(4.6)
(7) Net income		7.0	8.3	9.0	9.9	10.7
(8) Cash/Borrowing	0.0	17.0	16.3	15.4	14.4	13.1
(9) Working capital (non-cash)	100.0	90.0	99.0	108.9	119.8	131.8
(10) Total assets	100.0	107.0	115.3	124.3	134.2	144.9
(11) Liabilities	0.0	0.0	0.0	0.0	0.0	0.0
(12) Equity	100.0	107.0	115.3	124.3	134.2	144.9
(13) Total liabilities + Equity	100.0	107.0	115.3	124.3	134.2	144.9
(14) Net income		7.0	8.3	9.0	9.9	10.7
(15) Plus: Non-cash items		0.0	0.0	0.0	0.0	0.0
(16) Less: Investment in working capital		−10.0	9.0	9.9	10.9	12.0
(17) Less: Investment in fixed capital		0.0	0.0	0.0	0.0	0.0
(18) Change in cash		17.0	−0.7	−0.9	−1.0	−1.3
(19) Beginning cash		0.0	17.0	16.3	15.4	14.4
(20) Ending cash		17.0	16.3	15.4	14.4	13.1

Exhibit 2 indicates that at time 0, the company is formed with $100 of equity capital (Line 12). All of the company's capital is assumed to be immediately invested in working capital (Line 9). In future periods, because it is assumed that no dividends are paid, book equity increases each year by the amount of net income (Line 14). Future periods' required working capital (Line 9) is assumed to be 90 percent of annual sales (Line 1). Sales are assumed to be $100 in the first period and to grow at a constant rate of 10 percent per year (Line 1). The cost of goods sold is assumed to be constant at 20 percent of sales (Line 2), so the gross profit margin is 80 percent. Operating expenses are assumed to be 70 percent of sales each year (Line 3). Interest income (Line 4) is calculated as 5 percent of the beginning balance of cash/borrowing or the ending balance of the previous period (Line 8) and is an income item when there is a cash balance, as in this example. (If available cash is inadequate to cover required cash outflows, the shortfall is presumed to be covered by borrowing. This borrowing would be shown as a negative balance on Line 8 and an associated interest expense on Line 4. Alternatively, a forecast can be presented with separate lines for cash and borrowing.) Taxes of 30 percent are deducted to obtain net income (Line 7).

To calculate each period's cash flow, begin with net income (Line 7 = Line 14), add back any noncash items, such as depreciation (Line 15), deduct investment in working capital in the period or change in working capital over the period (Line 16), and deduct investment in fixed capital in the period (Line 17).[4] In this simple example, we are assuming that the company does not invest in any fixed capital (long-term assets) but, rather, rents furnished office space. Therefore, there is no depreciation and noncash items are zero. Each period's change in cash (Line 18) is added to the beginning cash balance (Line 19) to obtain the ending cash balance (Line 20 = Line 8).

Example 4 is simplified to demonstrate some principles of forecasting. In practice, each aspect of a forecast presents a range of challenges. Sales forecasts may be very detailed, with separate forecasts for each year of each product line, each geographical, and/or each business segment. Sales forecasts may be based on past results (for relatively stable businesses), management forecasts, industry studies, and/or macroeconomic forecasts. Similarly, gross profit margins may be based on past results or forecasted relationships and may be detailed. Expenses other than cost of goods sold may be broken down into more detailed line items, each of which may be forecasted on the basis of its relationship with sales (if variable) or on the basis of its historical levels. Working capital requirements may be estimated as a proportion of the amount of sales (as in Example 4) or the change in sales or as a compilation of specific forecasts for inventory, receivables, and payables. Most forecasts will involve some investment in fixed assets, in which case, depreciation amounts affect taxable income and net income but not cash flow. Example 4 makes the simplifying assumption that interest is paid on the beginning-of-year cash balance.

Example 4 develops a series of point estimates for future net income and cash flow. In practice, forecasting generally includes an analysis of the risk in forecasts—in this case, an assessment of the impact on income and cash flow if the realized values of variables differ significantly from the assumptions used in the base case or if actual sales are much different from forecasts. Quantifying the risk in forecasts requires an analysis of the economics of the company's businesses and expense structure and the potential impact of events affecting the company, the industry, and the economy in general. When that investigation is completed, the analyst can use scenario analysis or Monte Carlo simulation to assess risk. Scenario analysis involves specifying assumptions that differ from those used as the base-case assumptions. In Example 4, the projections of net income and cash flow could be recast in a more pessimistic scenario, with assumptions changed to reflect slower sales growth and higher costs. A Monte Carlo simulation involves specifying probability distributions of values for variables and random sampling from those distributions. In the analysis in Example 4, the projections would be repeatedly recast with the selected values for the drivers of net income and cash flow, thus permitting the analyst to evaluate a range of possible results and the probability of simulating the possible actual outcomes.

---

[4] Working capital represents funds that must be invested in the daily operations of a business to, for example, carry inventory and accounts receivable. The term "investment" in this context means "addition to" or "increase in." The "investment in fixed capital" is also referred to as "capital expenditure" ("capex").

An understanding of financial statements and ratios can enable an analyst to make more detailed projections of income statement, balance sheet, and cash flow statement items. For example, an analyst may collect information on normal inventory and receivables turnover and use this information to forecast accounts receivable, inventory, and cash flows based on sales projections rather than use a composite working capital investment assumption, as in Example 4.

As the analyst makes detailed forecasts, he or she must ensure that the forecasts are consistent with each other. For instance, in Example 5, the analyst's forecast concerning days of sales outstanding (which is an estimate of the average time to collect payment from sales made on credit) should flow from a model of the company that yields a forecast of the change in the average accounts receivable balance. Otherwise, predicted days of sales outstanding and accounts receivable will not be mutually consistent.

EXAMPLE 5

Consistency of Forecasts

Brown Corporation, a hypothetical company, had an average days-of-sales-outstanding (DSO) period of 19 days in 2017. An analyst thinks that Brown's DSO will decline in 2018 (because of expected improvements in the company's collections department) to match the industry average of 15 days. Total sales (all on credit) in 2017 were $300 million, and Brown expects total sales (all on credit) to increase to $320 million in 2018. To achieve the lower DSO, the change in the average accounts receivable balance from 2017 to 2018 that must occur is *closest* to:

A –$3.51 million.

B –$2.46 million.

C $2.46 million.

D $3.51 million.

Solution:

B is correct. The first step is to calculate accounts receivable turnover from the DSO collection period. Receivable turnover equals 365/19 (DSO) = 19.2 for 2017 and 365/15 = 24.3 in 2018. Next, the analyst uses the fact that the average accounts receivable balance equals sales/receivable turnover to conclude that for 2017, average accounts receivable was $300,000,000/19.2 = $15,625,000 and for 2018, it must equal $320,000,000/24.3 = $13,168,724. The difference is a reduction in receivables of $2,456,276.

The next section illustrates the application of financial statement analysis to credit risk analysis.

4 APPLICATION: ASSESSING CREDIT RISK

c describe the role of financial statement analysis in assessing the credit quality of a potential debt investment;

Credit risk is the risk of loss caused by a counterparty's or debtor's failure to make a promised payment. For example, credit risk with respect to a bond is the risk that the obligor (the issuer of the bond) will not be able to pay interest and/or principal according to the terms of the bond indenture (contract). **Credit analysis** is the evaluation of credit risk. Credit analysis may relate to the credit risk of an obligor in a particular transaction or to an obligor's overall creditworthiness.

In assessing an obligor's overall creditworthiness, one general approach is credit scoring, a statistical analysis of the determinants of credit default. Credit analysis for specific types of debt (e.g., acquisition financing and other highly leveraged financing) typically involves projections of period-by-period cash flows.

Whatever the techniques adopted, the analytical focus of credit analysis is on debt-paying ability. Unlike payments to equity investors, payments to debt investors are limited by the agreed contractual interest. If a company experiences financial success, its debt becomes less risky but its success does not increase the amount of payments to its debtholders. In contrast, if a company experiences financial distress, it may be unable to pay interest and principal on its debt obligations. Thus, credit analysis has a special concern with the sensitivity of debt-paying ability to adverse events and economic conditions—cases in which the creditor's promised returns may be most at risk. Because those returns are generally paid in cash, credit analysis usually focuses on cash flow rather than accrual income. Typically, credit analysts use return measures related to operating cash flow because it represents cash generated internally, which is available to pay creditors.

These themes are reflected in Example 6, which illustrates Moody's application of four quantitative factors in the credit analysis of the aerospace and defense industry.[5] These factors include

1. scale,
2. business profile,
3. leverage and coverage, and
4. financial policy.

"Scale" relates to a company's sensitivity to adverse events, adverse economic conditions, and other factors—such as market leadership, purchasing power with suppliers, and access to capital markets—that may affect debt-paying ability. "Business profile" represents a company's competitive position, stability of revenues, product and geographic diversity, growth prospects, and the stability and volatility of cash flows. "Leverage and coverage" reflects a company's "financial flexibility" and viability. Finally, "financial policy" relates to a company's financial risk tolerance and its capital structure.

---

[5] The information in this paragraph and in Example 7 are based upon the "Rating Methodology: Aerospace and Defense Industry" (Moody's, 2018).

EXAMPLE 6

Moody's Evaluation of Quantifiable Rating Factors for the Aerospace and Defense Industry

Moody's considers four broad rating factors for the aerospace and defense industry: scale; business profile, leverage and coverage; and financial policy. A company's ratings for each of these factors are weighted and aggregated in determining the overall credit rating assigned. The broad factors, the sub-factors, and weightings are as follows:

Broad Factor	Sub-factors	Sub-factor Weighting (%)	Broad Factor Weighting (%)
Scale	Total revenue	10	25
	Operating profit	15	
Business profile	Competitive position	10	20
	Expected revenue stability	10	
Leverage and coverage	Debt/EBITDA	10	35
	Retained cash flow[a]/Net debt	15	
	EBIT/Interest	10	
Financial policy	Financial policy	20	20
Total		100	100

[a] Retained cash flow is defined by Moody's as cash flow before working capital and after dividends.

Why might the leverage and coverage factor be weighted higher compared to the other rating factors?

Solution:

The level of debt relative to earnings and cash flow is a critical factor in assessing creditworthiness. Higher levels of debt for a company typically result in a higher risk in meeting interest and principal payments on its debt obligations.

A point to note regarding Example 6 is that the rating factors and the metrics used to represent each can vary by industry group.

Analyses of a company's historical and projected financial statements are an integral part of the credit evaluation process. Moody's and other rating agencies compute a variety of ratios in assessing creditworthiness. A comparison of a company's ratios with the ratios of its peers is informative in evaluating relative creditworthiness, as demonstrated in Example 7.

EXAMPLE 7

Peer Comparison of Ratios

A credit analyst is assessing the efficiency and leverage of two aerospace and defense companies based on certain sub-factors identified by Moody's in Example 7. The analyst collects the information from the companies' annual reports and calculates the following ratios:

	Company 1	Company 2
Debt/EBITDA	9.3	4.1
Retained cash flow/Net debt	2.6%	9.6%
EBIT/Interest	5.7	8.2

Based solely on the data given, which company is more likely to be assigned a higher credit rating, and why?

Solution:

The ratio comparisons are all in favor of Company 2, which has a lower level of debt relative to EBITDA, higher retained cash flow to net debt, and higher interest coverage. Based only on the data given, Company 2 is likely to be assigned a higher credit rating.

In calculating credit ratios, such as those presented in Example 8, analysts typically make certain adjustments to reported financial statements. We describe some common adjustments later in the reading.

Financial statement analysis, especially financial ratio analysis, can also be an important tool in selecting equity investments, as discussed in the next section.

5

SCREENING FOR POTENTIAL EQUITY INVESTMENTS

d describe the use of financial statement analysis in screening for potential equity investments;

Ratios constructed from financial statement data and market data are often used to screen for potential equity investments. **Screening** is the application of a set of criteria to reduce a set of potential investments to a smaller set having certain desired characteristics. Criteria involving financial ratios generally involve comparing one or more ratios with some pre-specified target or cutoff values.

A security selection approach incorporating financial ratios may be applied whether the investor uses top-down analysis or bottom-up analysis. **Top-down analysis** involves identifying attractive geographical segments and/or industry segments, from which the investor chooses the most attractive investments. **Bottom-up analysis** involves selection of specific investments from all companies within a specified investment universe. Regardless of the direction, screening for potential equity investments aims to identify companies that meet specific criteria. An analysis of this type may be used as the basis for directly forming a portfolio, or it may be undertaken as a preliminary part of a more thorough analysis of potential investment targets.

Fundamental to this type of analysis are decisions about which metrics to use as screens, how many metrics to include, what values of those metrics to use as cutoff points, and what weighting to give each metric. Metrics may include not only financial ratios but also characteristics such as market capitalization or membership as a component security in a specified index. Exhibit 3 presents a hypothetical example of a simple stock screen based on the following criteria: a valuation ratio (P/E) less than a specified value, a solvency ratio measuring financial leverage (total liabilities/total assets) not exceeding a specified value, positive operating margin, and dividend yield (dividends per share divided by price per share) greater than a specified value. Exhibit 3 shows the results of applying the screen in August 2018 to a set of 6,406 US companies with market capitalization greater than $100 million, which compose a hypothetical equity manager's investment universe.

Exhibit 3 Example of a Stock Screen

	Stocks Meeting Criterion	
Criterion	**Number**	**Percent of Total**
Market Capitalization > $100 million	4,357	68.01%
P/E < 15	1,104	17.23%
Total liabilities/Total Assets ≤ 0.9	61	0.95%
Operating Income/Sales > 0	3,509	54.78%
Dividend yield > 0.5%	2,391	37.32%
Meeting all five criteria simultaneously	17	0.27%

Source for data: http://google.com/finance/.

Several points about the screen in Exhibit 3 are consistent with many screens used in practice:

- Some criteria serve as checks on the results from applying other criteria. In this hypothetical example, the second criterion selects stocks that appear relatively cheaply valued. The stocks might be cheap for a good reason, however, such as poor profitability or excessive financial leverage. So, the requirement for net income to be positive serves as a check on profitability, and the limitation on financial leverage serves as a check on financial risk. Of course, financial ratios or other statistics cannot generally control for exposure to certain other types of risk (e.g., risk related to regulatory developments or technological innovation).
- If all the criteria were completely independent of each other, the set of stocks meeting all five criteria would be 2, equal to 6,406 times 0.023 percent—the product of the fraction of stocks satisfying the five criteria individually (i.e., $0.6801 \times 0.1723 \times 0.0095 \times 0.5478 \times 0.3732 = 0.000228$, or 0.023 percent). As the screen illustrates, criteria are often not independent, and the result is that more securities pass the screening than if criteria were independent. In this example, 17 of the securities pass all five screens simultaneously. For an example of the lack of independence, we note that dividend-paying status is probably positively correlated with the ability to generate positive operating margin. If stocks that pass one test tend to also pass another, few are eliminated after the application of the second test.
- The results of screens can sometimes be relatively concentrated in a subset of the sectors represented in the benchmark. The financial leverage criterion in Exhibit 3 would exclude banking stocks, for example. What constitutes a high or low value of a measure of a financial characteristic can be sensitive to the industry in which a company operates.

Screens can be used by both **growth investors** (focused on investing in high-earnings-growth companies), **value investors** (focused on paying a relatively low share price in relation to earnings or assets per share), and **market-oriented investors** (an intermediate grouping of investors whose investment disciplines cannot be clearly categorized as value or growth). Growth screens would typically feature criteria related to earnings growth and/or momentum. Value screens, as a rule, feature criteria setting upper limits for the value of one or more valuation ratios. Market-oriented screens would not strongly emphasize valuation or growth criteria. The use of screens involving financial ratios may be most common among value investors.

An analyst may want to evaluate how a portfolio based on a particular screen would have performed historically. For this purpose, the analyst uses a process known as "back-testing." **Back-testing** applies the portfolio selection rules to historical data and calculates what returns would have been earned if a particular strategy had been used. The relevance of back-testing to investment success in practice, however, may be limited. Haugen and Baker (1996) described some of these limitations:

- Survivorship bias: If the database used in back-testing eliminates companies that cease to exist because of a bankruptcy or merger, then the remaining companies collectively will appear to have performed better.
- Look-ahead bias: If a database includes financial data updated for restatements (where companies have restated previously issued financial statements to correct errors or reflect changes in accounting principles), then there is a mismatch between what investors would have actually known at the time of the investment decision and the information used in the back-testing.
- Data-snooping bias: If researchers build a model on the basis of previous researchers' findings, then use the same database to test that model, they are not actually testing the model's predictive ability. When each step is backward looking, the same rules may or may not produce similar results in the future. The predictive ability of the model's rules can validly be tested only by using future data. One academic study has argued that the apparent ability of value strategies to generate excess returns is largely explainable as the result of collective data snooping (Conrad, Cooper, and Kaul, 2003).

EXAMPLE 8

Ratio-Based Screening for Potential Equity Investments

Below are two alternative strategies under consideration by an investment firm:

> *Strategy A*: Invest in stocks that are components of a global equity index, have a ROE above the median ROE of all stocks in the index, and have a P/E less than the median P/E.
>
> *Strategy B*: Invest in stocks that are components of a broad-based US equity index, have a ratio of price to operating cash flow in the lowest quartile of companies in the index, and have shown increases in sales for at least the past three years.

Both strategies were developed with the use of back-testing.

1 How would you characterize the two strategies?

2 What concerns might you have about using such strategies?

Solution to 1:

Strategy A appears to aim for global diversification and combines a requirement for high relative profitability with a traditional measure of value (low P/E). Strategy B focuses on both large and small companies in a single market and apparently aims to identify companies that are growing and have a lower price multiple based on cash flow from operations.

Solution to 2:

The use of *any* approach to investment decisions depends on the objectives and risk profile of the investor. With that crucial consideration in mind, we note that ratio-based benchmarks may be an efficient way to screen for potential equity investments. In screening, however, many questions arise.

First, unintentional selections can be made if criteria are not specified carefully. For example, Strategy A might unintentionally select a loss-making company with negative shareholders' equity because negative net income divided by negative shareholders' equity arithmetically results in a positive ROE. Strategy B might unintentionally select a company with negative operating cash flow because price to operating cash flow will be negative and thus very low in the ranking. In both cases, the analyst can add additional screening criteria to avoid unintentional selections; these additional criteria could include requiring positive shareholders' equity in Strategy A and requiring positive operating cash flow in Strategy B.

Second, the inputs to ratio analysis are derived from financial statements, and companies may differ in the financial standards they apply (e.g., IFRS versus US GAAP), the specific accounting method(s) they choose within those allowed by the reporting standards, and/or the estimates made in applying an accounting method.

Third, back-testing may not provide a reliable indication of future performance because of survivorship bias, look-ahead bias, or data-snooping bias. Also, as suggested by finance theory and by common sense, the past is not necessarily indicative of the future.

Fourth, implementation decisions can dramatically affect returns. For example, decisions about frequency and timing of portfolio re-evaluation and changes affect transaction costs and taxes paid out of the portfolio.

FRAMEWORK FOR ANALYST ADJUSTMENTS & ADJUSTMENTS TO INVESTMENTS & ADJUSTMENTS TO INVENTORY

6

e explain appropriate analyst adjustments to a company's financial statements to facilitate comparison with another company.

When comparing companies that use different accounting methods or estimate key accounting inputs in different ways, analysts frequently adjust a company's financials. In this section, we first provide a framework for considering potential analyst adjustments to facilitate such comparisons and then provide examples of such adjustments. In practice, required adjustments vary widely. The examples presented here are not intended to be comprehensive but, rather, to illustrate the use of adjustments to facilitate a meaningful comparison.

6.1 A Framework for Analyst Adjustments

In this discussion of potential analyst adjustments to a company's financial statements, we use a framework focused on the *balance sheet*. Because the financial statements are interrelated, however, adjustments to items reported on one statement may also be reflected in adjustments to items on another financial statement. For example, an analyst adjustment to inventory on the balance sheet affects cost of goods sold on the income statement (and thus also affects net income and, subsequently, the retained earnings account on the balance sheet).

Regardless of the particular order in which an analyst considers the items that may require adjustment for comparability, the following aspects are appropriate:

- *Importance* (*materiality*). Is an adjustment to this item likely to affect the conclusions? In other words, does it matter? For example, in an industry where companies require minimal inventory, does it matter that two companies use different inventory accounting methods?
- *Body of standards*. Is there a difference in the body of standards being used (US GAAP versus IFRS)? If so, in which areas is the difference likely to affect a comparison?
- *Methods*. Is there a difference in accounting methods used by the companies being compared?
- *Estimates*. Is there a difference in important estimates used by the companies being compared?

The following sections illustrate analyst adjustments—first, those relating to the asset side of the balance sheet and then those relating to the liability side.

6.2 Analyst Adjustments Related to Investments

Accounting for investments in the debt and equity securities of other companies (other than investments accounted for under the equity method and investments in consolidated subsidiaries) depends on management's intention (i.e., whether to actively trade the securities, make them available for sale, or in the case of debt securities, hold them to maturity). When securities are classified as "financial assets measured at fair value through profit or loss" (similar to "trading" securities in US GAAP), unrealized gains and losses are reported in the income statement. When securities are classified as "financial assets measured at fair value through other comprehensive income" (similar to "available-for-sale" securities in US GAAP), unrealized gains and losses are not reported in the income statement and, instead, are recognized in equity. If two otherwise comparable companies have significant differences in the classification of investments, analyst adjustments may be useful to facilitate comparison.

6.3 Analyst Adjustments Related to Inventory

With inventory, adjustments may be required for different accounting methods. As described in previous readings, a company's decision about inventory method will affect the value of inventory shown on the balance sheet as well as the value of inventory that is sold (cost of goods sold). If a company not reporting under IFRS[6] uses LIFO (last-in, first-out) and another uses FIFO (first-in, first-out), comparability of the financial results of the two companies will suffer. Companies that use the LIFO method, must also, however, disclose the value of their inventory under the FIFO method. To recast inventory values for a company using LIFO reporting on a FIFO basis, the analyst adds the ending balance of the LIFO reserve to the ending value of inventory under LIFO accounting. To adjust cost of goods sold to a FIFO basis, the analyst subtracts the change in the LIFO reserve from the reported cost of goods sold under LIFO accounting. Example 9 illustrates the use of a disclosure of the value of inventory under the FIFO method to make a more consistent comparison of the current ratios of two companies reporting in different methods.

---

[6] IAS No. 2 does not permit the use of LIFO.

EXAMPLE 9

Adjustment for a Company Using LIFO Accounting for Inventories

An analyst is comparing the financial performance of LP Technology Corporation (LP Tech), a hypothetical company, with the financial performance of a similar company that uses IFRS for reporting. The company reporting under IFRS uses the FIFO method of inventory accounting. Therefore, the analyst converts LP Tech's results to a comparable basis. Exhibit 4 provides balance sheet information on LP Tech.

Exhibit 4 Data for LP Technology Corporation

	30 June	
	2018	**2017**
Total current assets	820.2	749.7
Total current liabilities	218.1	198.5

NOTE 6. INVENTORIES

Inventories consist of the following ($ millions):

	30 June	
	2018	**2017**
Raw materials	$30.7	$29.5
Work in process	109.1	90.8
Finished goods	63.8	65.1
	$203.6	$185.4

If the first-in, first-out method of inventory had been used instead of the LIFO method, inventories would have been $331.8 and $305.8 million higher as of June 30, 2018 and 2017, respectively.

1 Based on the information in Exhibit 4, calculate LP Tech's current ratio under FIFO and LIFO for 2017 and 2018.

2 LP Tech makes the following disclosure in the risk section of its MD&A. Assuming an effective tax rate of 35 percent, estimate the impact on LPTC's tax liability.

> **"We value most of our inventory using the LIFO method, which could be repealed resulting in adverse effects on our cash flows and financial condition.**
>
> The cost of our inventories is primarily determined using the Last-In First-Out ("LIFO") method. Under the LIFO inventory valuation method, changes in the cost of raw materials and production activities are recognized in cost of sales in the current period even though these materials and other costs may have been incurred at significantly different values due to the length of time of our production cycle. Generally in a period of rising prices, LIFO recognizes higher costs of goods sold, which both reduces current income and assigns a lower value to the year-end inventory. Recent proposals have been initiated aimed at repealing the election to use the LIFO method for income tax purposes. According to these proposals, generally taxpayers that currently use the LIFO method would be required to revalue their LIFO inventory to its first-in, first-out ("FIFO") value. As of June 30, 2018, if the FIFO method of inventory had been used instead of the LIFO method, our inventories would have been about $332 million higher. This increase in inventory would result in a one time increase in taxable income which would be taken into account ratably over the first taxable year and the following several taxable years. The repeal of LIFO could result in a substantial tax liability which could adversely impact our cash flows and financial condition."

3 LP Tech reported cash flow from operations of $115.2 million for the year ended 30 June 2018. In comparison with the company's operating cash flow, how significant is the additional potential tax liability?

Solution to 1:

The calculations of LP Tech's current ratio (current assets divided by current liabilities) are as follows:

	2018	2017
I. Current ratio (unadjusted)		
Total current assets	$820.2	$749.7
Total current liabilities	$218.1	$198.5
Current ratio (unadjusted)	3.8	3.8
II. Current ratio (adjusted)		
Total current assets	$820.2	$749.7
Adjust inventory to FIFO, add:	331.8	305.8
Total current assets (adjusted)	$1,152	$1,056
Total current liabilities	218.1	198.5
Current ratio (adjusted)	5.3	5.3

To adjust the LIFO inventory to FIFO, add the excess amounts of FIFO cost over LIFO cost to LIFO inventory and increase current assets by an equal amount. The effect of adjusting inventory on the current ratio is to increase the current ratio from 3.8 to 5.3 in both 2017 and 2018. LP Tech has greater liquidity according to the adjusted current ratio.

Solution to 2:

Assuming an effective tax rate of 35 percent, we find the total increase in LP Tech's tax liability to be $116.1 million (0.35 × $331.8 million).

Solution to 3:

The additional tax liability would be greater than the entire amount of the company's cash flow from operations of $115.2 million; the additional tax liability would be apportioned, however, over several years.

In summary, the information disclosed by companies that use LIFO allows an analyst to calculate the value of the company's inventory as if the company were using the FIFO method. If the LIFO method is used for a substantial part of a company's inventory and the LIFO reserve is large relative to reported inventory, however, the adjustment to a FIFO basis can be important for comparison of the LIFO-reporting company with a company that uses the FIFO method of inventory valuation. Example 10 illustrates a case in which such an adjustment would have a major impact on an analyst's conclusions.

EXAMPLE 10

Analyst Adjustment to Inventory Value for Comparability in a Current Ratio Comparison

Company A reports under IFRS and uses the FIFO method of inventory accounting. Company B reports under US GAAP and uses the LIFO method. Exhibit 5 gives data pertaining to current assets, LIFO reserves, and current liabilities of these companies.

Exhibit 5 Data for Companies Accounting for Inventory on Different Bases

	Company A (FIFO)	Company B (LIFO)
Current assets (includes inventory)	$ 300,000	$ 80,000
LIFO reserve	NA	$ 20,000
Current liabilities	$ 150,000	$ 45,000

NA = not applicable.

Based on the data given in Exhibit 5, compare the liquidity of the two companies as measured by the current ratio.

Solution:

Company A's current ratio is 2.0. Based on unadjusted balance sheet data, Company B's current ratio is 1.78. Company A's higher current ratio indicates that Company A appears to be more liquid than Company B; however, the use of unadjusted data for Company B is not appropriate for making comparisons with Company A.

After adjusting Company B's inventory to a comparable basis (i.e., to a FIFO basis), the conclusion changes. The following table summarizes the results when Company B's inventory is left on a LIFO basis and when it is placed on a FIFO basis for comparability with Company A.

		Company B	
	Company A (FIFO)	**Unadjusted (LIFO basis)**	**Adjusted (FIFO basis)**
Current assets (includes inventory)	$ 300,000	$ 80,000	$ 100,000
Current liabilities	$ 150,000	$ 45,000	$ 45,000
Current ratio	2.00	1.78	2.22

When both companies' inventories are stated on a FIFO basis, Company B appears to be the more liquid, as indicated by its current ratio of 2.22 versus Company A's ratio of 2.00.

The adjustment to place Company B's inventory on a FIFO basis was significant because Company B was assumed to use LIFO for its entire inventory and its inventory reserve was $20,000/$80,000 = 0.25, or 25 percent of its reported inventory.

As mentioned earlier, an analyst can also adjust the cost of goods sold for a company using LIFO to a FIFO basis by subtracting the change in the amount of the LIFO reserve from cost of goods sold. Such an adjustment would be appropriate for making profitability comparisons with a company reporting on a FIFO basis and is important to make when the impact of the adjustment would be material.

7

ADJUSTMENTS RELATED TO PROPERTY, PLANT, AND EQUIPMENT

e explain appropriate analyst adjustments to a company's financial statements to facilitate comparison with another company.

Management generally has considerable discretion in determination of depreciation expense. Depreciation expense affects the values of reported net income and reported net fixed assets. Analysts often consider management's choices related to depreciation as a qualitative factor in evaluating the quality of a company's financial reporting, and in some cases, analysts may adjust reported depreciation expense for a specific analytical purpose.

The amount of depreciation expense depends on both the accounting method and the estimates used in the calculations. Companies can use the straight-line method, an accelerated method, or a usage method to depreciate fixed assets (other than land). The straight-line method reports an equal amount of depreciation expense each period, and the expense is computed as the depreciable cost divided by the estimated useful life of the asset (when acquired, an asset's depreciable cost is calculated as its total cost minus its estimated salvage value). Accelerated methods depreciate the asset more quickly; they apportion a greater amount of the depreciable cost to depreciation expense in the earlier periods. Usage-based methods depreciate an asset in proportion to its usage. In addition to selecting a depreciation method, companies must estimate an asset's salvage value and useful life to compute depreciation.

Disclosures required for depreciation often do not facilitate specific adjustments, so comparisons of companies concerning their decisions in depreciating assets are often qualitative and general. The accounts that are associated with depreciation include the balance sheet accounts for gross property, plant, and equipment (PPE) and accumulated depreciation; the income statement amount for depreciation expense; and the statement of cash flows disclosure of capital expenditure (capex) and asset disposals. The relationships among these items can reveal various pieces of information. Note, however, that PPE typically includes a mix of assets with different depreciable lives and salvage values, so the items in the following list reflect general relationships in the total pool of assets.

- Accumulated depreciation divided by gross PPE, from the balance sheet, suggests how much of the useful life of the company's overall asset base has passed.
- Accumulated depreciation divided by depreciation expense suggests how many years' worth of depreciation expense have already been recognized (i.e., the average age of the asset base).
- Net PPE (net of accumulated depreciation) divided by depreciation expense is an approximate indicator of how many years of useful life remain for the company's overall asset base.
- Gross PPE divided by depreciation expense suggests the average life of the assets at installation.
- Capex divided by the sum of gross PPE plus capex can suggest what percentage of the asset base is being renewed through new capital investment.
- Capex in relation to asset disposal provides information on growth of the asset base.

As Example 11 shows, these relationships can be evaluated for companies in an industry to suggest differences in their strategies for asset utilization or areas for further investigation.

EXAMPLE 11

Differences in Depreciation

An analyst is evaluating the financial statements of two companies in the same industry. The companies have similar strategies with respect to the use of equipment in manufacturing their products. The following information is provided (amounts in millions):

	Company A	Company B
Net PPE	$1,200	$750
Depreciation expense	$120	$50

1. Based on the information given, estimate the average remaining useful lives of the asset bases of Company A and Company B.
2. Suppose that, based on a physical inspection of the companies' plants and other industry information, the analyst believes that the actual remaining useful lives of Company A's and Company B's assets are roughly equal at 10 years. Based only on the facts given, what might the analyst conclude about Company B's reported net income?

Solution to 1:

The estimated average remaining useful life of Company A's asset base is 10 years (calculated as net PPE divided by depreciation expense, or $1,200/$120 = 10 years). For Company B, the average remaining useful life of the asset base appears to be far longer, 15 years ($750/$50).

Solution to 2:

If 10 years were used to calculate Company B's depreciation expense, the expense would be $75 million (i.e., $25 million higher than reported) and higher depreciation expense would decrease net income. The analyst might conclude that Company B's reported net income reflects relatively more aggressive accounting estimates than estimates reflected in Company A's reported net income.

8

ADJUSTMENTS RELATED TO GOODWILL

e explain appropriate analyst adjustments to a company's financial statements to facilitate comparison with another company.

Goodwill arises when one company purchases another for a price that exceeds the fair value of the net identifiable assets acquired. Net identifiable assets include current assets, fixed assets, and certain intangible assets that have value and meet recognition criteria under accounting standards. A broad range of intangible assets might require valuation in the context of a business combination—for example, brands, technology, and customer lists. Goodwill is recorded as an asset and essentially represents the difference between the purchase price and the net identifiable assets. For example, assume ParentCo purchases TargetCo for a purchase price of $400 million and the fair value of TargetCo's identifiable assets is $300 million (which includes the fair values of current assets, fixed assets, and a recognized brand). ParentCo will record total assets of $400 million consisting of $300 million in identifiable assets (including the fair value of the brand) and $100 million of goodwill. The goodwill is tested annually for impairment and if the value of the goodwill is determined to be impaired, ParentCo will then reduce the amount of the asset and report a write-off resulting from impairment.

One of the conceptual difficulties with goodwill arises in comparative financial statement analysis. Consider, for example, two hypothetical US companies, one of which has grown by making an acquisition and the other of which has grown internally. Assume that the economic value of the two companies is identical: Each has an identically valuable branded product, well-trained workforce, and proprietary technology. The company that has grown by acquisition will have recorded the transaction to acquire the target company and its underlying net assets on the basis of the total consideration paid for the acquisition. The company that has grown internally will have done so by incurring expenditures for advertising, staff training, and research, all of which are expensed as incurred under US GAAP. Given the immediate expensing, the value of the internally generated assets is not capitalized onto the balance sheet and is thus not directly reflected on the company's balance sheet (revenues, income, and cash flows should reflect the benefits derived from the investment in the intangible assets). Ratios based on asset values and/or income, including profitability ratios (such as ROA) and market value to book value (MV/BV),[7] will generally differ for the two companies because of differences in the accounting values of assets and income related to acquired intangibles and goodwill, although, by assumption, the economic value of the companies is identical.

---

[7] MV/BV equals the total market value of the stock (the market capitalization) divided by total stockholders' equity. It is also referred to as the price-to-book ratio because it can also be calculated as price per share divided by stockholders' equity per share.

EXAMPLE 12

Ratio Comparisons for Goodwill

Miano Marseglia is an analyst who is evaluating the relative valuation of two securities brokerage companies: TD Ameritrade Holding Corporation (AMTD) and the Charles Schwab Corporation (SCHW). As one part of an overall analysis, Marseglia would like to see how the two companies compare with each other and with the industry based on market value to book value. Because both companies are large players in the industry, Marseglia expects them to sell at a higher MV/BV than the financial services sector median of 2.2. He collects the following data on the two companies.

	SCHW	AMTD
Market capitalization on 30 August 2018 (market price per share times the number of shares outstanding)	$68,620	$33,247
Total shareholders' equity (as of 30 June 2018 for both companies)	$20,097	$7,936
Goodwill	$1,227	$4,198
Other intangible assets	$93	$1,363

Marseglia computes the MV/BV for the companies as follows:

SCHW $68,620/$20,097 = 3.4

AMTD $33,247/$7,936 = 4.2

As expected, each company appears to be selling at a premium to the sector median MV/BV of 2.2. The companies have similar MV/BVs (i.e., they are somewhat equally valued relative to the book value of shareholders' equity). Marseglia is concerned, however, because he notes that AMTD has significant amounts of goodwill and acquired intangible assets. He wonders what the relative value would be if the MV/BV were computed after adjusting book value, first, to remove goodwill and, second, to remove all intangible assets. Book value reduced by all intangible assets (including goodwill) is known as "tangible book value."

1 Compute the MV/BV adjusted for goodwill and the price/tangible book value for each company.

2 Which company appears to be a better value based *solely* on this data? (Note that the MV/BV is only one part of a broader analysis. Much more evidence related to the valuations and the comparability of the companies would be required to reach a conclusion about whether one company is a better value.)

Solution to 1:

	($ millions)	
	SCHW	AMTD
Total stockholders' equity	$20,097	$7,936
Less: Goodwill	$1,227	$4,198
Book value, adjusted	$18,870	$3,738
Adjusted MV/BV	**3.6**	**8.9**

	($ millions)	
	SCHW	AMTD
Total stockholders' equity	$20,097	$7,936
Less: Goodwill	$1,227	$4,198
Less: Other intangible assets	$93	$1,363
Tangible book value	$18,777	$2,375
MV/tangible book value	**3.7**	**14.0**

Solution to 2:

After adjusting for goodwill, SCHW appears to be selling for a much lower price relative to book value than does AMTD (3.6 versus 8.9) after adjusting for goodwill. The difference is more extreme after adjusting for other intangibles.

SUMMARY

This reading described selected applications of financial statement analysis, including the evaluation of past financial performance, the projection of future financial performance, the assessment of credit risk, and the screening of potential equity investments. In addition, the reading introduced analyst adjustments to reported financials. In all cases, the analyst needs to have a good understanding of the financial reporting standards under which the financial statements were prepared. Because standards evolve over time, analysts must stay current in order to make good investment decisions.

The main points in the reading are as follows:

- Evaluating a company's historical performance addresses not only what happened but also the causes behind the company's performance and how the performance reflects the company's strategy.
- The projection of a company's future net income and cash flow often begins with a top-down sales forecast in which the analyst forecasts industry sales and the company's market share. By projecting profit margins or expenses and the level of investment in working and fixed capital needed to support projected sales, the analyst can forecast net income and cash flow.
- Projections of future performance are needed for discounted cash flow valuation of equity and are often needed in credit analysis to assess a borrower's ability to repay interest and principal of a debt obligation.
- Credit analysis uses financial statement analysis to evaluate credit-relevant factors, including tolerance for leverage, operational stability, and margin stability.
- When ratios constructed from financial statement data and market data are used to screen for potential equity investments, fundamental decisions include which metrics to use as screens, how many metrics to include, what values of those metrics to use as cutoff points, and what weighting to give each metric.
- Analyst adjustments to a company's reported financial statements are sometimes necessary (e.g., when comparing companies that use different accounting methods or assumptions). Adjustments can include those related to investments; inventory; property, plant, and equipment; and goodwill.

PRACTICE PROBLEMS

1 Projecting profit margins into the future on the basis of past results would be *most* reliable when the company:

A is in the commodities business.

B operates in a single business segment.

C is a large, diversified company operating in mature industries.

2 Galambos Corporation had an average receivables collection period of 19 days in 2003. Galambos has stated that it wants to decrease its collection period in 2004 to match the industry average of 15 days. Credit sales in 2003 were \$300 million, and analysts expect credit sales to increase to \$400 million in 2004. To achieve the company's goal of decreasing the collection period, the change in the average accounts receivable balance from 2003 to 2004 that must occur is *closest* to:

A –\$420,000.

B \$420,000.

C \$836,000.

3 Credit analysts are likely to consider which of the following in making a rating recommendation?

A Business risk but not financial risk

B Financial risk but not business risk

C Both business risk and financial risk

4 When screening for potential equity investments based on return on equity, to control risk, an analyst would be *most likely* to include a criterion that requires:

A positive net income.

B negative net income.

C negative shareholders' equity.

5 One concern when screening for stocks with low price-to-earnings ratios is that companies with low P/Es may be financially weak. What criterion might an analyst include to avoid inadvertently selecting weak companies?

A Net income less than zero

B Debt-to-total assets ratio below a certain cutoff point

C Current-year sales growth lower than prior-year sales growth

6 When a database eliminates companies that cease to exist because of a merger or bankruptcy, this can result in:

A look-ahead bias.

B back-testing bias.

C survivorship bias.

7 In a comprehensive financial analysis, financial statements should be:

A used as reported without adjustment.

B adjusted after completing ratio analysis.

C adjusted for differences in accounting standards, such as international financial reporting standards and US generally accepted accounting principles.

© 2019 CFA Institute. All rights reserved.

8 When comparing a US company that uses the last in, first out (LIFO) method of inventory with companies that prepare their financial statements under international financial reporting standards (IFRS), analysts should be aware that according to IFRS, the LIFO method of inventory:

A is never acceptable.

B is always acceptable.

C is acceptable when applied to finished goods inventory only.

9 An analyst is evaluating the balance sheet of a US company that uses last in, first out (LIFO) accounting for inventory. The analyst collects the following data:

	31 Dec 05	31 Dec 06
Inventory reported on balance sheet	$500,000	$600,000
LIFO reserve	$ 50,000	$70,000
Average tax rate	30%	30%

After adjusting the amounts to convert to the first in, first out (FIFO) method, inventory at 31 December 2006 would be closest to:

A $600,000.

B $620,000.

C $670,000.

10 An analyst gathered the following data for a company ($ millions):

	31 Dec 2000	31 Dec 2001
Gross investment in fixed assets	$2.8	$2.8
Accumulated depreciation	$1.2	$1.6

The average age and average depreciable life of the company's fixed assets at the end of 2001 are *closest* to:

	Average Age	Average Depreciable Life
A	1.75 years	7 years
B	1.75 years	14 years
C	4.00 years	7 years

11 To compute tangible book value, an analyst would:

A add goodwill to stockholders' equity.

B add all intangible assets to stockholders' equity.

C subtract all intangible assets from stockholders' equity.

SOLUTIONS

1 C is correct. For a large, diversified company, margin changes in different business segments may offset each other. Furthermore, margins are most likely to be stable in mature industries.

2 C is correct. Accounts receivable turnover is equal to 365/19 (collection period in days) = 19.2 for 2003 and needs to equal 365/15 = 24.3 in 2004 for Galambos to meet its goal. Sales/turnover equals the accounts receivable balance. For 2003, \$300,000,000/19.2 = \$15,625,000, and for 2004, \$400,000,000/24.3 = \$16,460,905. The difference of \$835,905 is the increase in receivables needed for Galambos to achieve its goal.

3 C is correct. Credit analysts consider both business risk and financial risk.

4 A is correct. Requiring that net income be positive would eliminate companies that report a positive return on equity only because both net income and shareholders' equity are negative.

5 B is correct. A lower value of debt/total assets indicates greater financial strength. Requiring that a company's debt/total assets be below a certain cutoff point would allow the analyst to screen out highly leveraged and, therefore, potentially financially weak companies.

6 C is correct. Survivorship bias exists when companies that merge or go bankrupt are dropped from the database and only surviving companies remain. Look-ahead bias involves using updated financial information in back-testing that would not have been available at the time the decision was made. Back-testing involves testing models in prior periods and is not, itself, a bias.

7 C is correct. Financial statements should be adjusted for differences in accounting standards (as well as accounting and operating choices). These adjustments should be made prior to common-size and ratio analysis.

8 A is correct. LIFO is not permitted under IFRS.

9 C is correct. To convert LIFO inventory to FIFO inventory, the entire LIFO reserve must be added back: \$600,000 + \$70,000 = \$670,000.

10 C is correct. The company made no additions to or deletions from the fixed asset account during the year, so depreciation expense is equal to the difference in accumulated depreciation at the beginning of the year and the end of the year, or \$0.4 million. Average age is equal to accumulated depreciation/depreciation expense, or \$1.6/\$0.4 = 4 years. Average depreciable life is equal to ending gross investment/depreciation expense = \$2.8/\$0.4 = 7 years.

11 C is correct. Tangible book value removes all intangible assets, including goodwill, from the balance sheet.

Corporate Issuers

STUDY SESSION

Study Session 9	Corporate Issuers (1)
Study Session 10	Corporate Issuers (2)

TOPIC LEVEL LEARNING OUTCOME

The candidate should be able to evaluate a company's corporate governance; to demonstrate methods used to make capital investment; to evaluate the management of working capital; to estimate a company's cost of capital; and to evaluate a company's operating and financial leverage.

Some academic studies have shown that well governed companies may perform better in financial terms. Increasingly, investment approaches that consider environmental, social, and governance factors, known as ESG, are being adopted. In addition to good governance practices, management decisions regarding investment and financing also play a central role in corporate profitability and performance. To remain in business as a going concern and to increase shareholder value over time, a company's management must consistently identify and invest in profitable long-term capital projects relative to cost of capital (financing) while making optimal use of leverage and working capital in day to day operations.

CORPORATE ISSUERS

STUDY SESSION

9

Corporate Issuers (1)

This study session provides an introduction to corporate governance and investing and financing decisions. An overview of corporate governance is presented along with a framework for understanding and analyzing corporate governance and stakeholder management. The growing impact of environmental and social considerations in investing is also highlighted. A discussion of the capital allocation process and the assessment of capital investment opportunities using NPV and IRR methods follows. The session ends with coverage of the short and long-term options companies may have to finance themselves and techniques for assessing a company's short-term liquidity management.

LEARNING OUTCOMES

Mastery	*The candidate should be able to:*
☐	**a.** describe corporate governance;
☐	**b.** describe a company's stakeholder groups, and compare interests of stakeholder groups;
☐	**c.** describe principal–agent and other relationships in corporate governance and the conflicts that may arise in these relationships;
☐	**d.** describe stakeholder management;
☐	**e.** describe mechanisms to manage stakeholder relationships and mitigate associated risks;
☐	**f.** describe functions and responsibilities of a company's board of directors and its committees;
☐	**g.** describe market and non-market factors that can affect stakeholder relationships and corporate governance;
☐	**h.** identify potential risks of poor corporate governance and stakeholder management, and identify benefits from effective corporate governance and stakeholder management;
☐	**i.** describe factors relevant to the analysis of corporate governance and stakeholder management;
☐	**j.** describe environmental and social considerations in investment analysis;
☐	**k.** describe how environmental, social, and governance factors may be used in investment analysis.

1 INTRODUCTION AND OVERVIEW OF CORPORATE GOVERNANCE

a describe corporate governance

Weak corporate governance is a common thread found in many company failures. Lack of proper oversight by the board of directors, inadequate protection for minority shareholders, and incentives at companies that promote excessive risk taking are just a few of the examples that can be problematic for a company. Poor corporate governance practices resulted in several high-profile accounting scandals and corporate bankruptcies over the past several decades and have been cited as significantly contributing to the 2008–2009 global financial crisis.

In response to these failures, regulations have been introduced to promote stronger governance practices to protect financial markets and investors. Academics, policy makers, and other groups have published numerous works discussing the benefits of good corporate governance and identifying core corporate governance principles believed to be essential to ensuring continuous, well-functioning capital markets and the stability of the financial system.

The investment community has also demonstrated a greater appreciation for the importance of good corporate governance. The assessment of a company's corporate governance structure and controls, including consideration of conflicts of interest and transparency of operations, has been an essential factor in investment analysis. More data availability and demands for better governance have increased the weight of corporate governance in the investment decision-making process. In addition, investors have become more attentive to environmental and social issues related to a company's operations. Collectively, these concepts often are referred to as environmental, social, and governance (**ESG**).

Section 1 of this reading provides an overview of corporate governance, including its underlying principles and theories. Section 2 discusses the various stakeholders of a company and conflicts of interest that exist among stakeholder groups. Section 3 describes the principal–agent and other relationships in corporate governance and the conflicts that may arise in these relationships. Section 4 describes stakeholder management, reflecting how companies manage their relationships with stakeholders. Section 5 focuses on mechanisms to manage stakeholder relationships and mitigate associated risks. Section 6 focuses on the role of the board of directors and its committees as overseers of the company. Section 7 explores certain key factors that affect stakeholder relationships and corporate governance. Section 8 highlights the risks and benefits that underlie a corporate governance structure. Section 9 synthesizes corporate governance concepts that should be considered by investment professionals. Finally, Section 10 discusses the growing use of environmental, social, and governance factors in investment analysis and portfolio construction processes.

1.1 Corporate Governance Overview

Corporate governance can be defined as "the system of internal controls and procedures by which individual companies are managed. It provides a framework that defines the rights, roles, and responsibilities of various groups within an organization. At its core, corporate governance is the arrangement of checks, balances, and incentives a company needs in order to minimize and manage the conflicting interests between insiders and external shareowners."[1]

Corporate governance practices differ among countries and jurisdictions, and even within countries different corporate governance systems may co-exist. The corporate governance systems adopted in most of the world typically reflect the influences of either *shareholder theory* or *stakeholder theory* to a varying extent, as well as historical, cultural, legal, political, and other influences specific to a region.

Shareholder theory takes the view that the most important responsibility of a company's managers is to maximize shareholder returns. Stakeholder theory broadens a company's focus beyond the interests of only its shareholders to its customers, suppliers, employees, and others who have an interest in the company. The approach to corporate governance in a given country typically places greater emphasis on one of the two theories but can also exhibit a combination of the two. Notwithstanding the system of corporate governance used, nearly all companies depend on contributions from a number of stakeholders for their long-term success. The company's strategy is set by the board of directors, which also oversees management. In turn, the company's strategy is executed by its managers; financial capital to fund the company's activities and operations is supplied by shareholders, creditors, and suppliers; human capital is provided by employees; and demand for goods and services comes from customers. Other stakeholders include governments and regulators, which seek to protect the interests and well-being of their citizens. Certain external forces, such as the legal environment and competition, affect the way a company operates and the relationships among its stakeholders.

Two reports issued during the 1990s, the Cadbury Report and the Principles of Corporate Governance, were particularly influential in shaping the global corporate governance landscape. In 1991, the Committee on the Financial Aspects of Corporate Governance was established in the United Kingdom by the Financial Reporting Council, the London Stock Exchange, and the accountancy profession to examine corporate governance. In the following year, the report of the committee—commonly referred to as the Cadbury Report, after its chairperson—defined corporate governance simply as "the system by which companies are directed and controlled." The report focused on the responsibilities of a company's board of directors, shareholders, and auditors, with shareholders implicitly identified as the primary stakeholders. In 1999, the Organisation for Economic Co-Operation and Development (OECD) produced the *Principles of Corporate Governance*, which expanded the scope of corporate governance to consider the interests of other stakeholders—notably, employees, creditors, and suppliers. According to the OECD, "Corporate governance includes a set of relationships between a company's management, its board, its shareholders, and other stakeholders." The *Principles of Corporate Governance*, which has been revised numerous times since its initial publication, also discusses potential positive outcomes of good corporate governance practices (including financial market stability and economic growth) and includes standards and guidelines designed to evaluate and improve the corporate governance framework throughout the world.

There is evidence that some movement toward global convergence of corporate governance systems is underway. One trend is the increased acceptance and adoption of corporate governance regulations with similar principles from one jurisdiction to another. For example, several countries implemented regulations similar to those of the US Sarbanes–Oxley Act of 2002 (SOX) in response to corporate and accounting scandals of the early 2000s. Although these regulations are not identical, they share the same objective of improving internal controls and restoring investor confidence in financial disclosures. Another trend is initiatives by international agencies to build greater consensus on important corporate governance principles. The *Principles of Corporate Governance*, for example, has been ratified by more than 30 member countries, representing a broad range of corporate governance models. The *Principles of Corporate Governance* do not mandate, or even promote, the adoption of a single corporate governance regime; rather, the principles were designed to serve as a framework that can be adopted by any number of corporate governance systems.

EXAMPLE 1

Corporate Governance Overview

Which statement regarding corporate governance is *most* accurate?

A Most countries have similar corporate governance regulations.

B A single definition of corporate governance is widely accepted in practice.

C Both shareholder theory and stakeholder theory consider the needs of a company's shareholders.

Solution:

C is correct. Both shareholder and stakeholder theories consider the needs of shareholders, with the latter extending to a broader group of stakeholders. A is incorrect because corporate governance regulations differ across countries, although there is a trend toward convergence. B is incorrect because a universally accepted definition of corporate governance remains elusive.

2

STAKEHOLDER GROUPS

b describe a company's stakeholder groups, and compare interests of stakeholder groups

A corporate governance system is likely to be influenced by several stakeholder groups. These groups do not necessarily share similar goals or needs; in fact, the interests of any one group may conflict with the interests of another group. The varying influences of these groups are important considerations for investment professionals when analyzing a corporate governance system. This section provides an overview of a corporation's primary stakeholder groups, followed by a discussion of principal–agent considerations and the conflicts that may arise among the groups.

2.1 Stakeholder Groups

The primary stakeholder groups of a corporation consist of shareholders, creditors, managers (or executives), other employees, board of directors, customers, suppliers, affected individuals and community groups, and governments/regulators. The interests of each of these groups are discussed in the following sections.

2.1.1 *Shareholders*

Shareholders own shares of stock in a corporation and are entitled to certain rights, such as the right to receive dividends and to vote on certain corporate issues.[2] In terms of capital structure, shareholders are the most junior class of capital providers; in case of a company bankruptcy, shareholders receive proceeds only after all creditors' claims are paid. Shareholder interests are, therefore, typically focused on growth in corporate profitability that maximizes the value of a company's equity.

As a company grows in size and its operations and structure become more complex, most individual shareholders have limited or no involvement in the company's activities. Shareholders maintain control over the company through their power to elect the board of directors and vote for specified resolutions. The board of directors is expected to represent shareholders—protecting their interests, appointing senior management, providing strategic direction, and monitoring company and management performance. In publicly traded companies that have dispersed ownership, the voting power in general meetings is distributed among a large number of shareholders. But in some companies, a particular shareholder or block of shareholders may hold a percentage of shares that gives them sufficient voting power to control the election of the board of directors and to influence the approval or blockage of a company resolution; these shareholders are known as **controlling shareholders**. In contrast, non-controlling shareholders (**minority shareholders**) hold a much smaller proportion of a company's outstanding shares, resulting in a more limited ability to exercise control in voting activities.

2.1.2 *Creditors*

Creditors, most commonly bondholders and banks, are a company's lenders and the providers of debt financing. Creditors do not hold voting power (unlike common shareholders) and typically have limited influence over a company's operations. Creditors may protect themselves and exert some control over a company by using covenants, which restrict activities of the borrower. In return for capital provided, creditors expect to receive interest and principal payments. These payments are pre-determined from the terms of a debt contract and are typically not contingent on the company's performance. Creditors usually do not participate in a company's superior performance beyond receiving promised interest and principal payments. The company's ability to generate cash flows, mainly through its operations, is the primary source of payments for creditors. Consequently, creditors generally prefer stability in company operations and performance, which contrasts with the interests of shareholders, who generally are inclined to tolerate higher risks in return for higher return potential from strong company performance.

2.1.3 *Managers and Employees*

Senior executives and other high-level managers are normally compensated through salary, bonuses, equity-based remuneration (or compensation),[3] and certain perquisites. As a result, managers may be motivated to maximize the value of their total remuneration while also protecting their employment positions. Lower-level employees typically seek fair remuneration, good working conditions, access to promotions, career development opportunities, training and development, job security, and a safe and healthy work environment. Overall, remuneration packages that are designed to prevent employees from chasing short-term profits are likely to be most effective and aligned with long-term shareholder interests.

---

[2] https://themoderncorporation.wordpress.com/company-law-memo/

[3] The terms "remuneration" and "compensation" are typically interchangeable, with compensation generally used in North America and remuneration generally used outside North America. In this reading, unless specifically identified with North America, we primarily use "remuneration."

As with shareholders and creditors, managers and employees have a significant interest in the company's viability. Managers and employees tend to benefit if the company performs well and are among the most adversely affected stakeholders if a company's financial position weakens. Despite some similarities, the interests of managers and employees and other stakeholders can conflict. For example, a company may be presented with a takeover offer that is attractive to shareholders but would jeopardize the interests of managers in preserving their employment at the company.

2.1.4 *Board of Directors*

A company's board of directors is elected by shareholders to protect shareholders' interests, provide strategic direction, and monitor company and management performance. A board is typically structured as either *one-tier* or *two-tier*.

A one-tier structure consists of a single board of directors, composed of executive and non-executive directors. Executive (sometimes called "internal") directors are employees, typically senior managers, of the company. Non-executive (sometimes called "external") directors are not employees of the company. Countries in which one-tier boards are common include the United States, the United Kingdom, and India. A two-tier structure consists of two separate boards: (1) a *supervisory board*, which is primarily composed of non-executive directors, and (2) a *management (executive) board*, which is composed of executive directors. The supervisory board oversees the management board. Two-tier boards are common in such countries as Germany, the Netherlands, Finland, and China.

In this reading, unless specified otherwise, the term "board" refers to the single board of directors in a one-tier structure and the supervisory board in a two-tier structure. Directors, both internal and external, are typically experienced individuals who are focused on fulfilling their responsibilities toward shareholders and the company while maintaining a good reputation in the business community. Directors are also typically concerned with their exposure to liability for breach of duty. Directors can mitigate this exposure, *inter alia*, by exercising appropriate levels of control over the company's operations and its management or by obtaining independent access to company documentation. A company's board of directors is discussed in more detail in Section 6 of this reading.

2.1.5 *Customers*

Customers expect a company's products or services to satisfy their needs and provide appropriate benefits given the price paid, as well as to meet applicable standards of safety. Depending on the type of product or service and the duration of their relationship with the company, customers may desire ongoing support, product guarantees, and after-sale service. Companies are concerned with customer satisfaction given its potential correlation with sales revenue and profit. They are also increasingly concerned about brand boycotts due to adverse environmental and social impacts and controversies caused by their products and services. Compared with other stakeholder groups, customers tend to be less concerned with, and affected by, a company's financial performance. However, customers, particularly those who are dependent on the goods or services provided by the company, typically have an interest in a company's stability.

2.1.6 *Suppliers*

A company's suppliers have a primary interest in being paid as contracted or agreed on, and in a timely manner, for products or services delivered to the company. Suppliers often seek to build long-term relationships with companies for the benefit of both parties and aim for these relationships to be fair and transparent. Suppliers, like creditors, are concerned with a company's ability to generate sufficient cash flows to meet its financial obligations.

2.1.7 *Governments/Regulators*

Governments and regulators seek to protect the interests of the general public and ensure the well-being of their nations' economies. Because corporations have a significant effect on a nation's economic output, capital flows, employment, and social welfare, among other factors, regulators have an interest in ensuring that corporations behave in a manner that is consistent with applicable laws. Moreover, as the collector of tax revenues from companies and their employees, a government can also be considered one of the company's major stakeholders.

STAKEHOLDERS IN NON-PROFIT ORGANIZATIONS

The stakeholders of a non-profit organization tend to differ from those of for-profit companies. Non-profit organizations do not have shareholders. Their stakeholders most commonly include board directors or trustees, employees, regulators, society, patrons of the organization, donors, and volunteers. The stakeholders of non-profit organizations are generally focused on ensuring that the organization is serving the intended cause and that donated funds are used as promised.

EXAMPLE 2

Stakeholder Groups

Which stakeholders would *most likely* realize the greatest benefit from a significant increase in the market value of the company?

A Creditors

B Customers

C Shareholders

Solution:

C is correct. Shareholders own shares of stock in the company, and their wealth is directly related to the market value of the company. A is incorrect because creditors are usually not entitled to any additional cash flows (beyond interest and debt repayment) if the company's value increases. B is incorrect because customers may have an interest in the company's stability and long-term viability, but they do not benefit directly from an increase in a company's value.

PRINCIPAL–AGENT AND OTHER RELATIONSHIPS IN CORPORATE GOVERNANCE

3

c describe principal–agent and other relationships in corporate governance and the conflicts that may arise in these relationships

A **principal–agent relationship** (also known as an agency relationship) is created when a principal hires an agent to perform a particular task or service. The principal–agent relationship involves obligations, trust, and expectations of loyalty; the agent is expected to act in the best interests of the principal. In a company, agency theory stipulates that principal–agent relationships often lead to conflicts—for example, when managers do not act in the best interests of shareholders.[4] Examples of principal–agent relationships and potential conflicts between the principal and agent are discussed in the following sections. Other conflicts among stakeholder groups not involving principal–agent relationships are also discussed.

3.1 Shareholder and Manager/Director Relationships

In shareholder-owned companies, shareholders typically grant directors and managers the responsibility to make most corporate decisions. According to traditional shareholder theory (discussed earlier), the central duty of directors and managers is to act in the best interests of shareholders. In certain circumstances, however, managers may seek to maximize their personal benefits (e.g., remuneration and perquisites) to the detriment of shareholders' interests.

Shareholder interests can also diverge from those of managers and directors with respect to risk tolerance. In some cases, shareholders with diversified investment portfolios may have a relatively high risk tolerance because the risk undertaken by a specific company can be diversified across the shareholders' investments. Managers and directors, however, are typically more risk averse in their corporate decision making so they can better protect their employment status. Such behavior may differ from the company's value creation objective. In addition, compared with shareholders, managers typically have greater access to information about the business and are more knowledgeable about its operations. Such "information asymmetry" (that is, unequal access to information) makes it easier for managers to make strategic decisions that are not necessarily in the best interest of shareholders and weakens the ability of shareholders to exercise control. Another conflict of interest might arise between shareholders and directors when the board is influenced by insiders. In this case, the ability of the board to properly perform its monitoring and control role may be hindered. Finally, a conflict between the two groups may occur if directors favor certain influential shareholders over other shareholders.

3.2 Controlling and Minority Shareholder Relationships

In companies in which a particular shareholder holds a controlling stake, conflicts of interest may arise among the controlling and minority shareholders. In such ownership structures, the opinions of minority shareholders are often outweighed or overshadowed by the influence of the controlling shareholders. Minority shareholders often have limited or no control over management and limited or no voice in director appointments or in major transactions that could have a direct effect on the value of their shares. For instance, in companies that adopt **straight voting** (that is, one vote for each share owned), controlling shareholders clearly wield the most influence in board of director elections, leaving minority shareholders with much less representation on the board.

---

[4] Agency theory considers the problems that can arise in a business relationship when one person delegates decision-making authority to another. The traditional view in the investment community is that directors and managers are agents of shareholders. More recently, however, many legal experts have argued that in several countries, corporations are separate "legal persons"; thus, directors and managers are agents of the corporations rather than shareholders (or a subset of shareholders). See https://themoderncorporation.wordpress.com/company-law-memo.

The decisions made by controlling shareholders, or their board representatives, could also have an effect on corporate performance and, consequently, on minority shareholders' wealth. Takeover transactions are notable situations in which controlling shareholders typically have greater influence than do minority shareholders with regard to the consideration received and other deal terms. A historical example of note occurred in 2007 when Qtel, Qatar's largest telecommunications company, executed a deal with a consortium of the shareholders of Wataniya, Kuwait's telecommunications company, to acquire the consortium's shares in Wataniya (representing a 51% stake in the target). The consortium of Wataniya's shareholders sold their shares to Qtel at a premium of 48% on the stock price to the exclusion of minority shareholders.

Related-party transactions are another example for which controlling shareholders may place their interests ahead of minority shareholders' interests. Such a situation could occur when a controlling shareholder maintains a financial interest in a transaction between the company and a third party and that transaction conflicts with the company's best interests. Consider, for example, a controlling shareholder that arranges a deal between the company and a third-party supplier that is owned by the shareholder's spouse whereby the supplier provides the company with inventory at above-market prices. Such a transaction would benefit the controlling shareholder and the spouse's interests but could harm the profitability of the company and the interests of minority shareholders.

Lastly, an equity structure with multiple share classes in which one class is non-voting or has limited voting rights creates a divergence between the ownership and control rights of different classes of shareholders. Under a multiple-class structure (traditionally called a *dual-class structure* when there are two share classes), the company's founders, executives, and other key insiders control the company by virtue of ownership of a share class with superior voting powers. The multiple-class structure enables controlling shareholders to mitigate dilution of their voting power when new shares are issued. Examples of companies that have adopted multiple-class stock structures are Alibaba and Facebook (each with two share classes).

3.3 Manager and Board Relationships

Given that a board of directors typically relies on management to operate the company, the board's monitoring role can be compromised in the event of limited information provided to the board. This conflict is particularly pronounced for non-executive directors who are typically not involved in the day-to-day operations of a company.

3.4 Shareholder versus Creditor Interests

Shareholders typically seek growth in corporate profitability because of the residual nature of equity returns. However, the pre-determined returns of debt obligations normally prevent creditors from receiving any cash flows beyond principal and interest payments but do expose creditors to default risk in case of extremely poor corporate performance. From an investment perspective, shareholders would likely prefer riskier projects with a strong likelihood of higher return potential, whereas creditors would likely prefer stable performance and lower-risk activities. A divergence in risk tolerance regarding the company's investments thus exists between shareholders and creditors.

Creditors may also find their interests jeopardized when the company attempts to increase its borrowings to a level that would increase default risk. If the company's operations and investments fail to generate sufficient returns required to repay the increased interest and debt obligations, creditors will be increasingly exposed to default risk. The distribution of excessive dividends to shareholders might also conflict with creditors' interests if it impairs the company's ability to pay interest and principal.

3.5 Other Stakeholder Conflicts

In a corporation, interests can also conflict among other stakeholders. Some of these situations are as follows:

- *Conflict between customers and shareholders*: For example, a company decides to charge a high price for its products or reduces product safety features to reduce costs.
- *Conflict between customers and suppliers*: A company offers overly lenient credit terms to its customers, whereby the company's ability to repay suppliers on time may be affected.
- *Conflict between shareholders and governments or regulators*: Examples of such conflicts may include a company adopting accounting and reporting practices that reduce its tax burden, thus potentially benefiting shareholders, or a bank's shareholders preferring a lower equity capital base while regulators prefer a higher capital position. This last conflict is fairly common in the banking industry and has been increasingly in focus since the global financial crisis of 2008–2009.

EXAMPLE 3

Stakeholder Relationships

A controlling shareholder of XYZ Company owns 55% of XYZ's shares, and the remaining shares are spread among a large group of shareholders. In this situation, conflicts of interest are *most likely* to arise between:

A shareholders and regulators.

B the controlling shareholder and managers.

C the controlling shareholder and minority shareholders.

Solution:

C is correct. In this ownership structure, the controlling shareholder's power is likely more influential than that of minority shareholders. Thus, the controlling shareholder may be able to exploit its position to the detriment of the interests of the remaining shareholders. Choices A and B are incorrect because the ownership structure in and of itself is unlikely to create material conflicts between shareholders and regulators or shareholders and managers.

4 OVERVIEW AND MECHANISMS OF STAKEHOLDER MANAGEMENT

d describe stakeholder management

e describe mechanisms to manage stakeholder relationships and mitigate associated risks

Because interests among stakeholder groups differ, companies often adopt mechanisms to more efficiently manage stakeholder relationships. **Stakeholder management** involves identifying, prioritizing, and understanding the interests of stakeholder groups, and, on that basis, managing the company's relationships with these groups.

4.1 Overview of Stakeholder Management

Effective communication and active engagement with the various stakeholders form the basis of stakeholder management. Although the practices underlying stakeholder management may vary, companies typically seek to balance the interests of their various stakeholders and thus limit the effect of conflicts.

To help balance these interests, corporate governance and stakeholder management frameworks reflect a legal, contractual, organizational, and governmental infrastructure that defines the rights, responsibilities, and powers of each group. The *legal infrastructure* defines the framework for rights established by law and the availability or ease of legal recourse for any violation of these rights. The *contractual infrastructure* is shaped by the contractual arrangements entered into by the company and its stakeholders that help define and secure the rights of both parties. The *organizational infrastructure* refers to internal systems, governance procedures, and practices adopted and controlled by the company in managing its stakeholder relationships. Lastly, the *governmental infrastructure* refers to regulations imposed on companies.

The corporate governance systems in such countries as France, Germany, and Japan focus on a broader range of stakeholders relative to the more shareholder-driven Anglo-American systems. Globally, there is a growing movement among regulators and practitioners to more effectively balance the interests of all stakeholders. For instance, the Companies Act 2006 in the United Kingdom introduced "enlightened shareholder value," which requires directors to consider the interests of all stakeholders—not just shareholders. Several regulators, such as those in the United Kingdom and Japan, have adopted stewardship codes that encourage more active engagement of institutional investors with companies.

EXAMPLE 4

Stakeholder Management

The component of stakeholder management in which a corporation has the *most* control is:

A legal infrastructure.

B contractual infrastructure.

C governmental infrastructure.

Solution:

B is correct. A corporation's contractual infrastructure refers to the contractual arrangements between the corporation and stakeholders. As such, the corporation has control over these arrangements. A is incorrect because the legal infrastructure is established by law, which is outside the corporation's own control. Similarly, C is incorrect because a corporation's governmental structure is largely imposed by regulators.

4.2 Mechanisms of Stakeholder Management

Stakeholder management and governance practices attempt to manage the interests of all stakeholders. As mentioned earlier, a prescribed or standard set of rights and practices does not exist across all companies, and the principles vary across countries and jurisdictions. Still, there are some common control elements and governance mechanisms among companies.

4.2.1 *General Meetings*

Corporate laws grant shareholders certain powers and controls. The participation of shareholders in general meetings, also known as general assemblies, and the exercise of their voting rights are among the most influential tools available. General meetings enable shareholders to participate in discussions and to vote on major corporate matters and transactions that are not delegated to the board of directors.

Companies are ordinarily required to hold an annual general meeting (AGM) within a certain period following the end of their fiscal year. The main purpose of those meetings is to present shareholders with the annual audited financial statements of the company, provide an overview of the company's performance and activities, and address shareholder questions. Shareholders also elect the directors at the AGM and, in some countries, may be required to approve the financial statements, discharge directors of their duties, appoint external auditors, or vote on the remuneration of the board and/or top management. Extraordinary general meetings can be called by the company or by shareholders throughout the year when significant resolutions requiring shareholder approval are proposed. These resolutions might relate to proposed material corporate changes, such as amendments to the company's bylaws or rights attached to a class of shares, mergers and acquisitions, or the sale of significant corporate assets or businesses.

All shareholders typically have the right to attend, speak at, and vote at general meetings. Regulations, particularly corporate laws, specify conditions for inviting shareholders to general meetings and circulating information to shareholders. These conditions vary across regulations but generally aim at ensuring the participation of a large number of shareholders in general meetings without imposing excessive restrictions on the ability of the company to hold a meeting. By engaging in general meetings, shareholders can exercise their voting rights on major corporate issues and better monitor the performance of the board and senior management. General meetings and the underlying voting procedures are among the most widely adopted practices by companies in mitigating agency problems and their associated risks.

Some resolutions, such as the approval of financial statements and the election of directors and auditors, are considered ordinary at general meetings because they require only a simple majority of votes to be passed. Decisions that are more material in nature may require a supermajority vote, such as two-thirds or 75% of votes, to be passed. Such special resolutions may include amendments to bylaws, voting on a merger or takeover transaction, or waiving pre-emptive rights. Depending on the ownership structure, supermajority requirements may make it harder for majority shareholders to influence corporate decisions at the expense of minority shareholders.

Proxy voting is a process that enables shareholders who are unable to attend a meeting to authorize another individual (for example, another shareholder or director) to vote on their behalf. Proxy voting is the most common form of investor participation in general meetings. Although most resolutions at most companies pass without controversy, sometimes minority shareholders attempt to strengthen their influence at companies via proxy voting. Several shareholders sometimes use this process to collectively vote their shares in favor of or in opposition to a certain resolution. **Cumulative voting** (as opposed to straight voting) enables shareholders to accumulate and vote all their shares for a single candidate in an election involving more than one director. This voting process raises the likelihood that minority shareholders are represented by at least one director on the board, but it may not be compatible with majority voting standards for director elections in which share ownership is widely dispersed. In terms of worldwide practice, the existence of cumulative voting varies; for example, it is mandated in Spain but not allowed in several countries, such as Germany, Japan, Singapore, and Turkey.

Minority shareholders are often granted rights to protect their interests in acquisitions. For example, companies in European Union member states are required to adopt sell-out rights. These rights allow minority shareholders who have voted against a merger offer to force a bidder with more than 90% of the target's voting rights to buy their shares at a fair price upon the deal's approval.

EXAMPLE 5

General Meetings

Which of the statements about extraordinary general meetings (EGMs) of shareholders is true?

A The appointment of external auditors occurs during the EGM.

B A corporation provides an overview of corporate performance at the EGM.

C An amendment to a corporation's bylaws typically occurs during the EGM.

Solution:

C is correct. An amendment to corporate bylaws would normally take place during an EGM, which covers significant changes to a company, such as bylaw amendments. A and B are incorrect because the appointment of external auditors and a corporate performance overview would typically take place during the AGM.

4.2.2 *Board of Director Mechanisms*

In companies with complex ownership structures and operations, it is impractical for shareholders to be involved in strategy formulation and day-to-day activities. Shareholders thus elect a board of directors to provide broad oversight of the company. Shareholders monitor the board's performance through exercise of voting power and participation in general meetings. The board, in turn, appoints the top management of the company. The board is accountable primarily to shareholders and is responsible for the proper governance of the company; in this regard, the board is the link between shareholders and managers. The board guides managers on the company's strategic direction, oversees and monitors management's actions in implementing the strategy, and evaluates and rewards or disciplines management performance. The board also supervises the company's audit, control, and risk management functions and ensures the adoption of proper governance systems and compliance with all applicable laws and regulations. In Section 6, we provide more detail regarding the functions and responsibilities of the board of directors and its committees.

4.2.3 *The Audit Function*

The audit function is an integral component of any governance structure. The function represents the systems, controls, and policies/procedures in place to examine the company's operations and financial records. Internal audits are conducted by an independent internal audit function or department. External auditors are independent from the company and conduct an annual audit of the company's financial records to provide reasonable and independent assurance of the accuracy of financial statements and their fair representation of the financial position of the company. External auditors are typically recommended by an audit committee (which we discuss later in the reading) for appointment by shareholders or, in some jurisdictions, by the board. The board of directors is generally required to receive and review the financial statements and auditors' reports and confirm their accuracy before they are presented to shareholders for approval at the AGM. Senior management of publicly traded companies is also required to review and provide assurance of the effectiveness of the internal control systems to the board of directors or to shareholders. Overall, a company's audit function limits insiders' discretion with regard to the use of company resources and to its financial reporting. The audit function is also designed to mitigate incidents of fraud or misstatements of accounting and financial information.

4.2.4 *Reporting and Transparency*

Shareholders have access to a range of financial and non-financial information concerning the company, typically through annual reports, proxy statements, disclosures on the company's website, the investor relations department, and other means of communication (e.g., social media). This information may relate to the company's operations, its strategic direction or objectives, audited financial statements, governance structure, ownership structure, remuneration policies, related-party transactions, and risk factors. Such information is essential for shareholders to

- reduce the extent of information asymmetry between shareholders and managers;
- assess the performance of the company and of its directors and managers;
- make informed decisions in valuing the company and deciding to purchase, sell, or transfer shares; and
- vote on key corporate matters or changes.

4.2.5 *Policies on Related-Party Transactions*

The development and implementation of policies for related-party transactions and other conflicts of interest is an increasingly common practice among companies. These policies establish the procedures for mitigating, managing, and disclosing such cases. Typically, directors and managers are required to disclose any actual or potential, or direct or indirect, conflict of interest they have with the company, as well as any material interests in a transaction that may affect the company. Often, these policies require such transactions or matters to be voted on by the board (or shareholders) excluding the director (or shareholder) holding the interest. The adoption of these policies and procedures aims at ensuring that related-party transactions are handled fairly and that they do not advance the interests of the related party at the expense of the interests of the company or other shareholders.

4.2.6 *Remuneration Policies*

Executive remuneration plans have gained significant attention in the investment world, with a primary goal of aligning the interests of managers with those of shareholders. For this purpose, incentive plans increasingly include a variable component—typically profit sharing, stocks, or stock options—that is contingent on corporate or stock price performance. However, the granting of stock-based remuneration does not serve its purpose if managers can improve their personal gains at the expense of the company while limiting their exposure to weak stock performance. As a result, companies are increasingly designing incentive plans that discourage either "short-termism" or excessive risk taking by managers. Some incentive plans include granting shares, rather than options, to managers and restricting their vesting or sale for several years or until retirement. A long-term incentive plan delays the payment of remuneration, either partially or in total, until company strategic objectives (typically performance targets) are met.

Regulators across the world are also increasingly focused on remuneration policies. In some cases, regulators require companies to base remuneration specifically on long-term performance measures. A number of regulators are requiring companies, including many in the financial industry, to adopt clawback provisions. These provisions allow a company to recover previously paid remuneration if certain events, such as financial restatements, misconduct, breach of the law, or risk management deficiencies, are uncovered.

4.2.7 *Say on Pay*

Given the role of remuneration plans in aligning the interests of executives with those of shareholders, regulators and companies are increasingly seeking shareholder views on pay. The concept of **say on pay** enables shareholders to vote on executive remuneration matters. Say on pay was first introduced in the United Kingdom in the early 2000s. In an early example of shareholder rejection, in 2003 the shareholders of GlaxoSmithKline rejected the company's remuneration report because of opposition to the proposed executive pay. This was the first such rejection by the shareholders of a large UK-based company. Shortly thereafter, the practice of say on pay spread to other parts of the world and was implemented in the United States as part of the Dodd–Frank Act in 2011. In 2018, there were a number of instances in which shareholders voted against remuneration reports. In the United Kingdom, for example, Inmarsat plc's remuneration report was rejected by 58% of voters over concerns that executive compensation was not aligned with company performance. In the United States, 52% of Walt Disney Co.'s shareholders voted against what they believed was an excessive executive compensation package.

The scope and effect of say on pay varies across countries and companies. Some countries, such as Canada, have a non-mandatory and advisory (non-binding) say on pay system in which shareholders signal, rather than impose, their views on proposed remuneration. In other countries, such as the United States, France, and South Africa, say on pay is mandatory but non-binding. In these countries, the board is required to enable shareholders to vote on remuneration plans or packages, but the board does not have to abide by the result of the vote. Conversely, countries in which shareholder votes on say on pay are binding include the Netherlands, the United Kingdom, and China.

Say on pay has been subject to criticism because of the fact that shareholders often have limited involvement in a company's strategy and operations. These opponents argue that the board is better suited to determine remuneration matters. Conversely, by allowing shareholders to express their views on remuneration-related matters, companies can limit the discretion of directors and managers in granting themselves excessive or inadequate remuneration. This approach could thus reduce a critical agency conflict in stakeholder management by better aligning the interests of principals and agents.

MECHANISMS TO MITIGATE ASSOCIATED STAKEHOLDER RISKS

5

e describe mechanisms to manage stakeholder relationships and mitigate associated risks

The rights of creditors are established by laws and according to contracts executed with the company. Laws vary by jurisdiction but commonly contain provisions to protect creditors' interests and provide legal recourse. One such provision is an **indenture**, which is a legal contract that describes the structure of a bond, the obligations of the issuer, and the rights of the bondholders. To limit creditors' risk during the term of a bond (or loan), debtholders may choose to impose **covenants** within indentures or contracts. Covenants are the terms and conditions of lending agreements, enabling creditors to specify the actions an issuer is obligated to perform or prohibited from performing. Affirmative covenants require bond issuers to perform certain actions, such as maintaining adequate levels of insurance. Restrictive covenants require bond issuers to not perform certain actions, such as allowing the liquidity level to fall below a minimum coverage ratio. **Collaterals** are another tool often used by creditors to guarantee repayment, representing assets or financial guarantees that are above and beyond an issuer's promise to repay its obligations.

To further protect their rights, creditors usually require the company to provide periodic information (including financial statements) to ensure that covenants are not violated and thus potential default risk is not increased. Because it is usually impractical and costly for individual bondholders to fully scrutinize a bond issue, companies often hire a financial institution to act as a trustee and monitor the issue on behalf of a class of bondholders. In some countries, credit committees, particularly for unsecured bondholders, are established once a company files for bankruptcy. Such committees are expected to represent bondholders throughout the bankruptcy proceedings and protect bondholder interests in any restructuring or liquidation.

5.1 Employee Laws and Contracts

Employee rights are primarily secured through labor laws, which define the standards for employees' rights and responsibilities and cover such matters as labor hours, pension and retirement plans, hiring and firing, and vacation and leave. In most countries, employees have the right to create unions. Unions seek to influence certain matters affecting employees. In the European Union, companies meeting specific size and geographic criteria are required to establish European Works Councils that are composed of employees who meet with management at least annually. Although not a common practice in the United States and many other parts of the world, employees are sometimes represented on the board of directors—or supervisory boards—of companies meeting certain size or ownership criteria (e.g., in Germany, Austria, and Luxembourg). In Japan, the employee model stresses reaching a consensus between management and employees in decision making.

At the individual level, employment contracts specify an employee's various rights and responsibilities. Employment contracts typically do not cover every situation between employees and employers, and thus there is some area of discretion in the employment relationship. Human resources policies also help companies manage their relationships with employees. Effective human resources policies seek to attract and recruit high-quality employees while providing remuneration, training/development, and career growth to improve employee retention. Some companies have employee stock ownership plans (ESOPs) to help retain and motivate employees. As part of an ESOP, a company establishes a fund consisting of cash and/or company shares. The shares, which have designated vesting periods, are granted to employees.

Codes of ethics and business conduct also serve an important role in the relationship between employees and the company. Such codes establish the company's values and the standards of ethical and legal behavior that employees must follow. Companies typically assign a compliance or corporate governance officer (or a board committee) to implement these codes, receive violation reports, and resolve ethical matters. In addition, whistleblower protection policies are another mechanism to ensure misconduct can be safely reported so as to mitigate associated stakeholder risks.

By managing its relationships with its employees, a company seeks to comply with employees' rights and mitigate legal or reputational risks in violation of these rights. Employee relationship management also helps ensure that employees are fulfilling their responsibilities toward the company and are qualified and motivated to act in the company's best interests.

5.2 Contractual Agreements with Customers and Suppliers

Both customers and suppliers enter into contractual agreements with a company that specify the products and services underlying the relationship, the prices or fees and the payment terms, the rights and responsibilities of each party, the after-sale relationship, and any guarantees. Contracts also specify actions to be taken and recourse available if either party breaches the terms of the contract.

5.3 Laws and Regulations

As part of their public service roles, governments and regulatory authorities develop laws that companies must follow and monitor companies' compliance with these laws. Such laws may address or protect the rights of a specific group, such as consumers or the environment. Some industries or sectors whose services, products, or operations are more likely to endanger the public or specific stakeholders' interests are usually subject to a more rigorous regulatory framework. Examples of these industries are banks, food manufacturers, and health care companies.

Many regulatory authorities have also adopted corporate governance codes that consist of guiding principles for publicly traded companies. Publicly traded companies, in turn, are generally required to annually publish corporate governance reports describing their governance structure and explain any deviations from guiding principles. Companies normally seek to adopt internal governance and compliance procedures and adhere to the relevant financial reporting and transparency requirements imposed by regulators.

EXAMPLE 6

Stakeholder Relationships

Which of the following is **not** typically used to protect creditors' rights?

A Proxy voting

B Collateral to secure debt obligations

C The imposition of a covenant to limit a company's debt level

Solution:

A is correct. Proxy voting is a practice adopted by shareholders, not creditors. B and C are incorrect because both collateral and covenants are used by creditors to help mitigate the default risk of a company.

COMPANY BOARDS AND COMMITTEES

6

f describe functions and responsibilities of a company's board of directors and its committees

As discussed earlier in the reading, the board of directors is a central component of a company's governance structure. The board serves as the link between shareholders and managers and acts as the shareholders' monitoring tool within the company. As the relevance of corporate governance has grown within the investment field, the responsibilities of the board of directors have also increased in importance.

6.1 Composition of the Board of Directors

The structure and composition of a board of directors vary by company and geography. There is no single or optimal structure, and the number of directors may differ depending on the company size, structure, and complexity of operations. Most corporate governance codes require that the board include a diverse mix of expertise, backgrounds, and competencies. Such qualifications may include specialized knowledge of the company's industry as well as experience in certain functions, such as strategy, finance/audit, risk management, human resources, or legal. Moreover, many companies seek age, gender, and racial diversity in board composition.

Boards with one-tier structures comprise a mix of executive and non-executive directors. Executive (or internal) directors are employed by the company and are typically members of senior management. Non-executive (or external) directors provide objective decision making, monitoring, and performance assessment. Additionally, non-executive directors can serve an important role in challenging management and using past expertise in strategy and board issues. An *independent director* is a specific type of non-executive director that does not have a material relationship with the company with regard to employment, ownership, or remuneration.

In two-tier structures, the supervisory and management boards are independent from each other. Regulators generally prohibit members of the management board from serving on the supervisory board or limit the number of individuals serving on both boards. Employee representatives are typically elected by the company's employees and could make up half of the supervisory board in large companies.

In many countries, the chief executive officer (CEO) and chairperson roles are increasingly separated. In the United States, many companies have historically had "CEO duality," in which the CEO also serves as chairperson of the board. Nevertheless, the percentage of companies separating the two roles, particularly in the United States, has increased considerably since the global financial crisis of 2008–2009. The appointment of a lead independent director is an alternative that is sometimes practiced by boards of companies with CEO duality. The lead independent director generally has the authority to request and oversee meetings of all independent directors. Duality is not applicable in two-tier structures that prohibit the members of the management board from serving on the supervisory board. In these models, the chairperson of the supervisory board is typically external and the CEO usually chairs the management board.

STAGGERED BOARDS

The general practice for boards is that elections occur simultaneously and for specified terms (three years, for example). Some companies, however, have **staggered boards**, whereby directors are typically divided into three classes that are elected separately in consecutive years—that is, one class every year. Because shareholders would need several years to replace a full board, this election process limits their ability to effect a major change of control at the company. The positive aspect of a staggered board, though, is that it provides continuous implementation of strategy and oversight without constantly being reassessed by new board members thereby bringing short-termism into company strategy. This staggered board model was historically prevalent in the United States but has been generally replaced by regular board election terms. In contrast, the practice is common in Australia.

6.2 Functions and Responsibilities of the Board

As mentioned earlier, a company's board of directors is elected by shareholders to act on their behalf. In fulfilling their functions, directors have a responsibility to consider the interests of all stakeholders. The duties of directors are mandated by law in many countries but vary across jurisdictions. Two widely established elements of directors' responsibilities are the *duty of care* and the *duty of loyalty*. According to the OECD's *Principles of Corporate Governance*, duty of care "requires board members to act on a fully informed basis, in good faith, with due diligence and care." The OECD further notes that duty of loyalty "is the duty of the board member to act in the interest of the company and shareholders. The duty of loyalty should prevent individual board members from acting in their own interest, or the interest of another individual or group, at the expense of the company and all shareholders."

A board of directors does not typically engage in the company's day-to-day activities; rather, those activities are delegated to management. The board guides and approves the company's strategic direction, taking into consideration the company's risk profile. It delegates the implementation of the company's strategy to senior management, oversees the execution of the strategy, and establishes milestones to monitor the progress in reaching the objectives. The board also reviews corporate performance and determines relevant courses of action accordingly. In doing so, the board can monitor and evaluate management's performance and determine whether senior executive remuneration is aligned with the long-term interests of the company. The board is also responsible for selecting, appointing, and terminating the employment of senior managers (or the management board in case of a two-tier structure). One of the board's main responsibilities is to ensure leadership continuity through succession planning for the CEO and other key executives.

The board plays a central role in ensuring the effectiveness of the company's audit and control systems. It sets the overall structure of these systems and oversees their implementation, including oversight of the financial reporting practices and review of the financial statements for fairness and accuracy. The board also oversees reports by internal audit, the audit committee, and the external auditors and proposes and follows up on remedial actions. The board has the ultimate responsibility to ensure that the company adopts and implements proper corporate governance principles and complies with all applicable internal and external laws and regulations, including ethical standards.

In addition, the board typically ensures that the company has an appropriate enterprise risk management system in place, whereby risks are identified, mitigated, assessed, and managed appropriately. The board monitors the effectiveness of these systems through regular reviews and reports received from both management and the company's risk function. The board also has the responsibility to review any proposals for corporate transactions or changes, such as major capital acquisitions, divestures, mergers, and acquisitions, before they are referred to shareholders for approval, if applicable.

6.3 Board of Directors Committees

A company's board of directors typically establishes committees that focus on specific functions. Such committees, in turn, provide recommendations that are reported to the board on a regular basis. Despite the delegation of responsibilities to committees, the overall board remains ultimately responsible to shareholders and is not discharged of its liabilities to shareholders. Although board committees may vary by organization, some of the most common committees are discussed in the following sections.

6.3.1 *Audit Committee*

The audit committee is perhaps the most common board committee among companies worldwide. The audit committee plays a key role in overseeing the audit and control systems at the company and ensuring their effectiveness. In this regard, the committee monitors the financial reporting process, including the application of accounting policies; ensures the integrity of financial statements; supervises the internal audit function and ensures its independence and competence; and presents an annual audit plan to the board and monitors its implementation by the internal audit function. The audit committee is also responsible for recommending the appointment of an independent external auditor, periodically assessing the independence of the external auditor, and proposing the auditor's remuneration. Both internal and external auditors report their findings to the audit committee, which in turn proposes remedial action for highlighted issues or matters.

6.3.2 *Governance Committee*

The primary role of the governance (or corporate governance) committee is to ensure that the company adopts good corporate governance practices. In doing so, the committee develops and oversees the implementation of the corporate governance code, the charters of the board and its committees, and the company's code of ethics and conflict of interest policy. The governance committee reviews these policies on a regular basis to incorporate any regulatory requirements or relevant developments in the field. Most importantly, the committee monitors the implementation of the governance policies and standards as well as the compliance with applicable laws and regulations throughout the company. Remedial actions are recommended if any flaws or breaches of laws or regulations are identified. In some companies, the governance committee may be responsible for overseeing an annual evaluation of the board to ensure that its structure and activities are aligned with the governance principles.

6.3.3 *Remuneration or Compensation Committee*

The remuneration (or compensation) committee of the board specializes in remuneration matters. This committee develops and proposes remuneration policies for the directors and key executives and presents them for approval by the board or shareholders. The committee may also be involved in handling the contracts of managers and directors as well as in setting performance criteria and evaluating the performance of managers. The responsibilities of the remuneration committee may extend to establishing human resources policies for the company when remuneration matters are involved. In some companies, the remuneration committee also sets and oversees the implementation of employee benefit plans, including insurance, pension, severance benefits, and retirement plans (including monitoring the investment performance of benefit plan funds).

6.3.4 *Nomination Committee*

The nomination committee identifies candidates who are qualified to serve as directors and recommends their nomination for election by shareholders. The committee also establishes the nomination procedures and policies, including the criteria for board directors, the search process, and the identification of qualified candidates for director positions. Director independence, including what constitutes an independent director, is also a function of the nomination committee. Through these roles, the nomination committee can help ensure that the board's composition is well balanced and aligned with the company's governance principles.

6.3.5 *Risk Committee*

The risk committee assists the board in determining the risk policy, profile, and appetite of the company. Accordingly, the committee oversees establishing enterprise risk management plans and monitors their implementation. It also supervises the risk management functions in the company, receives regular reports, and reports on its findings and recommendations to the board.

6.3.6 *Investment Committee*

The investment committee of the board reviews material investment opportunities proposed by management and considers their viability for the company. Such opportunities may include large projects, acquisitions, and expansion plans, as well as divestures or major asset disposals. The committee often challenges, when necessary, management assumptions underlying investment prospects, monitors the performance of investments, and reports its findings to the board. The committee also is typically responsible for establishing and revising the investment strategy and policies of the company.

The specific board committees discussed in previous sections are the most commonly used, although the composition and number of committees may vary depending on the jurisdiction or on company-specific factors (e.g., company size, industry, complexity of operations, or regulatory requirements). An audit committee, for instance, is a regulatory requirement in a large number of jurisdictions. For banks and other financial institutions, a risk committee is strongly recommended by some regulators and required by others. In Brazil, the Central Bank of Brazil requires financial institutions to establish a remuneration committee at the board level. Some companies choose to combine two or more committees into one—for example, a nomination and remuneration (or compensation) committee or an audit and risk committee. Companies may also find it valuable to establish committees with other specializations, such as a compliance committee, an ethics committee, a human resources committee, or a health/environmental/safety committee.

The composition of a board committee is normally aligned with its scope of responsibilities. For instance, many regulators request that executive (internal) directors do not rule on matters underlying conflicts of interest or on matters requiring an unbiased judgment (such as audit, remuneration, or related-party transaction matters). As such, a large number of rules, including those adopted by the London Stock Exchange and the New York Stock Exchange, require that the audit and the compensation committees be composed of independent directors only. Countries with less-stringent regulations may require the audit committee to be composed of external (non-executive) directors, the majority of which should be independent (including the chairperson).

EXAMPLE 7

Responsibilities of Board Committees

A primary responsibility of a board's audit committee does **not** include the:

A proper application of accounting policies.

B adoption of proper corporate governance.

C recommendation of remuneration for the external auditor(s).

Solution:

B is correct. The adoption of proper corporate governance is the responsibility of a corporation's governance committee. Both A and C are incorrect because proper application of accounting policies and the remuneration of external auditors fall under the domain of the audit committee.

7 RELEVANT FACTORS IN ANALYZING CORPORATE GOVERNANCE AND STAKEHOLDER MANAGEMENT

g describe market and non-market factors that can affect stakeholder relationships and corporate governance

This section explores ways in which certain factors, both market and non-market related, can affect stakeholder relationships and corporate governance. For this section, market factors include those that relate to capital markets, whereas non-market factors do not.

7.1 Market Factors

This section focuses on shareholder engagement, shareholder activism, and competitive forces, all of which are influential market factors for a company. Shareholder engagement involves a company's interactions with its shareholders to better understand how it manages its material risks and opportunities. Shareholder activism, on the other hand, involves more aggressive and sometimes public efforts by large shareholder(s) to create a significant change in a corporation's behavior. Meanwhile, competitive dynamics can help align managerial interests with those of its stakeholders.

7.1.1 *Shareholder Engagement*

The engagement of companies with shareholders—called **shareholder engagement**—has traditionally involved certain events, such as the annual shareholder meeting and analyst calls, the scope of which was limited to financial and strategic matters. There is a growing trend, however, for greater engagement between companies and their shareholders beyond these venues and topics. Companies have increasingly recognized the benefits that frequent, year-round engagement with shareholders can provide, such as building support against short-term activist investors, countering negative recommendations from proxy advisory firms, and receiving greater support for management's position.

7.1.2 *Shareholder Activism*

Shareholder activism refers to strategies used by shareholders to attempt to compel a company to act in a desired manner. Although shareholder activism can focus on a range of issues, including those involving social or political considerations, the primary motivation of activist shareholders is to increase shareholder value. Activist shareholders often pressure management through such tactics as initiating proxy battles (fights), proposing shareholder resolutions, and publicly raising awareness on issues of contention.

Shareholder activists may pursue additional tactics, such as shareholder derivative lawsuits, which are legal proceedings initiated by one or more shareholders against board directors, management, and/or controlling shareholders of the company. The theory behind this type of lawsuit is that the plaintiff shareholder is deemed to be acting on behalf of the company in place of its directors and officers who have failed to adequately act for the benefit of the company and its shareholders. In many countries, however, the law restricts shareholders from pursuing legal action via the court system—in some cases, by imposing thresholds that enable only shareholders with interests above a minimum amount to pursue legal actions or by denying legal action altogether.

Hedge funds are among the most predominant shareholder activists. Compared with most traditional institutional investors, the fee structure of hedge funds often provides a significant stake in the financial success of any activist campaign. Furthermore, unlike regulated investment entities that are typically subject to restrictions on their investments (e.g., limitations on leverage or ownership of distressed or illiquid securities), hedge funds are loosely regulated and can thus pursue a greater range of activist opportunities.

7.1.3 *Competition and Takeovers*

Metrics that measure a company's success, such as market share or earnings growth, provide information that is useful for shareholders to judge the performance of a company's management team or board of directors and compare such performance with that of competitors. Senior managers risk their employment status in the event of underperformance, and directors, in turn, can be voted out by shareholders.

The traditional view of the market for corporate control (often known as the takeover market) is one in which shareholders of a company hire and fire management to achieve better resource utilization. Corporate takeovers can be pursued in several different ways. One mechanism is the **proxy contest** (or proxy fight). In a proxy contest, shareholders are persuaded to vote for a group seeking a controlling position on a company's board of directors. Managerial teams can also be displaced through a **tender offer**, which involves shareholders selling their interests directly to the group seeking to gain control. A contest for corporate control may attract arbitrageurs and takeover specialists, who facilitate transfers of control by accumulating long positions from existing shareholders in the target company and later selling the positions to the highest bidder. Finally, a **hostile takeover** is an attempt by one entity to acquire a company without the consent of the company's management.

Preservation of their employment status serves as an incentive for board members and managers to focus on shareholder wealth maximization. This threat of removal, however, can also have negative implications for a company's corporate governance practices if the company chooses to adopt anti-takeover measures, such as a staggered board or a shareholder rights plan (also known as a poison pill) to reduce the likelihood of an unwanted takeover. Staggering director elections can dilute the value of shareholder voting rights by extending the term that each director serves and eliminating the ability of shareholders to replace the entire board at any given election. Shareholder rights plans enable shareholders to buy additional shares at a discount if another shareholder purchases a certain percentage of the company's shares. These plans are designed to increase the cost to any bidder seeking to take over a company.

EXAMPLE 8

Shareholder Activism

Which of the following is true of shareholder activism?

A Shareholder activists rarely include hedge funds.

B Regulators play a prominent role in shareholder activism.

C A primary goal of shareholder activism is to increase shareholder value.

Solution:

C is correct. Although the subject of shareholder activism may involve social and political issues, activist shareholders' primary motivation is to increase shareholder value. A is incorrect because hedge funds commonly serve as shareholder activists. B is incorrect because regulators play a prominent role in standard setting, not shareholder activism.

7.2 Non-Market Factors

This section focuses on certain non-market factors, such as a company's legal environment, the role of the media, and the corporate governance industry, that can have an effect on stakeholder relationships and corporate governance.

7.2.1 *Legal Environment*

The legal environment in which a company operates can significantly influence the rights and remedies of stakeholders. Countries that have a common law system (such as the United Kingdom, the United States, India, and Canada) are generally considered to offer superior protection of the interests of shareholders and creditors relative to those that have adopted a civil law system (such as France, Germany, Italy, and Japan). The key difference between the two systems lies in the ability of a judge to create laws. In civil law systems, laws are created primarily through statutes and codes enacted by the legislature. The role of judges is generally limited to rigidly applying the statutes and codes to the specific case brought before the court. In contrast, in common law systems, laws are created both from statutes enacted by the legislature and by judges through judicial opinions. In common law systems, shareholders and creditors have the ability to appeal to a judge to rule against management actions and decisions that are not expressly forbidden by statute or code, whereas in civil law systems, this option is generally not possible.

Regardless of a country's legal system, creditors are generally more successful in seeking remedies in court to enforce their rights than shareholders are because shareholder disputes often involve complex legal theories, such as whether a manager or director breached a duty owed to shareholders. In contrast, disputes involving creditors, such as whether the terms of an indenture or other debt contract have been breached, are more straightforward and therefore more easily determinable by a court.

7.2.2 *The Media*

The media can affect corporate governance and influence stakeholder relationships through its ability to spread information quickly and shape public opinion. As an example, negative media attention can adversely affect the reputation or public perception of a company or its managers and directors. Senior management's concern over reputational risk can thus reduce the cost of monitoring management activities by stakeholders. Media attention can motivate politicians and regulators to introduce corporate governance reforms or enforce laws that protect stakeholders and society at large. This influence was evident in the aftermath of the 2008–2009 global financial crisis, when significant media attention was a factor in the adoption of new laws and regulations designed to address perceived deficiencies in corporate governance.

Social media has become a powerful tool that stakeholders have increasingly used to protect their interests or enhance their influence on corporate matters. Prior to the advent of social media, companies typically had an advantage in distributing information because of their considerable resources as well as relationships with traditional media organizations. Through social media, stakeholders can instantly broadcast information with little cost or effort and are thus better able to compete with company management in influencing public sentiment.

7.2.3 *The Corporate Governance Industry*

An important catalyst for the rise of the corporate governance industry occurred in 2003, when the Securities and Exchange Commission (SEC) required US-registered mutual funds to disclose their proxy voting records annually. The same rule also required US mutual funds to adopt policies and procedures designed to reasonably ensure that proxies would be voted in the best interests of their clients. In the years following the SEC's 2003 mutual fund rule, institutional investors have, to varying degrees, committed additional resources to monitor and vote proxies for the large number of companies in which they invest.

With the increased importance and relevance of corporate governance among investors, the demand for external corporate governance services has grown considerably. In particular, some institutional investors have retained proxy voting firms to assist with corporate governance monitoring and proxy voting. In response to this demand, an industry that provides corporate governance services, including governance ratings and proxy advice, has developed. Because the corporate governance industry is relatively concentrated, these vendors have considerable influence in corporate governance practices, and in turn, corporations are generally compelled to pay attention to ratings and recommendations produced by the corporate governance industry.

RISKS AND BENEFITS OF CORPORATE GOVERNANCE AND STAKEHOLDER MANAGEMENT

8

h identify potential risks of poor corporate governance and stakeholder management, and identify benefits from effective corporate governance and stakeholder management

As illustrated thus far, good corporate governance and stakeholder management can have a meaningfully positive effect on a company. A company will likely not meet the expectations of all stakeholders if one group is able to extract private benefits at the expense of another group. Depending on their nature and magnitude, unmanaged conflicts of interest and weak control over a company's operations may expose the company to various risks, such as legal, regulatory, reputational, or default risks. By adopting effective guidelines for managing the interests of stakeholder groups and instituting adequate levels of control, corporate governance can be reflected in better company relationships, superior levels of efficiency in operations, and improved financial performance.

8.1 Risks of Poor Governance and Stakeholder Management

Weaknesses in stakeholder management mechanisms or the adoption of poor governance structures can create various risks for a company and its stakeholders. A weak control environment can encourage misconduct and hinder the ability of the company to identify and manage risks.

8.1.1 *Weak Control Systems*

In a company with weak control systems or inefficient monitoring tools, such as poor audit procedures or insufficient scrutiny by the board, one stakeholder group may benefit at the expense of the company or other stakeholders. This could consequently have an adverse effect on the company's resources, performance, and value. The audit deficiencies at Enron, for instance, prevented the uncovering of the acts of fraud, erroneous accounting records, and other related issues that led to one of the largest corporate bankruptcies in US history.

8.1.2 *Ineffective Decision Making*

When the quality and quantity of information available to managers are superior to those available to the board or shareholders, in the absence of sufficient monitoring tools, managers have an opportunity to make decisions that benefit themselves relative to the company or shareholders. Without proper scrutiny, such practices might go unnoticed. Deficient decisions could include managing the company with a lower risk profile relative to shareholders' tolerance, thus avoiding investment opportunities that could create value for the company. Conversely, manager overconfidence may result in poor investment decisions without proper examination of their effect on the company or on shareholders' wealth.

Remuneration policies for management could also have significant implications for the company. Outsized remuneration packages for executives could have an adverse effect on shareholders' wealth, constitute a burden on corporate performance, and affect the interests of other stakeholders, such as employees, customers, or creditors. Remuneration policies that are not carefully designed may also encourage managers to seek immediate personal gains by taking excessive risks or focusing on creating short-term performance or stock price increases. Related-party transactions that underlie unfair terms for the company are another example of activities that are not aligned with the objective of value creation and that could be facilitated by a poor governance system.

8.1.3 *Legal, Regulatory, and Reputational Risks*

Compliance weaknesses in the implementation of regulatory requirements or lack of proper reporting practices may expose the company to legal, regulatory, or reputational risks. In such cases, the company may become subject to investigation by government or regulatory authorities for violation of applicable laws. A company could also be exposed to lawsuits filed by shareholders, employees, creditors, or other parties for breach of contractual agreements or company bylaws or for violation of stakeholders' legal rights. In today's markets, information flows rapidly. Improperly managed conflicts of interest or governance failures could bring reputational damage to the company, and its associated costs could be significant. Such risks are particularly acute for publicly listed companies subject to scrutiny by investors, analysts, and other market participants.

8.1.4 *Default and Bankruptcy Risks*

Poor corporate governance, including weak management of creditors' interests, can affect the company's financial position and may hinder its ability to honor its debt obligations. To the extent that the deterioration of corporate performance results in a debt default, the company may be exposed to bankruptcy risk if creditors choose to take legal action. The adverse consequences of corporate failures are not limited to the company's shareholders; they extend to other stakeholders, such as managers and employees and even society and the environment.

8.2 Benefits of Effective Governance and Stakeholder Management

The development of good governance practices can play a vital role in aligning the interests of managers and the board of directors with those of shareholders, while balancing the interests of the company's stakeholders. A good governance structure can be reflected in operational efficiency, improved control processes, better financial performance, and lower levels of risk.

8.2.1 *Operational Efficiency*

As part of a good governance structure, an organization clarifies the delegation of responsibilities and reporting lines across the company and ensures that all employees have a clear understanding of their respective duties. When balanced with adequate internal control mechanisms, the governance structure can ensure that corporate decisions and activities are properly monitored and controlled to mitigate risk and help improve the operational efficiency of the company.

8.2.2 *Improved Control*

Governance practices seek to institute more effective control exercised at all corporate levels, from shareholders to the board of directors and management. These practices can help identify and manage risk at early stages that can otherwise hinder corporate performance and/or damage reputation. Control can be enhanced by the proper functioning of a company's audit committee and the effectiveness of its audit systems. By adopting procedures for monitoring compliance with internal policies and external regulations and for reporting any violations, the company can better mitigate regulatory or legal risks and their associated costs. Additionally, the adoption of formal procedures with regard to conflicts of interest and related-party transactions allows the company to ensure fairness in its relationships with those parties.

8.2.3 *Better Operating and Financial Performance*

Good governance and stakeholder management can help a company improve its operating performance and reduce the costs associated with weak control systems. The costs of poor investments, legal proceedings against the company, and excessive perquisites are just a few examples that could be mitigated by well-functioning governance systems. Enhanced corporate governance could also allow the company to improve its decision-making process and respond faster to market factors. Proper remuneration policies are another governance tool that can motivate managers to make decisions with the objective of creating corporate value.

8.2.4 *Lower Default Risk and Cost of Debt*

Good corporate governance can lower business and investment risk. Governance arrangements that manage conflicts of interest with creditors, and that help protect creditor rights, can reduce a company's cost of debt and default risk. Default risk can also often be mitigated by proper functioning of audit systems, improved transparency (e.g., reporting of earnings), and the control of information asymmetries between the company and its capital providers. With regard to credit risk, corporate governance mechanisms are increasingly relevant criteria among credit rating agencies when assessing a company's creditworthiness.

EXAMPLE 9

Benefits of Corporate Governance

Which of the following is **not** a benefit of an effective corporate governance structure?

A Operating performance can be improved.

B A corporation's cost of debt can be reduced.

C Corporate decisions and activities require less control.

Solution:

C is correct. A benefit of an effective corporate governance structure is to enable adequate scrutiny and control over operations. B is incorrect because an effective governance structure can reduce investors' perceived credit risk of a corporation, thus potentially lowering the corporation's cost of debt. A is incorrect because operating efficiency may indeed be a benefit of an effective corporate governance structure.

9

FACTORS RELEVANT TO CORPORATE GOVERNANCE AND STAKEHOLDER MANAGEMENT ANALYSIS

i. describe factors relevant to the analysis of corporate governance and stakeholder management

In the past, analysts may have considered corporate governance and stakeholder management issues to be only peripherally related to traditional fundamental analysis. Generally, these issues were seen as obscure and unlikely to be material drivers of performance. Following a number of governance failures since the early 2000s, the global financial crisis, and the rise of shareholder activism around the world, there is little doubt that governance and stakeholder issues have become increasingly important topics for analysts.

Some key questions that analysts may consider when assessing a company's corporate governance or stakeholder management system are as follows:

- What is the company's ownership and voting structure among shareholders?
- Who represents shareholders on this company's board?
- What are the main drivers of the management team's remuneration and incentive structure?
- Who are the significant investors in the company?
- How robust are the shareholder rights at the company, including relative to peers?
- How effectively is the company managing long-term risks, such as securing access to necessary resources, managing human capital, exhibiting integrity and leadership, and strengthening the long-term sustainability of the enterprise?

A qualitative analysis of these issues—typically provided by a company's proxy statements, annual reports, and sustainability reports, if available—can provide important insights about the quality of management and sources of potential risk.

9.1 Economic Ownership and Voting Control

Generally speaking, corporations with publicly traded equity have a voting structure that involves one vote for each share. That is, any shareholder's voting power is equal to the percentage of the company's outstanding shares owned by that shareholder. When there are exceptions to this norm and economic ownership becomes separated from control, investors can face significant potential risks.

In a small number of markets, dual-class structures are allowed under the local regulatory framework or exchange rules, which is the most common way that voting power is decoupled from ownership. In these cases, common shares may be divided into two classes, one of which has superior voting rights to the other. A common arrangement is when a share class (for example, Class A) carries one vote per share and is publicly traded, whereas another share class (for example, Class B) carries several votes per share and is held exclusively by company insiders or family members. This structure is used by Facebook, for example. In this way, the founders and/or insiders of a company may continue to control board elections, strategic decisions, and all other significant voting matters for a long period—even once their ownership level declines to less than 50% of the company's shares.

Another mechanism used to separate voting control from economic ownership is when one class of stock (held by insiders) elects a majority of the board; outside shareholders who hold a different share class would then be entitled to elect only a minority of the board. Technically, each share carries equal voting rights, but with this structure, the insiders retain substantial power over the affairs of the corporation because they control a majority of the board. Alibaba's partnership structure is one example of this type of control.

Proponents of dual-share systems, such as those just mentioned, argue that the systems promote company stability and enable management to make long-term strategic investments, insulated from the short-term pressures of outside investors. Critics of these structures believe they create conflicts of interest between the providers of capital and the management of the business.

It is virtually impossible for outside investors to dismantle dual-class structures because of the inherent design of their unequal voting rights. Therefore, these structures can remain in place even through generational changes within a founding family. Investors with long time horizons may want to consider the motivations of the controlling stockholders, generational dynamics, succession planning, and the relationship between the board and management. In addition, there may be potential valuation implications because dual-class companies tend to trade at a discount to their peers.

9.2 Board of Directors Representation

In most markets, investors have access to basic biographical information about the non-executive members of corporate boards. Analysts can assess the available information to determine whether the experience and skill sets on the board match the current and future needs of the company.

In particular, questions regarding directors' independence, tenure, experience, and diversity may bring useful investment insights. For example, if the board has multiple directors engaging in related-party transactions with the company, investors may have cause for concern about any conflicts of interest that arise. The issue of board tenure can also be a useful tool for investors. Directors with long periods of service to a company clearly offer valuable experience and expertise, but if the board composition is dominated by such long-tenured members, it may have a negative effect on the board's diversity and adaptability.

An example in which board composition had a significant effect on company performance occurred at a European pharmaceutical company. At one point in its history, the company had become overleveraged and faced significant financial distress. In response, non-executive directors with banking and turnaround experience were added to the board. With the help of these directors, the company recovered. Seven years later, the most promising product in the company's pharmaceutical portfolio began to cause serious side effects in its patient population. The situation required both a meaningful understanding of the medical issues involved and a rapid response from the company. However, the board was still composed of directors with financial expertise rather than medical training. The company struggled with its response to the crisis, and its stock price fell sharply. This situation was one in which the board's composition had been ideal for a certain point in the company's history, but ultimately the directors failed to refresh the board's membership as the needs of the business changed.

9.3 Remuneration and Company Performance

The availability and quality of information about executive remuneration plans varies widely across markets. In those markets where such disclosures are available, analysts can assess the elements of the remuneration program to determine whether they support or conflict with the key drivers of performance for the company.

Generally speaking, current executive remuneration programs consist of a base salary, a short-term bonus usually delivered in the form of cash, and a multi-year incentive plan delivered in one or more forms of equity (options, time-vested shares, and/or performance-vested shares). Often, these short-term and long-term plans are contingent on achieving financial or operational objectives, and often these objectives are disclosed. In these situations, an analyst can assess whether the primary drivers of the remuneration plan are the same factors that, in the analyst's view, drive overall company results.

Assessment of the suitability of a remuneration plan for a particular company is a subjective exercise and is highly dependent on industry and geographic norms. But there are some warning signs that may warrant particular scrutiny:

- **Plans offering little alignment with shareholders.** As an example, if a plan offers only cash-based payouts and no equity, there may be a misalignment of incentives between executives and investors unless management already owns a significant stake in the company.
- **Plans exhibiting little variation in results over multiple years.** If an award is described as performance-based but still pays in full every year regardless of the company's results, investors may have concerns about the rigor of the performance hurdles underlying the awards.
- **Plans with excessive payouts relative to comparable companies with comparable performance.** Investors may want to understand the cause of the anomaly and whether it is a temporary issue or a result of flawed remuneration plan design.
- **Plans that may have specific strategic implications.** As an example, some remuneration plans contain payouts tied to specific milestones, such as regulatory approval of a product, completion of an acquisition, or achievement of specific cost reductions. In addition, some companies offer particularly high post-employment pay arrangements tied to the sale of the company, whereas

others offer no such arrangements. These factors are not necessarily negative features, but investors may want to understand whether the milestones driving the incentive plan align with the company's objectives.

- **Plans based on incentives from an earlier period in the company's life cycle.** A frequent example of such a plan relates to a company that has matured beyond its fast growth phase. The company's business may have matured, and competition may have limited the opportunity for market share gains. Investors may believe the company should become more focused on both returns and disciplined capital allocation. Even after the company communicates to the investor community a more returns-oriented strategy, the financial incentives in the remuneration plan may still be based purely on revenue growth. Investors may want to understand such potential misalignment of interests.

9.4 Investors in the Company

Examining the composition of investors in a company can be another source of useful insight for analysts. The behavior of these investors can result in both limitations and catalysts with regard to changes in the corporation. For example, cross-shareholdings are still prevalent in a number of markets. This situation occurs when a company, particularly a publicly listed one, holds a large, passive, minority stake in another company. Such holdings generally help to protect management from shareholder pressures because implicit in a cross-shareholding arrangement is the guarantee that the owner of the shares will support management on all voting issues. In effect, these shareholdings act as takeover defenses.

Similarly, the presence of a sizable affiliated stockholder (such as an individual, family trust, endowment, or private equity fund) can shield a company from the effects of voting by outside shareholders. As an example, a US consumer goods company has an affiliated charitable foundation that owns more than 20% of the outstanding shares. The company also has a provision in its corporate charter requiring that any changes to the charter must be approved by two-thirds of outstanding shares. As a result, it is virtually impossible for any measure to pass without the support of the foundation. The interests of the foundation thus conflict with the interests of the overall shareholder base. In effect, this single minority shareholder most likely holds the power to block the votes of the majority.

Analysts should note that market context is important in assessing the potential effects of affiliated stockholders. In certain countries, the presence of such shareholders is common, viewed by local market participants as a means of enhancing stability, strengthening the relationship between companies and their business partners, and fostering a long-term perspective by protecting the company against hostile takeover bids.

A final aspect of investor composition that has become increasingly relevant relates to activist shareholders, which we discussed earlier. The presence of activist shareholders can meaningfully and rapidly change the investment thesis for a company. Experienced activists, together with short-term-oriented investors who follow their activities, can create substantial turnover in a company's shareholder composition in a short amount of time. This is because an activist often serves as a catalyst for new strategic alternatives at a company and can attract new investors and/or arbitrageurs.

9.5 Strength of Shareholders' Rights

Within a framework of regional regulations and corporate governance codes, analysts may want to understand whether the shareholder rights of a particular company are strong, weak, or average compared with other companies. For example, if an analyst's viewpoint includes the possibility that a company will enter into a merger transaction in the future, he or she may want to understand whether there are significant structural obstacles to transactions that are embedded in the company's charter or bylaws. Similarly, if the thesis involves an outside catalyst, such as an activist shareholder who will introduce change at the company and improve performance, the analyst must take a position on whether shareholders are sufficiently empowered to advance such a change. If it is impossible for shareholders to remove directors from the board or to convene special stockholder meetings, it will be difficult for external initiatives to be successful.

In a number of developed markets, including the United Kingdom, the Netherlands, and Japan, regulatory agencies or stock exchanges have adopted governance codes, which are standards of governance reflecting local investors' expectations with regard to disclosure, board composition, shareholder rights, and other related issues. Often, these governance codes are implemented on a "comply or explain" basis, which indicates that standards are voluntary in nature. However, any deviation from the code must be explained by the company in a public disclosure. If a company has elected to deviate from the locally accepted governance practice, the analyst may want to understand the reasoning behind the decision.

9.6 Managing Long-Term Risks

Analysts may uncover useful insights regarding how a company manages various issues, such as long-term environmental risks, management of human capital, transparency, and treatment of investors and other stakeholders. Of particular note, the academic evidence linking these and other management quality issues to share price performance remains mixed, in part because indicators of management quality are often correlated with each other and, therefore, difficult to isolate. However, poor stakeholder relations and inadequate management of long-term risks have indeed had an enormous negative effect on share value in certain instances. Therefore, analysts may consider the assessment of such issues to be a useful component of their overall risk assessment of the company.

One way to evaluate management quality issues is to assess whether the company demonstrates a persistent pattern of wrongdoings, fines, regulatory penalties, investigations, and the like. A notable example is Toshiba Corp., beginning in 2015 when an investigation revealed that company managers had manufactured nearly $2 billion in profits since 2008. Poor internal controls allowed the fraudulent accounting to remain undetected for seven years. Over the next several years, Toshiba experienced the massive write-down of its Westinghouse Electric Co. unit, clashes with its auditors, negative equity, and legal disputes. Toshiba's dividend was withdrawn, Westinghouse filed for bankruptcy protection, and the company was forced to sell its profitable semiconductor unit along with other business units. Ultimately, the company's shares were moved to the second section of the Tokyo Stock Exchange, triggering forced sales from funds that track the first section (TOPIX) or the Nikkei 225 indexes. Even in the absence of circumstances as extreme as these, poor management of stakeholder interests can have a significant effect on company operations, reputation, and valuation.

9.7 Summary of Analyst Considerations

The analysis of corporate governance, stakeholder management, and other non-financial (often termed "extra-financial") considerations is inherently a subjective exercise. Governance practices that may raise the risk profile of one company may be perfectly acceptable in a different context, depending on geographic norms, mitigating circumstances, or the investor's risk tolerance and investment thesis. In this section, we have provided a basic framework for investors interested in uncovering incremental insights about a company by analyzing its governance standards, practices, and risks.

EXAMPLE 10

Analyst Considerations

1 Which of the following *best* describes dual-class share structures?
   - **A** Dual-class share structures can be easily changed over time.
   - **B** Company insiders can maintain significant power over the organization.
   - **C** Conflicts of interest between management and stakeholder groups are less likely than with single-share structures.

2 An investment analyst would likely be *most* concerned with an executive remuneration plan that:
   - **A** varies each year.
   - **B** is consistent with a company's competitors.
   - **C** is cash-based only, without an equity component.

3 Which of the following *best* describes activist shareholders? Activist shareholders:
   - **A** help stabilize a company's strategic direction.
   - **B** have little effect on the company's long-term investors.
   - **C** can alter the composition of a company's shareholder base.

Solution to 1:

B is correct. Under dual-class share systems, company founders or insiders may control board elections, strategic decisions, and other significant voting matters. A is incorrect because dual-share systems are virtually impossible to dismantle once adopted. C is incorrect because conflicts of interest between management and stakeholders are more likely than with single-share structures because of the potential control element under dual systems.

Solution to 2:

C is correct. If an executive remuneration plan offers cash only, the incentives between management and investors and other stakeholders may be misaligned. A is incorrect because a plan that varies over time would typically be of less concern to an analyst compared with one that did not change. B is incorrect because an analyst would likely be concerned if a company's executives were excessively compensated relative to competitors.

Solution to 3:

C is correct. The presence of activist shareholders can create substantial turnover in the company's shareholder composition. A is incorrect because the presence of activist shareholders can materially change a company's strategic direction. B is incorrect because long-term investors in a company need to consider how activist shareholders affect the company.

10

ESG CONSIDERATIONS FOR INVESTORS AND ANALYSTS

j describe environmental and social considerations in investment analysis

k describe how environmental, social, and governance factors may be used in investment analysis

10.1 Introduction to Environmental, Social, and Governance issues

The inclusion of governance factors in investment analysis has evolved considerably. Management and accountability structures are relatively transparent, and information regarding them is widely available. Also, the risks of poor corporate governance have long been understood by analysts and shareholders. In contrast, the practice of systematically considering environmental and social factors, which collectively with governance form the commonly used acronym "ESG," has evolved more slowly. Issues driving the inclusion of environmental and social information in the investment process include scarcity of natural resources, physical impacts of climate change, global economic and demographic trends, diversity and inclusion, treatment of workers, and the rise of social media. A non- exhaustive list of ESG issues are shown in Exhibit 1. Typically, a smaller set of ESG factors are material for each company, influenced by the business segments it operates in as well as its geography of operation.

Exhibit 1 Example of ESG Factors

Environmental Issues

- Climate change and carbon emissions
- Air and water pollution
- Biodiversity
- Deforestation
- Energy efficiency
- Waste management
- Water scarcity

Social Issues

- Customer satisfaction & product responsibility
- Data security and privacy
- Gender and diversity
- Occupational health & safety
- Treatment of workers
- Community relations & charitable activities
- Human rights
- Labor standards

Governance Issues

- Board composition (independence & diversity)
- Audit committee structure
- Bribery and corruption
- Executive compensation
- Shareholder rights
- Lobbying & political contributions
- Whistleblower schemes

ESG factors were once regarded as intangible or qualitative information. Increased corporate disclosures and refinements in the identification and analysis of ESG factors have resulted in increasingly quantifiable and decision-useful information. Social issues, such as human capital management, are less quantifiable; however, they are not necessarily more difficult to integrate as qualitative factors into investment analysis. The process of reflecting quantitative ESG-related information and data—both quantitative and qualitative—in financial valuation continues to evolve.

10.2 ESG Investment Strategies

There is a lack of consensus on several ESG strategy-related terms used in the investment community. For the purposes of this reading, we define ESG investment strategies as the following:

Responsible investing is the broadest (umbrella) term used to describe investment strategies that incorporate environmental, social, and governance (ESG) factors into their approaches. Overall, responsible investing includes the following:

- ESG integration
- Socially Responsible Investing (SRI)
- Thematic investing
- Impact investing

Sustainable investing is a term used in a similar context to responsible investing, but its key focus is on factoring in sustainability issues while investing.

ESG integration generally refers to the careful consideration of *material* ESG factors in the investment analysis and portfolio construction processes. **ESG investing** is often used interchangeably with ESG integration. A material factor is one whose omission or misstatement could influence an investment decision and ultimately the product's investment objectives. The materiality of ESG factors in investment analysis, particularly environmental and social factors, often differs meaningfully among sectors. An ESG factor is considered material when it has a potential to impact a company's ability to generate sustainable returns in the long term. For example, environmental factors, such as carbon emissions and water usage, will likely be material for utilities or mining companies yet are relatively inconsequential for financial institutions.

Socially responsible investing (SRI) is a related term that tends to have multiple meanings, creating confusion among investors. Socially responsible investing has traditionally referred to the practice of excluding investments in companies or industries, such as controversial weapons or tobacco, that deviate from an investor's beliefs, either moral or faith-based. The term has evolved to include investment objectives that promote positive environmental or social attributes, often by investing in companies with favorable environmental or social profiles.

Thematic investing refers to investment in themes or assets specifically related to ESG factors. This approach is often based on needs arising from economic or social trends.

Impact investing refers to investments made with the intention to generate positive, measurable social and environmental impact alongside a financial return.

GREEN FINANCE

Green finance is a responsible investing approach that utilizes financial instruments that support a green economy. According to the Organisation for Economic Co-Operation and Development (OECD), green finance relates to "achieving economic growth while reducing pollution and greenhouse gas emissions, minimising waste and improving efficiency in the use of natural resources."[5] As with other previously mentioned ESG terms, there are several definitions for green finance in practice. The primary investment vehicles used in green finance are **green bonds**, in which issuers earmark the proceeds toward environmental-related projects. Green bond issuance has grown significantly. According to the Climate Bonds Initiative, total worldwide green bond issuance for 2019 totaled USD255 billion, compared to USD171.1 billion for 2018. The United States continues to be the largest green bond market in the world, with China being the second largest, accounting for about 12% of global green bond issuance in 2019. China's first green bond was issued in July 2015 as the country prioritized environmental projects to address air and water pollution issues resulting from its rapid growth. In addition to green bonds, **sustainability linked loans** (including **green loans**) are also gradually being employed across the globe. Sustainability linked loans are any types of loan instruments and/or contingent facilities (such as bonding lines, guarantee lines, or letters of credit) that incentivize the borrower's achievement of ambitious, predetermined sustainability performance objectives.

10.3 ESG Investment Approaches

ESG investment approaches range from *value*-based to *values*-based. The objective of a *value*-based approach is to mitigate risks and identify opportunities by analyzing and incorporating material ESG considerations in addition to traditional financial metrics. Conversely, the objective of a *values*-based approach is to express the moral or faith-based beliefs of an investor. Between the value-based and the values-based approaches lie a continuum of approaches that strives for value creation through values investing.

There is a lack of consensus in the investment community on terminology to classify specific ESG investment approaches. For the purposes of this reading, we define six generic ESG investment approaches:

- Negative screening
- Positive screening
- ESG integration
- Thematic investing
- Engagement/active ownership
- Impact investing

Negative screening is the exclusion of certain sectors, companies, or practices from a fund or portfolio based on specific ESG criteria. Examples of a negative screen include excluding the fossil fuel extraction/production sector or excluding companies that deviate from globally accepted standards, in areas such as human rights or environmental management, from a portfolio. Many of these negative screens use a specific set of standards, such as the UN Global Compact's Ten Principles on human rights, labor, the environment, and corruption.

In contrast to negative screening, the **positive screening** approach focuses on investments that manage their material ESG risks well relative to industry peers. Positive screening, typically implemented through an ESG ranking or scoring approach, is the inclusion of certain sectors, companies, or practices in a fund or portfolio based on specific ESG criteria. For example, positive screening may include seeking companies that promote employee rights, exhibit diversity in the workplace and in board rooms, or perform well in customer safety. While seeking to invest in sectors, companies, or projects that demonstrate best-in-class ESG performance relative to industry peers, this approach does not exclude any sectors. Instead, it focuses on finding the companies within each sector that perform best on the chosen criteria. This approach typically maintains sector weightings comparable to a relative benchmark index to avoid excessively overweighting or underweighting risk exposures.

ESG integration entails a systematic consideration of material ESG factors in asset allocation, security selection, and portfolio construction decisions for the purpose of achieving the product's stated investment objectives. There is an explicit inclusion of ESG factors into traditional financial analysis of individual stocks or bonds, such as inputs into cash flow forecasts, credit/default risk forecasts, and/or cost-of-capital estimates. The focus of ESG integration is to identify risks and opportunities arising from material ESG factors and to determine whether a company is properly managing these or not.

Thematic investing is investment in themes or assets specifically related to ESG factors, such as clean energy, green technology, sustainable agriculture, gender diversity, or affordable housing. This approach is often based on needs arising from economic or social trends. Two common investment themes focus on increased demand for energy and water, as well as the availability of alternative sources of each. Global economic development has raised the demand for energy at the same time as increased greenhouse gas emissions are widely believed to negatively affect the earth's climate. Similarly, rising global living standards and industrial needs have created a greater demand for water along with the need to prevent drought or increase access to clean drinking water in certain regions of the world. While these themes are based on trends related to environmental issues, social issues—such as access to affordable health care and nutrition, especially in the poorest countries in the world—are also of great interest to thematic investors.

Engagement/active ownership is the use of shareholder or bondholder power to influence corporate behavior through direct corporate engagement (i.e., communicating with senior management and/or boards of companies), filing or co-filing shareholder proposals, and proxy voting that is directed by ESG guidelines. Engagement/active ownership seeks to achieve targeted social or environmental objectives along with measurable financial returns. Engagement/active ownership can be executed through various asset classes and investment vehicles and often through direct transactions, such as venture capital investing. Collaborative engagement initiatives entail multiple investors collectively engaging with company management to influence positive action in managing their material ESG risks. Climate Action 100+, backed by more than 450 investors with over USD40 trillion in assets collectively under management (as of July 2020), is one such widely supported initiative that aims to influence the world's largest corporate greenhouse gas emitters to take necessary action on climate change. Other key ESG issues on which investors frequently engage are air pollution, plastic waste management, human and labor rights in the supply chain, and executive remuneration.

Impact investing is a relatively smaller segment of the broader sustainable and responsible investing market. Impact investments are investments made with the intention to generate positive, measurable social and environmental impact alongside a financial return.[6] An example would include investing in products or services that help achieve one (or more) of the 17 Sustainable Development Goals (SDGs) launched by the United Nations in 2015, such as "SDG 6: Clean Water and Sanitation—Ensure availability and sustainable management of water and sanitation for all" and "SDG 11: Sustainable Cities and Communities—Make cities and human settlements inclusive, safe, resilient and sustainable."

A summary of the six generic ESG Investment approaches and mapping to other classifications is shown in Exhibit 2.

Exhibit 2 ESG Investment Approaches

		Mapping to Other Classifications	
ESG Investment Approach	**Description**	***Financial Analysts Journal***	***Global Sustainable Investment Review***
Negative screening	Excluding companies or sectors based on business activities or environmental or social concerns	Negative screening	Negative/exclusionary screening Norms-based screening
Positive screening	Including sectors or companies based on specific ESG criteria, typically ESG performance relative to industry peers	Positive screening Relative/best-in-class screening	Positive/Best-in-class screening
ESG integration	Systematic consideration of material ESG factors in asset allocation, security selection, and portfolio construction decisions for the purpose of achieving or exceeding the product's stated investment objectives	Full integration Overlay/Portfolio tilt Risk factor/Risk premium	ESG integration
Thematic investing	Investing in themes or assets related to ESG factors	Thematic investing	Sustainability-themed investing
Engagement/active ownership	Using shareholder power to influence corporate behavior to achieve targeted ESG objectives along with financial returns	Engagement/Active ownership	Corporate engagement/Shareholder action
Impact investing	Investments made with the intention to generate positive, measurable social and environmental impact alongside a financial return	N/A	Impact/Community investing

Notes: For information on the *Financial Analysts Journal* column under "Mapping to Other Classifications," see www.tandfonline.com/doi/full/10.2469/faj.v74.n3.2. For the *Global Sustainable Investment Review* column, see http://www.gsi-alliance.org/wp-content/uploads/2019/06/GSIR_Review2018F.pdf.

10.4 Catalysts for Growth in ESG Investing

ESG considerations have become increasingly relevant for two key reasons. First, ESG issues are having more material financial impacts on a company's fair value. Many investors have suffered substantial losses due to mismanagement of ESG issues by corporations, which resulted in environmental disasters, social controversies, or governance deficiencies. Second, a greater number of younger investors are increasingly demanding that their inherited wealth or their pension contributions be managed using investment strategies that systematically consider material ESG risks as well as negative environmental and societal impacts of their portfolio investments.

Historically, environmental and social issues, such as climate change, air pollution, and societal impacts of a company's products and services, have been treated as negative externalities—ones whose costs are not borne by the concerned company.

However, increased stakeholder awareness and strengthening regulations are internalizing environmental and societal costs onto the company's income statement either explicitly or implicitly by responsible investors.

At a *macro level*, such environmental risks as physical impacts of climate change—floods, droughts, wildfires, air pollution—are impacting our day-to-day lives both more frequently and on a larger scale than ever imagined. Wildfires in California, the Amazon forest, and Australia have caused loss of human life and billions of dollars in damages. Major cities, like Cape Town and Chennai, have had severe water shortages. The 2020 global slowdown due to Covid-19 demonstrated that such social factors as inequality, access to health care, and vulnerable labor can also have significant impacts on growth. While macro-level environmental and social risks have received widespread attention only since 2010, investors have been evaluating macro-level governance risks, such as quality of institutions and corruption, into their analysis since the 1990s.

At a *micro level*, there have been numerous examples of stakeholders penalizing companies that are unable to manage material ESG risks well. Facebook's Cambridge Analytica scandal, in which the personal data of over 80 million users were allegedly shared without consent and used in influencing voters, not only led to one of the largest US government fines in the technology sector (USD5 billion), but it also made a significant dent on user trust. Other examples of ESG risks materializing are shared later in this reading. As prudent fiduciaries, investors are paying more attention to these factors while constructing portfolios and engaging with company management.

Another investor development that has supported ESG growth is the adoption of more sophisticated views about sustainable growth and its effect on investment performance. To this end, some large institutional asset owners embrace the concept of being "universal owners." **Universal owners** are long-term investors, such as pension funds, that have significant assets invested in globally diversified portfolios. Given their size and scope, the investment portfolios of universal owners are linked to economic growth and unavoidably exposed to costs resulting from external factors or externalities, such as environmental damages. Some universal owners strive to positively influence the way companies conduct business to minimize exposure to ESG-related costs because both their funds' long-term performance and the interests of their beneficiaries are at stake. Institutions that adhere to the universal owner philosophy believe that sustainable global economic growth is essential to successful investment performance.

10.5 ESG Market Overview

Reflecting the growth of ESG-related information in the marketplace, the amount of global assets under management (AUM) dedicated to the consideration of ESG factors in portfolio selection and management has increased substantially. According to the Global Sustainable Investment Alliance (GSIA), a collaboration of organizations dedicated to advancing sustainable investing in the financial markets, nearly USD31 trillion of AUM were dedicated toward sustainable investment mandates at the start of 2018, a 34% increase in two years. Europe (49%) and the United States (39%) accounted for the vast majority of these AUM. Determining the true size of the ESG investment universe is difficult, however, because managers and investors define and implement sustainable and ESG mandates in many different ways. There are often differences regarding which ESG factors should be considered—as well as how they are considered—in the investment analysis and portfolio construction processes.

The increased interest in sustainable investing has led to increased corporate disclosures of ESG issues, as well as a growing number of companies that collect and analyze ESG data. In addition to the GSIA, several organizations have been formed to monitor and advance the mission of sustainable investing. For example, the Global Reporting Initiative (GRI), a non-profit organization formed in 1997, produces a sustainability reporting framework that measures and reports sustainability-related issues and performance. In 2006, the United Nations and a consortium of institutional investors launched the Principles for Responsible Investment (PRI) Initiative to support investors committed to including ESG issues in their investment decision-making and ownership practices. In 2011, the non-profit Sustainability Accounting Standards Board (SASB) was formed to develop sustainability accounting standards for companies when disclosing material ESG information. To help educate investors, CFA Institute and PRI published "Guidance and Case Studies for ESG Integration: Equities and Fixed Income" in 2018. In addition to these key organizations, several others exist that promote the advancement of sustainable investing.

10.6 ESG Factors in Investment Analysis

Environmental factors that are generally considered material in investment analysis include natural resource management, pollution prevention, water conservation, energy efficiency and reduced emissions, the existence of carbon assets, and adherence to environmental safety and regulatory standards. A specific concern among investors of energy companies is the existence of "stranded assets," which are carbon-intensive assets at risk of no longer being economically viable because of changes in regulation or investor sentiment. Analysts may find it difficult to assess potentially significant financial risks of energy companies because of limited information on the existence of these companies' carbon assets, as well as the difficulty in determining political and regulatory risks. Material environmental effects can arise from strategic or operational decisions based on inadequate governance processes or errors in judgment. For example, oil spills, industrial waste contamination events, and local resource depletion can result from poor environmental standards, breaches in safety standards, or unsustainable business models. Such events can be costly in terms of regulatory fines, litigation, clean-up costs, reputational risk, and resource management.

TOXIC EMISSIONS AND WASTE AS AN ENVIRONMENTAL RISK

Historically, environmental issues, such as toxic emissions and waste, have been treated as externalities and thus not fully provisioned for in a company's financial reporting. However, with growing awareness among all stakeholders, including the regulators, companies may now face financial liabilities associated with pollution, contamination, and the emission of toxic or carcinogenic substances and hence are required to manage these risks well. Gross mismanagement of these risks could not only lead to a permanent loss of a company's license to operate but also to other severe financial penalties.

In one notable example, the 2019 collapse of Dam I of the Córrego do Feijão Mine in Brumadinho, Brazil, resulted in the spillage of millions of tons of non-toxic mud. The plant and surrounding communities experienced the loss of 270 lives as well as the contamination of the nearby Paraopeba River. The mine was owned and operated by Vale, which has since been accused of hiding information about the dam's instability for many years to avoid hurting the company's reputation. Several employees from the company, including its ex-CEO, and its auditor, TÜV SÜD, were charged with murder and environmental crimes. Vale was also fined millions of dollars in addition to bearing clean-up costs.

Social factors considered in ESG implementation generally pertain to the management of the human capital of a business. These include human rights and welfare concerns in the workplace; data privacy and security; access to affordable health care products; and, in some cases, community impact. Staff turnover, worker training and safety, employee morale, ethics policies, employee diversity, and supply chain management can all affect a company's ability to sustain its competitive advantage. In addition, minimizing social risks can lower a company's costs (e.g., through higher employee productivity, lower employee turnover, and reduced litigation potential) and reduce its reputational risk.

DATA PRIVACY AND SECURITY AS A SOCIAL RISK

Data privacy and security focuses on how companies gather, use, and secure personally identifiable information and other meta-data collected from individuals. In some industries, such as internet software and services, this includes managing the risks associated with government requests that may result in violations of civil and political rights.

With the proliferation of the internet across the globe, more and more services are offered online. Consumers of such services are leaving a large digital footprint behind, often unknowingly. Some of this information may be personally identifiable in nature, leaving users vulnerable in case of theft or misuse. As per the "2019 Cost of a Data Breach Report" released by IBM and Ponemon Institute, the average cost of data breach is USD3.9 million, with cost per record lost being USD150.

Given the large amounts of sensitive data being managed by some of the largest internet and financial services companies today, mismanagement of data privacy and security risk can have materially damaging consequences both for a company's business model as well as financial performance. As an example, lax cybersecurity measures at Equifax, Inc., led to a data breach and the theft of identity and financial data belonging to more than 140 million US citizens in 2017. Equifax has since incurred hundreds of millions of dollars in expenses resulting from the breach and has faced numerous lawsuits and investigations.

As mentioned earlier, governance factors have long been recognized in investment analysis. Many performance indicators can help evaluate risks arising from governance issues, such as ownership structure, board independence and composition, and compensation. Although several governance factors may apply across industries and geographic regions, other factors are unique, such as systemic risk management for financial services companies. Wider adoption of responsible investing strategies enhances mainstream governance analysis via the addition of such factors as management oversight of environmental and social issues and tax transparency.

CORPORATE GOVERNANCE: AN ALL-ENCOMPASSING RISK

An example of investor loss related to corporate governance occurred in 2015 at German automaker Volkswagen. Volkswagen's "Dieselgate" scandal involved use of software to manipulate diesel vehicle emissions of more than 11 million cars globally. Specifically, many investors believed that inadequate governance oversight at Volkswagen permitted its diesel cars to pass emissions tests yet emit unlawful amounts of nitrogen oxide. Many investors attributed their losses to internal audit and compliance shortcomings as well as a lack of independence in Volkswagen's board of directors. The company has already incurred several billion dollars of civil and criminal penalties, and the scandal continues to pose significant legal and financial risks for the company.

One area of debate has been whether the consideration of ESG factors is consistent with fiduciary duty—particularly when overseeing and managing pension fund assets. Pension fund regulation regarding ESG considerations varies globally, however. PRI and the United Nations Environment Programme Finance Initiative (UNEP FI) promote the belief that ESG integration is a key part of investment analysis: "Investors that fail to incorporate ESG issues are failing their fiduciary duties and are increasingly likely to be subject to legal challenge."

EXAMPLE 11

ESG Investment Approach

The ESG investment approach that is *most* associated with excluding certain sectors or companies is:

A thematic investing.

B negative screening.

C positive screening.

Solution:

B is correct. Negative screening entails excluding certain companies or sectors, such as fossil fuel extraction, from a portfolio. A is incorrect because thematic investing typically focuses on investing in companies within a specific sector or following a specific theme, such as energy efficiency or climate change, as opposed to merely excluding a set of companies or industries from a portfolio. Likewise, C is incorrect because positive screening focuses on including companies that rank (or score) most favorably compared to their peers with regard to ESG factors.

SUMMARY

The investment community has increasingly recognized the importance of corporate governance as well as environmental and social considerations. Although practices concerning corporate governance (and ESG overall) will undoubtedly continue to evolve, investment analysts who have a good understanding of these concepts can better appreciate the implications of ESG considerations in investment decision making. The core concepts covered in this reading are as follows:

- Corporate governance can be defined as a system of controls and procedures by which individual companies are managed.
- There are many systems of corporate governance, most reflecting the influences of either shareholder theory or stakeholder theory, or both. Current trends, however, point to increasing convergence.
- A corporation's governance system is influenced by several stakeholder groups, and the interests of the groups often diverge or conflict.
- The primary stakeholder groups of a corporation consist of shareholders, creditors, managers and employees, the board of directors, customers, suppliers, and government/regulators.
- A principal–agent relationship (or agency relationship) entails a principal hiring an agent to perform a particular task or service. In a corporate structure, such relationships often lead to conflicts among various stakeholders.
- Stakeholder management involves identifying, prioritizing, and understanding the interests of stakeholder groups and on that basis managing the company's relationships with stakeholders. The framework of corporate governance and stakeholder management reflects a legal, contractual, organizational, and governmental infrastructure.

- Mechanisms of stakeholder management may include general meetings, a board of directors, the audit function, company reporting and transparency, related-party transactions, remuneration policies (including say on pay), and other mechanisms to manage the company's relationship with its creditors, employees, customers, suppliers, and regulators.
- A board of directors is the central pillar of the governance structure, serves as the link between shareholders and managers, and acts as the shareholders' internal monitoring tool within the company.
- The structure and composition of a board of directors vary across countries and companies. The number of directors may vary, and the board typically includes a mix of expertise levels, backgrounds, and competencies.
- Executive (internal) directors are employed by the company and are typically members of senior management. Non-executive (external) directors have limited involvement in daily operations but serve an important oversight role.
- Two primary duties of a board of directors are duty of care and duty of loyalty.
- A company's board of directors typically has several committees that are responsible for specific functions and report to the board. Although the types of committees may vary across organization, the most common are the audit committee, governance committee, remuneration (compensation) committee, nomination committee, risk committee, and investment committee.
- Stakeholder relationships and corporate governance are continually shaped and influenced by a variety of market and non-market factors.
- Shareholder engagement by a company can provide benefits that include building support against short-term activist investors, countering negative recommendations from proxy advisory firms, and receiving greater support for management's position.
- Shareholder activism encompasses a range of strategies that may be used by shareholders when seeking to compel a company to act in a desired manner.
- From a corporation's perspective, risks of poor governance include weak control systems; ineffective decision making; and legal, regulatory, reputational, and default risk. Benefits include better operational efficiency, control, and operating and financial performance, as well as lower default risk (or cost of debt).
- Key analyst considerations in corporate governance and stakeholder management include economic ownership and voting control, board of directors representation, remuneration and company performance, investor composition, strength of shareholders' rights, and the management of long-term risks.
- ESG investment approaches range from *value*-based to *values*-based. There are six broad ESG investment approaches: Negative screening, Positive screening, ESG integration, Thematic investing, Engagement/active ownership, and Impact investing.
- Historically, environmental and social issues, such as climate change, air pollution, and societal impacts of a company's products and services, have been treated as negative externalities. However, increased stakeholder awareness and strengthening regulations are internalizing environmental and societal costs onto the company's income statement by responsible investors.

PRACTICE PROBLEMS

1 Corporate governance:

- **A** complies with a set of global standards.
- **B** is independent of both shareholder theory and stakeholder theory.
- **C** seeks to minimize and manage conflicting interests between insiders and external shareholders.

2 Which group of company stakeholders would be *least* affected if the firm's financial position weakens?

- **A** Suppliers
- **B** Customers
- **C** Managers and employees

3 Which of the following represents a principal–agent conflict between shareholders and management?

- **A** Risk tolerance
- **B** Multiple share classes
- **C** Accounting and reporting practices

4 Which of the following issues discussed at a shareholders' general meeting would *most likely* require only a simple majority vote for approval?

- **A** Voting on a merger
- **B** Election of directors
- **C** Amendments to bylaws

5 Which of the following statements regarding stakeholder management is *most* accurate?

- **A** Company management ensures compliance with all applicable laws and regulations.
- **B** Directors are excluded from voting on transactions in which they hold material interest.
- **C** The use of variable incentive plans in executive remuneration is decreasing.

6 Which of the following represents a responsibility of a company's board of directors?

- **A** Implementation of strategy
- **B** Enterprise risk management
- **C** Considering the interests of shareholders only

7 Which of the following statements about non-market factors in corporate governance is *most* accurate?

- **A** Stakeholders can spread information quickly and shape public opinion.
- **B** A civil law system offers better protection of shareholder interests than does a common law system.
- **C** Vendors providing corporate governance services have limited influence on corporate governance practices.

8 Which of the following statements regarding corporate shareholders is *most* accurate?

- **A** Cross-shareholdings help promote corporate mergers.

© 2017 CFA Institute. All rights reserved.

- **B** Dual-class structures are used to align economic ownership with control.
- **C** Affiliated shareholders can protect a company against hostile takeover bids.

9 Which of the following statements about environmental, social, and governance (ESG) in investment analysis is correct?

- **A** ESG factors are strictly intangible in nature.
- **B** ESG terminology is easily distinguishable among investors.
- **C** Environmental and social factors have been adopted in investment analysis more slowly than governance factors.

10 Which of the following statements regarding ESG investment approaches is *most accurate*?

- **A** Negative screening is the most commonly applied method.
- **B** Thematic investing considers multiple factors.
- **C** Positive screening excludes industries with unfavorable ESG aspects.

SOLUTIONS

1 C is correct. Corporate governance is the arrangement of checks, balances, and incentives a company needs to minimize and manage the conflicting interests between insiders and external shareholders.

2 B is correct. Compared with other stakeholder groups, customers tend to be less concerned with, and affected by, a company's financial performance.

3 A is correct. Shareholder and manager interests can diverge with respect to risk tolerance. In some cases, shareholders with diversified investment portfolios can have a fairly high risk tolerance because specific company risk can be diversified away. Managers are typically more risk averse in their corporate decision making to better protect their employment status.

4 B is correct. The election of directors is considered an ordinary resolution and, therefore, requires only a simple majority of votes to be passed.

5 B is correct. Often, policies on related-party transactions require that such transactions or matters be voted on by the board (or shareholders), excluding the director holding the interest.

6 B is correct. The board typically ensures that the company has an appropriate enterprise risk management system in place.

7 A is correct. Social media has become a powerful tool for stakeholders to instantly broadcast information with little cost or effort and to compete with company management in influencing public sentiment.

8 C is correct. The presence of a sizable affiliated stockholder (such as an individual, family trust, endowment, or private equity fund) can shield a company from the effects of voting by outside shareholders.

9 C is correct. The risks of poor corporate governance have long been understood by analysts and shareholders. In contrast, the practice of considering environmental and social factors has been slower to take hold.

10 A is correct. Negative screening, which refers to the practice of excluding certain sectors, companies, or practices that violate accepted standards in such areas as human rights or environmental concerns, is the most common ESG investment approach.

Uses of Capital

by John D. Stowe, PhD, CFA, and Jacques R. Gagné, FSA, CFA, CIPM

John D. Stowe, PhD, CFA, is at Ohio University (USA). Jacques R. Gagné, FSA, CFA, CIPM, is at ENAP (Canada).

LEARNING OUTCOMES

Mastery	*The candidate should be able to:*
☐	**a.** describe the capital allocation process and basic principles of capital allocation;
☐	**b.** demonstrate the use of net present value (NPV) and internal rate of return (IRR) in allocating capital and describe the advantages and disadvantages of each method;
☐	**c.** describe expected relations among a company's investments, company value, and share price;
☐	**d.** describe types of real options relevant to capital investment;
☐	**e.** describe common capital allocation pitfalls.

INTRODUCTION

1

To achieve profitability and reach sustainability, a company must use its resources effectively and make long-term investments that increase revenues and profits. Investment opportunities returning long-term benefits and future cash flows greater than their associated cost to fund generate value for companies and corresponding wealth for their owners. Decisions on where and when to make long-term capital investments are, therefore, key management decisions central to a company's operating success and longevity. Understanding how companies allocate their capital among competing priorities and their resulting portfolios of investment activity is a fundamental area of knowledge for financial analysts for many reasons.

The allocation and investment of capital are important corporate activities. Capital investments (also referred to here as capital projects) are investments with a life of one year or longer, and they make up the long-term asset portion of the balance sheet. They can be so large that sound capital allocation decisions ultimately decide the future success of many corporations. Capital investments also describe a company's future prospects better than its working capital or capital structure, which

© 2021 CFA Institute. All rights reserved.

are intangible and often similar for companies. Analysts may attempt to estimate the process, within reason, for companies that are not too complex and, in doing so, better evaluate corporate decisions that extend to financing and other related activity. Analysts may also be able to appraise the quality of the company's capital allocation process—for example, on the basis of whether the company has an accounting focus or an economic focus. In doing so, analysts derive insights into how the company is creating value for investors.

This reading is organized as follows: Section 2 presents the steps taken by companies in a typical capital allocation process and the basic principles of capital allocation. In Section 3, we introduce basic investment decision criteria, and in Section 4, we discuss capital allocation options—known as real options—that allow their holders, in this case companies, to make decisions in the future that alter the value of their capital investment decisions made today. Section 5 covers a discussion of the common capital allocation pitfalls often made by companies, and a summary concludes the reading.

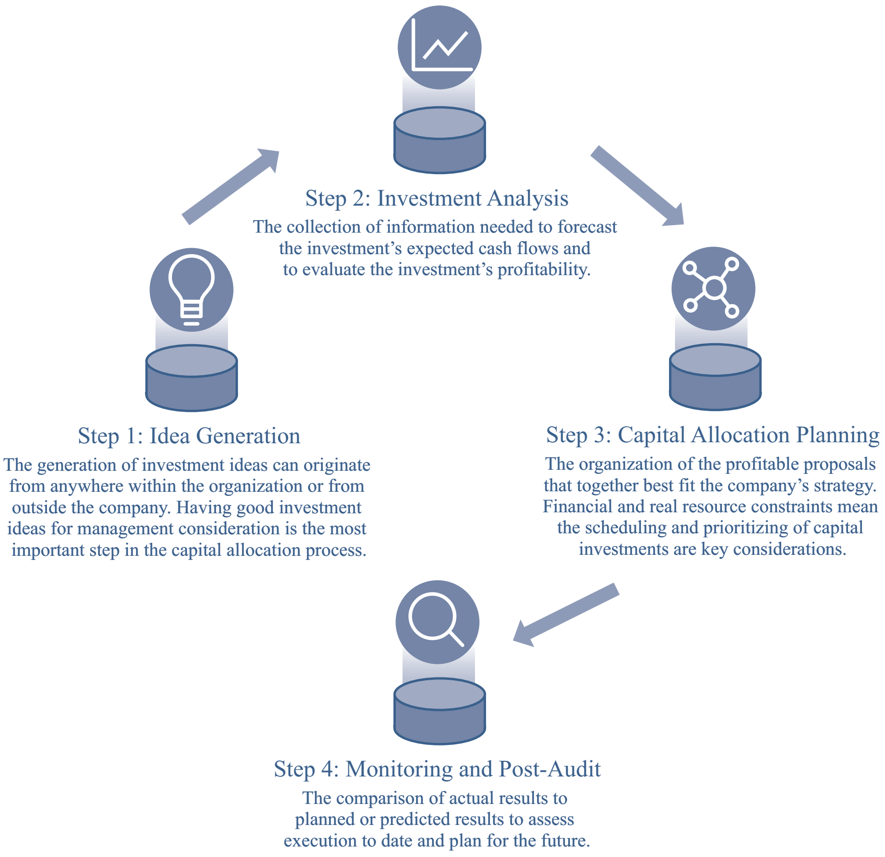
2

THE CAPITAL ALLOCATION PROCESS

a. describe the capital allocation process and basic principles of capital allocation

The **capital allocation process**—the process used by a company to make capital investment decisions—depends on factors specific to the company, such as management tenure and experience, the size and complexity of the capital investment being evaluated, and the size of the organization. The typical steps taken by a company in the capital allocation process are shown in Exhibit 1.

Exhibit 1 Steps in the Capital Allocation Process



Step 1: Idea Generation

The generation of investment ideas can originate from anywhere within the organization or from outside the company. Having good investment ideas for management consideration is the most important step in the capital allocation process.

Step 2: Investment Analysis

The collection of information needed to forecast the investment's expected cash flows and to evaluate the investment's profitability.

Step 3: Capital Allocation Planning

The organization of the profitable proposals that together best fit the company's strategy. Financial and real resource constraints mean the scheduling and prioritizing of capital investments are key considerations.

Step 4: Monitoring and Post-Audit

The comparison of actual results to planned or predicted results to assess execution to date and plan for the future.

Following the generation of investment ideas, an important part of the investment analysis is to accurately forecast the timing, duration, and volatility of each investment's expected cash flows in addition to their probability of occurrence. Capital allocation planning then involves the selection and prioritization of profitable investment opportunities that, when considered together, are most value enhancing for the firm's strategy. Some projects that look attractive when considered in isolation may be undesirable strategically. Opportunities that are not profitable or fail to generate returns sufficient to cover their associated cost of funding should not be pursued. In these cases, the firm is better off returning cash to shareholders as dividends or share repurchases.

Post-auditing capital projects and comparing an investment's realized revenues, expenses, and cash flows with the predictions are important for several reasons. First, they help monitor the forecasts and analysis that underlie the capital allocation process. Systematic errors, such as overly optimistic forecasts, become apparent. Second, they help improve business operations. If sales or costs are out of line, this process will focus attention on bringing performance closer to expectations if at all possible. Finally, monitoring and post-auditing recent capital investments will produce concrete ideas for future investments. Managers can decide to invest more heavily in profitable areas and scale down or cancel investments in areas that are disappointing.

Planning for capital investments can be very complex, often involving many persons inside and outside the company. Information across multiple disciplines such as marketing, technology, engineering, regulation, taxation, finance, production, and behavioral issues must be systematically gathered and evaluated by the company. Management's authority to make capital decisions depends on the size and complexity of the investment in question. Lower-level managers may have discretion to make decisions that involve less than a given amount of money or that do not exceed a given capital allocation. Larger and more complex decisions are reserved for top management, and some are so significant that the company's board of directors ultimately has the decision-making authority.

Like other business activities, the capital allocation activity is a cost–benefit exercise for the company. At the margin, the benefits from the improved decision making should exceed the costs of the capital allocation efforts.

Companies often put capital allocation projects into some basic categories for analysis. These classifications are summarized in Exhibit 2.

Exhibit 2 Types of Capital Projects

01.

Replacement Projects

Investment projects that maintain the existing size of the business.

02.

Expansion Projects

Investment projects that expand business size and often involve greater uncertainty and management consideration than replacement projects.

03.

New Products and Services

Investments in new products or services involving more stakeholders and higher degrees of risk (uncertainty).

04.

Regulatory, Safety, and Environmental Projects

Investment projects required by a third party, such as the government or an insurance company, to meet specified standards. These may not generate revenues and might not be otherwise undertaken by a company maximizing its own interests.

05.

Other

Investment projects, such as management pet projects and high-risk investments, which escape, or fall outside, normal project analyses.

Replacement projects are among the easier capital allocation decisions for management. If a piece of equipment breaks down or wears out, whether to replace it may not require in-depth analysis. If the expenditure is modest and if not investing has significant implications for production, operations, or sales, it would be a waste of corporate resources to overanalyze the decision. The investment should just be made.

For regulatory, safety, and environmental projects, often the company will accept the required investment and continue to operate. Occasionally, however, the cost of such projects is sufficiently high that the company would be better off to cease operating altogether or to shut down any part of the business that is related to the project.

Capital allocation relies on a few basic principles and usually involves the assumptions shown in Exhibit 3.

Exhibit 3 Capital Allocation Assumptions

1. Decisions are based on cash flows.

Decisions are not based on accounting concepts (net income or operating income), which are done on an accrual basis and subtract non-cash expenses, such as depreciation.

2. Cash flows are not accounting net income or operating income.

Accounting income reflects non-cash charges, such as depreciation, while economic income (cash flows plus change in company's market value) does not and is based on changes in the company's market value, not book value.

3. Cash flows are based on opportunity costs.

What incremental cash flows occur with the investment compared with what they would have been without the investment?

4. Cash flows are analyzed on an after-tax basis.

Decisions must reflect the impact of taxes.

5. Timing of cash flows is crucial

Detailed analysis is needed to accurately forecast the timing, duration, and volatility of expected cash flows and their probability of occurrence.

6. Financing costs are ignored.

Financing costs are reflected in the required rate of return and thus ignored in cash flows to avoid double-counting.

In ignoring financing costs, we referred to the rate used in discounting the cash flows as the "required rate of return." The required rate of return is the discount rate that investors, or suppliers of capital, require given the riskiness of the project. This discount rate is frequently called the "opportunity cost of funds" or the "cost of capital." If the company can invest elsewhere and earn a return of r or if the company can repay its sources of capital and save a cost of r, then r is the company's opportunity cost of funds. If the company cannot earn more than its opportunity cost of funds on an investment, it should not undertake that investment. Unless an investment earns more than the cost of funds from its suppliers of capital, the investment should not be undertaken. The cost of capital concept is discussed more extensively elsewhere. Regardless of what it is called, an economically sound discount rate is essential for making capital allocation decisions.

Although the principles of capital allocation are simple, they are easily confused in practice, leading to unfortunate decisions made by companies. The following are some important capital allocation concepts useful to financial analysts.

- A **sunk cost** is one that has already been incurred. One cannot change a sunk cost. Decisions made today, however, should be based on current and future cash flows and should not be affected by prior, or sunk, costs.
- An **opportunity cost** is what a resource is worth in its next-best use. For example, if a company uses some idle property, what should it record as the investment outlay: the purchase price several years ago, the current market value, or nothing? If the company invests $10 million, what is the opportunity cost? The answers to these questions are, respectively, the current market value and $10 million (which the company could invest elsewhere).

- An **incremental cash flow** is the cash flow that is realized because of an investment decision: the cash flow *with* a decision minus the cash flow *without* that decision. If opportunity costs are correctly assessed by the company, the incremental cash flows provide a sound basis for capital allocation.
- An **externality** is the effect of an investment on things other than the investment itself. Frequently, an investment affects the cash flows of other parts of the company, and these externalities can be positive or negative. A positive externality occurring within the company would be expected synergies with existing projects or business activities that result from making the investment. The production and sale of a new complimentary product or service may increase demand or lower costs for an existing product or service the company offers. **Cannibalization** is an example of a negative externality occurring within the company. Cannibalization occurs when an investment takes customers and sales away from another part of the company. If possible, companies should consider externalities in the investment decision. Often the adjustments are subjective because the company cannot get a precise estimate. Sometimes externalities occur outside the company. An investment might benefit (or harm) other companies or society at large, and yet the company is not compensated for these benefits (or charged for the costs).
- **Conventional cash flows** versus **nonconventional cash flows**: A conventional cash flow pattern is one with an initial outflow followed by a series of inflows. In a nonconventional cash flow pattern, the initial outflow is not followed by inflows only, but the cash flows can flip from being positive (inflows) to negative (outflows) again or possibly change signs several times. An investment that involved outlays (negative cash flows) for the first couple of years that were followed by positive cash flows would be considered to have a conventional pattern. If cash flows change signs once, the pattern is conventional. If cash flows change signs two or more times, the pattern is nonconventional.

  For example, a crude oil refining facility might require an initial investment outlay that produces positive cash flows for several years followed by additional investments to refurbish the facilities needed to produce additional positive cash flows. Or an investment in a nuclear power facility that generates electricity for a number of years might be followed by another cash outlay to decommission the power plant.

In assessing potential investment opportunities, several types of project interactions make the incremental cash flow analysis challenging for companies. The following are some of these interactions:

- **Independent projects** versus **mutually exclusive projects**: Independent projects are capital investments whose cash flows are independent of each other. Mutually exclusive projects compete directly with each other. For example, if Projects A and B are mutually exclusive, the company can choose to invest in A or B but cannot choose both. Sometimes management may be presented with several mutually exclusive projects and can choose only one from the group.
- **Project sequencing**: Many capital projects are sequenced over time, so that investing in a project creates the option to invest in future projects. For example, the company might invest in a project today and one year later invest in a second project if the financial results of the first project or new economic conditions are favorable. If the results of the first project or new economic conditions are not favorable, the company would not invest in the second project.
- **Unlimited funds** versus **capital rationing**: An unlimited funds environment assumes that the company can raise the funds it wants for all profitable projects simply by paying the required rate of return. Capital rationing exists when

the company has a fixed amount of funds to invest. If the company has more profitable projects than it has funds for, it must allocate the funds to achieve the maximum shareholder value subject to the funding constraints.

INVESTMENT DECISION CRITERIA

3

b demonstrate the use of net present value (NPV) and internal rate of return (IRR) in allocating capital and describe the advantages and disadvantages of each method

Several criteria can be used by companies to evaluate capital investment opportunities. The two most comprehensive measures to assess whether an investment is profitable or unprofitable are the **net present value** (NPV) and **internal rate of return** (IRR). An analyst should understand the economic logic behind each of these investment decision criteria as well as their strengths and limitations in practice.

3.1 Net Present Value

For a capital investment with one investment outlay, made initially, the net present value is the present value of the future after-tax cash flows minus the investment outlay, or

$$\text{NPV} = \sum_{t=1}^{n} \frac{\text{CF}_t}{(1+r)^t} - \text{Outlay}, \tag{1}$$

where

CF_t = After-tax cash flow at time t

r = Required rate of return for the investment

Outlay = Investment cash flow at time zero

To illustrate the net present value criterion, we will consider a simple example. Assume that Gerhardt Corporation is considering a capital investment of €50 million that will return after-tax cash flows of €16 million per year for the next four years plus another €20 million in Year 5. The company's required rate of return is 10%.

For the Gerhardt example, the NPV would be

$$\text{NPV} = \frac{16}{1.10^1} + \frac{16}{1.10^2} + \frac{16}{1.10^3} + \frac{16}{1.10^4} + \frac{20}{1.10^5} - 50.$$

$$\text{NPV} = 14.545 + 13.223 + 12.021 + 10.928 + 12.418 - 50.$$

$$\text{NPV} = 63.136 - 50 = €13.136 \text{ million}.$$

The investment has a total value, or present value of future cash flows, of €63.136 million. Since this investment can be acquired at a cost of €50 million, the company is giving up €50 million of its wealth in exchange for an investment worth €63.136 million. The investment increases the wealth of the company by a net amount of €13.136 million.

Because the NPV is the amount by which the company's wealth increases as a result of the investment, the decision rule for the NPV is as follows:

Invest if	$\text{NPV} > 0$.
Do not invest if	$\text{NPV} < 0$.

Positive-NPV investments are wealth increasing for the company and its shareholders, whereas negative-NPV investments are wealth decreasing for the company and its shareholders. In the rare case that NPV turns out to be zero, the project could be accepted because it meets the required rate of return. Keep in mind, however, that NPV analysis relies on estimated future cash flows. A zero-NPV project leaves no room for error.

Many investments have cash flow patterns in which outflows may occur not only at time zero but also at future dates. It is useful to consider the NPV to be the present value of all cash flows:

$$\text{NPV} = \text{CF}_0 + \frac{\text{CF}_1}{(1+r)^1} + \frac{\text{CF}_2}{(1+r)^2} + \cdots + \frac{\text{CF}_n}{(1+r)^n}, \text{ or}$$

$$\text{NPV} = \sum_{t=0}^{n} \frac{\text{CF}_t}{(1+r)^t}. \tag{2}$$

In Equation 2, the investment outlay, CF_0, is simply a negative cash flow. Future cash flows can also be negative.

3.2 Internal Rate of Return

The internal rate of return is one of the most frequently used concepts in capital allocation and in security analysis. For a capital investment with one investment outlay, made initially, the IRR is the discount rate that makes the present value of the future after-tax cash flows equal that investment outlay. Expressed in equation form, the IRR solves the following equation:

$$\sum_{t=1}^{n} \frac{\text{CF}_t}{(1+\text{IRR})^t} = \text{Outlay},$$

where IRR is the internal rate of return. The left-hand side of this equation is the present value of the capital investment's future cash flows, which, discounted at the IRR, equals the investment outlay. This equation will also be seen rearranged as

$$\sum_{t=1}^{n} \frac{\text{CF}_t}{(1+\text{IRR})^t} - \text{Outlay} = 0. \tag{3}$$

In this form, Equation 3 looks like the NPV equation, Equation 1, except that the discount rate is the IRR instead of r (the required rate of return). Discounted at the IRR, the NPV is equal to zero.

In the Gerhardt Corporation example, we want to find a discount rate that makes the total present value of all cash flows, the NPV, equal zero. In equation form, the IRR is the discount rate that solves the following equation:

$$-50 + \frac{16}{(1+\text{IRR})^1} + \frac{16}{(1+\text{IRR})^2} + \frac{16}{(1+\text{IRR})^3} + \frac{16}{(1+\text{IRR})^4} + \frac{20}{(1+\text{IRR})^5} = 0.$$

Algebraically, this equation would be difficult to solve. Without the use of a financial calculator, we would have to resort to trial and error, systematically choosing various discount rates until we find one, the IRR, that satisfies the equation. This process can be long and tedious. Fortunately, financial calculators can derive the IRR quickly. Even before using a calculator, however, we have some sense of what the IRR is. We previously discounted these cash flows at 10% and found the NPV to be €13.136 million. Since the NPV is positive, the IRR must be greater than 10%. If we use 20% as the discount rate, the NPV is –€0.543 million, so 20% is a little high. One might try several other discount rates until the NPV is equal to zero; this approach is illustrated in Exhibit 4.

Exhibit 4. Trial and Error Process for Finding IRR

Discount Rate (%)	NPV
10	13.136
20	−0.543
19	0.598
19.5	0.022
19.51	0.011
19.52	0.000

The IRR is 19.52%. To repeat, financial calculators and spreadsheet software can quickly calculate the IRR for us so that we do not have to go through this trial and error procedure ourselves.

The decision rule for the IRR is to invest if the IRR exceeds the required rate of return for a capital investment:

Invest if	IRR > r.
Do not invest if	IRR < r.

The required rate of return is often called the **hurdle rate**, the rate that a project's IRR must exceed for the project to be accepted by the company. In the unlikely event that the IRR is equal to r, the project is theoretically acceptable because it meets the required return. In fact, NPV equals zero when IRR equals r. In the Gerhardt example, since the IRR of 19.52% exceeds the project's required rate of return of 10%, Gerhardt should invest.

It is common to define the IRR as the discount rate that makes the present values of all cash flows sum to zero:

$$\sum_{t=0}^{n} \frac{\mathrm{CF}_t}{(1+\mathrm{IRR})^t} = 0. \tag{4}$$

Equation 4 is a more general version of Equation 3.

NPV and IRR criteria will usually indicate the same investment decision for a given capital investment. They will usually both recommend acceptance or rejection of the investment. In the case of mutually exclusive investment projects, a company could, on occasion, face the following situation: Project A might have a larger NPV than Project B, but Project B has a higher IRR than Project A. Since the company can invest in only one project, which should it be—Project A or Project B?

The correct choice is Project A, the one with the higher NPV. To understand why, consider this simple example. Suppose you could choose just one of two investments. The first allows you to double your initial outlay of $100 in just one year. The second requires an investment of $100,000, which will grow by 20% in a year. Which should you choose? The first investment gives you a profit of $100. The second gives you a $20,000 profit. Assuming you can access the required funds, the second choice is preferred. Even though it offers a smaller percentage return, it increases your wealth by much more.

When the choice is between two mutually exclusive projects and the NPV and IRR rank the two projects differently, the NPV criterion is strongly preferred. There are good reasons for this preference. The NPV shows the amount of gain, or wealth increase in company value, as a currency amount. The NPV assumes reinvestment of cash flows at the required rate of return, while the IRR assumes reinvestment at the IRR. In using the opportunity cost of funds, the reinvestment assumption of the NPV is the more economically realistic measure. Mathematically, whenever you discount a cash flow at a particular discount rate, you are implicitly assuming that you can reinvest a cash flow at that same discount rate. It is more realistic to assume reinvestment at a lower rate. The IRR does give a rate of return, but the IRR could be for a small investment size or for only a short period of time. As a practical matter, once a corporation has the data to calculate the NPV, it is fairly trivial to then calculate the IRR and other capital allocation criteria. However, the most appropriate and theoretically sound criterion is the NPV.

Another issue is that when the cash flows are nonconventional (i.e., they change sign more than once), there are multiple IRRs. This problem with the IRR criterion is known as the multiple IRR problem. We can illustrate this problem with the following nonconventional cash flow pattern:

Time	0	1	2
Cash flow	−1,000	5,000	−6,000

The IRR for these cash flows satisfies this equation:

$$-1{,}000 + \frac{5{,}000}{(1 + \text{IRR})^1} + \frac{-6{,}000}{(1 + \text{IRR})^2} = 0.$$

It turns out that there are two values of IRR that satisfy the equation: IRR = 1 = 100% and IRR = 2 = 200%. As a result, the IRR is not useful for nonconventional cash flow projects.

This brings up the following question: If NPV is always preferred over IRR for selecting projects, why do companies even bother with IRR? The answer is that many people find it easy to understand a rate of return. If they know that the required return is 10%, they can easily understand that a project returning more than 10% is desirable. If they are simply told the NPV amount, they may not find it as meaningful. In practice, most companies use both metrics. They typically use NPV to make the investment decisions, but they also report the IRR to help their audience understand.

3.3 Corporate Usage of Capital Allocation Methods

c describe expected relations among a company's investments, company value, and share price

Analysts should understand the basic logic of the various capital allocation criteria as well as the practicalities involved in their use at corporations. The usefulness of any analytical tool always depends on the specific application.

If the company can invest elsewhere and earn a return of *r* or if the company can repay its sources of capital and save a cost of *r*, then *r* is the company's opportunity cost of funds. If the company can make an investment that earns more than its opportunity cost of funds, then the investment is creating value for the company and corresponding wealth for shareholders and should be undertaken. Similarly, if the investment earns less than the company's opportunity cost of funds, the investment decreases value in the company, leaving shareholders less wealthy, and should not be undertaken.

The **return on invested capital** (ROIC) is a measure of the profitability of a company relative to the amount of capital invested by the equity- and debtholders. ROIC reflects how effectively a company's management is able to convert capital into profits. The ratio is calculated by dividing the after-tax net profit by the average book value of invested capital (common, preferred, and debt).

The ROIC measure is often compared with the associated **cost of capital** (COC), the required return used in the NPV calculation and the company's associated cost of funds. If the ROIC measure is higher than the COC, the company is generating a higher return for investors compared with the required return, thereby increasing the firm's value for shareholders. The inverse is true if the COC is higher than the ROIC.

Capital allocation criterion and analysis are thus essential tools for corporate managers. Because a corporation's investing decisions ultimately determine the value of its financial obligations, the corporation's investing processes and activity are vital. The NPV criterion is the criterion most directly related to stock prices. If a corporation invests in positive-NPV projects, they should add to the wealth of the company and the corresponding wealth of its shareholders. Example 1 illustrates this scenario for a company making a new investment.

EXAMPLE 1

NPVs and Stock Prices

Freitag Corporation is investing €600 million in distribution facilities. The present value of the future after-tax cash flows is estimated to be €850 million. Freitag has 200 million outstanding shares with a current market price of €32.00 per share. This investment is new information, and it is independent of other expectations about the company. What should be the investment's effect on the value of the company and the stock price?

Solution:

The NPV of the investment is €850 million − €600 million = €250 million. The total market value of the company prior to the investment is €32.00 × 200 million shares = €6,400 million. The value of the company should increase by €250 million, to €6,650 million. The price per share should increase by the NPV per share, or €250 million/200 million shares = €1.25 per share. The share price should increase from €32.00 to €33.25.

The effect of a capital investment's positive or negative NPV on share price is more complicated than in Example 1, in which the value of the stock increased by the investment's NPV.

The value of a company is the value of its existing investments plus the net present values of all its future investments, accounting for any externalities. If an analyst learns of an investment, the impact of that investment on the company's stock price will depend on whether the investment's profitability is more or less than expected. For example, an analyst could learn of a positive-NPV project, but if the project's profitability is less than expected, the company's stock price might drop because of this news. Alternatively, news of a particular capital project might be considered a signal about other capital investments underway or in the future. An investment that by itself might add, say, €0.25 to the value of the stock might signal the existence of other profitable projects. News of this investment might increase the stock price by far more than €0.25.

Inflation affects a company's capital allocation analysis in several ways. The first is whether the investment analysis is done in "nominal" terms or in "real" terms. Nominal cash flows include the effects of inflation, whereas real cash flows are adjusted downward to remove the effects of inflation. Companies may choose to do the analysis in either nominal or real terms, and sound decisions can be made either way.

The cash flows and discount rate used by the company should both be nominal or both be real. In other words, nominal cash flows should be discounted at a nominal discount rate, and real cash flows should be discounted at a real rate. The real rate, just like real cash flows, has had the effect of inflation removed.

Inflation reduces the value of depreciation tax savings to the company (unless the tax system adjusts depreciation for inflation), effectively increasing its real taxes. The effect of expected inflation is captured in the discounted cash flow analysis. If inflation is higher than expected, the profitability of the investment is correspondingly lower than expected. Inflation essentially shifts wealth from the taxpayer (i.e., company) to the government. Conversely, lower-than-expected inflation reduces real taxes for the company (the depreciation tax shelters are more valuable than expected) and results in higher-than-expected profitability of the investment and a corresponding wealth increase for the company.

Inflation does not affect all revenues and costs uniformly. The company's after-tax cash flows will be better or worse than expected depending on how particular sales outputs or cost inputs are affected. Furthermore, contracting with customers, suppliers, employees, and sources of capital can be complicated as inflation rises. Although the capital allocation model accommodates the effects of inflation, inflation complicates the capital allocation process (and the operations of a business, in general).

Finally, a company's capital allocation processes can demonstrate two things about the quality of management: the degree to which management embraces the goal of shareholder wealth maximization and management's effectiveness in pursuing that goal. Both are key for shareholders and potential investors in assessing management's success in value creation for the company.

4

REAL OPTIONS

d describe types of real options relevant to capital investment

Real options are options that allow companies to make decisions in the future that alter the value of capital investment decisions made today. Instead of making all capital investment decisions now, at time zero, a company can wait and make additional decisions at future dates when these future decisions are contingent on future economic events or information. Rather than one-time decisions, it is more reasonable to assume that a company is making decisions sequentially, some now and some in the future. A combination of optimal current and future decisions is what will maximize company value. Real options, by providing future decision-making flexibility to companies, can be an important piece of the value in many capital investments.

Real options are like financial options—except that they deal with real assets instead of financial assets.

EXAMPLE 2

Financial Option Similarity

A simple financial option could be a call option on a share of stock. Suppose the stock is selling for $50, you own a call option with an exercise (strike) price of $50, and the option expires in one year.

A What action should you take if the stock price increases to $60?

B What action should you take if the stock price falls to $40?

Solution:

A Since the stock price ($60) is greater than the option exercise price ($50), you should exercise the option, which allows you to buy the stock, worth $60, for a price of $50. In effect, you have a $10 gain less what you paid for the option.

B Since the stock price ($40) is less than the option exercise price ($50), you should not exercise the option. After all, why would you pay $50 for a stock that is now worth only $40? If you really want to own the stock, it would be cheaper to buy it in the market for $40.

Real options, like financial options, entail the right to make a decision but not the obligation to do so. The company should exercise a real option only if it is value enhancing.

Just as financial options are contingent on an underlying asset, real options are contingent on future events. The flexibility that real options give to companies can greatly enhance the NPV of the company's capital investments. The following are four types of real options.

4.1 Timing Options

Instead of investing now, the company can delay investing. Delaying an investment and basing the decision on hopefully improved information that you might have in, say, a year could help improve the NPV of the projects selected. Project sequencing options allow the company to defer the decision to invest in a future investment until the outcome of some or all of a current investment is known. Investments are sequenced over time, so that investing in a project creates the option to make future investments.

4.2 Sizing Options

If after investing the company can abandon the investment if the financial results are disappointing, it has an **abandonment option**. At some future date, if the cash flow from abandoning an investment exceeds the present value of the cash flows from continuing the investment, the company should exercise the abandonment option. Conversely, if the company can make additional investments when future financial results are strong, the company has a **growth option** or an expansion option. When estimating the cash flows from an expansion, the analyst must also be wary of cannibalization.

4.3 Flexibility Options

Once an investment is made, operational flexibilities besides abandonment or expansion may be available. For example, suppose demand exceeds capacity. Management may be able to exercise a **price-setting option**. By increasing prices, the company could benefit from the excess demand, which it cannot do by increasing production. There are also **production-flexibility options**, which offer the operational flexibility to alter production when demand varies from what is forecast. Even though it is expensive, the company can profit from working overtime or from adding additional shifts. The company can also work with customers and suppliers for their mutual benefit whenever a demand–supply mismatch occurs. This type of option also includes the possibility of using different inputs or producing different outputs.

4.4 Fundamental Options

In such cases as the aforementioned, there are options embedded in a project that can raise its value. In other cases, the whole investment is essentially an option. The payoffs from the investment are contingent on an underlying asset, just like most financial options. For example, the value of an oil well or refinery investment is contingent on the price of oil. The value of a gold mine is contingent on the price of gold. If oil prices were low, you likely would not choose to drill a well. If oil prices were high, you would go ahead and drill. Many R&D (research and development) projects also look like options.

There are several approaches a company's management may use in evaluating capital investments with real options. Analysis of real options can be very complicated for companies. Management can take the following common sense approaches to real option analysis:

1. Use DCF (discounted cash flow) analysis without considering options. If the NPV is positive without considering real options and the project has real options that would simply add more value, it is unnecessary to evaluate the options. Management should simply undertake the investment.
2. Consider the Project NPV = NPV (based on DCF alone) – Cost of options + Value of options. Calculate the NPV based on expected cash flows. Then simply add the value associated with real options less their incremental cost.
3. Use decision trees. Although they are not as conceptually sound as option pricing models, decision trees can capture the essence of many sequential decision-making problems for companies.
4. Use option pricing models.

In carrying out capital allocation, management must consider (1) a variety of real options that investments may possess and (2) a decision about how to reasonably value these options. Example 3 deals with production flexibility; in this case, an additional investment outlay gives the company an option to use alternative fuel sources.

EXAMPLE 3

Production-Flexibility Option

Auvergne AquaFarms has estimated the NPV of the expected cash flows from a new processing plant to be –€0.40 million. Auvergne is evaluating an incremental investment of €0.30 million that would give management the flexibility to switch among coal, natural gas, and oil as energy sources. The original plant relied only on coal. The option to switch to cheaper sources of energy when they are available has an estimated value of €1.20 million. What is the value of the new processing plant including this real option to use alternative energy sources?

Solution:

The NPV, including the real option, should be

$$\begin{aligned}\text{Project NPV} &= \text{NPV (based on DCF alone)} - \text{Cost of options} + \\ &\quad \text{Value of options.}\\ \text{Project NPV} &= -0.40 \text{ million} - 0.30 \text{ million} + 1.20 \text{ million}\\ &= €0.50 \text{ million.}\end{aligned}$$

Without the flexibility offered by the real option, the plant is unprofitable. The real option to adapt to cheaper energy sources adds enough to the value of this investment to give it a positive NPV. The company should undertake the investment, which would add to its value.

COMMON CAPITAL ALLOCATION PITFALLS

5

e describe common capital allocation pitfalls

Although the principles of capital allocation may be easy to understand, applying the principles to real-world investment opportunities can be challenging for companies. Some of the common capital allocation mistakes that companies make are listed here.

- **Not incorporating economic responses into the investment analysis:** Economic responses to an investment often affect its profitability, and these responses have to be correctly anticipated by companies. For example, in response to a successful investment, competitors can enter and reduce the investment's profitability. Companies that make highly profitable investments often find that a competitive marketplace eventually causes profitability to revert to normal levels.
- **Misusing capital allocation templates:** Because hundreds or even thousands of investments need to be analyzed over time, individuals assessing these opportunities on behalf of the company sometimes use standardized capital allocation templates in evaluating investments. This situation creates risks if the template model does not match the investment or if inappropriate information is used.
- **Pushing pet projects:** Often **pet projects** are selected at companies without undergoing normal capital allocation analysis. Or the pet project receives the analysis, but overly optimistic projections are used to inflate the investment's profitability.
- **Basing investment decisions on EPS, net income, or ROE:** Companies sometimes have incentives to boost earnings per share, net income, or return on equity. Many investments, even those with strong NPVs, do not increase these accounting numbers in the short run and may even reduce them. Paying too much attention to short-run accounting numbers can result in a company choosing investments that are not in the long-run economic interests of its shareholders.
- **Using IRR to make investment decisions:** The NPV criterion is economically sound. The IRR criterion is also sound for companies undertaking independent investments with conventional cash flow patterns. For investment opportunities that are mutually exclusive, or competitive with each other, using IRR criterion and not NPV can result in suboptimal investment decisions. Furthermore, the IRR methodology should never be used with nonconventional cash flow projects because it results in more than one solution.
- **Incorrectly accounting for cash flows:** In analyzing a complicated investment, individuals assessing the investment for the company may erroneously omit relevant cash flows, double-count cash flows, and mishandle taxes.

- **Over- or underestimating overhead costs:** In large companies, the cost of an investment may include the overhead it generates for such things as management time, information technology support, financial systems, and other support. Although these items are hard to estimate, over- or underestimating these overhead costs can lead to incorrect analysis by companies.
- **Not using the appropriate risk-adjusted discount rate:** The required rate of return for an investment should be based on its risk. If the company is financing an investment with debt (or with equity), the investment's required rate of return—not the company's **cost of debt** (or **cost of equity**)—should still be used. Similarly, a high-risk investment being considered should be discounted not at the company's overall cost of capital but at the investment's required rate of return. Discount rate errors have a huge impact on the computed NPVs of long-lived investments.
- **Overspending and underspending the capital allocation:** Spending all the investment allocation just because it is available is another common mistake made by companies. In a well-run company, managers will return excess funds whenever their profitable investments cost less than their allocation, and managers will make a sound case for extra funds if their allocation is too small.
- **Failing to consider investment alternatives or alternative states:** Generating good investment ideas is the most basic step in the capital allocation process, and many good alternatives are never even considered at some companies. In addition, many companies fail to consider differing states of the world, which can and should be incorporated through breakeven, scenario, and simulation analyses.
- **Incorrectly handling sunk costs and opportunity costs:** Ignoring sunk costs is difficult for companies to do. Further, not identifying the economic alternatives (real and financial) that are the opportunity costs is probably the biggest failure by companies in their analyses. Only costs that change with the decision are relevant.

SUMMARY

Capital allocation is the process that companies use for decision making on capital investments—those investments with a life of a year or longer. This reading developed the principles behind the basic capital allocation model, the cash flows that go into the model, and several extensions of the basic model.

- Capital allocation supports the most critical investments for many corporations—their investments in long-term assets. The principles of capital allocation have been applied to other corporate investing and financing decisions and to security analysis and portfolio management.
- The typical steps in the capital allocation process are (1) generating ideas, (2) analyzing investment opportunities, (3) planning the capital allocation, and (4) monitoring and post-auditing.
- Types of investments appropriate for the capital allocation process can be categorized as (1) replacement, (2) expansion, (3) new products and services, and (4) regulatory, safety, and environmental.

- Capital allocation decisions are based on incremental after-tax cash flows discounted at the opportunity cost of funds. Financing costs are ignored because both the cost of debt and the cost of other capital are captured in the discount rate.
- The net present value is the present value of all after-tax cash flows, or

  $$\mathrm{NPV} = \sum_{t=0}^{n} \frac{\mathrm{CF}_t}{(1+r)^t},$$

  where the investment outlays are negative cash flows included in the CF_t's and where r is the required rate of return for the investment.
- The IRR is the discount rate that makes the present value of all future cash flows sum to zero. This equation can be solved for the IRR:

  $$\sum_{t=0}^{n} \frac{\mathrm{CF}_t}{(1+\mathrm{IRR})^t} = 0.$$

- The capital allocation decision rules are to invest if the NPV > 0 or if the IRR > r.
- For mutually exclusive investments that are ranked differently by the NPV and IRR, the NPV criterion is more economically sound.
- The fact that projects with positive NPVs theoretically increase the value of the company and the value of its stock could explain the popularity of NPV as an evaluation method.
- Real options can be classified as (1) timing options; (2) sizing options, which can be abandonment options or growth (expansion) options; (3) flexibility options, which can be price-setting options or production-flexibility options; and (4) fundamental options.

PRACTICE PROBLEMS

1 The net present value (NPV) of an investment is equal to the sum of the expected cash flows discounted at the:

A internal rate of return.

B risk-free rate.

C opportunity cost of capital.

2 A $2.2 million investment will result in the following cash flows:

Year	Year-End Cash Flow (millions)
1	$1.3
2	$1.6
3	$1.9
4	$0.8

Using an 8% opportunity cost of capital, the investment's net present value is *closest* to:

A $2.47 million.

B $3.40 million.

C $4.67 million.

3 The internal rate of return (IRR) is *best* described as the:

A opportunity cost of capital.

B time-weighted rate of return.

C discount rate that makes the net present value equal to zero.

4 A three-year investment requires an initial outlay of £1,000. It is expected to provide three year-end cash flows of £200 plus a net salvage value of £700 at the end of three years. Its internal rate of return is *closest* to:

A 10%.

B 11%.

C 20%.

5 Given the following cash flows for a capital investment, calculate the NPV and IRR. The required rate of return is 8%.

Year	0	1	2	3	4	5
Cash flow	–50,000	15,000	15,000	20,000	10,000	5,000

	NPV	IRR
A	$1,905	10.9%
B	$1,905	26.0%
C	$3,379	10.9%

© 2021 CFA Institute. All rights reserved.

6 An investment of \$100 generates after-tax cash flows of \$40 in Year 1, \$80 in Year 2, and \$120 in Year 3. The required rate of return is 20%. The net present value is *closest* to:

- **A** \$42.22.
- **B** \$58.33.
- **C** \$68.52.

7 An investment of \$150,000 is expected to generate an after-tax cash flow of \$100,000 in one year and another \$120,000 in two years. The cost of capital is 10%. What is the internal rate of return?

- **A** 28.39%.
- **B** 28.59%.
- **C** 28.79%.

8 Kim Corporation is considering an investment of 750 million won with expected after-tax cash inflows of 175 million won per year for seven years. The required rate of return is 10%. What is the investment's:

	NPV?	IRR?
A	102 million won	14.0%
B	157 million won	23.3%
C	193 million won	10.0%

9 Erin Chou is reviewing a profitable investment that has a conventional cash flow pattern. If the cash flows for the investment, initial outlay, and future after-tax cash flows all double, Chou would predict that the IRR would:

- **A** increase and the NPV would increase.
- **B** stay the same and the NPV would increase.
- **C** stay the same and the NPV would stay the same.

10 Catherine Ndereba is an energy analyst tasked with evaluating a crude oil exploration and production company. The company previously announced that it plans to embark on a new project to drill for oil offshore. As a result of this announcement, the stock price ran up by 10%. After conducting her analysis, Ms. Ndereba concludes that the project does indeed have a positive NPV. Which statement is true?

- **A** The stock price should remain where it is because Ms. Ndereba's analysis confirms that the recent run-up was justified.
- **B** The stock price should go even higher now that an independent source has confirmed that the NPV is positive.
- **C** The stock price could remain steady, move higher, or move lower.

11 The Bearing Corp. invests only in positive-NPV projects. Which of the following statements is true?

- **A** Bearing's return on invested capital (ROIC) is greater than its cost of capital (COC).
- **B** Bearing's COC is greater than its ROIC.
- **C** We can't reach any conclusions about the relationship between the company's ROIC and COC.

12 Investments 1 and 2 have similar outlays, although the patterns of future cash flows are different. The cash flows as well as the NPV and IRR for the two investments are shown below. For both investments, the required rate of return is 10%.

	Cash Flows						
Year	**0**	**1**	**2**	**3**	**4**	**NPV**	**IRR (%)**
Investment 1	–50	20	20	20	20	13.40	21.86
Investment 2	–50	0	0	0	100	18.30	18.92

The two projects are mutually exclusive. What is the appropriate investment decision?

A Invest in both investments.

B Invest in Investment 1 because it has the higher IRR.

C Invest in Investment 2 because it has the higher NPV.

13 Consider the two investments below. The cash flows as well as the NPV and IRR for the two investments are given. For both investments, the required rate of return is 10%.

	Cash Flows						
Year	**0**	**1**	**2**	**3**	**4**	**NPV**	**IRR (%)**
Investment 1	–100	36	36	36	36	14.12	16.37
Investment 2	–100	0	0	0	175	19.53	15.02

What discount rate would result in the same NPV for both investments?

A A rate between 0.00% and 10.00%

B A rate between 10.00% and 15.02%

C A rate between 15.02% and 16.37%

14 Wilson Flannery is concerned that the following investment has multiple IRRs.

Year	**0**	**1**	**2**	**3**
Cash flows	–50	100	0	–50

How many discount rates produce a zero NPV for this investment?

A One, a discount rate of 0%

B Two, discount rates of 0% and 32%

C Two, discount rates of 0% and 62%

15 With regard to capital allocation, an appropriate estimate of the incremental cash flows from an investment is *least likely* to include:

A externalities.

B interest costs.

C opportunity costs.

The following information relates to Questions 16–18

Bouchard Industries is a Canadian company that manufactures gutters for residential houses. Its management believes it has developed a new process that produces a superior product. The company must make an initial investment of C$190 million to begin production. If demand is high, cash flows are expected to be C$40 million per year. If demand is low, cash flows will be only C$20 million per year. Management believes there is an equal chance that demand will be high or low. The investment also gives the company a production-flexibility option allowing the company to add shifts at the end of the first year if demand turns out to be high. If the company exercises this option, net cash flows would increase by an additional C$5 million in Years 2–10. Bouchard's opportunity cost of funds is 10%.

The internal auditor for Bouchard Industries has made two suggestions for improving capital allocation processes at the company. The internal auditor's suggestions are as follows:

Suggestion 1	"In order to treat all capital allocation proposals in a fair manner, the investments should all use the risk-free rate for the required rate of return."
Suggestion 2	"When rationing capital, it is better to choose the portfolio of investments that maximizes the company NPV than the portfolio that maximizes the company IRR."

16 What is the NPV (C$ millions) of the original project for Bouchard Industries without considering the production-flexibility option?

A –C$6.11 million

B –C$5.66 million

C C$2.33 million

17 What is the NPV (C$ millions) of the optimal set of investment decisions for Bouchard Industries including the production-flexibility option?

A –C$6.34 million

B C$7.43 million

C C$31.03 million

18 Should the capital allocation committee accept the internal auditor's suggestions?

A No for Suggestions 1 and 2

B No for Suggestion 1 and yes for Suggestion 2

C Yes for Suggestion 1 and no for Suggestion 2

SOLUTIONS

1 C is correct. The NPV sums the investment's expected cash flows (CF) discounted at the opportunity cost of capital. The NPV calculation is

$$\text{NPV} = \sum_{t=0}^{N} \frac{\text{CF}_t}{(1+r)^t},$$

where

CF_t = the expected net cash flow at time t
N = the investment's projected life
r = the discount rate or opportunity cost of capital

2 A is correct.

$$\text{NPV} = -\$2.2 + \frac{\$1.3}{(1.08)} + \frac{\$1.6}{(1.08)^2} + \frac{\$1.9}{(1.08)^3} + \frac{\$0.8}{(1.08)^4} = \$2.47 \text{ million.}$$

3 C is correct. The internal rate of return is computed by identifying all cash flows and solving for the rate that makes the net present value of those cash flows equal to zero.

4 B is correct. IRR is determined by setting the net present value equal to zero for the cash flows shown in the following table.

Year	Cash Flow (£)
0	–1,000
1	200
2	200
3	900

5 C is correct.

$$\text{NPV} = -50{,}000 + \frac{15{,}000}{1.08} + \frac{15{,}000}{1.08^2} + \frac{20{,}000}{1.08^3} + \frac{10{,}000}{1.08^4} + \frac{5{,}000}{1.08^5}.$$

$$\text{NPV} = -50{,}000 + 13{,}888.89 + 12{,}860.08 + 15{,}876.64 + 7{,}350.30 + 3{,}402.92.$$

$$\text{NPV} = -50{,}000 + 53{,}378.83 = 3{,}378.83.$$

The IRR, found with a financial calculator, is 10.88%.

6 B is correct.

$$\text{NPV} = \sum_{t=0}^{3} \frac{\text{CF}_t}{(1+r)^t} = -100 + \frac{40}{1.20} + \frac{80}{1.20^2} + \frac{120}{1.20^3} = \$58.33.$$

7 C is correct. The IRR can be found using a financial calculator or by trial and error. Using either method, the IRR is 28.79%. The cost of capital, which is stated as 10%, is not used to solve the problem.

Year	Cash Flow	Present Value			
		28.19%	28.39%	28.59%	28.79%
0	−150,000	−150,000	−150,000	−150,000	−150,000
1	100,000	78,009	77,888	77,767	77,646
2	120,000	73,025	72,798	72,572	72,346
Total		1,034	686	338	−8

A more precise IRR of 28.7854% has a total PV closer to zero.

8 A is correct.

$$\text{NPV} = -750 + \sum_{t=1}^{7} \frac{175}{1.10^t} = -750 + 851.97 = 101.97 \text{ million won.}$$

The IRR, found with a financial calculator, is 14.02%. (PV is −750, $N = 7$, and PMT = 175.)

9 B is correct. The IRR would stay the same because both the initial outlay and the after-tax cash flows double, so the return on each dollar invested would remain the same. All the cash flows and their present values double. The difference between the total present value of the future cash flows and the initial outlay (the NPV) also doubles.

10 C is correct. There are many factors that can affect the stock price, including whether Ms. Ndereba's analysis indicates that the project is more or less profitable than investors expected.

11 A is correct. Since all of Bearing's projects have a positive NPV, they are all providing a return that is greater than the opportunity cost of capital. Therefore, the ROIC must be greater than the COC.

12 C is correct. When valuing mutually exclusive investments, the decision should be made with the NPV method because this method uses the most realistic discount rate—namely, the opportunity cost of funds. In this example, the reinvestment rate for the NPV method (here, 10%) is more realistic than the reinvestment rate for the IRR method (here, 21.86% or 18.92%).

13 B is correct. For these investments, a discount rate of 13.16% would yield the same NPV for both (an NPV of 6.73).

14 C is correct. Discount rates of 0% and approximately 61.8% both give an NPV of zero.

Rate	0%	20%	40%	60%	61.8%	80%	100%
NPV	0.00	4.40	3.21	0.29	0.00	−3.02	−6.25

15 B is correct. Costs to finance the investment are taken into account when the cash flows are discounted at the appropriate cost of capital; including interest costs in the cash flows would result in double-counting the cost of debt.

16 B is correct.

If demand is "high," the NPV is as follows:

$$\text{NPV} = -190 + \sum_{t=1}^{10} \frac{40}{1.10^t} = \text{C\$55.78 million.}$$

If demand is "low," the NPV is

$$\text{NPV} = -190 + \sum_{t=1}^{10} \frac{20}{1.10^t} = -\text{C\$67.11 million.}$$

The expected NPV is 0.50(55.78) + 0.50(–67.11) = –C$5.66 million.

17 B is correct. The additional NPV of adding shifts if demand is "high" is

$$\text{NPV} = \sum\nolimits_{t=2}^{10} \frac{5}{1.10^t} = \text{C\$26.18 million.}$$

If demand is low, the production-flexibility option will not be exercised. The optimal decision is to add shifts only if demand is high.

Because the production-flexibility option is exercised only when demand is high, which happens 50% of the time, the expected present value of adding shifts is

NPV = 0.50(26.18) = C$13.09 million.

The total NPV of the initial project and the production-flexibility option is

NPV = –C$5.66 million + C$13.09 million = C$7.43 million.

The option to add shifts, handled optimally, adds sufficient value to make this a positive-NPV project.

18 B is correct. In valuing investments, expected cash flows should be discounted at required rates of return that reflect their risk, not at a risk-free rate that ignores risk. NPV is superior to IRR. Choosing projects based on IRR might cause the company to concentrate on short-term investments that do not maximize the company's NPV.

Sources of Capital

by Edgar A. Norton, Jr., PhD, CFA, Kenneth L. Parkinson, MBA, CCM, Pamela Peterson Drake, PhD, CFA, and John D. Stowe, PhD, CFA

Edgar A. Norton, Jr., PhD, CFA, is at Illinois State University (USA). Kenneth L. Parkinson, MBA, CCM, is at Treasury Information Services, LLC (USA). Pamela Peterson Drake, PhD, CFA, is at James Madison University (USA). John D. Stowe, PhD, CFA, is at Ohio University (USA).

LEARNING OUTCOMES

Mastery	*The candidate should be able to:*
☐	**a.** describe types of financing methods and considerations in their selection;
☐	**b.** describe primary and secondary sources of liquidity and factors that influence a company's liquidity position;
☐	**c.** compare a company's liquidity position with that of peer companies;
☐	**d.** evaluate choices of short-term funding.

INTRODUCTION

1

Raising capital is a fundamental business activity, and companies have multiple short-term and long-term financing choices. Short-term funds without explicit interest rates, such as accounts payable, are part of **working capital management**, which is the management of short-term assets and liabilities. Other debt and equity obligations used to finance the business longer term are considered part of the firm's **capital structure**. The goal of effective working capital management is to ensure that a company has adequate, ready access to the funds necessary for day-to-day operations, while at the same time making sure that the company's assets are invested in the most productive way. The goal of capital structure management is to balance the risks and costs of the firm's long-term finances. In this reading, we examine a variety of debt and equity claims that companies rely on for their sources of capital. This reading also considers sources of liquidity and how to judge the liquidity positions of firms.

CORPORATE FINANCING OPTIONS

a Describe types of financing methods and considerations in their selection

Businesses have a complex set of assets and liabilities, as illustrated by the financial statements of any publicly traded company. The specific instruments chosen depend on their costs and risks to the borrower (company) and the returns and risks to the investor (equity owner or debtholder), in addition to market conditions, regulatory requirements, and the services of agents, brokers, dealers, and financial intermediaries working in this market. In addition, many other financing options that were also considered are likely not shown on the balance sheet. Here we overview the types of short- and long-term financing sources available to companies. When a company issues stocks and bonds, it is using external sources for funding. Funding can also be generated internally by reinvesting cash flow from operations, delaying payment of liabilities such as accounts payable, or selling or borrowing against assets such as accounts receivable.

Although companies might have an identified target capital structure, in practice, they rarely issue securities in amounts that precisely maintain that target capital structure. For example, if target weights are 20% debt, 20% preferred stock, and 60% common stock, the company would not issue securities in exactly these proportions every time it needs financing. It might issue debt now and common stock or preferred stock the next time it raises capital. However, it tries to keep the overall capital structure near the target over time.

It is important to recognize that the risks of each source of capital are different for the company and for the investor. Debt, for example, is a safer investment than common stock for the investor because it has a higher priority in claims in the event of financial distress. As a result, investors are usually willing to settle for a lower required return from debt securities than from common equity. This is also why the cost of debt to the issuing company is lower than the cost of equity, even on a before-tax basis. From the company's point of view, however, while debt financing is cheaper than equity financing, it is also riskier in that having more debt increases the probability of financial distress.

Exhibit 1 shows some of the major internal and external sources of capital. For large, profitable companies, internal financing is frequently the primary source of funds for financing growth. Short-term sources include financing from operating activities such as accounts payable, short-term loans, and short-term instruments sold, or issued, by the company in the capital markets. To fund longer-term investment activity or for larger amounts of capital, companies have several external financing options. Long-term sources include bonds and leases, common shareholders' equity, and, to lesser extents, hybrids such as preferred shares and convertible debt.

Each of the common sources of finance in Exhibit 1 provide funding for a business and investment opportunities for outside investors.

Exhibit 1 Internal and External Funding Sources

Internal	External		
	Financial intermediaries	Capital markets	Other
After-tax operating cash flows Accounts payable Accounts receivable Inventory & marketable securities	Uncommitted lines of credit Committed lines of credit Revolving credit Secured loans Factoring	Commercial paper Public & private debt Hybrid securities Preferred equity Convertibles Common equity	Leasing

2.1 Internal Financing

Companies can generate internal financing and liquidity from shorter-term operating activities in several ways. These include

- generating more after-tax operating cash flow;
- increasing working capital efficiency, such as extending a company's payables period, reducing its receivables period, or shortening its asset conversion cycle; and
- converting liquid assets such as receivables, inventories, and marketable securities to cash.

Operating Cash Flows

These are the company's after-tax operating cash flows less interest and dividend payments (adjusted for taxes) that can be used to invest in assets and are equal to net income plus depreciation charges minus dividend payments. A company with higher, more predictable after-tax operating cash flows has greater ability to internally finance itself.

Accounts Payable

Accounts payable are amounts due suppliers of goods and services that have not been paid. They arise from **trade credit**, which is a spontaneous form of credit in which a purchaser of the goods or service is, effectively, financing its purchase by delaying the date on which payment is made. Trade credit might involve a delay of payment, with a discount for early payment. The terms of the latter form of credit are generally stated in the discount form: A discount from the purchase price is allowed if payment is received within a specified number of days; otherwise, the full amount is due by a specified date. For example, the terms "2/10, net 30" indicate that a 2% discount is available if the account is paid within 10 days; otherwise, the full amount is due by the 30th day. The terms will differ among industries, influenced by tradition within the industry, terms of competitors, and current interest rates.

Accounts Receivable

Accounts receivable can be thought of as being the opposite of accounts payable. Instead of representing amounts due to suppliers, accounts receivable are amounts owed by customers. In general, businesses prefer to delay paying what they owe, but prefer to receive what is owed to them as quickly as possible. One company's accounts payable represent another company's accounts receivable. The sooner a company can collect what it is owed, the lesser its need to finance its operations in some other way.

Inventory

Like accounts receivable, inventory is a current asset on the balance sheet. These are goods waiting to be sold. Investing in and holding inventory costs money. Companies would prefer not to put a lot of money into inventory when that money could be used for more productive means. The longer the inventory remains unsold, the longer that money is tied up and not usable for other purposes. As a result, an efficient company holds as little inventory as is necessary and sells or turns over the inventory as quickly as possible. Many companies use a just-in-time inventory system, which means the inventory arrives from suppliers when it is needed. That way, it does not sit in storage waiting to be used or sold. This approach makes the supply chain much more efficient, but it also increases the risk of a critical component or item being out of stock when needed. Once inventory is sold, the purchase amount moves into accounts receivable, and the money becomes available once the customer makes payment.

Marketable Securities

Marketable securities are financial instruments, such as stocks and bonds, that can be quickly sold and converted to cash. They are listed as a current asset because the company intends to liquidate them within a year. They could consist of short-term debt that matures within a year, long-term debt, and even common stocks (which have no maturity date) that will be sold within a year. Companies often invest in marketable securities to earn a rate of return that is greater than what they would earn by holding cash. Companies can sell marketable securities if they need funds for any reason, such as when making a capital expenditure.

2.2 Financial Intermediaries

Financial intermediaries can also be a means of financing. These can be bank or non-bank lenders. The main types of short-term bank financing include uncommitted bank lines of credit, committed bank lines of credit and revolving credit agreements, or revolvers. The latter two types can be unsecured or secured, depending on the company's financial strength and the general credit situation, which can vary from country to country. Uncommitted lines and revolvers are more common in the United States, whereas regular committed lines are more common in other parts of the world.

Uncommitted lines of credit are, as the name suggests, the least reliable form of bank borrowing. A bank can offer an uncommitted line of credit for an extended period of time but reserves the right to refuse to honor any request for use of the line. In other words, an uncommitted line is very unstable and is only as good as the bank's desire to offer it. Therefore, companies should not rely very much on uncommitted lines. In fact, banks will not "officially" acknowledge that an uncommitted line is usable, which means that uncommitted lines cannot be shown as a financial reserve in a footnote to the company's financial statements. The primary attraction of uncommitted lines is that they do not require any compensation other than interest.

Committed (regular) lines of credit are the form of bank line of credit that most companies refer to as regular lines of credit. They are more reliable than uncommitted lines because of the bank's formal commitment, which can be verified through an acknowledgment letter as part of the annual financial audit and can be footnoted in the company's annual report. These lines of credit are in effect for 364 days, less than a full year. This term length benefits companies by minimizing amounts needed to meet bank capital requirements. For commitments of a year or longer, banks require more capital. This also effectively ensures that they are short-term liabilities, usually classified as notes payable or the equivalent, on the financial statements.

Regular lines are unsecured and are pre-payable without any penalties. The borrowing rate paid by the company is a negotiated item. The most common interest rates negotiated are borrowing at the bank's prime rate or at a money market rate plus a spread. The most common money market rate is a benchmark reference rate plus a spread. The spread varies depending on the borrower's **creditworthiness**, which is the perceived ability of the borrower to pay its debt obligations in a timely manner and represents the ability of a company to withstand adverse impacts on its cash flows. Regular lines, unlike uncommitted lines, require compensation, usually in the form of a commitment fee to the lender. The fee is typically a fractional percent (e.g., 0.50%) of the full amount or the unused amount of the line, depending on bank–company negotiations.

Revolving credit agreements, also referred to as "revolvers," are the most reliable form of short-term bank borrowing. They involve formal legal agreements that define the aspects of the agreement. These agreements are similar to those for regular lines with respect to borrowing rates, compensation, and being unsecured. Revolvers differ in that they are in effect for multiple years (e.g., three to five years) and can have optional medium-term loan features. In addition, they are often used for much larger amounts than a regular line, and these larger amounts are spread out among more than one bank. With revolvers, borrowers draw down and pay back amounts periodically.

Secured ("asset-based") loans are loans in which the lender requires the company to provide collateral in the form of an asset, such as a fixed asset that the company owns or high-quality receivables and inventory. These assets are pledged against the loan, and the lender files a lien against them. This lien becomes part of the borrower's financial record and is shown on its credit report. Companies that lack sufficient credit quality to qualify for unsecured loans might arrange for secured loans. For example, a company can use its accounts receivable to generate cash flow through the **assignment of accounts receivable**, which is the use of these receivables as collateral for a loan.

A company can also sell its accounts receivable to a lender (called a factor), typically at a substantial discount. In an assignment arrangement, the company remains responsible for the collection of the accounts, whereas in a **factoring arrangement**, the company shifts the credit granting and collection process to the lender or factor. The cost of this credit (i.e., the amount of the discount) depends on the credit quality of the accounts and the costs of collection. Similarly, inventory can be used in different ways as collateral for a loan.

Web-based lenders and **non-bank lenders** are recent innovations not typically used by larger companies. Web-based lenders operate primarily on the internet, offering loans in relatively small amounts, typically to small businesses in need of cash. Non-bank lenders also lend to businesses, but unlike typical banks, which make loans and take deposits, these lenders only make loans.

Many short-term loans have historically been tied to Libor (London Inter-bank Offered Rate), such as Libor plus 0.50% (50 basis points). However, in 2021, Libor and other similar global benchmark rates were replaced with alternative reference rates in the United States, Europe, Switzerland, Great Britain, and Japan. Both bank and non-bank lenders often charge additional commissions and fees beyond the quoted interest rate.

2.3 Capital Markets

Commercial Paper

Commercial paper is a short-term, unsecured instrument typically issued by large and well-rated companies. Commercial paper can be sold directly to investors or through dealers. To avoid registration costs with national regulatory agencies, maturities for commercial paper typically range from a few days up to 270 days. Although a significant amount of asset-backed commercial paper exists, most commercial paper is unsecured, with no specific collateral. It is a feasible source of funds for large, highly creditworthy companies. Issuers of commercial paper are often required to have a backup line of credit. The short-term nature of commercial paper, along with the creditworthiness of the borrower and the backup line of credit, generally make commercial paper a low-risk investment for investors.

Next we look at debt and common equity to contrast these two very different forms of financing, before turning to hybrid securities, which have characteristics of both debt and equity.

Debt vs. Equity Financing

Businesses are generally financed longer term using a combination of debt and equity securities. There are key differences between debt and equity obligations. Exhibit 2 summarizes these differences.

Exhibit 2 Debt vs. Equity Summary

	Debt	**Equity**
Legal Agreement	Company has a contractual obligation to debtholders	Shareholders are residual owners of the company
Claim Priority	Debtholder interest and principal payments have priority	Residual claimants to distributions and corporate assets
Distributions	Periodic, contractual interest payments and repayment of principal at maturity	Discretionary dividend payments declared by the Board of Directors
Taxation (some variation across jurisdictions)	Interest payments are tax-deductible expenses	Dividend payments and share repurchases are not tax-deductible expenses
Term	Stated term to maturity	No finite term
Voting Rights	Generally no voting rights	Voting rights
Cost to Company	Generally lower cost to company	Generally higher cost to company
Investor Risk	Generally lower risk to investors	Generally higher risk to investors

One key difference is that the company has a binding contract with debtholders that requires their claims be fully paid before the company can make distributions to equity owners. In other words, debtholders have a prior legal claim on the company's cash flows and assets over the claims of equity owners. Another difference is that interest payments to debtholders are generally treated as a tax-deductible expense for the company, while dividend payments to shareholders are not. Finally, equity holders represent a more permanent source of capital and have voting rights to elect the board of directors, which oversees the management of the company. In contrast, debt represents a generally cheaper financing source for companies and a lower risk investment than equity.

Long-Term Debt

Long-term debt has a maturity of at least one year. Conventionally, money market instruments have a maturity of less than a year, notes have maturities from one to ten years, and bonds have maturities of at least ten years. Because of their long maturities, bonds are riskier from both an interest rate and credit risk perspective than notes or money market instruments. Hence, bond lenders (investors) and borrowers (companies) agree to bond covenants that are detailed contracts specifying the rights of the lender and restrictions on the borrower (company). These covenants regulate the company's use and disposition of assets, restrict its ability to pay dividends, and restrict its ability to issue additional debt that might dilute the value of a bond.

Public debt is negotiable and approved for sale on open markets. In this context, a negotiable instrument is a written document describing the promise to pay that is transferable and can be sold to another party. Private debt can also be negotiable; however, private debt does not trade on a market. As a result, private debt is more difficult for the holder to sell. While some private debt instruments are not negotiable, such as savings bonds and certificates of deposit, private debt issued by businesses can usually be sold by one party to another.

Common Equity

Common equity, or common shares, represents ownership in a company and is considered a more permanent source of capital. Shareholders have claims on the company's profits after its obligations under other contractual claims are satisfied. Shareholders receive dividends distributed by the company and are entitled to the residual value of the assets if the company goes out of business. Shareholders elect the company's board of directors and thereby, conceptually, at least, have control over how the company is managed and operated.

In addition to publicly traded equity, private equity is an important corporate financing alternative in many countries. Private equity is equity that is not registered with the national security regulatory agency and cannot be traded in the public equity markets. Much private equity consists of family and personal investments in small private businesses. Also, large organizations that are not publicly traded are called private equity firms and provide private equity financing to companies. Some of these private equity firms invest in venture capital firms, and others own a portfolio of publicly and non-publicly traded companies.

Preferred Equity

Preferred shares, or preferred equity, are hybrid securities that are issued by companies and have characteristics of both bonds and common equity. Like interest obligations on debt, dividends on preferred shares are often fixed but can be variable. For example, "participating" preferred shares pay dividends based on a company's profitability. However, preferred dividends paid are not a tax-deductible expense for the company, and unlike with debt instruments, a company can choose to defer or decline to pay dividends on preferred equity. In some cases, preferred dividends are cumulative, meaning the company must pay any skipped preferred dividend payments before it can make any dividend payments on common equity. In case of business failure, bondholders have seniority (have a prior claim) over preferred shareholders on assets or cash flows, and preferred shareholders have similar seniority over common shareholders. Historically, the number of common stock issues by companies and their related proceeds has been substantially greater than financing from preferred issues.

Other Hybrid Securities

Convertible debt and convertible preferreds are hybrid securities issued by companies and are convertible into a fixed number of the companies' common shares. These securities are considered hybrids because they are neither pure equity nor pure debt in nature. They are similar to regular preferred equity or debt but provide the owner with an option to convert to common stock. If the company's share price remains low, there may be no financial benefit to converting, and convertible owners will retain ownership of their convertible security while continuing to receive its dividend or interest payments. If the share price rises sufficiently, however, convertible owners may choose to convert their security to common stock in the company, given the appreciation in value of their investment. The option to convert is a valuable right. As a result, companies can offer smaller dividends or interest payments on convertible securities.

2.4 Other Financing

Leasing Obligations

Some companies might also be able to finance by leasing. In a leasing arrangement, the purchase of an asset and its financing are bundled instead of being separate transactions. In some cases, the leasing of real property or equipment might offer lower joint costs for the company and for suppliers of capital than buying and financing separately. The lease is a debt instrument where the asset owner (the lessor) gives another party (the lessee) the right to use the asset. The lessee agrees to make a set of contractually fixed payments. The leasing contract specifies the length of time the lessee can use the asset, whether the lessee is responsible for maintenance of the asset, and whether the lessee can buy the asset at the end of the leasing period and if so, at what price.

2.5 Considerations Affecting Financing Choices

A company's financing choices depend on the nature of its needs and business, the general economic environment, and market conditions. In different parts of the world, the dominant sources of external financing can be 1) the capital markets, 2) large commercial banks, or 3) the sovereign state. Many countries are assigned to one of these three cases, but in reality, most countries are varying blends of these. Because companies in a particular industry have many common traits, the business models in an industry frequently exhibit similar patterns of external financing.

In addition to geographic location and industry, firm-specific and general economic considerations affect financing choices. These are summarized in Exhibit 3.

Exhibit 3 Financing Considerations

Firm Specific	Macroeconomic
Company size	Taxation
Riskiness of assets	Inflation
Assets for collateral	Government policy
Public versus private equity	Monetary policy
Asset liability management	
Debt maturity structure	
Currency risks	
Agency costs	

Exhibit 3 (Continued)

Firm Specific	Macroeconomic
Bankruptcy costs	
Flotation costs	

2.5.1 *Firm-Specific Financing Considerations*

Company Size The size of a company affects its financing options. Small companies generally do not have access to funding sources such as commercial paper and publicly issued debt and equity. Smaller companies might not have the positive and predictable cash flows needed to meet fixed, periodic debt payments. Large companies with strong operating cash flows can rely more heavily on internal financing, while smaller companies, especially those that are younger and faster growing, or without cash flow, cannot satisfy their capital needs internally and must rely more on external financing—in particular, private equity. Because smaller companies typically lack the positive, predictable cash flows often required by lenders, and because debt financing may not be available or is too expensive, equity financing is usually the predominant source of financing.

Riskiness of Assets Companies with higher volatility of operating cash flows rely primarily on equity financing and tend to use little if any debt financing. High levels of uncertainty or volatility in operating cash flows can make servicing debt obligations challenging. Companies having a high degree of business risk may seek to minimize financial risks and leverage. Business risks are non-financial risks for the company and include technological change, political risks, marketing and production uncertainties, managerial risks, and many others. For example, Moderna, an American biotechnology company best known for using a unique technology to develop a vaccine for COVID-19, has some lease obligations but does not use other kinds of debt financing. NIO Inc., a Chinese electric car manufacturer, used very little debt financing until unit sales and revenues began to accelerate.

Assets for Collateral Real property and equipment are good collateral for mortgages and asset-backed bonds. In the case of bankruptcy, mortgage bondholders have first claim on the collateral and are still general creditors for any claims left unsatisfied by repossession of the collateral. Assets that are unique, highly specialized, and intangible might not be valuable as collateral. Sound collateral can increase a company's access to debt financing as well as reduce its costs. Macy's, for example, operates department stores across the United States and owns a significant amount of real estate, which it can easily borrow against. In contrast, Workhorse Group, a US manufacturer of medium-duty electric trucks, has little revenues and assets that cannot be easily converted to other uses. As a result, the company has more difficulty issuing debt at favorable terms.

Public vs. Private Equity For companies that have issued public equity, shares are available and easily traded through public stock markets. For companies that finance through private equity, shares are available directly from the company or from non-public transactions. The extraordinary size of many publicly traded companies could not be attained without public trading of their securities. Many private companies are simply too small to sell their debt and equity securities publicly. An advantage large, publicly traded companies have is that their securities are liquid and trade frequently, while private company claims are not liquid and do not trade in secondary markets. Some large private equity firms are organized as limited partnerships and own a portfolio of large companies, some of which were once publicly traded, were bought by the private equity firm, and are no longer traded. One perceived advantage private equity firms have is that they can reduce the agency costs associated with manager and shareholder conflicts of interest.

Asset Liability Management Businesses tend to match the maturity structures of their assets and liabilities. A mismatch of asset and liability maturity structures can be problematic. For example, if a company finances its long-term assets with short-term obligations, its profitability might be threatened if the cost of its short-term financing increases. Commercial banks carefully manage the maturity structure of their asset portfolios with the maturity structure of their financing. Non-financial businesses such as utilities, manufacturing firms, real estate firms, and others that have long-term assets can safely use more long-term financing than firms with short-term assets.

Debt Maturity Structure If interest rates on short-term debt are generally less than those on long-term debt, a less expensive option for the company would be to finance with short-term debt and continually refinance with new short-term debt whenever current debt matures. This risk, sometimes called rollover risk, materializes when interest rates go up or when company-specific or general economic conditions cause the company to be unable to refinance or issue new debt.

Currency Risks A company's business revenues and its financing can be in different currencies. For example, suppose the company's business operations are in the domestic currency and its debt financing is in a foreign currency. If the domestic currency declines in value, the company might not be able to repay its debts. Short-term debt contracts can be hedged in derivatives markets with currency swaps, options, and forwards. However, because the market for long-term derivatives is relatively small, the company's best option to hedge currency risks is to execute its debt and equity financing in the same currency as its business operations. Large, well-rated multinational companies will finance themselves in different currencies to match the currency exposure of their local operations.

Agency Costs Debtholders can suffer losses if the borrowing company increases its riskiness beyond its original expectations. This can occur in several ways. A major risk is asset substitution, wherein the company replaces assets that were fairly safe with much riskier assets. The risk of financial distress or default rises for unsecured lenders if the company distributes too much cash to owners or managers, or pledges significant assets to secured creditors. The company can also become riskier if it uses more financial leverage, replacing equity financing with increased levels of new debt financing. Debtholders try to protect their interests by having bond covenants that restrict the company from taking certain actions that would be detrimental to bondholders. Debt covenants are often used in bank revolvers and some lines of credit.

Bankruptcy Costs The costs and risks of financing a business are normally shared among debtholders and shareholders. Bankruptcy introduces additional costs, with some company resources being consumed by third parties, the legal system, and other administrative costs of bankruptcy, which is a net loss to the company's suppliers of capital. The possibility of bankruptcy and the costs of financial distress can also affect customers, suppliers, managers, employees, and the community at large. Because of these costs, suppliers of capital might be averse to financial structures that risk bankruptcy.

Flotation Costs A publicly traded company incurs flotation costs when it issues new debt or equity securities. These costs can include various expenses that are company specific, such as legal fees, registration fees, audit fees, and underwriting fees. Flotation costs as a percentage of the capital raised are generally lower for debt offerings than for equity offerings. Flotation costs increase the cost of financing and can affect a company's financing decisions.

2.5.2 *General Economic Considerations*

In addition to company-specific considerations, economic factors and governmental policies external to the company affect its financing choices.

Taxation The cost of debt financing is typically lower than the cost of equity financing. If interest payments on debt financing are tax-deductible and distributions on equity financing are not, the after-tax cost of debt financing is even more attractive, relative to equity financing, for profitable companies. By allowing interest payments to be tax-deductible, governments provide companies an incentive to use more financial leverage. However, greater use of debt by companies increases the risk of financial distress, particularly during economic downturns.

Inflation Normally, the nominal rate of return is a sum of the real rate and the expected inflation rate. However, uncertainty over inflation rates can make longer-term, fixed-rate contracts unattractive to the company (borrower) or investor (lender). If inflation is expected to rise, companies would prefer to borrow at a fixed rate, while investors would prefer to lend at a variable rate. If inflation is expected to decline, the opposite would be true.

Government Policy Governmental fiscal policies can be used to stimulate the economy or to subsidize specific industries. A government agency, for example, can directly make loans at lower interest rates than would be required by capital markets. The government can provide loan guarantees where the principal and interest payments are guaranteed, which would increase capital amounts and lower the interest rates on the guaranteed loans.

Monetary Policy Central banks around the world have at times driven interest rates to historically low and even negative levels. The intent was to stimulate economies by making access to capital cheaper for companies and to give investors an incentive to take more risk with their cash. Many companies used the opportunity to increase leverage at low rates to refinance existing debt and repurchase common stock with the proceeds rather than make capital investments.

EXAMPLE 1

Estimating External Financing Needs

Fllama Company is planning its sources of financing for a substantial investment of £30 million next year. The assumptions for Fllama's plan are the following:

- Investments of £5 million in receivables and £5 million in inventory. Fixed capital investments of £20 million, including £5 million to replace depreciated equipment and £15 million of net new investments. Total investments will be £30 million.
- Net income of £10 million and depreciation charges of £5 million. Dividend payments will be £4 million.
- Short-term financing from accounts payable of £3 million is expected. The company will use receivables as collateral for another £3 million loan. The company will also issue a £4 million short-term note to a commercial bank.
- Any additional external financing needed can be raised from an increase in long-term bonds. If additional financing is not needed, any excess funds will be used to repurchase common shares.

Part A: Describe how Fllama would determine its financing needs.

Part B: How much, if any, does Fllama need to issue in long-term bonds?

A Fllama does not need to issue any bonds.

B Fllama will need to issue £4 million of bonds.

C Fllama will need to issue £9 million of bonds.

Solution:

Part A: Fllama should begin by considering its various sources of net cash to determine whether its net cash is sufficient to meet its investment needs. The facts state that the company will generate net income and will also have depreciation charges and make dividend payments. Because depreciation is a non-cash expense, it should be added to net income as a source of cash. Dividends, however, are paid from net income, are a use of cash, and reduce the net cash available for funding. Other sources of cash include the amounts generated from accounts payable, accounts receivable, and the short-term note from the bank.

Part B: C is correct. Fllama must issue £9 million of bonds.

Source	Amount (£)
Internal Financing	
Operating cash flow (Net income + depreciation – dividends)	11,000,000
Accounts payable	3,000,000
Short-Term Intermediary Financing	
Bank loan against receivables	3,000,000
Short-term note	4,000,000
Total sources	21,000,000

Because the company requires £30 million of financing and the planned sources total £21 million, Fllama will need to issue £9 million of new bonds.

3 MANAGING AND MEASURING LIQUIDITY

b describe primary and secondary sources of liquidity and factors that influence a company's liquidity position

Liquidity is the extent to which a company is able to meet its short-term obligations using cash flows and those assets that can be readily transformed into cash. When we evaluate the liquidity of an asset, we focus on two dimensions: the type of asset and the speed at which the asset can be converted to cash, either by sale or financing. Unlike many aspects of corporate finance, corporate liquidity management does not involve a great deal of theory or generally accepted principles. For companies that have the luxury of large excesses of cash, liquidity is typically taken for granted, and the focus is on putting the excess liquidity to its most productive use. In the event no productive use within the company can be identified, shareholders will pressure companies to return this cash to owners in the form of share buybacks or dividends. On the other hand, when a company faces tighter financial situations, having effective liquidity management is important to ensure solvency. Unfortunately, this recognition comes too late for some companies, with bankruptcy and possible liquidation representing the companies' final choice.

3.1 Defining Liquidity Management

Liquidity management refers to an organization's ability to generate cash when and where it is needed. Liquidity refers to the cash balances, borrowing capacity, and ability to convert other assets or extend other liabilities into cash for use in keeping the entity solvent (i.e., being able to pay bills and continue in operation). For the most part, we associate liquidity with short-term assets and liabilities, yet longer-term assets such as marketable securities can be converted into cash to provide liquidity. In addition, longer-term liabilities can also be renegotiated to reduce the drain on cash, thereby providing liquidity by preserving the limited supply of cash. Of course, these last two methods might come at a price because they tend to reduce the company's overall financial strength.

The challenges of managing liquidity include developing, implementing, and maintaining a liquidity policy. To do this effectively, a company must manage all its key sources of liquidity efficiently. These key sources can vary from company to company, but they generally include primary sources of liquidity, such as cash balances, and secondary sources of liquidity, such as selling assets.

3.1.1 *Primary Sources of Liquidity*

Primary sources of liquidity represent the most readily accessible resources available. They can be held as cash or as near-cash securities. Primary sources include the following:

- Free cash flow, which is the firm's after-tax operating cash flow less planned short- and long-term investments. For a profitable firm, free cash flow provides substantial liquidity. A rapidly growing firm has less free cash flow because of the investments required to facilitate the firm's growth.
- Ready cash balances, which is cash available in bank accounts, resulting from payment collections, investment income, liquidation of near-cash securities (i.e., those with maturities of fewer than 90 days), and other cash flows.
- Short-term funds, which can include items such as trade credit, bank lines of credit, and short-term investment portfolios.
- Cash flow management, which is the company's effectiveness in its cash management system and practices, and the degree of decentralization of the collections or payments processes. The more decentralized the system of collections, for example, the more likely the company will be to have cash tied up in the system and not available for use.

These sources represent liquidity that is typical for most companies. They represent funds that are readily accessible at relatively low cost.

3.1.2 *Secondary Sources of Liquidity*

The main difference between primary and secondary sources of liquidity is that using a primary source is not likely to affect the normal operations of the company, whereas using a secondary source might result in a change in the company's financial and operating positions. Secondary sources include

- negotiating debt contracts, relieving pressures from high interest payments or principal repayments, and negotiating contracts with customers and suppliers;

- liquidating assets, which depends on the degree to which short-term and/or long-term assets can be liquidated and converted into cash without substantial loss in value; and
- filing for bankruptcy protection and reorganization.

The use of secondary sources might signal a company's deteriorating financial health and provide liquidity at a high price—the cost of giving up a company asset to produce emergency cash. This last source, reorganization through bankruptcy, can also be considered a liquidity tool because a company under bankruptcy protection that generates operating cash will be liquid and generally able to continue business operations until a restructuring has been devised and approved. However, this option is likely to be at a significant cost, or disadvantage, to existing equityholders.

Example 2 shows the net proceeds from the primary and secondary sources of liquidity for a company in a financial crisis. The example also shows the liquidation costs incurred by the company when using these sources to raise funds. These costs can include the fees and commissions involved with the asset sale as well as any discount in asset value due to illiquidity issues.

EXAMPLE 2

Estimating Costs of Liquidity for OM Distributors

One of the companies in your portfolio, OM Distributors (OM), is having a liquidity crisis. You have identified four potential actions that OM could take to raise funds. You have estimated, in local currency, the fair value of the assets and the liquidation costs OM might incur.

Source of Funds	Fair Value (Local, millions)	Liquidation Cost (%)
Sell short-term marketable securities	10	0
Sell select inventories and receivables	20	10
Sell excess real estate property	50	15
Sell a subsidiary of the firm	30	20

The liquidation costs include the fees and commissions of selling an asset as well as any reduction in the value of the asset, because it is an illiquid asset being sold quickly. In this case, liquidation costs for marketable securities are rounded to 0%.

Net of liquidation costs how much liquidity can OM raise if all four sources of funds are used, and what are the total liquidation costs incurred by OM? In local currency, these amounts are:

A 110 million, 9.5 million

B 94.5 million, 15.5 million

C 125.5 million, 15.5 million

Solution:

The costs and net funds raised are summarized in this table:

Source of Funds	Fair Value (local, millions)	Liquidation Costs %	Liquidation Costs (local, millions)	Net Proceeds (local, millions)
Marketable securities	10	0	0	10
Inventories & receivables	20	10	2	18
Real estate property	50	15	7.5	42.5
Subsidiary of the firm	30	20	6	24
Total			15.5	94.5

B is correct. Shown in the table above in local currency terms, the total net proceeds are 94.5 million, and the total liquidation costs incurred are 15.5 million.

3.1.3 *Drags and Pulls on Liquidity*

Cash flow transactions—that is, cash receipts and disbursements—have significant effects on a company's liquidity position. We refer to these effects as drags and pulls on liquidity. A **drag on liquidity** is when receipts lag, creating pressure from the decreased available funds; a **pull on liquidity** is when disbursements are paid too quickly or trade credit availability is limited, requiring companies to expend funds before they receive funds from sales that could cover the liability.

Major drags on receipts involve pressures from credit management and deterioration in other assets and include the following:

- *Uncollected receivables.* The longer these are outstanding, the greater the risk that they will not be collected at all. They are indicated by the large number of days of receivables and high levels of bad debt expenses. Just as the drags on receipts might cause increased pressure on working capital, pulls on outgoing payments could have similar effects.
- *Obsolete inventory.* If inventory stands unused for long periods, it might be an indication that it is no longer usable. Slow inventory turnover ratios can also indicate obsolete inventory. Once identified, obsolete inventory should be attended to as soon as possible to minimize storage and other costs.
- *Tight credit.* When economic conditions make capital scarcer, short-term debt becomes more expensive to arrange and use. Attempting to smooth out peak borrowings can help blunt the impact of tight credit, as can improving the company's collections.

In many cases, drags can be alleviated by stricter enforcement of credit and collection practices.

However, managing the cash outflows might be as important as managing the inflows. If suppliers and other vendors who offer credit terms perceive a weakened financial position or are unfamiliar with a company, they might restrict payment terms so much that the company's liquidity reserves are stretched thin. Major pulls on payments include the following:

- *Making payments early.* By paying vendors, employees, or others before the due dates, companies forgo the use of funds. Effective payment management means not making early payments. Payables managers typically hold payments until they can be made by the due date.

- *Reduced credit limits.* If a company has a history of making late payments, suppliers might cut the amount of credit they will allow to be outstanding at any time, which can squeeze the company's liquidity. Some companies try to extend payment periods as long as possible, disregarding the possible impact of reduced credit limits.
- *Limits on short-term lines of credit.* If a company's bank reduces the line of credit it offers the company, a liquidity squeeze might result. Credit line restrictions can be government mandated, market related, or simply company specific. Many companies try to avert this situation by establishing credit lines far in excess of what they are likely to need. This "overbanking" approach is often commonplace in emerging economies or even in more-developed countries when the banking system is not sound and the economy is shaky.
- *Low liquidity positions.* Many companies face chronic liquidity shortages, often because of their particular industry or from their weaker financial position. The major remedy for this situation is, of course, to improve the company's financial position, perhaps by issuing additional equity or hybrid securities. If not, the company could be heavily affected by interest rates and credit availability, in which case it might have to turn to secured borrowing to obtain working capital funds. Therefore, these companies must identify ahead of time the assets that can be used to help support their short-term borrowing activities.

Identifying these drags and pulls as soon as possible is critical, including before they happen or when they have just arisen. In Example 3, an analyst is trying to identify changes in the firm that are affecting the its liquidity position.

EXAMPLE 3

Drags and Pulls on Liquidity

Arya Rajavade's firm is experiencing liquidity challenges. Several things might be contributing to this. Rajavade is reviewing three notable changes that have been suggested to her as drags or pulls on liquidity:

- The increasing days in receivables are a drag on liquidity.
- Lower inventory turnover is a drag on liquidity
- Increased credit limits by lenders is a pull on liquidity.

Which of these does not contribute to the firm's tight liquidity situation?

A The change in days in receivables

B The change in inventory turnover

C The change in credit limits

Solution:

C is correct. The increase in credit limits is not a pull on liquidity but is in fact the opposite; it provides liquidity.

3.2 Measuring Liquidity

c compare a company's liquidity position with that of peer companies

Liquidity contributes to a company's creditworthiness. Creditworthiness allows the company to obtain lower borrowing costs and better terms for trade credit and contributes to the company's investment flexibility, enabling it to exploit profitable opportunities.

The less liquid the company, the greater the risk it will suffer financial distress or, in the extreme case, insolvency or bankruptcy. Because debt obligations are paid with cash, the company's cash flows ultimately determine solvency. Immediate sources of funds for paying bills are cash on hand, proceeds from the sale of marketable securities, and the collection of accounts receivable. Additional liquidity comes from inventory that can be sold and thus converted into cash, either directly through cash sales or indirectly through credit sales (i.e., accounts receivable).

At some point, however, a company might have too much invested in low- and non-earning assets. Cash, marketable securities, accounts receivable, and inventory represent a company's liquidity, but these investments are low earning relative to the long-term, capital investment opportunities that companies might have available.

Various financial ratios can be used to assess a company's liquidity as well as its management of assets over time. Here we will look at some of these ratios in a little more detail. Introduced in the coverage of Financial Reporting and Analysis, several liquidity and activity ratios are summarized in Exhibit 4.

Exhibit 4 Ratios Used for Assessing Company Liquidity

Liquidity Ratios
$\text{Current ratio} = \dfrac{\text{Current assets}}{\text{Current liabilities}}$
$\text{Quick ratio} = \dfrac{\text{Cash} + \text{Short-term marketable instruments} + \text{Receivables}}{\text{Current liabilities}}$
$\text{Cash ratio} = \dfrac{\text{Cash} + \text{Short-term marketable instruments}}{\text{Current liabilities}}$
Activity Ratios
$\text{Accounts receivable turnover} = \dfrac{\text{Credit sales}}{\text{Average receivables}}$
$\text{Inventory turnover} = \dfrac{\text{Cost of goods sold}}{\text{Average inventory}}$
$\text{Number of days of receivables} = \dfrac{\text{Average accounts receivable}}{\text{Average day's sales on credit}} = \dfrac{\text{Average accounts receivable}}{\text{Sales on credit/365}}$
$\text{Number of days of inventory} = \dfrac{\text{Average inventory}}{\text{Average day's cost of goods sold}} = \dfrac{\text{Average inventory}}{\text{Cost of goods sold/365}}$

(continued)

Exhibit 4 (Continued)

$$\text{Number of days of payables} = \frac{\text{Average accounts payable}}{\text{Average day's purchases}}$$

$$= \frac{\text{Average accounts payable}}{\text{Purchases/365}}$$

Cash conversion cycle = Days of inventory + Days of receivables − Days of payables

We calculate **liquidity ratios** to measure a company's ability to meet short-term obligations to creditors as they mature or come due. This form of liquidity analysis focuses on the relationship between current assets and current liabilities and the rapidity with which receivables and inventory can be converted into cash during normal business operations. The levels of these ratios, trends or changes in the ratios over time, and comparisons with competitors or the industry are used to judge a firm's liquidity position.

In addition to looking at the relationships among these balance sheet accounts, we can also estimate **activity ratios**, which measure how well key current assets are managed over time. These ratios use information from the income statement and the balance sheet to help tell the story of how well a company is managing its liquid assets.

Some of the major applications of this type of analysis include performance evaluation, monitoring, creditworthiness assessment, and financial projections. But ratios are useful only when they can be compared. The comparison should be done in two ways: comparisons over time for the same company and over time for the company compared with its peer group. Peer groups can include competitors from the same industry as the company as well as other companies of comparable size with comparable financial situations.

Consider Daimler AG, a producer of cars, trucks, and vans. We can see the change in the company's current, quick, and cash ratios over a decade, the fiscal years 2010 through 2019, in Exhibit 5, Panel A. Here, we see that the current ratio and the quick ratio increased over the time period. The cash ratio, over the decade, did not show the upward trend that the quick and current ratios exhibited. We can see what is driving these trends in the calculation of the cash conversion cycle in Panel B of the exhibit. Over the 10 years, the cash conversion cycle increased by more than 40 days. The slight increase in days of payables outstanding would have decreased the cash conversion cycle slightly. The days of inventory increased by approximately 9 days, and the days of receivables increased by approximately 37 days. Although the increase in inventory certainly puts a demand on liquidity, for Daimler, the impact of the increase in receivables was more dramatic. Over the decade, however, based on the liquidity and activity ratios, this company seemed to have good control of its liquidity position.

Exhibit 5 Liquidity Analysis of Daimler AG, 10 Years Ending December 2019

	2019	**2018**	**2017**	**2016**	**2015**	**2014**	**2013**	**2012**	**2011**	**2010**
Panel A: Current, Quick, and Cash Ratios, December 2010–2019										
Current Ratio	1.21	1.24	1.22	1.21	1.19	1.15	1.19	1.15	1.11	1.07
Quick Ratio	0.93	0.94	0.93	0.91	0.88	0.84	0.90	0.85	0.80	0.80
Cash Ratio	0.25	0.25	0.26	0.25	0.23	0.23	0.30	0.26	0.20	0.25

Exhibit 5 (Continued)

	2019	2018	2017	2016	2015	2014	2013	2012	2011	2010
Panel B: Days of Inventory, Receivables, Payables, and Cash Conversion Cycle, December 2010–2019										
Days of Inventory on Hand	75.2	74.9	71.6	73.9	69.1	68.5	69.2	71.5	71.2	66.6
+ Days of Receivables	136.8	127.9	118.8	118.4	104.6	102.6	105.5	104.6	104.2	100.0
– Days of Payables Outstanding	34.1	35.2	33.6	32.8	31.3	33.4	35.5	37.4	37.5	31.6
= Cash Conversion Cycle	177.9	167.6	156.8	159.5	142.4	137.7	139.2	138.7	137.9	135.0

Now consider Walmart, Target Corporation, Kohl's Corporation, and Costco Wholesale Corporation. Selected ratios for these large US discount retailers are shown in Exhibit 6. The data are from the fiscal year ending January 2020, except for Costco, whose fiscal year ended in August 2019. We see some differences among these four competitors. These differences can be explained, in part, by the retailers' different product mixes (e.g., Walmart and Costco have more sales from grocery lines than the other two), as well as their different inventory management systems and different inventory suppliers. None of the four firms invests heavily in accounts receivable, and customers generally pay with credit cards. The different need for liquidity can also be explained, in part, by the companies' different operating cycles. The most striking difference is for Kohl's. Walmart, Target, and Costco have investments in inventory that are largely matched and paid for by accounts payable. Kohl's, notably, has the highest investment in inventory, which is not financed by payables. Because it includes more of such items as clothing, Kohl's inventory is also more seasonal than that of the other companies. Hence, Kohl's has the highest current ratio because much of its inventory must be financed by non-current liabilities.

Exhibit 6 Liquidity Ratios among Discount Retailers

	Company			
Ratio for January 2020 Fiscal Year	**Walmart**	**Target**	**Kohl's**	**Costco**
Current ratio	0.79	0.89	1.68	1.01
Quick ratio	0.22	0.27	0.40	0.52
Days of inventory on hand	41.0	59.1	98.0	30.8
Days of receivables	4.4	4.5	0.4	3.8
Days of payables outstanding	43.5	56.2	33.3	31.4
Cash conversion cycle	1.9	7.4	65.1	3.2

EXAMPLE 4

Measuring Liquidity

Given the following ratios, how well has the company been managing its liquidity?

	Current Fiscal Year		Average for the Previous Five Fiscal Years	
Ratio	**Company**	**Industry**	**Company**	**Industry**
Current ratio	1.9	2.5	1.1	2.3
Quick ratio	0.7	1.0	0.4	0.9
Days of receivables	39.0	34.0	44.0	32.5
Days of inventory on hand	41.0	30.3	45.0	27.4
Days of payables outstanding	34.3	36.0	29.4	35.5

Solution:

The ratios should be compared in two ways: over time (the trend over time would typically be examined) and with the trend in the industry. In all ratios shown here, the current year shows improvement over the previous years in terms of increased liquidity. In each case, however, the company remains behind the industry average in terms of liquidity. A brief snapshot such as this example could be the starting point in assessing management's ability to deliver future improvement and reach or beat the industry standards.

4

EVALUATING SHORT-TERM FINANCING CHOICES

d evaluate choices of short-term funding

Because so many short-term financing alternatives are available, the company must know how various financing instruments and markets can affect its liquidity position and risks. The costs of the financing alternatives can also be crucial.

When companies do not explore their options sufficiently, their liquidity might be inadequate, and they might not take advantage of cost savings that some forms of borrowing offer. This situation can arise if a company's treasurer is not familiar with the common forms of short-term borrowing or has not formulated an effective borrowing strategy. Given the various forms of short-term borrowing, having a planned strategy is essential for a borrower to avoid getting stuck in an uneconomical situation. If a company spends too little time establishing a sound strategy for its short-term borrowing, in a crisis, it might not be able to borrow at all, from any source.

The major objectives of a short-term borrowing strategy include the following:

- Ensuring that sufficient capacity exists to handle peak cash needs
- Maintaining sufficient sources of credit to be able to fund ongoing cash needs
- Ensuring that rates obtained are cost-effective and do not substantially exceed market averages

In addition, several factors will influence a company's short-term borrowing strategies, such as the following:

- *Size and creditworthiness.* A borrower's size can dictate the options available. Larger companies can take advantage of economies of scale to access commercial paper, banker's acceptances, and so on. The lender's size is also an important criterion, because larger banks have higher house or legal lending limits. The borrower's creditworthiness will determine the rate, compensation, or even whether the loan will be made at all.
- *Legal and regulatory considerations.* Some countries impose constraints on how much a company can borrow and under what terms it can borrow. Structure is usually greater for companies operating in developed countries with well-defined legal systems than for those operating in countries with emerging economies. Also, in developed countries, some industries are strongly regulated. Regulated companies, such as utilities and banks, might be restricted in how much they can borrow and the kind of borrowing they can engage in. Utilities typically have steady and predictable income streams and are often allowed to borrow larger amounts. Banks in the United States have come under greater scrutiny since the financial crisis and recession of 2007–2009. They are now required to have a greater amount of equity capital.
- *Sufficient access.* Borrowers should diversify to have adequate alternatives and not be too reliant on one lender or form of lending if the amount of their borrowing is very large. Even so, using one alternative primarily, but often with more than one provider, is typical for borrowers. Borrowers should be ready to go to other sources and know how to do so. Borrowers should not stay too long with just one source or with the lowest rates. Many borrowers are usually prepared (somewhat) to trade rates for certainty. Market power can help a company dictate more favorable terms for accounts payable, allowing it to delay payments without having to forgo discounts. Having marketable securities on hand that can be quickly sold to meet short-term needs is also helpful.
- *Flexibility of borrowing options.* Flexibility means the ability to manage maturities efficiently; that is, there should not be any "big" days, when significant amounts of loans mature. To effectively manage loan maturities, borrowers need active maturity management, awareness of the market conditions (e.g., knowing when the market or certain maturities should be avoided), and the ability to pre-pay loans when unexpected cash receipts occur.

Borrowing strategies, like investment strategies, can be either passive or active. Passive strategies usually involve minimal activity, with one source or type of borrowing and with little (if any) planning. A passive strategy is often reactive in responding to immediate needs for liquidity. Passive strategies are characterized by steady, often routine rollovers of borrowings for the same amount of funds each time, without much comparison shopping. Passive strategies might also arise when borrowing is restricted, such as when borrowers are limited to one or two lenders by agreement (e.g., in a secured loan arrangement).

Active strategies are usually more flexible and reflect planning, reliable forecasting, and comparison pricing. With active strategies, borrowers are more in control and do not fall into the rollover "trap" that is possible with passive strategies.

Many active strategies are matching strategies. Matching borrowing strategies function in a manner similar to matching investment strategies: loans are scheduled to mature when large cash receipts are expected. These receipts can pay back the loan, so the company does not have to invest the funds at potentially lower rates than the borrowing cost, thereby creating unnecessary costs.

EXAMPLE 5

Evaluating Short-Term Choices

When contemplating the possibilities for short-term financing needs, a company should consider which of the following items?

A Cost of the funds borrowed

B The flexibility offered by the source

C The ease with which the funds can be accessed

D Any legal or regulatory constraints that might favor one source over another

E All of the above

Solution

The correct answer is E. Cost of funds is the most obvious item to consider, but borrowing at a slightly higher cost sometimes makes sense when taking all the other items into consideration.

EXAMPLE 6

Meeting Short-Term Financing Need

The Keown Corp. has accounts payable of €2 million with terms of 2/10, net 30. Accounts receivable also stands at €2 million. In addition, the company has €5 million in marketable securities. Keown has a short-term need of €200,000 to meet payroll. Which of the following options makes the most sense for raising the €200,000?

A The company should issue long-term debt.

B The company should issue common stock.

C The company should delay paying accounts payable and forgo the 2% discount.

D The company should sell some of its accounts receivable to a factor at a 10% discount.

E The company should sell some of its marketable securities at a 0.5% brokerage cost.

Solution:

A and B would not be appropriate for raising €200,000 for a short-term need. These options take time to arrange, and they are more appropriate for long-term capital needs and for much larger financing amounts.

C, D, and E are all appropriate options for meeting short-term financing needs. However, C and D are costly.

The options for raising €200,000 are summarized in this table:

Source of Funds	Action	Liquidation Costs %	 €
C. Accounts payable (2/10, net 30)	Delay €200,000 in payment, and forgo 2% discount	2.0	4,000
D. Accounts receivable	Sell €222,222 in value at 10% discount to raise €200,000	10.0	22,222
E. Marketable securities	Sell €200,000 in value	0.5	1,000

Choosing C means forgoing a 2% discount, which on €200,000 amounts to a cost of €4,000. To net €200,000 using option D, the company would have to sell €222,222 of accounts receivable to a factor, representing a cost of €22,222. E appears to be the best choice. Marketable securities are liquid and can be easily sold for market value, less the relatively minor brokerage cost of €1,000.

SUMMARY

In this reading, we considered key aspects of capital alternatives and short-term financial management: the financing choices available to a company and effective liquidity management. Both are critical in ensuring a company's solvency and ability to remain in business. If done improperly, the results can be disastrous for the company.

This reading covered the following:

- Describing internal and external sources of capital and the considerations that lead to their selection
- Describing primary and secondary sources of liquidity and factors that can enhance a company's liquidity position
- Understanding how to evaluate a company's liquidity position and comparing it to peer companies
- Evaluating the short-term financing choices available to a company based on their characteristics and their effective costs.

PRACTICE PROBLEMS

1 Two analysts are discussing the costs of external financing sources. The first states that the company's bonds have a known interest rate but that the interest rate on accounts payable and the interest rate on equity financing are not specified. They are implicitly zero. Upon hearing this, the second analyst advocates financing the firm with greater amounts of accounts payable and common shareholders equity. Is the second analyst correct in his analysis?

A He is correct in his analysis of accounts payable only.

B He is correct in his analysis of common equity financing only.

C He is not correct in his analysis of either accounts payable or equity financing.

2 A company has arranged a $20 million line of credit with a bank, allowing the company the flexibility to borrow and repay any amount of funds as long as the balance does not exceed the line of credit. These arrangements are called:

A convertibles.

B factoring.

C revolvers.

3 SOA Company needs to raise 75 million, in local currency, for substantial new investments next year. Specific details, all in local currency, are as follows:

Investments of 10 million in receivables and 15 million in inventory. Fixed capital investments of 50 million, including 10 million to replace depreciated equipment and 40 million of net new investments.

Net income is expected to be 30 million, and dividend payments will be 12 million. Depreciation charges will be 10 million.

Short-term financing from accounts payable of 6 million is expected. The firm will use receivables as collateral for an 8 million loan. The firm will also issue a 14 million short-term note to a commercial bank.

Any additional external financing needed can be raised from an increase in long-term bonds. If additional financing is not needed, any excess funds will be used to repurchase common shares.

What additional financing does SOA require?

A SOA will need to issue 19 million of bonds.

B SOA will need to issue 26 million of bonds.

C SOA can repurchase 2 million of common shares.

4 Kwam Solutions must raise €120 million. Kwam has two primary sources of liquidity: €60 million of marketable securities (which can be sold with minimal liquidation/brokerage costs) and €30 million of bonds (which can be sold with 3% liquidation costs). Kwam can sell some or all of either of these portfolios. Kwam has a secondary source of liquidity, which would be to sell a large piece of real estate valued at €70 million (which would incur 10% liquidation costs). If Kwam sells the real estate, it must be sold entirely (a fractional sale is not possible). What is the lowest cost strategy for raising the needed €120 million?

A Sell €60 million of the marketable securities, €30 million of the bonds, and €34.3 million of the real estate property.

B Sell the real estate property and €50 million of the marketable securities.

© 2021 CFA Institute. All rights reserved.

C Sell the real estate property and €57 million of the marketable securities.

5 A company increasing its credit terms for customers from 1/10, net 30, to 1/10, net 60, will *most likely* experience:

A an increase in cash on hand.

B a lower level of uncollectible accounts.

C an increase in the average collection period.

6 Paloma Villarreal has received three suggestions from her staff about how to address her firm's liquidity problems.

Suggestion 1. Reduce the firm's inventory turnover rate.

Suggestion 2. Reduce the average collection period on accounts receivable.

Suggestion 3. Accelerate the payments on accounts payable by paying invoices before their due dates.

Which suggestion should Villarreal employ to improve the firm's liquidity position?

A Suggestion 1

B Suggestion 2

C Suggestion 3

7 Selected liquidity ratios for three firms in the leisure products industry are given in the table below. The most recent fiscal year ratio is shown, along with the average of the previous five years.

	Company H		Company J		Company S	
	Most recent	Five-year average	Most recent	Five-year average	Most recent	Five-year average
Current ratio	5.37	2.51	3.67	3.04	3.05	2.53
Quick ratio	5.01	2.19	2.60	2.01	1.78	1.44
Cash ratio	3.66	0.97	1.96	1.28	0.96	0.67

Relative to their peers and relative to their own prior performance, which company is in the most liquid position?

A Company H

B Company J

C Company S

8 An analyst is examining the cash conversion cycles and their components for three companies that she covers in the leisure products industry. She believes that changes in the investments in these working capital accounts can reveal liquidity stresses on a company.

	2021	2020	2019	2018	2017	2016
Company H						
Days of Inventory on Hand	68.4	70.5	60	57.8	59.8	59.8
+ Days of Receivables	101.8	103.4	95.6	92.4	94.7	93.3
– Days of Payables Outstanding	52.1	54.6	48	41.9	36.8	35.9
= Cash Conversion Cycle	118.1	119.3	107.6	108.3	117.7	117.2
Company J						

(continued)

	2021	2020	2019	2018	2017	2016
Days of Inventory on Hand	105.6	101.4	96.3	105.2	103.2	101.4
+ Days of Receivables	27.7	29.4	32.9	36.3	37.8	38
– Days of Payables Outstanding	36.6	38.5	35.3	39.3	37.8	40.2
= Cash Conversion Cycle	96.7	92.3	93.9	102.2	103.2	99.2
Company S						
Days of Inventory on Hand	135.8	131	118.9	69.2	63.4	81.7
+ Days of Receivables	49.1	42.5	54.2	36.2	29.1	38.3
– Days of Payables Outstanding	30.9	27.9	34.6	29.8	31.8	35.9
= Cash Conversion Cycle	154.0	145.6	138.5	75.6	60.7	84.1

Which company's operating cycle appears to have caused the most liquidity stress?

A Company H's

B Company J's

C Company S's

SOLUTIONS

1 C is correct. Although accounts payable do not charge an explicit interest rate, the cost of accounts payable is reflected in the costs of the services or products purchased and in the costs of any discounts not taken. Accounts payable can have a very high implicit cost. Similarly, equity financing is not free. A required return is expected on shareholder financing just as on any other form of financing.

2 C is correct. A revolver is a short-term borrowing facility in which a bank allows the firm to borrow and repay loans during the life of the line of credit.

3 A is correct. SOA must issue 19 million of bonds.

Source	Amount (local, millions)
Accounts payable	6
Bank loan against receivables	8
Short-term note	14
Net income + depreciation – dividends	28
Total sources	56

The firm requires 75 million of financing in local currency terms. Given the planned sources (before bond financing or repurchases) total 56 million, SOA will need to issue 19 million of new bonds.

4 C is correct. Kwam must sell the entire real estate property because the two primary sources (marketable securities and bonds) will not raise the needed €120 million. A is incorrect because it assumes a fractional real estate sale. The real estate sale will raise a net of €63 million (€70 million minus 10% liquidation expenses). To raise the rest of the funds needed (€120 million - €63 million = €57 million), Kwam can sell €57 million of marketable securities, which have minimal liquidation/brokerage costs.

5 C is correct. A longer average collection period will certainly occur. Higher cash balances and a lower level of uncollectible accounts will not occur.

6 B is correct. Reducing the average collection period would speed up receipts and improve the firm's liquidity position. The other two suggestions would worsen the firm's liquidity position.

7 A is correct. Relative to peers, Company H has the highest set of ratios. Relative to historical average ratios, Company H's recent ratios show the greatest increases. The cash ratio is the most relevant for judging liquidity, and Company H's cash ratio is quite high.

8 C is correct. Company S's cash conversion cycle nearly doubled over recent years, while the cash conversion cycles for Companies H and J are nearly unchanged. The days of inventory on hand and days of receivables both increased substantially for Company S, and its days of payables outstanding decreased very slightly. The net effect was the large increase in the cash conversion cycle. Although changes occurred in the components of the cash conversion cycles for Companies H and J, the net effect on their cash conversion cycles was small.

Glossary

A priori probability A probability based on logical analysis rather than on observation or personal judgment.

Abandonment option The ability to terminate an investment at some future time if the financial results are disappointing.

Abnormal return The amount by which a security's actual return differs from its expected return, given the security's risk and the market's return.

Absolute advantage A country's ability to produce a good or service at a lower absolute cost than its trading partner.

Absolute dispersion The amount of variability present without comparison to any reference point or benchmark.

Absolute frequency The actual number of observations counted for each unique value of the variable (also called raw frequency).

Accelerated book build An offering of securities by an investment bank acting as principal that is accomplished in only one or two days.

Accelerated methods Depreciation methods that allocate a relatively large proportion of the cost of an asset to the early years of the asset's useful life.

Accounting costs Monetary value of economic resources used in performing an activity. These can be explicit, out-of-pocket, current payments, or an allocation of historical payments (depreciation) for resources. They do not include implicit opportunity costs.

Accounting profit Income as reported on the income statement, in accordance with prevailing accounting standards, before the provisions for income tax expense. Also called *income before taxes* or *pretax income*.

Accounts payable Amounts that a business owes to its vendors for goods and services that were purchased from them but which have not yet been paid.

Accrued expenses Liabilities related to expenses that have been incurred but not yet paid as of the end of an accounting period—an example of an accrued expense is rent that has been incurred but not yet paid, resulting in a liability "rent payable." Also called *accrued liabilities*.

Accrued interest Interest earned but not yet paid.

Acquisition method A method of accounting for a business combination where the acquirer is required to measure each identifiable asset and liability at fair value. This method was the result of a joint project of the IASB and FASB aiming at convergence in standards for the accounting of business combinations.

Action lag Delay from policy decisions to implementation.

Active investment An approach to investing in which the investor seeks to outperform a given benchmark.

Active return The return on a portfolio minus the return on the portfolio's benchmark.

Activity ratios Ratios that measure how efficiently a company performs day-to-day tasks, such as the collection of receivables and management of inventory. Also called *asset utilization ratios* or *operating efficiency ratios*.

Add-on rates Bank certificates of deposit, repos, and indexes such as Libor and Euribor are quoted on an add-on rate basis (bond equivalent yield basis).

Addition rule for probabilities A principle stating that the probability that *A* or *B* occurs (both occur) equals the probability that *A* occurs, plus the probability that *B* occurs, minus the probability that both *A* and *B* occur.

Agency bond See *quasi-government bond*.

Agency costs Costs associated with the conflict of interest present between principals and agents when a company is managed by non-owners. Agency costs result from the inherent conflicts of interest between managers, bondholders, and equity owners.

Agency costs of debt Costs arising from conflicts of interest between managers and debtholders.

Agency costs of equity The smaller the stake managers have in the company, the less their share in bearing the cost of excessive perquisite consumption—consequently, the less their desire to give their best efforts in running the company.

Agency RMBS In the United States, securities backed by residential mortgage loans and guaranteed by a federal agency or guaranteed by either of the two GSEs (Fannie Mae and Freddie Mac).

Aggregate demand The quantity of goods and services that households, businesses, government, and non-domestic customers want to buy at any given level of prices.

Aggregate demand curve Inverse relationship between the price level and real output.

Aggregate income The value of all the payments earned by the suppliers of factors used in the production of goods and services.

Aggregate output The value of all the goods and services produced during a specified period.

Aggregate supply The quantity of goods and services producers are willing to supply at any given level of price.

Aggregate supply curve The level of domestic output that companies will produce at each price level.

All-or-nothing (AON) orders An order that includes the instruction to trade only if the trade fills the entire quantity (size) specified.

Allocationally efficient A characteristic of a market, a financial system, or an economy that promotes the allocation of resources to their highest value uses.

Alternative data Non-traditional data types generated by the use of electronic devices, social media, satellite and sensor networks, and company exhaust.

Alternative hypothesis The hypothesis that is accepted if the null hypothesis is rejected.

Alternative investment markets Market for investments other than traditional securities investments (i.e., traditional common and preferred shares and traditional fixed income instruments). The term usually encompasses direct and indirect investment in real estate (including timberland and farmland) and commodities (including precious metals); hedge funds, private equity, and other investments requiring specialized due diligence.

Alternative trading systems Trading venues that function like exchanges but that do not exercise regulatory authority over their subscribers except with respect to the conduct

of the subscribers' trading in their trading systems. Also called *electronic communications networks* or *multilateral trading facilities*.

American depository receipt A US dollar-denominated security that trades like a common share on US exchanges.

American depository share The underlying shares on which American depository receipts are based. They trade in the issuing company's domestic market.

American-style Type of option contract that can be exercised at any time up to the option's expiration date.

Amortisation The process of allocating the cost of intangible long-term assets having a finite useful life to accounting periods; the allocation of the amount of a bond premium or discount to the periods remaining until bond maturity.

Amortised cost The historical cost (initially recognised cost) of an asset, adjusted for amortisation and impairment.

Amortizing bond Bond with a payment schedule that calls for periodic payments of interest and repayments of principal.

Amortizing loans Loans with a payment schedule that calls for periodic payments of interest and repayments of principal.

Analysis of variance (ANOVA) The analysis that breaks the total variability of a dataset (such as observations on the dependent variable in a regression) into components representing different sources of variation. With reference to regression, ANOVA provides the inputs for an *F*-test of the significance of the regression as a whole, as well as the inputs for the coefficient of determination and the standard error of the estimate.

Analytical duration The use of mathematical formulas to estimate the impact of benchmark yield-to-maturity changes on bond prices.

Anchoring and adjustment bias An information-processing bias in which the use of a psychological heuristic influences the way people estimate probabilities.

Annual percentage rate The cost of borrowing expressed as a yearly rate.

Annuity A finite set of level sequential cash flows.

Annuity due An annuity having a first cash flow that is paid immediately.

Anomalies Apparent deviations from market efficiency.

Antidilutive With reference to a transaction or a security, one that would increase earnings per share (EPS) or result in EPS higher than the company's basic EPS—antidilutive securities are not included in the calculation of diluted EPS.

Arbitrage 1) The simultaneous purchase of an undervalued asset or portfolio and sale of an overvalued but equivalent asset or portfolio, in order to obtain a riskless profit on the price differential. Taking advantage of a market inefficiency in a risk-free manner. 2) The condition in a financial market in which equivalent assets or combinations of assets sell for two different prices, creating an opportunity to profit at no risk with no commitment of money. In a well-functioning financial market, few arbitrage opportunities are possible. 3) A risk-free operation that earns an expected positive net profit but requires no net investment of money.

Arbitrage-free pricing The overall process of pricing derivatives by arbitrage and risk neutrality. Also called the *principle of no arbitrage*.

Arbitrageurs Traders who engage in arbitrage. See *arbitrage*.

Arithmetic mean The sum of the observations divided by the number of observations.

Artificial intelligence Computer systems that exhibit cognitive and decision-making ability comparable (or superior) to that of humans.

Ask The price at which a dealer or trader is willing to sell an asset, typically qualified by a maximum quantity (ask size). See *offer*.

Ask size The maximum quantity of an asset that pertains to a specific ask price from a trader. For example, if the ask for a share issue is $30 for a size of 1,000 shares, the trader is offering to sell at $30 up to 1,000 shares.

Asset allocation The process of determining how investment funds should be distributed among asset classes.

Asset-backed securities A type of bond issued by a legal entity called a *special purpose entity* (SPE) on a collection of assets that the SPE owns. Also, securities backed by receivables and loans other than mortgages.

Asset-based valuation models Valuation based on estimates of the market value of a company's assets.

Asset beta The unlevered beta; which reflects the business risk of the assets; the assets' systematic risk.

Asset class A group of assets that have similar characteristics, attributes, and risk–return relationships.

Asset swap Converts the periodic fixed coupon of a specific bond to an MRR plus or minus a spread.

Asset utilization ratios Ratios that measure how efficiently a company performs day-to-day tasks, such as the collection of receivables and management of inventory.

Assets Resources controlled by an enterprise as a result of past events and from which future economic benefits to the enterprise are expected to flow.

Assignment of accounts receivable The use of accounts receivable as collateral for a loan.

Asymmetric information The differential of information between corporate insiders and outsiders regarding the company's performance and prospects. Managers typically have more information about the company's performance and prospects than owners and creditors.

At the money An option in which the underlying's price equals the exercise price.

Auction A type of bond issuing mechanism often used for sovereign bonds that involves bidding.

Autarkic price The price of a good or service in an autarkic economy.

Autarky A state in which a country does not trade with other countries.

Automatic stabilizer A countercyclical factor that automatically comes into play as an economy slows and unemployment rises.

Availability bias An information-processing bias in which people take a heuristic approach to estimating the probability of an outcome based on how easily the outcome comes to mind.

Available-for-sale Under US GAAP, debt securities not classified as either held-to-maturity or held-for-trading securities. The investor is willing to sell but not actively planning to sell. In general, available-for-sale debt securities are reported at fair value on the balance sheet, with unrealized gains included as a component of other comprehensive income.

Average fixed cost Total fixed cost divided by quantity produced.

Average life See *weighted average life*.

Average product Measures the productivity of inputs on average and is calculated by dividing total product by the total number of units for a given input that is used to generate that output.

Average revenue Total revenue divided by quantity sold.

Average total cost Total cost divided by quantity produced.

Average variable cost Total variable cost divided by quantity produced.

Back-testing With reference to portfolio strategies, the application of a strategy's portfolio selection rules to historical data to assess what would have been the strategy's historical performance.

Backfill bias A bias introduced if a fund backfills its past performance data to the database when it first starts reporting actual performance.

Backtesting With reference to portfolio strategies, the application of a strategy's portfolio selection rules to historical data to assess what would have been the strategy's historical performance.

Backup line of credit A type of credit enhancement provided by a bank to an issuer of commercial paper to ensure that the issuer will have access to sufficient liquidity to repay maturing commercial paper if issuing new paper is not a viable option.

Backwardation A condition in the futures markets in which the spot price exceeds the futures price, the forward curve is downward sloping, and the convenience yield is high.

Balance of payments A double-entry bookkeeping system that summarizes a country's economic transactions with the rest of the world for a particular period of time, typically a calendar quarter or year.

Balance of trade deficit When the domestic economy is spending more on non-domestic goods and services than non-domestic economies are spending on domestic goods and services.

Balance sheet The financial statement that presents an entity's current financial position by disclosing resources the entity controls (its assets) and the claims on those resources (its liabilities and equity claims), as of a particular point in time (the date of the balance sheet). Also called *statement of financial position* or *statement of financial condition.*

Balance sheet ratios Financial ratios involving balance sheet items only.

Balanced With respect to a government budget, one in which spending and revenues (taxes) are equal.

Balloon payment Large payment required at maturity to retire a bond's outstanding principal amount.

Bar chart A chart for plotting the frequency distribution of categorical data, where each bar represents a distinct category and each bar's height is proportional to the frequency of the corresponding category. In technical analysis, a bar chart that plots four bits of data for each time interval—the high, low, opening, and closing prices. A vertical line connects the high and low prices. A cross-hatch left indicates the opening price and a cross-hatch right indicates the closing price.

Barter economy An economy where economic agents as house-holds, corporations, and governments "pay" for goods and services with another good or service.

Base-rate neglect A type of representativeness bias in which the base rate or probability of the categorization is not adequately considered.

Base rates The reference rate on which a bank bases lending rates to all other customers.

Basic EPS Net earnings available to common shareholders (i.e., net income minus preferred dividends) divided by the weighted average number of common shares outstanding.

Basis point Used in stating yield spreads, one basis point equals one-hundredth of a percentage point, or 0.01%.

Basket of listed depository receipts An exchange-traded fund (ETF) that represents a portfolio of depository receipts.

Bayes' formula The rule for updating the probability of an event of interest—given a set of prior probabilities for the event, information, and information given the event—if you receive new information.

Bearer bonds Bonds for which ownership is not recorded; only the clearing system knows who the bond owner is.

Bearish crossover A technical analysis term that describes a situation where a short-term moving average crosses a longer-term moving average from above; this movement is considered bearish. A **death cross** is a bearish crossover based on 50-day and 200-day moving averages.

Behavioral finance A field of finance that examines the psychological variables that affect and often distort the investment decision making of investors, analysts, and portfolio managers.

Behind the market Said of prices specified in orders that are worse than the best current price; e.g., for a limit buy order, a limit price below the best bid.

Benchmark A comparison portfolio; a point of reference or comparison.

Benchmark issue The latest sovereign bond issue for a given maturity. It serves as a benchmark against which to compare bonds that have the same features but that are issued by another type of issuer.

Benchmark rate Typically the yield-to-maturity on a government bond having the same or close to the same time-to-maturity.

Benchmark spread The yield spread over a specific benchmark, usually measured in basis points.

Bernoulli random variable A random variable having the outcomes 0 and 1.

Bernoulli trial An experiment that can produce one of two outcomes.

Best bid The highest bid in the market.

Best effort offering An offering of a security using an investment bank in which the investment bank, as agent for the issuer, promises to use its best efforts to sell the offering but does not guarantee that a specific amount will be sold.

Best-efforts offering An offering of a security using an investment bank in which the investment bank, as agent for the issuer, promises to use its best efforts to sell the offering but does not guarantee that a specific amount will be sold.

Best-in-class An ESG implementation approach that seeks to identify the most favorable companies in an industry based on ESG considerations.

Best offer The lowest offer (ask price) in the market.

Beta A measure of the sensitivity of a given investment or portfolio to movements in the overall market.

Bid The price at which a dealer or trader is willing to buy an asset, typically qualified by a maximum quantity.

Bid–ask spread The difference between the prices at which dealers will buy from a customer (bid) and sell to a customer (offer or ask). It is often used as an indicator of liquidity.

Bid–offer spread The difference between the prices at which dealers will buy from a customer (bid) and sell to a customer (offer or ask). It is often used as an indicator of liquidity.

Bid size The maximum quantity of an asset that pertains to a specific bid price from a trader.

Big Data The vast amount of data being generated by industry, governments, individuals, and electronic devices that arises from both traditional and non-traditional data sources.

Bilateral loan A loan from a single lender to a single borrower.

Bimodal A distribution that has two most frequently occurring values.

Binomial model A model for pricing options in which the underlying price can move to only one of two possible new prices.

Binomial random variable The number of successes in n Bernoulli trials for which the probability of success is constant for all trials and the trials are independent.

Binomial tree The graphical representation of a model of asset price dynamics in which, at each period, the asset moves up with probability p or down with probability $(1 - p)$.

Bitcoin A cryptocurrency using blockchain technology that was created in 2009.

Bivariate correlation See *Pearson correlation*.

Block brokers A broker (agent) that provides brokerage services for large-size trades.

Blockchain A type of digital ledger in which information is recorded sequentially and then linked together and secured using cryptographic methods.

Blue chip Widely held large market capitalization companies that are considered financially sound and are leaders in their respective industry or local stock market.

Bollinger Bands A price-based technical analysis indicator consisting of a line representing the moving average, a higher line representing the moving average plus a set number of standard deviations from the average (for the same number of periods as was used to calculate the moving average), and a lower line representing the moving average minus the same number of standard deviations.

Bond Contractual agreement between the issuer and the bondholders.

Bond equivalent yield A calculation of yield that is annualized using the ratio of 365 to the number of days to maturity. Bond equivalent yield allows for the restatement and comparison of securities with different compounding periods.

Bond indenture The governing legal credit agreement, typically incorporated by reference in the prospectus. Also called *trust deed*.

Bond market vigilantes Bond market participants who might reduce their demand for long-term bonds, thus pushing up their yields.

Bond yield plus risk premium approach An estimate of the cost of common equity that is produced by summing the before-tax cost of debt and a risk premium that captures the additional yield on a company's stock relative to its bonds. The additional yield is often estimated using historical spreads between bond yields and stock yields.

Bonus issue of shares A type of dividend in which a company distributes additional shares of its common stock to shareholders instead of cash.

Book building Investment bankers' process of compiling a "book" or list of indications of interest to buy part of an offering.

Book value The net amount shown for an asset or liability on the balance sheet; book value may also refer to the company's excess of total assets over total liabilities. Also called *carrying value*.

Boom An expansionary phase characterized by economic growth "testing the limits" of the economy.

Bootstrap A resampling method that repeatedly draws samples with replacement of the selected elements from the original observed sample. Bootstrap is usually conducted by using computer simulation and is often used to find standard error or construct confidence intervals of population parameters.

Bottom-up analysis An investment selection approach that focuses on company-specific circumstances rather than emphasizing economic cycles or industry analysis.

Box and whisker plot A graphic for visualizing the dispersion of data across quartiles. It consists of a "box" with "whiskers" connected to the box.

Breakdown A breakdown occurs when the price of an asset moves below a support level.

Breakeven point The number of units produced and sold at which the company's net income is zero (Revenues = Total cost); in the case of perfect competition, the quantity at which price, average revenue, and marginal revenue equal average total cost.

Breakout A breakout occurs when the price of an asset moves above a resistance level.

Bridge financing Interim financing that provides funds until permanent financing can be arranged.

Broad money Encompasses narrow money plus the entire range of liquid assets that can be used to make purchases.

Broker 1) An agent who executes orders to buy or sell securities on behalf of a client in exchange for a commission. 2) See *futures commission merchants*.

Broker–dealer A financial intermediary (often a company) that may function as a principal (dealer) or as an agent (broker) depending on the type of trade.

Brokered market A market in which brokers arrange trades among their clients.

Brownfield investment Investing in *existing* infrastructure assets.

Bubble line chart A line chart that uses varying-sized bubbles to represent a third dimension of the data. The bubbles are sometimes color-coded to present additional information.

Budget surplus/deficit The difference between government revenue and expenditure for a stated fixed period of time.

Bullet bond Bond in which the principal repayment is made entirely at maturity.

Bullish crossover A technical analysis term that describes a situation where a short-term moving average crosses a longer-term moving average from below; this movement is considered bullish. A **golden cross** is a bullish crossover based on 50-day and 200-day moving averages.

Business cycles Are recurrent expansions and contractions in economic activity affecting broad segments of the economy.

Business risk The risk associated with operating earnings. Operating earnings are uncertain because total revenues and many of the expenditures contributed to produce those revenues are uncertain.

Buy-side firm An investment management company or other investor that uses the services of brokers or dealers (i.e., the client of the sell side firms).

Buyback A transaction in which a company buys back its own shares. Unlike stock dividends and stock splits, share repurchases use corporate cash.

Call An option that gives the holder the right to buy an underlying asset from another party at a fixed price over a specific period of time.

Call market A market in which trades occur only at a particular time and place (i.e., when the market is called).

Call money rate The interest rate that buyers pay for their margin loan.

Call option An option that gives the holder the right to buy an underlying asset from another party at a fixed price over a specific period of time.

Call protection The time during which the issuer of the bond is not allowed to exercise the call option.

Callable bond A bond containing an embedded call option that gives the issuer the right to buy the bond back from the investor at specified prices on pre-determined dates.

Calmar ratio A comparison of the average annual compounded return to the maximum drawdown risk.

Candlestick chart A price chart with four bits of data for each time interval. A candle indicates the opening and closing price for the interval. The body of the candle is shaded if the opening price was higher than the closing price, and the body is white (or clear) if the opening price was lower than the closing price. Vertical lines known as wicks or shadows extend from the top and bottom of the candle to indicate, respectively, the high and low prices for the interval.

Cannibalization Cannibalization occurs when an investment takes customers and sales away from another part of the company.

Cap rate A metric by which real estate managers are often judged; the annual rent actually earned (net of any vacancies) divided by the price originally paid for the property.

Capacity The ability of the borrower to make its debt payments on time.

Capital account A component of the balance of payments account that measures transfers of capital.

Capital allocation line (CAL) A graph line that describes the combinations of expected return and standard deviation of return available to an investor from combining the optimal portfolio of risky assets with the risk-free asset.

Capital allocation process The process that companies use for decision making on capital investments—those projects with a life of one year or longer.

Capital asset pricing model (CAPM) An equation describing the expected return on any asset (or portfolio) as a linear function of its beta relative to the market portfolio.

Capital consumption allowance A measure of the wear and tear (depreciation) of the capital stock that occurs in the production of goods and services.

Capital deepening investment Increases the stock of capital relative to labor.

Capital expenditure Expenditure on physical capital (fixed assets).

Capital light Capital light businesses require little incremental investment in fixed assets or working capital to enable revenue growth.

Capital loss ratio The percentage of capital in deals that have been realized below cost, net of any recovered proceeds, divided by total invested capital.

Capital market expectations An investor's expectations concerning the risk and return prospects of asset classes.

Capital market line (CML) The line with an intercept point equal to the risk-free rate that is tangent to the efficient frontier of risky assets; represents the efficient frontier when a risk-free asset is available for investment.

Capital market securities Securities with maturities at issuance longer than one year.

Capital markets Financial markets that trade securities of longer duration, such as bonds and equities.

Capital rationing A capital rationing environment assumes that the company has a fixed amount of funds to invest.

Capital restrictions Controls placed on foreigners' ability to own domestic assets and/or domestic residents' ability to own foreign assets.

Capital stock The accumulated amount of buildings, machinery, and equipment used to produce goods and services.

Capital structure The mix of debt and equity that a company uses to finance its business; a company's specific mixture of long-term financing.

Carry The net of the costs and benefits of holding, storing, or "carrying" an asset.

Carrying amount The amount at which an asset or liability is valued according to accounting principles.

Carrying value The net amount shown for an asset or liability on the balance sheet; book value may also refer to the company's excess of total assets over total liabilities. For a bond, the purchase price plus (or minus) the amortized amount of the discount (or premium).

Cartel Participants in collusive agreements that are made openly and formally.

Cash collateral account Form of external credit enhancement whereby the issuer immediately borrows the credit-enhancement amount and then invests that amount, usually in highly rated short-term commercial paper.

Cash conversion cycle A financial metric that measures the length of time required for a company to convert cash invested in its operations to cash received as a result of its operations; equal to days of inventory on hand + days of sales outstanding – number of days of payables. Also called *net operating cycle*.

Cash flow additivity principle The principle that dollar amounts indexed at the same point in time are additive.

Cash flow from operating activities The net amount of cash provided from operating activities.

Cash flow from operations The net amount of cash provided from operating activities.

Cash flow yield The internal rate of return on a series of cash flows.

Cash market securities Money market securities settled on a "same day" or "cash settlement" basis.

Cash markets See *spot markets*.

Cash prices See *spot prices*.

Cash-settled forwards See *non-deliverable forwards*.

Catch-up clause A clause in an agreement that favors the GP. For a GP who earns a 20% performance fee, a catch-up clause allows the GP to receive 100% of the distributions above the hurdle rate *until* she receives 20% of the profits generated, and then every excess dollar is split 80/20 between the LPs and GP.

Categorical data Values that describe a quality or characteristic of a group of observations and therefore can be used as labels to divide a dataset into groups to summarize and visualize (also called **qualitative data**).

CBOE Volatility Index (VIX) A measure of near-term market volatility as conveyed by S&P 500 stock index option prices.

Central bank funds market The market in which deposit-taking banks that have an excess reserve with their national central bank can lend money to banks that need funds for maturities ranging from overnight to one year. Called the Federal or Fed funds market in the United States.

Central bank funds rate Interest rate at which central bank funds are bought (borrowed) and sold (lent) for maturities ranging from overnight to one year. Called Federal or Fed funds rate in the United States.

Central banks The dominant bank in a country, usually with official or semi-official governmental status.

Central limit theorem The theorem that states the sum (and the mean) of a set of independent, identically distributed random variables with finite variances is normally distributed, whatever distribution the random variables follow.

Certificate of deposit An instrument that represents a specified amount of funds on deposit with a bank for a specified maturity and interest rate. CDs are issued in various denominations and can be negotiable or non-negotiable.

Change in polarity principle A tenet of technical analysis that states that once a support level is breached, it becomes a resistance level. The same holds true for resistance levels: Once breached, they become support levels.

Change of control put A covenant giving bondholders the right to require the issuer to buy back their debt, often at par or at some small premium to par value, in the event that the borrower is acquired.

Character The quality of a debt issuer's management.

Chartist An individual who uses charts or graphs of a security's historical prices or levels to forecast its future trends.

Chi-square test of independence A statistical test for detecting a potential association between categorical variables.

Classical cycle Refers to fluctuations in the level of economic activity when measured by GDP in volume terms.

Classified balance sheet A balance sheet organized so as to group together the various assets and liabilities into subcategories (e.g., current and noncurrent).

Clawback A requirement that the general partner return any funds distributed as incentive fees until the limited partners have received back their initial investment and a percentage of the total profit.

Clearing The process by which the exchange verifies the execution of a transaction and records the participants' identities.

Clearing instructions Instructions that indicate how to arrange the final settlement ("clearing") of a trade.

Clearinghouse An entity associated with a futures market that acts as middleman between the contracting parties and guarantees to each party the performance of the other.

Closed economy An economy that does not trade with other countries; an *autarkic economy*.

Closed-end fund A mutual fund in which no new investment money is accepted. New investors invest by buying existing shares, and investors in the fund liquidate by selling their shares to other investors.

Cluster sampling A procedure that divides a population into subpopulation groups (clusters) representative of the population and then randomly draws certain clusters to form a sample.

Clustered bar chart See *grouped bar chart*.

Co-investing In co-investing, the investor invests in assets *indirectly* through the fund but also possesses rights (known as co-investment rights) to invest *directly* in the same assets. Through co-investing, an investor is able to make an investment *alongside* a fund when the fund identifies deals.

Code of ethics An established guide that communicates an organization's values and overall expectations regarding member behavior. A code of ethics serves as a general guide for how community members should act.

Coefficient of determination The percentage of the variation of the dependent variable that is explained by the independent variable. Also referred to as the "R-squared" or "R^2."

Coefficient of variation The ratio of a set of observations' standard deviation to the observations' mean value.

Cognitive cost The effort involved in processing new information and updating beliefs.

Cognitive dissonance The mental discomfort that occurs when new information conflicts with previously held beliefs or cognitions.

Cognitive errors Behavioral biases resulting from faulty reasoning; cognitive errors stem from basic statistical, information-processing, or memory errors.

Coincident economic indicators Turning points that are usually close to those of the overall economy; they are believed to have value for identifying the economy's present state.

Collateral Assets or financial guarantees underlying a debt obligation that are above and beyond the issuer's promise to pay.

Collateral manager Buys and sells debt obligations for and from the CDO's portfolio of assets (i.e., the collateral) to generate sufficient cash flows to meet the obligations to the CDO bondholders.

Collateral trust bonds Bonds secured by securities, such as common shares, other bonds, or other financial assets.

Collateralized bond obligations A structured asset-backed security that is collateralized by a pool of bonds.

Collateralized debt obligation Generic term used to describe a security backed by a diversified pool of one or more debt obligations.

Collateralized loan obligations A structured asset-backed security that is collateralized by a pool of loans.

Collateralized mortgage obligation A security created through the securitization of a pool of mortgage-related products (mortgage pass-through securities or pools of loans).

Collateralized mortgage obligations Securities created through the securitization of a pool of mortgage-related products (mortgage pass-through securities or pools of loans).

Collaterals Assets or financial guarantees underlying a debt obligation that are above and beyond the issuer's promise to pay.

Combination A listing in which the order of the listed items does not matter.

Combination formula (binomial formula) The number of ways that we can choose r objects from a total of n objects, when the order in which the r objects are listed does not matter, is ${}_nC_r = \binom{n}{r} = \dfrac{n!}{(n-r)!r!}$.

Commercial paper A short-term, negotiable, unsecured promissory note that represents a debt obligation of the issuer.

Committed (Regular) lines of credit A bank commitment to extend credit up to a pre-specified amount; the commitment is considered a short-term liability and is usually in effect for 364 days (one day short of a full year).

Committed capital The amount that the limited partners have agreed to provide to the private equity fund.

Commodity swap A swap in which the underlying is a commodity such as oil, gold, or an agricultural product.

Common market Level of economic integration that incorporates all aspects of the customs union and extends it by allowing free movement of factors of production among members.

Common shares A type of security that represent an ownership interest in a company.

Common-size analysis The restatement of financial statement items using a common denominator or reference item that allows one to identify trends and major differences; an example is an income statement in which all items are expressed as a percent of revenue.

Common stock See *common shares.*

Company analysis Analysis of an individual company.

Comparable company A company that has similar business risk, usually in the same industry and preferably with a single line of business.

Comparative advantage A country's ability to produce a good or service at a lower relative cost, or opportunity cost, than its trading partner.

Competitive strategy A company's plans for responding to the threats and opportunities presented by the external environment.

Complement The event not-S, written S^C, given the event S. Note that $P(S) + P(S^C) = 1$.

Complements Goods that tend to be used together; technically, two goods whose cross-price elasticity of demand is negative.

Complete markets Informally, markets in which the variety of distinct securities traded is so broad that any desired payoff in a future state-of-the-world is achievable.

Component cost of capital The rate of return required by suppliers of capital for an individual source of a company's funding, such as debt or equity.

Compounding The process of accumulating interest on interest.

Comprehensive income The change in equity of a business enterprise during a period from nonowner sources; includes all changes in equity during a period except those resulting from investments by owners and distributions to owners; comprehensive income equals net income plus other comprehensive income.

Conditional expected value The expected value of a stated event given that another event has occurred.

Conditional pass-through covered bonds Covered bonds that convert to pass-through securities after the original maturity date if all bond payments have not yet been made and the sponsor is in default.

Conditional probability The probability of an event given (conditioned on) another event.

Conditional variances The variance of one variable, given the outcome of another.

Confidence level The complement of the level of significance.

Confirmation bias A belief perseverance bias in which people tend to look for and notice what confirms their beliefs, to ignore or undervalue what contradicts their beliefs, and to misinterpret information as support for their beliefs.

Confusion matrix A type of contingency table used for evaluating the performance of a classification model.

Conservatism bias A belief perseverance bias in which people maintain their prior views or forecasts by inadequately incorporating new information.

Consolidation The movement of a stock's price within a well-defined range of trading levels for a period of time. The price consolidates between a support level and a resistance level.

Constant-yield price trajectory A graph that illustrates the change in the price of a fixed-income bond over time assuming no change in yield-to-maturity. The trajectory shows the "pull to par" effect on the price of a bond trading at a premium or a discount to par value.

Constituent securities With respect to an index, the individual securities within an index.

Consumer surplus The difference between the value that a consumer places on units purchased and the amount of money that was required to pay for them.

Contango A condition in the futures markets in which the spot price is lower than the futures price, the forward curve is upward sloping, and there is little or no convenience yield.

Contingency provision Clause in a legal document that allows for some action if a specific event or circumstance occurs.

Contingency table A tabular format that displays the frequency distributions of two or more categorical variables simultaneously and is used for finding patterns between the variables. A contingency table for two categorical variables is also known as a two-way table.

Contingent claim A security whose value is based on some other underlying security.

Contingent claims Derivatives in which the payoffs occur if a specific event occurs; generally referred to as options.

Contingent convertible bonds Bonds that automatically convert into equity if a specific event or circumstance occurs, such as the issuer's equity capital falling below the minimum requirement set by the regulators. Also called *CoCos.*

Continuation pattern A type of pattern used in technical analysis to predict the resumption of a market trend that was in place prior to the formation of a pattern.

Continuous data Data that can be measured and can take on any numerical value in a specified range of values.

Continuous random variable A random variable for which the range of possible outcomes is the real line (all real numbers between $-\infty$ and $+\infty$) or some subset of the real line.

Continuous trading market A market in which trades can be arranged and executed any time the market is open.

Continuously compounded return The natural logarithm of 1 plus the holding period return, or equivalently, the natural logarithm of the ending price over the beginning price.

Contra account An account that offsets another account.

Contract rate See *mortgage rate.*

Contraction The period of a business cycle after the peak and before the trough; often called a *recession* or, if exceptionally severe, called a *depression*.

Contraction risk The risk that when interest rates decline, the security will have a shorter maturity than was anticipated at the time of purchase because borrowers refinance at the new, lower interest rates.

Contractionary Tending to cause the real economy to contract.

Contractionary fiscal policy A fiscal policy that has the objective to make the real economy contract.

Contracts for differences See *non-deliverable forwards.*

Contribution margin The amount available for fixed costs and profit after paying variable costs; revenue minus variable costs.

Controlling shareholders A particular shareholder or block of shareholders holding a percentage of shares that gives them significant voting power.

Convenience sampling A procedure of selecting an element from a population on the basis of whether or not it is accessible to a researcher or how easy it is for a researcher to access the element.

Convenience yield A non-monetary advantage of holding an asset.

Conventional bond See *plain vanilla bond*.

Conventional cash flows A conventional cash flow pattern is one with an initial outflow followed by a series of inflows.

Convergence The tendency for differences in output per capita across countries to diminish over time. In technical analysis, the term describes the case when an indicator moves in the same manner as the security being analyzed.

Conversion premium The difference between the convertible bond's price and its conversion value.

Conversion price For a convertible bond, the price per share at which the bond can be converted into shares.

Conversion ratio For a convertible bond, the number of common shares that each bond can be converted into.

Conversion value For a convertible bond, the current share price multiplied by the conversion ratio.

Convertible bond Bond that gives the bondholder the right to exchange the bond for a specified number of common shares in the issuing company.

Convertible preference shares A type of equity security that entitles shareholders to convert their shares into a specified number of common shares.

Convexity adjustment For a bond, one half of the annual or approximate convexity statistic multiplied by the change in the yield-to-maturity squared.

Core inflation Refers to the inflation rate calculated based on a price index of goods and services except food and energy.

Corporate governance The system of internal controls and procedures by which individual companies are managed.

Correlation A measure of the linear relationship between two random variables.

Correlation coefficient A number between −1 and +1 that measures the consistency or tendency for two investments to act in a similar way. It is used to determine the effect on portfolio risk when two assets are combined.

Cost averaging The periodic investment of a fixed amount of money.

Cost of capital The cost of financing to a company; the rate of return that suppliers of capital require as compensation for their contribution of capital.

Cost of carry See *carry*.

Cost of debt The cost of debt financing to a company, such as when it issues a bond or takes out a bank loan; the rate of return required by a company's bondholders.

Cost of equity The rate of return required by a company's common stockholders.

Cost of preferred stock The cost to a company of issuing preferred stock; the dividend yield that a company must commit to pay preferred stockholders.

Cost structure The mix of a company's variable costs and fixed costs.

Counterparty risk The risk that the other party to a contract will fail to honor the terms of the contract.

Coupon rate The interest rate promised in a contract; this is the rate used to calculate the periodic interest payments.

Cournot assumption Assumption in which each firm determines its profit-maximizing production level assuming that the other firms' output will not change.

Covariance A measure of the co-movement (linear association) between two random variables.

Covariance matrix A matrix or square array whose entries are covariances; also known as a variance–covariance matrix.

Covenants The terms and conditions of lending agreements that the issuer must comply with; they specify the actions that an issuer is obligated to perform (affirmative covenant) or prohibited from performing (negative covenant).

Covered bond Debt obligation secured by a segregated pool of assets called the cover pool. The issuer must maintain the value of the cover pool. In the event of default, bondholders have recourse against both the issuer and the cover pool.

Covered bonds Senior debt obligations issued by a financial institution and backed by a segregated pool of assets. Covered bond investors have recourse to both the underlying assets and the financial institution.

Credit analysis The evaluation of credit risk; the evaluation of the creditworthiness of a borrower or counterparty.

Credit default swap (CDS) A type of credit derivative in which one party, the credit protection buyer who is seeking credit protection against a third party, makes a series of regularly scheduled payments to the other party, the credit protection seller. The seller makes no payments until a credit event occurs.

Credit derivatives A contract in which one party has the right to claim a payment from another party in the event that a specific credit event occurs over the life of the contract.

Credit enhancements Provisions that may be used to reduce the credit risk of a bond issue.

Credit-linked coupon bond Bond for which the coupon changes when the bond's credit rating changes.

Credit-linked note (CLN) Fixed-income security in which the holder of the security has the right to withhold payment of the full amount due at maturity if a credit event occurs.

Credit migration risk The risk that a bond issuer's creditworthiness deteriorates, or migrates lower, leading investors to believe the risk of default is higher. Also called *downgrade risk*.

Credit risk The risk of loss caused by a counterparty's or debtor's failure to make a promised payment. Also called *default risk*.

Credit spread option An option on the yield spread on a bond.

Credit tranching A structure used to redistribute the credit risk associated with the collateral; a set of bond classes created to allow investors a choice in the amount of credit risk that they prefer to bear.

Creditworthiness The perceived ability of the borrower to pay its debt obligations in a timely manner; it represents the ability of a company to withstand adverse impacts on its cash flows.

Critical values Values of the test statistic at which the decision changes from fail to reject the null hypothesis to reject the null hypothesis.

Cross-default Covenant or contract clause that specifies a borrower is considered in default if they default on another debt obligation.

Cross-default provisions Provisions whereby events of default, such as non-payment of interest on one bond, trigger default on all outstanding debt; implies the same default probability for all issues.

Cross-price elasticity of demand The percentage change in quantity demanded for a given percentage change in the price of another good; the responsiveness of the demand for Product A that is associated with the change in price of Product B.

Cross-sectional analysis Analysis that involves comparisons across individuals in a group over a given time period or at a given point in time.

Cross-sectional data A list of the observations of a specific variable from multiple observational units at a given point in time. The observational units can be individuals, groups, companies, trading markets, regions, etc.

Crossing networks Trading systems that match buyers and sellers who are willing to trade at prices obtained from other markets.

Crowding out The thesis that government borrowing may divert private sector investment from taking place.

Cryptocurrency An electronic medium of exchange that lacks physical form.

Cryptography An algorithmic process to encrypt data, making the data unusable if received by unauthorized parties.

Cumulative absolute frequency Cumulates (i.e., adds up) in a frequency distribution the absolute frequencies as one moves from the first bin to the last bin.

Cumulative distribution function A function giving the probability that a random variable is less than or equal to a specified value.

Cumulative frequency distribution chart A chart that plots either the cumulative absolute frequency or the cumulative relative frequency on the y-axis against the upper limit of the interval and allows one to see the number or the percentage of the observations that lie below a certain value.

Cumulative preference shares Preference shares for which any dividends that are not paid accrue and must be paid in full before dividends on common shares can be paid.

Cumulative relative frequency A sequence of partial sums of the relative frequencies in a frequency distribution.

Cumulative voting A voting process whereby shareholders can accumulate and vote all their shares for a single candidate in an election, as opposed to having to allocate their voting rights evenly among all candidates.

Currencies Monies issued by national monetary authorities.

Currency option bonds Bonds that give bondholders the right to choose the currency in which they want to receive interest payments and principal repayments.

Currency swap A swap in which each party makes interest payments to the other in different currencies.

Current account A component of the balance of payments account that measures the flow of goods and services.

Current assets Assets that are expected to be consumed or converted into cash in the near future, typically one year or less. *Also called liquid assets.*

Current cost With reference to assets, the amount of cash or cash equivalents that would have to be paid to buy the same or an equivalent asset today; with reference to liabilities, the undiscounted amount of cash or cash equivalents that would be required to settle the obligation today.

Current government spending With respect to government expenditures, spending on goods and services that are provided on a regular, recurring basis including health, education, and defense.

Current liabilities Short-term obligations, such as accounts payable, wages payable, or accrued liabilities, that are expected to be settled in the near future, typically one year or less.

Current yield The sum of the coupon payments received over the year divided by the flat price; also called the *income* or *interest yield* or *running yield*.

Curve duration The sensitivity of the bond price (or the market value of a financial asset or liability) with respect to a benchmark yield curve.

Customs union Extends the free trade area (FTA) by not only allowing free movement of goods and services among members, but also creating a common trade policy against nonmembers.

CVaR Conditional VaR, a tail loss measure. The weighted average of all loss outcomes in the statistical distribution that exceed the VaR loss.

Cyclical A cyclical company is one whose profits are strongly correlated with the strength of the overall economy.

Cyclical companies Companies with sales and profits that regularly expand and contract with the business cycle or state of economy.

Daily settlement See *mark to market* and *marking to market.*

Dark pools Alternative trading systems that do not display the orders that their clients send to them.

Data A collection of numbers, characters, words, and text—as well as images, audio, and video—in a raw or organized format to represent facts or information.

Data mining The practice of determining a model by extensive searching through a dataset for statistically significant patterns. Also called *data snooping.*

Data science An interdisciplinary field that brings computer science, statistics, and other disciplines together to analyze and produce insights from Big Data.

Data snooping The practice of determining a model by extensive searching through a dataset for statistically significant patterns.

Data table see **two-dimensional rectangular array**.

Day order An order that is good for the day on which it is submitted. If it has not been filled by the close of business, the order expires unfilled.

Days of inventory on hand An activity ratio equal to the number of days in the period divided by inventory turnover over the period.

Dealers A financial intermediary that acts as a principal in trades.

Dealing securities Securities held by banks or other financial intermediaries for trading purposes.

Death cross See **Bearish crossover**.

Debentures Type of bond that can be secured or unsecured.

Debt rating An independent measure of the quality and safety of a company's debt based upon an analysis of the company's ability to pay the promised cash flows in full and on time. It includes an analysis of any indentures.

Debt-rating approach A method for estimating a company's before-tax cost of debt based on the yield on comparably rated bonds for maturities that closely match that of the company's existing debt.

Debt tax shield The tax benefit from interest paid on debt being tax deductible from income, equal to the marginal tax rate multiplied by the value of the debt.

Debt-to-assets ratio A solvency ratio calculated as total debt divided by total assets.

Debt-to-capital ratio A solvency ratio calculated as total debt divided by total debt plus total shareholders' equity.

Debt-to-equity ratio A solvency ratio calculated as total debt divided by total shareholders' equity.

Deciles Quantiles that divide a distribution into 10 equal parts.

Declaration date The day that the corporation issues a statement declaring a specific dividend.

Decreasing returns to scale When a production process leads to increases in output that are proportionately smaller than the increase in inputs.

Deductible temporary differences Temporary differences that result in a reduction of or deduction from taxable income in a future period when the balance sheet item is recovered or settled.

Deep learning Machine learning using neural networks with many hidden layers.

Deep learning nets Machine learning using neural networks with many hidden layers.

Default probability The probability that a borrower defaults or fails to meet its obligation to make full and timely payments of principal and interest, according to the terms of the debt security. Also called *default risk*.

Default risk The probability that a borrower defaults or fails to meet its obligation to make full and timely payments of principal and interest, according to the terms of the debt security. Also called *default probability*.

Default risk premium An extra return that compensates investors for the possibility that the borrower will fail to make a promised payment at the contracted time and in the contracted amount.

Defensive companies Companies with sales and profits that have little sensitivity to the business cycle or state of the economy.

Defensive interval ratio A liquidity ratio that estimates the number of days that an entity could meet cash needs from liquid assets; calculated as (cash + short-term marketable investments + receivables) divided by daily cash expenditures.

Deferred coupon bond Bond that pays no coupons for its first few years but then pays a higher coupon than it otherwise normally would for the remainder of its life. Also called *split coupon bond*.

Deferred income A liability account for money that has been collected for goods or services that have not yet been delivered; payment received in advance of providing a good or service.

Deferred revenue A liability account for money that has been collected for goods or services that have not yet been delivered; payment received in advance of providing a good or service.

Deferred tax assets A balance sheet asset that arises when an excess amount is paid for income taxes relative to accounting profit. The taxable income is higher than accounting profit and income tax payable exceeds tax expense. The company expects to recover the difference during the course of future operations when tax expense exceeds income tax payable.

Deferred tax liabilities A balance sheet liability that arises when a deficit amount is paid for income taxes relative to accounting profit. The taxable income is less than the accounting profit and income tax payable is less than tax expense. The company expects to eliminate the liability over the course of future operations when income tax payable exceeds tax expense.

Defined benefit pension plans Plans in which the company promises to pay a certain annual amount (defined benefit) to the employee after retirement. The company bears the investment risk of the plan assets.

Defined contribution pension plans Individual accounts to which an employee and typically the employer makes contributions during their working years and expect to draw on the accumulated funds at retirement. The employee bears the investment and inflation risk of the plan assets.

Deflation Negative inflation.

Degree of confidence The probability that a confidence interval includes the unknown population parameter.

Degree of financial leverage (DFL) The ratio of the percentage change in net income to the percentage change in operating income; the sensitivity of the cash flows available to owners when operating income changes.

Degree of operating leverage (DOL) The ratio of the percentage change in operating income to the percentage change in units sold; the sensitivity of operating income to changes in units sold.

Degree of total leverage The ratio of the percentage change in net income to the percentage change in units sold; the sensitivity of the cash flows to owners to changes in the number of units produced and sold.

Degrees of freedom The number of independent variables used in defining sample statistics, such as variance, and the probability distributions they measure.

Delta The sensitivity of the derivative price to a small change in the value of the underlying asset.

Demand curve Graph of the inverse demand function. A graph showing the demand relation, either the highest quantity willingly purchased at each price or the highest price willingly paid for each quantity.

Demand function A relationship that expresses the quantity demanded of a good or service as a function of own-price and possibly other variables.

Demand shock A typically unexpected disturbance to demand, such as an unexpected interruption in trade or transportation.

Dependent With reference to events, the property that the probability of one event occurring depends on (is related to) the occurrence of another event.

Dependent variable The variable whose variation about its mean is to be explained by the regression; the left-side variable in a regression equation. Also referred to as the *explained variable*.

Depository bank A bank that raises funds from depositors and other investors and lends it to borrowers.

Depository institutions Commercial banks, savings and loan banks, credit unions, and similar institutions that raise funds from depositors and other investors and lend it to borrowers.

Depository receipt A security that trades like an ordinary share on a local exchange and represents an economic interest in a foreign company.

Depreciation The process of systematically allocating the cost of long-lived (tangible) assets to the periods during which the assets are expected to provide economic benefits.

Derivative pricing rule A pricing rule used by crossing networks in which a price is taken (derived) from the price that is current in the asset's primary market.

Derivatives A financial instrument whose value depends on the value of some underlying asset or factor (e.g., a stock price, an interest rate, or exchange rate).

Descriptive statistics Measures that summarize central tendency and spread variation in the data's distribution.

Diffuse prior The assumption of equal prior probabilities.

Diffusion index Reflects the proportion of the index's components that are moving in a pattern consistent with the overall index.

Diluted EPS The EPS that would result if all dilutive securities were converted into common shares.

Diluted shares The number of shares that would be outstanding if all potentially dilutive claims on common shares (e.g., convertible debt, convertible preferred stock, and employee stock options) were exercised.

Diminishing balance method An accelerated depreciation method, i.e., one that allocates a relatively large proportion of the cost of an asset to the early years of the asset's useful life.

Diminishing marginal productivity Describes a state in which each additional unit of input produces less output than previously.

Direct format With reference to the cash flow statement, a format for the presentation of the statement in which cash flow from operating activities is shown as operating cash receipts less operating cash disbursements. Also called *direct method*.

Direct investing Occurs when an investor makes a direct investment in an asset without the use of an intermediary.

Direct method See *direct format.*

Direct taxes Taxes levied directly on income, wealth, and corporate profits.

Direct write-off method An approach to recognizing credit losses on customer receivables in which the company waits until such time as a customer has defaulted and only then recognizes the loss.

Discount To reduce the value of a future payment in allowance for how far away it is in time; to calculate the present value of some future amount. Also, the amount by which an instrument is priced below its face (par) value.

Discount margin See *required margin.*

Discount rates In general, the interest rates used to calculate present values. In the money market, however, a discount rate is a specific type of quoted rate.

Discounted cash flow models Valuation models that estimate the intrinsic value of a security as the present value of the future benefits expected to be received from the security.

Discouraged worker A person who has stopped looking for a job or has given up seeking employment.

Discrete data Numerical values that result from a counting process; therefore, practically speaking, the data are limited to a finite number of values.

Discrete random variable A random variable that can take on at most a countable number of possible values.

Discriminatory pricing rule A pricing rule used in continuous markets in which the limit price of the order or quote that first arrived determines the trade price.

Diseconomies of scale Increase in cost per unit resulting from increased production.

Dispersion The variability of a population or sample of observations around the central tendency.

Display size The size of an order displayed to public view.

Disposition effect As a result of loss aversion, an emotional bias whereby investors are reluctant to dispose of losers. This reluctance results in an inefficient and gradual adjustment to deterioration in fundamental value.

Distributed ledger A type of database that may be shared among entities in a network.

Distributed ledger technology Technology based on a distributed ledger.

Divergence In technical analysis, a term that describes the case when an indicator moves differently from the security being analyzed.

Diversification ratio The ratio of the standard deviation of an equally weighted portfolio to the standard deviation of a randomly selected security.

Dividend A distribution paid to shareholders based on the number of shares owned.

Dividend discount model (DDM) A present value model that estimates the intrinsic value of an equity share based on the present value of its expected future dividends.

Dividend payout ratio The ratio of cash dividends paid to earnings for a period.

Divisor A number (denominator) used to determine the value of a price return index. It is initially chosen at the inception of an index and subsequently adjusted by the index provider, as necessary, to avoid changes in the index value that are unrelated to changes in the prices of its constituent securities.

Doji In the Japanese terminology used in candlestick charting, the doji signifies that after a full day of trading, the positive price influence of buyers and the negative price influence of sellers exactly counteracted each other—with opening and closing prices that are virtually equal—which suggests that the market under analysis is in balance.

Domestic content provisions Stipulate that some percentage of the value added or components used in production should be of domestic origin.

Double bottom In technical analysis, a reversal pattern that is formed when the price reaches a low, rebounds, and then declines back to the first low level. A double bottom is used to predict a change from a downtrend to an uptrend.

Double coincidence of wants A prerequisite to barter trades, in particular that both economic agents in the transaction want what the other is selling.

Double declining balance depreciation An accelerated depreciation method that involves depreciating the asset at double the straight-line rate. This rate is multiplied by the book value of the asset at the beginning of the period (a declining balance) to calculate depreciation expense.

Double top In technical analysis, a reversal pattern that is formed when an uptrend reverses twice at roughly the same high price level. A double top is used to predict a change from an uptrend to a downtrend.

Down transition probability The probability that an asset's value moves down in a model of asset price dynamics.

Downgrade risk The risk that a bond issuer's creditworthiness deteriorates, or migrates lower, leading investors to believe the risk of default is higher. Also called *credit migration risk.*

Downside risk Risk of incurring returns below a specified value.

Downtrend A pattern that occurs when the price of an asset moves lower over a period of time.

Drag on liquidity When receipts lag, creating pressure from the decreased available funds.

Drawdown A percentage peak-to-trough reduction in net asset value.

Dual-currency bonds Bonds that make coupon payments in one currency and pay the par value at maturity in another currency.

DuPont analysis An approach to decomposing return on investment, e.g., return on equity, as the product of other financial ratios.

Duration A measure of the approximate sensitivity of a security to a change in interest rates (i.e., a measure of interest rate risk).

Duration gap A bond's Macaulay duration minus the investment horizon.

Dutch Book Theorem A result in probability theory stating that inconsistent probabilities create profit opportunities.

Early repayment option See *prepayment option*.

Earnings per share The amount of income earned during a period per share of common stock.

Earnings surprise The portion of a company's earnings that is unanticipated by investors and, according to the efficient market hypothesis, merits a price adjustment.

Economic costs All the remuneration needed to keep a productive resource in its current employment or to acquire the resource for productive use; the sum of total accounting costs and implicit opportunity costs.

Economic indicator A variable that provides information on the state of the overall economy.

Economic loss The amount by which accounting profit is less than normal profit.

Economic profit Equal to accounting profit less the implicit opportunity costs not included in total accounting costs; the difference between total revenue (TR) and total cost (TC). Also called *abnormal profit* or *supernormal profit*.

Economic stabilization Reduction of the magnitude of economic fluctuations.

Economic union Incorporates all aspects of a common market and in addition requires common economic institutions and coordination of economic policies among members.

Economies of scale Reduction in cost per unit resulting from increased production.

Effective annual rate The amount by which a unit of currency will grow in a year with interest on interest included.

Effective convexity A *curve convexity* statistic that measures the secondary effect of a change in a benchmark yield curve on a bond's price.

Effective duration The sensitivity of a bond's price to a change in a benchmark yield curve.

Effective interest rate The borrowing rate or market rate that a company incurs at the time of issuance of a bond.

Efficient market A market in which asset prices reflect new information quickly and rationally.

Elastic Said of a good or service when the magnitude of elasticity is greater than one.

Elasticity The percentage change in one variable for a percentage change in another variable; a general measure of how sensitive one variable is to a change in the value of another variable.

Elasticity of demand A measure of the sensitivity of quantity demanded to a change in a product's own price: $\%\Delta Q^D/\%\Delta P$.

Elasticity of supply A measure of the sensitivity of quantity supplied to a change in price: $\%\Delta Q^S/\%\Delta P$.

Electronic communications networks See *alternative trading systems*.

Embedded option Contingency provisions that provide the issuer or the bondholders the right, but not the obligation, to take action. These options are not part of the security and cannot be traded separately.

Embedded options Contingency provisions that provide the issuer or the bondholders the right, but not the obligation, to take action. These options are not part of the security and cannot be traded separately.

Emotional biases Behavioral biases resulting from reasoning influenced by feelings; emotional biases stem from impulse or intuition.

Empirical duration The use of statistical methods and historical bond prices to estimate the price–yield relationship for a specific bond or portfolio of bonds.

Empirical probability The probability of an event estimated as a relative frequency of occurrence.

Employed The number of people with a job.

Endowment bias An emotional bias in which people value an asset more when they hold rights to it than when they do not.

Engagement/active ownership An ESG investment approach that uses shareholder power to influence corporate behavior through direct corporate engagement (i.e., communicating with senior management and/or boards of companies), filing or co-filing shareholder proposals, and proxy voting that is directed by ESG guidelines.

Enterprise risk management An overall assessment of a company's risk position. A centralized approach to risk management sometimes called firmwide risk management.

Enterprise value A measure of a company's total market value from which the value of cash and short-term investments have been subtracted.

Equal weighting An index weighting method in which an equal weight is assigned to each constituent security at inception.

Equipment trust certificates Bonds secured by specific types of equipment or physical assets.

Equity Assets less liabilities; the residual interest in the assets after subtracting the liabilities.

Equity risk premium The expected return on equities minus the risk-free rate; the premium that investors demand for investing in equities.

Equity swap A swap transaction in which at least one cash flow is tied to the return to an equity portfolio position, often an equity index.

Error term The difference between an observation and its expected value, where the expected value is based on the true underlying population relation between the dependent and independent variables. Also known simply as the *error*.

ESG An acronym that encompasses environmental, social, and governance.

ESG integration An ESG investment approach that focuses on systematic consideration of material ESG factors in asset allocation, security selection, and portfolio construction decisions for the purpose of achieving the product's stated investment objectives. Used interchangeably with **ESG investing**.

ESG investing The consideration of environmental, social, and governance factors in the investment process. Used interchangeably with **ESG integration**.

Estimate The particular value calculated from sample observations using an estimator.

Estimated parameters With reference to a regression analysis, the estimated values of the population intercept and population slope coefficients in a regression.

Estimator An estimation formula; the formula used to compute the sample mean and other sample statistics are examples of estimators.

Ethical principles Beliefs regarding what is good, acceptable, or obligatory behavior and what is bad, unacceptable, or forbidden behavior.

Ethics The study of moral principles or of making good choices. Ethics encompasses a set of moral principles and rules of conduct that provide guidance for our behavior.

Eurobonds Type of bond issued internationally, outside the jurisdiction of the country in whose currency the bond is denominated.

European-style Said of an option contract that can only be exercised on the option's expiration date.

Event Any outcome or specified set of outcomes of a random variable.

Ex-dividend date The first date that a share trades without (i.e., "ex") the dividend.

Excess kurtosis Degree of kurtosis (fatness of tails) relative to the kurtosis of the normal distribution.

Exchanges Places where traders can meet to arrange their trades.

Execution instructions Instructions that indicate how to fill an order.

Exercise The process of using an option to buy or sell the underlying.

Exercise price The fixed price at which an option holder can buy or sell the underlying. Also called *strike price*, *striking price*, or *strike*.

Exercise value The value obtained if an option is exercised based on current conditions. Also known as *intrinsic value*.

Exhaustive Covering or containing all possible outcomes.

Expansion The period of a business cycle after its lowest point and before its highest point.

Expansionary Tending to cause the real economy to grow.

Expansionary fiscal policy Fiscal policy aimed at achieving real economic growth.

Expected inflation The level of inflation that economic agents expect in the future.

Expected loss Default probability times loss severity given default.

Expected return on the portfolio ($E(R_p)$) The weighted average of the expected returns (R_1 to R_n) on the component securities using their respective weights (w_1 to w_n).

Expected value The probability-weighted average of the possible outcomes of a random variable.

Expenses Outflows of economic resources or increases in liabilities that result in decreases in equity (other than decreases because of distributions to owners); reductions in net assets associated with the creation of revenues.

Export subsidy Paid by the government to the firm when it exports a unit of a good that is being subsidized.

Exports Goods and services that an economy sells to other countries.

Extension risk The risk that when interest rates rise, fewer prepayments will occur because homeowners are reluctant to give up the benefits of a contractual interest rate that now looks low. As a result, the security becomes longer in maturity than anticipated at the time of purchase.

Externalities Spillover effects of production and consumption activities onto others who are not directly involved in a particular transaction, activity, or decision.

Externality An effect of a market transaction that is borne by parties other than those who transacted.

Extra dividend A dividend paid by a company that does not pay dividends on a regular schedule, or a dividend that supplements regular cash dividends with an extra payment.

Extreme value theory A branch of statistics that focuses primarily on extreme outcomes.

Face value The amount of cash payable by a company to the bondholders when the bonds mature; the promised payment at maturity separate from any coupon payment.

Factoring arrangement When a company sells its accounts receivable to a lender (known as a factor) who assumes responsibility for the credit granting and collection process.

Fair value The amount at which an asset could be exchanged, or a liability settled, between knowledgeable, willing parties in an arm's-length transaction; the price that would be received to sell an asset or paid to transfer a liability in an orderly transaction between market participants.

False discovery approach An adjustment in the p-values for tests performed multiple times.

False discovery rate The rate of Type I errors in testing a null hypothesis multiple times for a given level of significance.

Fat-Tailed Describes a distribution that has fatter tails than a normal distribution (also called leptokurtic).

Fed funds rate The US interbank lending rate on overnight borrowings of reserves.

Federal funds rate The US interbank lending rate on overnight borrowings of reserves.

Fiat money Money that is not convertible into any other commodity.

Fiduciary An entity designated to represent the rights and responsibilities of a beneficiary whose assets they are managing, such as a bond trustee acting on behalf of fixed-income investors.

Fiduciary call A combination of a European call and a risk-free bond that matures on the option expiration day and has a face value equal to the exercise price of the call.

FIFO method The first in, first out, method of accounting for inventory, which matches sales against the costs of items of inventory in the order in which they were placed in inventory.

Fill or kill See *immediate or cancel order*.

Finance lease From the lessee perspective, under US GAAP, a type of lease which is more akin to the purchase of an asset by the lessee. From the lessor perspective, under IFRS, a lease which "transfers substantially all the risks and rewards incidental to ownership of an underlying asset."

Financial account A component of the balance of payments account that records investment flows.

Financial distress Heightened uncertainty regarding a company's ability to meet its various obligations because of diminished earnings power or actual current losses.

Financial flexibility The ability to react and adapt to financial adversity and opportunities.

Financial leverage The extent to which a company can effect, through the use of debt, a proportional change in the return on common equity that is greater than a given proportional change in operating income; also, short for the financial leverage ratio.

Financial leverage ratio A measure of financial leverage calculated as average total assets divided by average total equity.

Financial risk The risk that environmental, social, or governance risk factors will result in significant costs or other losses to a company and its shareholders; the risk arising from a company's obligation to meet required payments under its financing agreements.

Financing activities Activities related to obtaining or repaying capital to be used in the business (e.g., equity and long-term debt).

Fintech Technological innovation in the design and delivery of financial services and products in the financial industry.

Firm commitment offering See *underwritten offering*.

First-degree price discrimination Where a monopolist is able to charge each customer the highest price the customer is willing to pay.

First lien debt Debt secured by a pledge of certain assets that could include buildings, but it may also include property and equipment, licenses, patents, brands, etc.

First mortgage debt Debt secured by a pledge of a specific property.

Fiscal multiplier The ratio of a change in national income to a change in government spending.

Fiscal policy The use of taxes and government spending to affect the level of aggregate expenditures.

Fisher effect The thesis that the real rate of interest in an economy is stable over time so that changes in nominal interest rates are the result of changes in expected inflation.

Fixed charge coverage A solvency ratio measuring the number of times interest and lease payments are covered by operating income, calculated as (EBIT + lease payments) divided by (interest payments + lease payments).

Fixed costs Costs that remain at the same level regardless of a company's level of production and sales.

Fixed-for-floating interest rate swap An interest rate swap in which one party pays a fixed rate and the other pays a floating rate, with both sets of payments in the same currency. Also called *plain vanilla swap* or *vanilla swap*.

Fixed-rate perpetual preferred stock Nonconvertible, noncallable preferred stock that has a fixed dividend rate and no maturity date.

Flag A technical analysis continuation pattern formed by parallel trendlines, typically over a short period.

Flat price The full price of a bond minus the accrued interest; also called the *quoted* or *clean* price.

Float-adjusted market-capitalization weighting An index weighting method in which the weight assigned to each constituent security is determined by adjusting its market capitalization for its market float.

Floaters See *floating-rate notes*.

Floating-rate notes Notes on which interest payments are not fixed but instead vary from period to period depending on the current level of a reference interest rate.

Flotation cost Fees charged to companies by investment bankers and other costs associated with raising new capital.

Foreclosure Allows the lender to take possession of a mortgaged property if the borrower defaults and then sell it to recover funds.

Foreign currency reserves Holding by the central bank of non-domestic currency deposits and non-domestic bonds.

Foreign direct investment Direct investment by a firm in one country (the source country) in productive assets in a foreign country (the host country).

Foreign exchange gains (or losses) Gains (or losses) that occur when the exchange rate changes between the investor's currency and the currency that foreign securities are denominated in.

Foreign portfolio investment Shorter-term investment by individuals, firms, and institutional investors (e.g., pension funds) in foreign financial instruments such as foreign stocks and foreign government bonds.

Forward commitments Class of derivatives that provides the ability to lock in a price to transact in the future at a previously agreed-upon price.

Forward contract An agreement between two parties in which one party, the buyer, agrees to buy from the other party, the seller, an underlying asset at a later date for a price established at the start of the contract.

Forward curve A series of forward rates, each having the same time frame.

Forward market For future delivery, beyond the usual settlement time period in the cash market.

Forward price The fixed price or rate at which the transaction scheduled to occur at the expiration of a forward contract will take place. This price is agreed on at the initiation date of the contract.

Forward rate The interest rate on a bond or money market instrument traded in a forward market. A forward rate can be interpreted as an incremental, or marginal, return for extending the time-to-maturity for an additional time period.

Forward rate agreements A forward contract calling for one party to make a fixed interest payment and the other to make an interest payment at a rate to be determined at the contract expiration.

Fractile A value at or below which a stated fraction of the data lies. Also called quantile.

Fractional reserve banking Banking in which reserves constitute a fraction of deposits.

Framing bias An information-processing bias in which a person answers a question differently based on the way in which it is asked (framed).

Free cash flow The actual cash that would be available to the company's investors after making all investments necessary to maintain the company as an ongoing enterprise (also referred to as free cash flow to the firm); the internally generated funds that can be distributed to the company's investors (e.g., shareholders and bondholders) without impairing the value of the company.

Free cash flow hypothesis The hypothesis that higher debt levels discipline managers by forcing them to make fixed debt service payments and by reducing the company's free cash flow.

Free-cash-flow-to-equity models Valuation models based on discounting expected future free cash flow to equity.

Free float The number of shares that are readily and freely tradable in the secondary market.

Free trade When there are no government restrictions on a country's ability to trade.

Free trade areas One of the most prevalent forms of regional integration, in which all barriers to the flow of goods and services among members have been eliminated.

Frequency distribution A tabular display of data constructed either by counting the observations of a variable by distinct values or groups or by tallying the values of a numerical variable into a set of numerically ordered bins (also called a one-way table).

Frequency polygon A graph of a frequency distribution obtained by drawing straight lines joining successive points representing the class frequencies.

Frequency table A representation of the frequency of occurrence of two discrete variables.

Full price The price of a security with accrued interest; also called the *invoice* or *dirty* price.

Fund investing In fund investing, the investor invests in assets indirectly by contributing capital to a fund as part of a group of investors. Fund investing is available for all major alternative investment types.

Fundamental analysis The examination of publicly available information and the formulation of forecasts to estimate the intrinsic value of assets.

Fundamental value The underlying or true value of an asset based on an analysis of its qualitative and quantitative characteristics. Also called *intrinsic value*.

Fundamental weighting An index weighting method in which the weight assigned to each constituent security is based on its underlying company's size. It attempts to address the disadvantages of market-capitalization weighting by using measures that are independent of the constituent security's price.

Funds of hedge funds Funds that hold a portfolio of hedge funds, more commonly shortened to *funds of funds*.

Fungible Freely exchangeable, interchangeable, or substitutable with other things of the same type. Money and commodities are the most common examples.

Future value (FV) The amount to which a payment or series of payments will grow by a stated future date.

Futures contract A variation of a forward contract that has essentially the same basic definition but with some additional features, such as a clearinghouse guarantee against credit losses, a daily settlement of gains and losses, and an organized electronic or floor trading facility.

Futures price The agreed-upon price of a futures contract.

FX swap The combination of a spot and a forward FX transaction.

G-spread The yield spread in basis points over an actual or interpolated government bond.

Gains Asset inflows not directly related to the ordinary activities of the business.

Game theory The set of tools decision makers use to incorporate responses by rival decision makers into their strategies.

Gamma A numerical measure of how sensitive an option's delta (the sensitivity of the derivative's price) is to a change in the value of the underlying.

Gap opening A gap is an area of a chart where a security's price either rises or falls from the previous day's close with no trading occurring in between. A gap opening is the start of a new trading session with a gap.

GDP deflator A gauge of prices and inflation that measures the aggregate changes in prices across the overall economy.

General partner (GP) The partner that runs the business and theoretically bears unlimited liability for the business's debts and obligations.

Geometric mean A measure of central tendency computed by taking the nth root of the product of n non-negative values.

Giffen goods Goods that are consumed more as the price of the good rises because it is a very inferior good whose income effect overwhelms its substitution effect when price changes.

Gilts Bonds issued by the UK government.

Global depository receipt A depository receipt that is issued outside of the company's home country and outside of the United States.

Global minimum-variance portfolio The portfolio on the minimum-variance frontier with the smallest variance of return.

Global registered share A common share that is traded on different stock exchanges around the world in different currencies.

Gold standard With respect to a currency, if a currency is on the gold standard a given amount can be converted into a prespecified amount of gold.

Golden Cross See **Bullish crossover**.

Good-on-close An execution instruction specifying that an order can only be filled at the close of trading. Also called *market on close*.

Good-on-open An execution instruction specifying that an order can only be filled at the opening of trading.

Good-till-cancelled order An order specifying that it is valid until the entity placing the order has cancelled it (or, commonly, until some specified amount of time such as 60 days has elapsed, whichever comes sooner).

Goodwill An intangible asset that represents the excess of the purchase price of an acquired company over the value of the net assets acquired.

Government equivalent yield A yield that restates a yield-to-maturity based on a 30/360 day count to one based on actual/actual.

Green bonds Bonds used in green finance whereby the proceeds are earmarked toward environmental-related products.

Green finance A type of finance that addresses environmental concerns while achieving economic growth.

Green loans Any loan instruments made available exclusively to finance or re-finance, in whole or in part, new and/or existing eligible green projects. Green loans are commonly aligned in the market with the Green Loan Principles.

Greenfield investment Investing in infrastructure assets *that are to be constructed*.

Grey market The forward market for bonds about to be issued. Also called "when issued" market.

Gross domestic product The market value of all final goods and services produced within the economy during a given period (output definition) or, equivalently, the aggregate income earned by all households, all companies, and the government within the economy during a given period (income definition).

Gross margin Sales minus the cost of sales (i.e., the cost of goods sold for a manufacturing company).

Gross profit Sales minus the cost of sales (i.e., the cost of goods sold for a manufacturing company).

Gross profit margin The ratio of gross profit to revenues.

Grouped bar chart A bar chart for showing joint frequencies for two categorical variables (also known as a **clustered bar chart**).

Grouping by function With reference to the presentation of expenses in an income statement, the grouping together of expenses serving the same function, e.g. all items that are costs of goods sold.

Grouping by nature With reference to the presentation of expenses in an income statement, the grouping together of expenses by similar nature, e.g., all depreciation expenses.

Growth cycle Refers to fluctuations in economic activity around the long-term potential trend growth level, focusing on how much actual economic activity is below or above trend growth in economic activity.

Growth cyclical A term sometimes used to describe companies that are growing rapidly on a long-term basis but that still experience above-average fluctuation in their revenues and profits over the course of a business cycle.

Growth investors With reference to equity investors, investors who seek to invest in high-earnings-growth companies.

Growth option The ability to make additional investments in a project at some future time if the financial results are strong. Also called *expansion option*.

Growth rate cycle Refers to fluctuations in the growth rate of economic activity.

Guarantee certificate A type of structured financial instrument that provides investors with capital protection. It combines a zero-coupon bond and a call option on some underlying asset.

Haircut See *repo margin*.

Halo effect An emotional bias that extends a favorable evaluation of some characteristics to other characteristics.

Hard-bullet covered bonds Covered bonds for which a bond default is triggered and bond payments are accelerated in the event of sponsor default if payments do not occur according to the original maturity schedule.

Harmonic mean A type of weighted mean computed as the reciprocal of the arithmetic average of the reciprocals.

Head and shoulders pattern In technical analysis, a reversal pattern that is formed in three parts: a left shoulder, a head, and a right shoulder. A head and shoulders pattern is used to predict a change from an uptrend to a downtrend.

Headline inflation Refers to the inflation rate calculated based on the price index that includes all goods and services in an economy.

Heat map A type of graphic that organizes and summarizes data in a tabular format and represents it using a color spectrum.

Hedge funds Private investment vehicles that typically use leverage, derivatives, and long and short investment strategies.

Hedge portfolio A hypothetical combination of the derivative and its underlying that eliminates risk.

Held-to-maturity Debt (fixed-income) securities that a company intends to hold to maturity; these are presented at their original cost, updated for any amortisation of discounts or premiums.

Herding Clustered trading that may or may not be based on information.

Heteroskedasticity A violation of the simple linear regression assumption of homoskedasticity; with heteroskedasticity, the variability of the residuals is not equal across all observations.

Hidden order An order that is exposed not to the public but only to the brokers or exchanges that receive it.

High-frequency trading A form of algorithmic trading that makes use of vast quantities of data to execute trades on ultra-high-speed networks in fractions of a second.

High-water mark The highest value, net of fees, which a fund has reached in history. It reflects the highest cumulative return used to calculate an incentive fee.

Hindsight bias A bias with selective perception and retention aspects in which people may see past events as having been predictable and reasonable to expect.

Histogram A chart that presents the distribution of numerical data by using the height of a bar or column to represent the absolute frequency of each bin or interval in the distribution.

Historical cost In reference to assets, the amount paid to purchase an asset, including any costs of acquisition and/or preparation; with reference to liabilities, the amount of proceeds received in exchange in issuing the liability.

Historical equity risk premium approach An estimate of a country's equity risk premium that is based on the historical averages of the risk-free rate and the rate of return on the market portfolio.

Holder-of-record date The date that a shareholder listed on the corporation's books will be deemed to have ownership of the shares for purposes of receiving an upcoming dividend.

Holding period return The return that an investor earns during a specified holding period; a synonym for total return.

Home bias A preference for securities listed on the exchanges of one's home country.

Homogeneity of expectations The assumption that all investors have the same economic expectations and thus have the same expectations of prices, cash flows, and other investment characteristics.

Homoskedasticity An assumption of simple linear regression such that the variability of the residuals is equal across all observations.

Horizon yield The internal rate of return between the total return (the sum of reinvested coupon payments and the sale price or redemption amount) and the purchase price of the bond.

Horizontal analysis Common-size analysis that involves comparing a specific financial statement with that statement in prior or future time periods; also, cross-sectional analysis of one company with another.

Horizontal demand schedule Implies that at a given price, the response in the quantity demanded is infinite.

Hostile takeover An attempt by one entity to acquire a company without the consent of the company's management.

Household A person or a group of people living in the same residence, taken as a basic unit in economic analysis.

Human capital The accumulated knowledge and skill that workers acquire from education, training, or life experience and the corresponding present value of future earnings to be generated by said skilled individual.

Hurdle rate The minimum rate of return on investment that a fund must reach before a GP receives carried interest.

Hypothesis A proposed explanation or theory that can be tested.

Hypothesis testing The process of testing of hypotheses about one or more populations using statistical inference.

I-spread The yield spread of a specific bond over the standard swap rate in that currency of the same tenor.

Iceberg order An order in which the display size is less than the order's full size.

If-converted method A method for accounting for the effect of convertible securities on earnings per share (EPS) that specifies what EPS would have been if the convertible securities had been converted at the beginning of the period, taking account of the effects of conversion on net income and the weighted average number of shares outstanding.

Illusion of control bias A bias in which people tend to believe that they can control or influence outcomes when, in fact, they cannot.

Immediate or cancel order An order that is valid only upon receipt by the broker or exchange. If such an order cannot be filled in part or in whole upon receipt, it cancels immediately. Also called *fill or kill*.

Impact investing Investments made with the intention to generate positive, measurable social and environmental impact alongside a financial return.

Impact lag The lag associated with the result of actions affecting the economy with delay.

Implicit price deflator for GDP A gauge of prices and inflation that measures the aggregate changes in prices across the overall economy.

Implicit selection bias One type of selection bias introduced through the presence of a threshold that filters out some unqualified members.

Implied forward rates Calculated from spot rates, an implied forward rate is a breakeven reinvestment rate that links the return on an investment in a shorter-term zero-coupon bond to the return on an investment in a longer-term zero-coupon bond.

Implied volatility The volatility that option traders use to price an option, implied by the price of the option and a particular option-pricing model.

Import license Specifies the quantity of a good that can be imported into a country.

Imports Goods and services that a domestic economy (i.e., house-holds, firms, and government) purchases from other countries.

In the money Options that, if exercised, would result in the value received being worth more than the payment required to exercise.

Income Increases in economic benefits in the form of inflows or enhancements of assets, or decreases of liabilities that result in an increase in equity (other than increases resulting from contributions by owners).

Income elasticity of demand A measure of the responsiveness of demand to changes in income, defined as the percentage change in quantity demanded divided by the percentage change in income.

Income tax paid The actual amount paid for income taxes in the period; not a provision, but the actual cash outflow.

Income tax payable The income tax owed by the company on the basis of taxable income.

Increasing marginal returns When the marginal product of a resource increases as additional units of that input are employed.

Increasing returns to scale When a production process leads to increases in output that are proportionately larger than the increase in inputs.

Incremental cash flow The cash flow that is realized because of a decision; the changes or increments to cash flows resulting from a decision or action.

Indenture Legal contract that describes the form of a bond, the obligations of the issuer, and the rights of the bondholders. Also called the *trust deed*.

Independent With reference to events, the property that the occurrence of one event does not affect the probability of another event occurring. With reference to two random variables X and Y, they are independent if and only if $P(X,Y) = P(X)P(Y)$.

Independent projects Independent projects are capital investments whose cash flows are independent of each other.

Independent variable A variable used to explain the dependent variable in a regression; a right-side variable in a regression equation. Also referred to as the *explanatory variable*.

Independently and identically distributed With respect to random variables, the property of random variables that are independent of each other but follow the identical probability distribution.

Index-linked bond Bond for which coupon payments and/or principal repayment are linked to a specified index.

Indexing An investment strategy in which an investor constructs a portfolio to mirror the performance of a specified index.

Indicator variable A variable that takes on only one of two values, 0 or 1, based on a condition. In simple linear regression, the slope is the difference in the dependent variable for the two conditions. Also referred to as a *dummy variable*.

Indifference curve A curve representing all the combinations of two goods or attributes such that the consumer is entirely indifferent among them.

Indirect format With reference to cash flow statements, a format for the presentation of the statement which, in the operating cash flow section, begins with net income then shows additions and subtractions to arrive at operating cash flow. Also called *indirect method*.

Indirect method See *indirect format*.

Indirect taxes Taxes such as taxes on spending, as opposed to direct taxes.

Industry A group of companies offering similar products and/or services.

Industry analysis The analysis of a specific branch of manufacturing, service, or trade.

Inelastic Said of a good or service when the magnitude of elasticity is less than one. Insensitive to price changes.

Inferior goods A good whose consumption decreases as income increases.

Inflation The percentage increase in the general price level from one period to the next; a sustained rise in the overall level of prices in an economy.

Inflation-linked bond Type of index-linked bond that offers investors protection against inflation by linking the bond's coupon payments and/or the principal repayment to an index of consumer prices. Also called *linkers*.

Inflation premium An extra return that compensates investors for expected inflation.

Inflation reports A type of economic publication put out by many central banks.

Inflation uncertainty The degree to which economic agents view future rates of inflation as difficult to forecast.

Information cascade The transmission of information from those participants who act first and whose decisions influence the decisions of others.

Information-motivated traders Traders that trade to profit from information that they believe allows them to predict future prices.

Informationally efficient market A market in which asset prices reflect new information quickly and rationally.

Initial coin offering An unregulated process whereby companies raise capital by selling crypto tokens to investors in exchange for fiat money or another agreed-upon cryptocurrency.

Initial margin The amount that must be deposited in a clearinghouse account when entering into a futures contract.

Initial margin requirement The margin requirement on the first day of a transaction as well as on any day in which additional margin funds must be deposited.

Initial public offering (IPO) The first issuance of common shares to the public by a formerly private corporation.

Input productivity The amount of output produced by workers in a given period of time—for example, output per hour worked; measures the efficiency of labor.

Intangible assets Assets lacking physical substance, such as patents and trademarks.

Interbank market The market of loans and deposits between banks for maturities ranging from overnight to one year.

Intercept The expected value of the dependent variable when the independent variable in a simple linear regression is equal to zero.

Interest Payment for lending funds.

Interest coverage A solvency ratio calculated as EBIT divided by interest payments.

Interest-only mortgage A loan in which no scheduled principal repayment is specified for a certain number of years.

Interest rate A rate of return that reflects the relationship between differently dated cash flows; a discount rate.

Interest rate effect The effect through which price level changes, through demand for money, impact interest rate, which in turn impacts investment and consumption.

Interest rate swap A swap in which the underlying is an interest rate. Can be viewed as a currency swap in which both currencies are the same and can be created as a combination of currency swaps.

Intermarket analysis A field within technical analysis that combines analysis of the major categories of securities—namely, equities, bonds, currencies, and commodities—to identify market trends and possible inflections in trends.

Internal rate of return The discount rate that makes net present value equal 0; the discount rate that makes the present value of an investment's costs (outflows) equal to the present value of the investment's benefits (inflows).

Internet of Things A network arrangement of structures and devices whereby the objects on the network are able to interact and share information.

Interpolated spread The yield spread of a specific bond over the standard swap rate in that currency of the same tenor.

Interquartile range The difference between the third and first quartiles of a dataset.

Interval With reference to grouped data, a set of values within which an observation falls.

Intrinsic value See *exercise value*.

Inventory investment Net change in business inventory.

Inventory turnover An activity ratio calculated as cost of goods sold divided by average inventory.

Inverse demand function A restatement of the demand function in which price is stated as a function of quantity.

Inverse floater A type of leveraged structured financial instrument. The cash flows are adjusted periodically and move in the opposite direction of changes in the reference rate.

Inverse transformation method A method using randomly generated numbers from the continuous uniform distribution to generate random observations from any distribution.

Investing activities Activities associated with the acquisition and disposal of property, plant, and equipment; intangible assets; other long-term assets; and both long-term and short-term investments in the equity and debt (bonds and loans) issued by other companies.

Investment banks Financial intermediaries that provide advice to their mostly corporate clients and help them arrange transactions such as initial and seasoned securities offerings.

Investment policy statement (IPS) A written planning document that describes a client's investment objectives and risk tolerance over a relevant time horizon, along with constraints that apply to the client's portfolio.

Investment property Property used to earn rental income or capital appreciation (or both).

Jackknife A resampling method that repeatedly draws samples by taking the original observed data sample and leaving out one observation at a time (without replacement) from the set.

January effect Calendar anomaly that stock market returns in January are significantly higher compared to the rest of the months of the year, with most of the abnormal returns reported during the first five trading days in January. Also called *turn-of-the-year effect*.

Joint frequencies The entry in the cells of the contingency table that represent the joining of one variable from a row and the other variable from a column to count observations.

Joint probability The probability of the joint occurrence of stated events.

Joint probability function A function giving the probability of joint occurrences of values of stated random variables.

Judgmental Sampling A procedure of selectively handpicking elements from the population based on a researcher's knowledge and professional judgment.

Key rate duration A method of measuring the interest rate sensitivities of a fixed-income instrument or portfolio to shifts in key points along the yield curve.

Keynesians Economists who believe that fiscal policy can have powerful effects on aggregate demand, output, and employment when there is substantial spare capacity in an economy.

Kurtosis The statistical measure that indicates the combined weight of the tails of a distribution relative to the rest of the distribution.

Labor force The portion of the working age population (over the age of 16) that is employed or is available for work but not working (unemployed).

Labor productivity The quantity of goods and services (real GDP) that a worker can produce in one hour of work.

Lagging economic indicators Turning points that take place later than those of the overall economy; they are believed to have value in identifying the economy's past condition.

Law of demand The principle that as the price of a good rises, buyers will choose to buy less of it, and as its price falls, they will buy more.

Law of diminishing marginal returns The observation that a variable factor's marginal product must eventually fall as more of it is added to a fixed amount of the other factors.

Law of diminishing returns The smallest output that a firm can produce such that its long run average costs are minimized.

Law of one price The condition in a financial market in which two equivalent financial instruments or combinations of financial instruments can sell for only one price. Equivalent to the principle that no arbitrage opportunities are possible.

Lead underwriter The lead investment bank in a syndicate of investment banks and broker–dealers involved in a securities underwriting.

Leading economic indicators Turning points that usually precede those of the overall economy; they are believed to have value for predicting the economy's future state, usually near-term.

Lease A contract that conveys the right to use an asset for a period of time in exchange for consideration.

Legal tender Something that must be accepted when offered in exchange for goods and services.

Lender of last resort An entity willing to lend money when no other entity is ready to do so.

Leptokurtic Describes a distribution that has fatter tails than a normal distribution (also called fat-tailed).

Lessee The party obtaining the use of an asset through a lease.

Lessor The owner of an asset that grants the right to use the asset to another party.

Letter of credit Form of external credit enhancement whereby a financial institution provides the issuer with a credit line to reimburse any cash flow shortfalls from the assets backing the issue.

Level of significance The probability of a Type I error in testing a hypothesis.

Leverage In the context of corporate finance, leverage refers to the use of fixed costs within a company's cost structure. Fixed costs that are operating costs (such as depreciation or rent) create operating leverage. Fixed costs that are financial costs (such as interest expense) create financial leverage.

Leveraged buyout A transaction whereby the target company's management team converts the target to a privately held company by using heavy borrowing to finance the purchase of the target company's outstanding shares.

Liabilities Present obligations of an enterprise arising from past events, the settlement of which is expected to result in an outflow of resources embodying economic benefits; creditors' claims on the resources of a company.

LIFO layer liquidation With respect to the application of the LIFO inventory method, the liquidation of old, relatively low-priced inventory; happens when the volume of sales rises above the volume of recent purchases so that some sales are made from relatively old, low-priced inventory. Also called *LIFO liquidation*.

LIFO method The last in, first out, method of accounting for inventory, which matches sales against the costs of items of inventory in the reverse order the items were placed in inventory (i.e., inventory produced or acquired last are assumed to be sold first).

LIFO reserve The difference between the reported LIFO inventory carrying amount and the inventory amount that would have been reported if the FIFO method had been used (in other words, the FIFO inventory value less the LIFO inventory value).

Likelihood The probability of an observation, given a particular set of conditions.

Limit down A limit move in the futures market in which the price at which a transaction would be made is at or below the lower limit.

Limit order Instructions to a broker or exchange to obtain the best price immediately available when filling an order, but in no event accept a price higher than a specified (limit) price when buying or accept a price lower than a specified (limit) price when selling.

Limit order book The book or list of limit orders to buy and sell that pertains to a security.

Limit up A limit move in the futures market in which the price at which a transaction would be made is at or above the upper limit.

Limitations on liens Meant to put limits on how much secured debt an issuer can have.

Limited partners Partners with limited liability. Limited partnerships in hedge and private equity funds are typically restricted to investors who are expected to understand and to be able to assume the risks associated with the investments.

Limited partnership agreement (LPA) A legal document that outlines the rules of the partnership and establishes the framework that ultimately guides the fund's operations throughout its life.

Lin-log model A regression model in which the independent variable is in logarithmic form.

Line chart A type of graph used to visualize ordered observations. In technical analysis, a plot of price data, typically closing prices, with a line connecting the points.

Linear interpolation The estimation of an unknown value on the basis of two known values that bracket it, using a straight line between the two known values.

Linear regression Regression that models the straight-line relationship between the dependent and independent variables. Also known as *least squares regression* and *ordinary least squares regression*.

Linear scale A scale in which equal distances correspond to equal absolute amounts. Also called an *arithmetic scale*.

Linker See *inflation-linked bond*.

Liquid market Said of a market in which traders can buy or sell with low total transaction costs when they want to trade.

Liquidation To sell the assets of a company, division, or subsidiary piecemeal, typically because of bankruptcy; the form of bankruptcy that allows for the orderly satisfaction of creditors' claims after which the company ceases to exist.

Liquidity The extent to which a company is able to meet its short-term obligations using cash flows and those assets that can be readily transformed into cash.

Liquidity premium An extra return that compensates investors for the risk of loss relative to an investment's fair value if the investment needs to be converted to cash quickly.

Liquidity ratios Financial ratios measuring the company's ability to meet its short-term obligations to creditors.

Liquidity risk The risk that a financial instrument cannot be purchased or sold without a significant concession in price due to the size of the market.

Liquidity trap A condition in which the demand for money becomes infinitely elastic (horizontal demand curve) so that injections of money into the economy will not lower interest rates or affect real activity.

Load fund A mutual fund in which, in addition to the annual fee, a percentage fee is charged to invest in the fund and/or for redemptions from the fund.

Loan-to-value ratio The amount of the property's mortgage divided by the purchase price

Locked limit A condition in the futures markets in which a transaction cannot take place because the price would be beyond the limits.

Lockup period The minimum holding period before investors are allowed to make withdrawals or redeem shares from a fund.

Log-lin model A regression model in which the dependent variable is in logarithmic form.

Log-log model A regression model in which both the dependent and independent variables are in logarithmic form. Also known as the *double-log model*.

Logarithmic scale A scale in which equal distances represent equal proportional changes in the underlying quantity.

London interbank offered rate (Libor) Collective name for multiple rates at which a select set of banks believes they could borrow unsecured funds from other banks in the London interbank market for different currencies and different borrowing periods ranging from overnight to one year.

Long The buyer of a derivative contract. Also refers to the position of owning a derivative.

Long-lived assets Assets that are expected to provide economic benefits over a future period of time, typically greater than one year. Also called *long-term assets*.

Long position A position in an asset or contract in which one owns the asset or has an exercisable right under the contract.

Long-run average total cost The curve describing average total cost when no costs are considered fixed.

Look-ahead bias A bias caused by using information that was unavailable on the test date.

Loss aversion The tendency of people to dislike losses more than they like comparable gains.

Loss-aversion bias A bias in which people tend to strongly prefer avoiding losses as opposed to achieving gains.

Loss severity Portion of a bond's value (including unpaid interest) an investor loses in the event of default.

Losses Asset outflows not directly related to the ordinary activities of the business.

Lower bound The lowest possible value of an option.

M^2 A measure of what a portfolio would have returned if it had taken on the same total risk as the market index.

M^2 alpha Difference between the risk-adjusted performance of the portfolio and the performance of the benchmark.

Macaulay duration The approximate amount of time a bond would have to be held for the market discount rate at purchase to be realized if there is a single change in interest rate. It indicates the point in time when the coupon reinvestment and price effects of a change in yield-to-maturity offset each other.

Machine learning Computer based techniques that seek to extract knowledge from large amounts of data by "learning" from known examples and then generating structure or predictions. ML algorithms aim to "find the pattern, apply the pattern."

Macroeconomics The branch of economics that deals with aggregate economic quantities, such as national output and national income.

Maintenance covenants Covenants in bank loan agreements that require the borrower to satisfy certain financial ratio tests while the loan is outstanding.

Maintenance margin The minimum amount that is required by a futures clearinghouse to maintain a margin account and to protect against default. Participants whose margin balances drop below the required maintenance margin must replenish their accounts.

Maintenance margin requirement The margin requirement on any day other than the first day of a transaction.

Management buy-in Leveraged buyout in which the current management team is being replaced and the acquiring team will be involved in managing the company.

Management buyout A leveraged buyout event in which a group of investors consisting primarily of the company's existing management purchases at least controlling interest in its outstanding shares. At the extreme, they may purchase all shares and take the company private.

Management fee A fee based on assets under management or committed capital, as applicable—also called a *base fee*.

MAR ratio A variation of the Calmar ratio that uses a full investment history and the average drawdown.

Margin The amount of money that a trader deposits in a margin account. The term is derived from the stock market practice in which an investor borrows a portion of the money required to purchase a certain amount of stock. In futures markets, there is no borrowing so the margin is more of a down payment or performance bond.

Margin bond A cash deposit required by the clearinghouse from the participants to a contract to provide a credit guarantee. Also called a *performance bond*.

Margin call A request for the short to deposit additional funds to bring their balance up to the initial margin.

Margin loan Money borrowed from a broker to purchase securities.

Marginal cost The cost of producing an additional unit of a good.

Marginal frequencies The sums determined by adding joint frequencies across rows or across columns in a contingency table.

Marginal product Measures the productivity of each unit of input and is calculated by taking the difference in total product from adding another unit of input (assuming other resource quantities are held constant).

Marginal propensity to consume The proportion of an additional unit of disposable income that is consumed or spent; the change in consumption for a small change in income.

Marginal propensity to save The proportion of an additional unit of disposable income that is saved (not spent).

Marginal revenue The change in total revenue divided by the change in quantity sold; simply, the additional revenue from selling one more unit.

Marginal value curve A curve describing the highest price consumers are willing to pay for each additional unit of a good.

Mark to market The revaluation of a financial asset or liability to its current market value or fair value.

Mark-to-market Refers to the current expected fair market value for which a given security would likely be available for purchase or sale if traded in current market conditions.

Market anomaly Change in the price or return of a security that cannot directly be linked to current relevant information known in the market or to the release of new information into the market.

Market bid–ask spread The difference between the best bid and the best offer.

Market-capitalization weighting An index weighting method in which the weight assigned to each constituent security is determined by dividing its market capitalization by the total market capitalization (sum of the market capitalization) of all securities in the index. Also called *value weighting*.

Market discount rate The rate of return required by investors given the risk of the investment in a bond; also called the *required yield* or the *required rate of return*.

Market float The number of shares that are available to the investing public.

Market liquidity risk The risk that the price at which investors can actually transact—buying or selling—may differ from the price indicated in the market.

Market model A regression equation that specifies a linear relationship between the return on a security (or portfolio) and the return on a broad market index.

Market multiple models Valuation models based on share price multiples or enterprise value multiples.

Market-on-close An execution instruction specifying that an order can only be filled at the close of trading.

Market order Instructions to a broker or exchange to obtain the best price immediately available when filling an order.

Market-oriented investors With reference to equity investors, investors whose investment disciplines cannot be clearly categorized as value or growth.

Market rate of interest The rate demanded by purchasers of bonds, given the risks associated with future cash payment obligations of the particular bond issue.

Market reference rate (MRR) Collective name for a set of rates covering different currencies for different maturities, ranging from overnight to one year.

Market risk The risk that arises from movements in interest rates, stock prices, exchange rates, and commodity prices.

Market value The price at which an asset or security can currently be bought or sold in an open market.

Marketable limit order A buy limit order in which the limit price is placed above the best offer, or a sell limit order in which the limit price is placed below the best bid. Such orders generally will partially or completely fill right away.

Markowitz efficient frontier The graph of the set of portfolios offering the maximum expected return for their level of risk (standard deviation of return).

Matching principle The accounting principle that expenses should be recognized in the same period in which the associated revenue is recognized.

Matrix pricing Process of estimating the market discount rate and price of a bond based on the quoted or flat prices of more frequently traded comparable bonds.

Maturity premium An extra return that compensates investors for the increased sensitivity of the market value of debt to a change in market interest rates as maturity is extended.

Maturity structure A factor explaining the differences in yields on similar bonds; also called *term structure*.

Mean absolute deviation With reference to a sample, the mean of the absolute values of deviations from the sample mean.

Mean square error (MSE) The sum of squares error divided by the degrees of freedom, $n - k - 1$; in a simple linear regression, $n - k - 1 = n - 2$.

Mean square regression (MSR) The sum of squares regression divided by the number of independent variables k; in a simple linear regression, $k = 1$.

Mean–variance analysis An approach to portfolio analysis using expected means, variances, and covariances of asset returns.

Measure of central tendency A quantitative measure that specifies where data are centered.

Measure of value A standard for measuring value; a function of money.

Measures of location Quantitative measures that describe the location or distribution of data. They include not only measures of central tendency but also other measures, such as percentiles.

Median The value of the middle item of a set of items that has been sorted into ascending or descending order (i.e., the 50th percentile).

Medium of exchange Any asset that can be used to purchase goods and services or to repay debts; a function of money.

Medium-term note A corporate bond offered continuously to investors by an agent of the issuer, designed to fill the funding gap between commercial paper and long-term bonds.

Mental accounting bias An information-processing bias in which people treat one sum of money differently from another equal-sized sum based on which mental account the money is assigned to.

Menu costs A cost of inflation in which businesses constantly have to incur the costs of changing the advertised prices of their goods and services.

Mesokurtic Describes a distribution with kurtosis equal to that of the normal distribution, namely, kurtosis equal to three.

Microeconomics The branch of economics that deals with markets and decision making of individual economic units, including consumers and businesses.

Minimum efficient scale The smallest output that a firm can produce such that its long-run average total cost is minimized.

Minimum-variance portfolio The portfolio with the minimum variance for each given level of expected return.

Minority shareholders Particular shareholders or a block of shareholders holding a small proportion of a company's outstanding shares, resulting in a limited ability to exercise control in voting activities.

Minsky moment Named for Hyman Minksy. A point in a business cycle when, after individuals become overextended in borrowing to finance speculative investments, people start realizing that something is likely to go wrong and a panic ensues, leading to asset sell-offs.

Modal interval With reference to grouped data, the interval containing the greatest number of observations (i.e., highest frequency).

Mode The most frequently occurring value in a distribution.

Modern portfolio theory (MPT) The analysis of rational portfolio choices based on the efficient use of risk.

Modified duration A measure of the percentage price change of a bond given a change in its yield-to-maturity.

Momentum oscillator A graphical representation of market sentiment that is constructed from price data and calculated so that it oscillates either between a low and a high or around some number.

Monetarists Economists who believe that the rate of growth of the money supply is the primary determinant of the rate of inflation.

Monetary policy Actions taken by a nation's central bank to affect aggregate output and prices through changes in bank reserves, reserve requirements, or its target interest rate.

Monetary transmission mechanism The process whereby a central bank's interest rate gets transmitted through the economy and ultimately affects the rate of increase of prices.

Monetary union An economic union in which the members adopt a common currency.

Money A generally accepted medium of exchange and unit of account.

Money convexity For a bond, the annual or approximate convexity multiplied by the full price.

Money creation The process by which changes in bank reserves translate into changes in the money supply.

Money duration A measure of the price change in units of the currency in which the bond is denominated given a change in its yield-to-maturity.

Money market The market for short-term debt instruments (one-year maturity or less).

Money market securities Fixed-income securities with maturities at issuance of one year or less.

Money multiplier Describes how a change in reserves is expected to affect the money supply; in its simplest form, 1 divided by the reserve requirement.

Money neutrality The thesis that an increase in the money supply leads in the long-run to an increase in the price level, while leaving real variables like output and employment unaffected.

Money-weighted return The internal rate of return on a portfolio, taking account of all cash flows.

Moneyness The relationship between the price of the underlying and an option's exercise price.

Monopolistic competition Highly competitive form of imperfect competition; the competitive characteristic is a notably large number of firms, while the monopoly aspect is the result of product differentiation.

Monopoly In pure monopoly markets, there are no substitutes for the given product or service. There is a single seller, which exercises considerable power over pricing and output decisions.

Monte Carlo simulation A technique involving the use of computer software to represent the operation of a complex financial system. A characteristic feature is the generation of a large number of random samples from a specified probability distribution or distributions to represent the role of risk in the system.

Moral principles Beliefs regarding what is good, acceptable, or obligatory behavior and what is bad, unacceptable, or forbidden behavior.

Mortgage-backed securities Debt obligations that represent claims to the cash flows from pools of mortgage loans, most commonly on residential property.

Mortgage loan A loan secured by the collateral of some specified real estate property that obliges the borrower to make a predetermined series of payments to the lender.

Mortgage pass-through security A security created when one or more holders of mortgages form a pool of mortgages and sell shares or participation certificates in the pool.

Mortgage rate The interest rate on a mortgage loan; also called *contract rate* or *note rate*.

Moving average The average of the closing price of a security over a specified number of periods. With each new period, the average is recalculated.

Moving-average convergence/divergence oscillator A momentum oscillator that is based on the difference between short-term and long-term moving averages of a security's price.

Multi-factor model A model that explains a variable in terms of the values of a set of factors.

Multi-market indexes Comprised of indexes from different countries, designed to represent multiple security markets.

Multi-step format With respect to the format of the income statement, a format that presents a subtotal for gross profit (revenue minus cost of goods sold).

Multilateral trading facilities See *alternative trading systems*.

Multinational corporation A company operating in more than one country or having subsidiary firms in more than one country.

Multinomial formula (general formula for labeling problems) The number of ways that n objects can be labeled with k different labels, with n_1 of the first type, n_2 of the second type, and so on, with $n_1 + n_2 + \ldots + n_k = n$, is given by $\dfrac{n!}{n_1!n_2!\ldots n_k!}$.

Multiple of invested capital (MOIC) A simplified calculation that measures the total value of all distributions and residual asset values relative to an initial total investment; also known as a *money multiple*.

Multiple testing problem The risk of getting statistically significant test results when performing a test multiple times.

Multiplication rule for counting If one task can be done in n_1 ways, and a second task, given the first, can be done in n_2 ways, and a third task, given the first two tasks, can be done in n_3 ways, and so on for k tasks, then the number of ways the k tasks can be done is $(n_1)(n_2)(n_3) \ldots (n_k)$.

Multiplication rule for expected value of the product of uncorrelated random variables This rule is $E(XY) = E(X)E(Y)$ if X and Y are uncorrelated.

Multiplication rule for independent events The rule that when two events are independent, the joint probability of A and B equals the product of the individual probabilities of A and B.

Multiplication rule for probability The rule that the joint probability of events A and B equals the probability of A given B times the probability of B.

Multiplier models Valuation models based on share price multiples or enterprise value multiples.

Multivariate distribution A probability distribution that specifies the probabilities for a group of related random variables.

Multivariate normal distribution A probability distribution for a group of random variables that is completely defined by the means and variances of the variables plus all the correlations between pairs of the variables.

Muni See *municipal bond*.

Municipal bond A type of non-sovereign bond issued by a state or local government in the United States. It very often (but not always) offers income tax exemptions.

Mutual fund A comingled investment pool in which investors in the fund each have a pro-rata claim on the income and value of the fund.

Mutually exclusive Indicates that only one event can occur at a time.

Mutually exclusive projects Mutually exclusive projects compete directly with each other. For example, if Projects A and B are mutually exclusive, you can choose A or B but you cannot choose both.

***n* Factorial** For a positive integer n, the product of the first n positive integers; 0 factorial equals 1 by definition. n factorial is written as $n!$.

Narrow money The notes and coins in circulation in an economy, plus other very highly liquid deposits.

Nash equilibrium When two or more participants in a non-coop-erative game have no incentive to deviate from their respective equilibrium strategies given their opponent's strategies.

National income The income received by all factors of production used in the generation of final output. National income equals gross domestic product (or, in some countries, gross national product) minus the capital consumption allowance and a statistical discrepancy.

Natural language processing Computer programs developed to analyze and interpret human language.

Natural rate of unemployment Effective unemployment rate, below which pressure emerges in labor markets.

Negative screening An ESG investment style that focuses on the exclusion of certain sectors, companies, or practices in a fund or portfolio on the basis of specific ESG criteria.

Net book value The remaining (undepreciated) balance of an asset's purchase cost. For liabilities, the face value of a bond minus any unamortized discount, or plus any unamortized premium.

Net exports The difference between the value of a country's exports and the value of its imports (i.e., value of exports minus imports).

Net income The difference between revenue and expenses; what remains after subtracting all expenses (including depreciation, interest, and taxes) from revenue.

Net present value The present value of an investment's cash inflows (benefits) minus the present value of its cash outflows (costs).

Net profit margin An indicator of profitability, calculated as net income divided by revenue; indicates how much of each dollar of revenues is left after all costs and expenses. Also called *profit margin* or *return on sales*.

Net realisable value Estimated selling price in the ordinary course of business less the estimated costs necessary to make the sale.

Net revenue Revenue after adjustments (e.g., for estimated returns or for amounts unlikely to be collected).

Net tax rate The tax rate net of transfer payments.

Neural networks Computer programs based on how our own brains learn and process information.

Neutral rate of interest The rate of interest that neither spurs on nor slows down the underlying economy.

No-load fund A mutual fund in which there is no fee for investing in the fund or for redeeming fund shares, although there is an annual fee based on a percentage of the fund's net asset value.

Node Each value on a binomial tree from which successive moves or outcomes branch.

Nominal data Categorical values that are not amenable to being organized in a logical order. An example of nominal data is the classification of publicly listed stocks into sectors.

Nominal GDP The value of goods and services measured at current prices.

Nominal risk-free interest rate The sum of the real risk-free interest rate and the inflation premium.

Non-accelerating inflation rate of unemployment Effective unemployment rate below which pressure emerges in labor markets.

Non-agency RMBS In the United States, securities issued by private entities that are not guaranteed by a federal agency or a GSE.

Non-Bank lender Unlike typical banks, which make loans and take deposits, these lenders only make loans. Although they lend money to companies, they usually specialize in issuing mortgages to first-time homebuyers and parties looking to refinance an existing mortgage.

Non-cumulative preference shares Preference shares for which dividends that are not paid in the current or subsequent periods are forfeited permanently (instead of being accrued and paid at a later date).

Non-current assets Assets that are expected to benefit the company over an extended period of time (usually more than one year).

Non-current liabilities Obligations that broadly represent a probable sacrifice of economic benefits in periods generally greater than one year in the future.

Non-cyclical A company whose performance is largely independent of the business cycle. Also known as defensive.

Non-deliverable forwards Cash-settled forward contracts, used predominately with respect to foreign exchange forwards. Also called *contracts for differences*.

Non-financial risks Risks that arise from sources other than changes in the external financial markets, such as changes in accounting rules, legal environment, or tax rates.

Non-participating preference shares Preference shares that do not entitle shareholders to share in the profits of the company. Instead, shareholders are only entitled to receive a fixed dividend payment and the par value of the shares in the event of liquidation.

Non-probability sampling A sampling plan dependent on factors other than probability considerations, such as a sampler's judgment or the convenience to access data.

Non-recourse loan A loan in which the lender does not have a shortfall claim against the borrower, so the lender can look only to the property to recover the outstanding mortgage balance.

Non-renewable resources Finite resources that are depleted once they are consumed, such as oil and coal.

Non-sovereign bond A bond issued by a government below the national level, such as a province, region, state, or city.

Nonconventional cash flows In a nonconventional cash flow pattern, the initial outflow is not followed by inflows only, but the cash flows can flip from positive (inflows) to negative (outflows) again or even change signs several times.

Nonparametric test A test that is not concerned with a parameter or that makes minimal assumptions about the population from which a sample comes.

Nonsystematic risk Unique risk that is local or limited to a particular asset or industry that need not affect assets outside of that asset class.

Normal distribution A continuous, symmetric probability distribution that is completely described by its mean and its variance.

Normal goods Goods that are consumed in greater quantities as income increases.

Normal profit The level of accounting profit needed to just cover the implicit opportunity costs ignored in accounting costs.

Notching Ratings adjustment methodology where specific issues from the same borrower may be assigned different credit ratings.

Note rate See *mortgage rate*.

Notice period The length of time (typically 30 to 90 days) in advance that investors may be required to notify a fund of their intent to redeem some or all of their investment.

Notional principal An imputed principal amount.

Null hypothesis The hypothesis that is tested.

Numerical data Values that represent measured or counted quantities as a number. Also called **quantitative data**.

Objective probabilities Probabilities that generally do not vary from person to person; includes a priori and empirical probabilities.

Observation The value of a specific variable collected at a point in time or over a specified period of time.

Odds against *E* The reciprocal of odds for *E*.

Odds for *E* The probability of *E* divided by 1 minus the probability of *E*.

Off-the-run Seasoned government bonds are off-the-run securities; they are not the most recently issued or the most actively traded.

Offer The price at which a dealer or trader is willing to sell an asset, typically qualified by a maximum quantity (ask size).

Official interest rate An interest rate that a central bank sets and announces publicly; normally the rate at which it is willing to lend money to the commercial banks. Also called *official policy rate* or *policy rate*.

Official policy rate An interest rate that a central bank sets and announces publicly; normally the rate at which it is willing to lend money to the commercial banks.

Oligopoly Market structure with a relatively small number of firms supplying the market.

On-the-run The most recently issued and most actively traded sovereign securities.

One-dimensional array The simplest format for representing a collection of data of the same data type.

One-sided hypothesis test A test in which the null hypothesis is rejected only if the evidence indicates that the population parameter is greater than or less than the hypothesized parameter; occurs when the alternative hypothesis is stated either as greater than or less than the hypothesized population parameter.

Open economy An economy that trades with other countries.

Open-end fund A mutual fund that accepts new investment money and issues additional shares at a value equal to the net asset value of the fund at the time of investment.

Open interest The number of outstanding contracts in a clearinghouse at any given time. The open interest figure changes daily as some parties open up new positions, while other parties offset their old positions.

Open market operations The purchase or sale of bonds by the national central bank to implement monetary policy. The bonds traded are usually sovereign bonds issued by the national government.

Operating activities Activities that are part of the day-to-day business functioning of an entity, such as selling inventory and providing services.

Operating breakeven The number of units produced and sold at which the company's operating profit is zero (revenues = operating costs).

Operating cash flow The net amount of cash provided from operating activities.

Operating efficiency ratios Ratios that measure how efficiently a company performs day-to-day tasks, such as the collection of receivables and management of inventory.

Operating lease A type of lease which is more akin to the rental of the underlying asset.

Operating leverage The use of fixed costs in operations.

Operating profit A company's profits on its usual business activities before deducting taxes. Also called *operating income*.

Operating profit margin A profitability ratio calculated as operating income (i.e., income before interest and taxes) divided by revenue. Also called *operating margin*.

Operating risk The risk attributed to the operating cost structure, in particular the use of fixed costs in operations; the risk arising from the mix of fixed and variable costs; the risk that a company's operations may be severely affected by environmental, social, and governance risk factors.

Operational independence A bank's ability to execute monetary policy and set interest rates in the way it thought would best meet the inflation target.

Operational risk The risk that arises from inadequate or failed people, systems, and internal policies, procedures, and processes, as well as from external events that are beyond the control of the organization but that affect its operations.

Operationally efficient Said of a market, a financial system, or an economy that has relatively low transaction costs.

Opportunity cost The value that investors forgo by choosing a particular course of action; the value of something in its best alternative use.

Optimal capital structure The capital structure at which the value of the company is maximized.

Option A financial instrument that gives one party the right, but not the obligation, to buy or sell an underlying asset from or to another party at a fixed price over a specific period of time. Also referred to as *contingent claim* or *option contract.*

Option-adjusted price The value of the embedded option plus the flat price of the bond.

Option-adjusted spread OAS = Z-spread – Option value (in basis points per year).

Option-adjusted yield The required market discount rate whereby the price is adjusted for the value of the embedded option.

Option contract See *option*.

Option premium The amount of money a buyer pays and seller receives to engage in an option transaction.

Order A specification of what instrument to trade, how much to trade, and whether to buy or sell.

Order-driven markets A market (generally an auction market) that uses rules to arrange trades based on the orders that traders submit; in their pure form, such markets do not make use of dealers.

Order precedence hierarchy With respect to the execution of orders to trade, a set of rules that determines which orders execute before other orders.

Ordinal data Categorical values that can be logically ordered or ranked.

Ordinary annuity An annuity with a first cash flow that is paid one period from the present.

Ordinary shares Equity shares that are subordinate to all other types of equity (e.g., preferred equity). Also called *common stock* or *common shares.*

Organized exchange A securities marketplace where buyers and seller can meet to arrange their trades.

Other comprehensive income Items of comprehensive income that are not reported on the income statement; comprehensive income minus net income.

Out-of-sample test A test of a strategy or model using a sample outside the period on which the strategy or model was developed.

Out of the money Options that, if exercised, would require the payment of more money than the value received and therefore would not be currently exercised.

Outcome A possible value of a random variable.

Over-the-counter (OTC) market A decentralized market where buy and sell orders initiated from various locations are matched through a communications network.

Overbought A market condition in which market sentiment is thought to be unsustainably bullish.

Overcollateralization Form of internal credit enhancement that refers to the process of posting more collateral than needed to obtain or secure financing.

Overconfidence bias A bias in which people demonstrate unwarranted faith in their own intuitive reasoning, judgments, and/or cognitive abilities.

Overfitting An undesirable result from fitting a model so closely to a dataset that it does not perform well on new data.

Oversold A market condition in which market sentiment is thought to be unsustainably bearish.

Own price The price of a good or service itself (as opposed to the price of something else).

Own-price elasticity of demand The percentage change in quantity demanded for a percentage change in good's own price, holding all other things constant.

Owners' equity The excess of assets over liabilities; the residual interest of shareholders in the assets of an entity after deducting the entity's liabilities. Also called *shareholders' equity* or *shareholders' funds*.

***p*-Value** The smallest level of significance at which the null is rejected.

Paired comparisons test See *test of the mean of the differences.*

Panel data A mix of time-series and cross-sectional data that contains observations through time on characteristics of across multiple observational units.

Par curve A sequence of yields-to-maturity such that each bond is priced at par value. The bonds are assumed to have the same currency, credit risk, liquidity, tax status, and annual yields stated for the same periodicity.

Par value The amount of principal on a bond.

Parallel shift A parallel yield curve shift implies that all rates change by the same amount in the same direction.

Parameter A descriptive measure computed from or used to describe a population of data, conventionally represented by Greek letters.

Parametric test Any test (or procedure) concerned with parameters or whose validity depends on assumptions concerning the population generating the sample.

Pari passu Covenant or contract clause that ensures a debt obligation is treated the same as the borrower's other senior debt instruments and is not subordinated to similar obligations.

Partial duration See *key rate duration.*

Participating preference shares Preference shares that entitle shareholders to receive the standard preferred dividend plus the opportunity to receive an additional dividend if the company's profits exceed a pre-specified level.

Pass-through rate The coupon rate of a mortgage pass-through security.

Passive investment A buy and hold approach in which an investor does not make portfolio changes based on short-term expectations of changing market or security performance.

Payable date The day that the company actually mails out (or electronically transfers) a dividend payment.

Payment date The day that the company actually mails out (or electronically transfers) a dividend payment.

Payments system The system for the transfer of money.

Pearson correlation A parametric measure of the relationship between two variables.

Pecking order theory The theory that managers consider how their actions might be interpreted by outsiders and thus order their preferences for various forms of corporate financing. Forms of financing that are least visible to outsiders (e.g., internally generated funds) are most preferable to managers, and those that are most visible (e.g., equity) are least preferable.

Peer company See *comparable company*.

Peer group A group of companies engaged in similar business activities whose economics and valuation are influenced by closely related factors.

Pennant A technical analysis continuation pattern formed by trendlines that converge to form a triangle, typically over a short period.

Per capita real GDP Real GDP divided by the size of the population, often used as a measure of a country's average standard of living.

Per unit contribution margin The amount that each unit sold contributes to covering fixed costs—that is, the difference between the price per unit and the variable cost per unit.

Percentiles Quantiles that divide a distribution into 100 equal parts that sum to 100.

Perfect capital markets Markets in which, by assumption, there are no taxes, transaction costs, or bankruptcy costs and in which all investors have equal ("symmetric") information.

Perfect competition A market structure in which the individual firm has virtually no impact on market price, because it is assumed to be a very small seller among a very large number of firms selling essentially identical products.

Perfectly elastic When the quantity demanded or supplied of a given good is infinitely sensitive to a change in the value of a specified variable (e.g., price).

Perfectly inelastic When the quantity demanded or supplied of a given good is completely insensitive to a change in the value of a specified variable (e.g., price).

Performance bond See *margin bond.*

Performance evaluation The measurement and assessment of the outcomes of investment management decisions.

Performance fee Fees paid to the general partner from the limited partner(s) based on realized net profits.

Period costs Costs (e.g., executives' salaries) that cannot be directly matched with the timing of revenues and which are thus expensed immediately.

Periodicity The assumed number of periods in the year; typically matches the frequency of coupon payments.

Permanent differences Differences between tax and financial reporting of revenue (expenses) that will not be reversed at some future date. These result in a difference between the company's effective tax rate and statutory tax rate and do not result in a deferred tax item.

Permissioned networks Networks that are fully open only to select participants on a DLT network.

Permissionless networks Networks that are fully open to any user on a DLT network.

Permutation An ordered listing.

Permutation formula The number of ways that we can choose r objects from a total of n objects, when the order in which the r objects are listed does matter, is ${}_nP_r = \dfrac{n!}{(n-r)!}$.

Perpetual bonds Bonds with no stated maturity date.

Perpetuity A perpetual annuity, or a set of never-ending level sequential cash flows, with the first cash flow occurring one period from now. A bond that does not mature.

Personal income A broad measure of household income that includes all income received by households, whether earned or unearned; measures the ability of consumers to make purchases.

Pet projects Investments in which influential managers want the corporation to invest. Often, unfortunately, pet projects are selected without undergoing normal capital allocation analysis.

Plain vanilla bond Bond that makes periodic, fixed coupon payments during the bond's life and a lump-sum payment of principal at maturity. Also called *conventional bond*.

Platykurtic Describes a distribution that has relatively less weight in the tails than the normal distribution (also called thin-tailed).

Point estimate A single numerical estimate of an unknown quantity, such as a population parameter.

Policy rate An interest rate that a central bank sets and announces publicly; normally the rate at which it is willing to lend money to the commercial banks.

Population All members of a specified group.

Portfolio company In private equity, the company in which the private equity fund is investing.

Portfolio demand for money The demand to hold speculative money balances based on the potential opportunities or risks that are inherent in other financial instruments.

Portfolio planning The process of creating a plan for building a portfolio that is expected to satisfy a client's investment objectives.

Position The quantity of an asset that an entity owns or owes.

Positive screening The process of including sectors or companies based on specific ESG criteria, typically ESG performance relative to industry peers

Posterior probability An updated probability that reflects or comes after new information.

Potential GDP The level of real GDP that can be produced at full employment; measures the productive capacity of the economy.

Power of a test The probability of correctly rejecting the null—that is, rejecting the null hypothesis when it is false.

Precautionary money balances Money held to provide a buffer against unforeseen events that might require money.

Preference shares A type of equity interest which ranks above common shares with respect to the payment of dividends and the distribution of the company's net assets upon liquidation. They have characteristics of both debt and equity securities. Also called *preferred stock*.

Preferred stock See *preference shares*.

Premium In the case of bonds, premium refers to the amount by which a bond is priced above its face (par) value. In the case of an option, the amount paid for the option contract.

Prepaid expense A normal operating expense that has been paid in advance of when it is due.

Prepayment option Contractual provision that entitles the borrower to prepay all or part of the outstanding mortgage principal prior to the scheduled due date when the principal must be repaid. Also called *early repayment option*.

Prepayment penalty mortgages Mortgages that stipulate a monetary penalty if a borrower prepays within a certain time period after the mortgage is originated.

Prepayment risk The uncertainty that the timing of the actual cash flows will be different from the scheduled cash flows as set forth in the loan agreement due to the borrowers' ability to alter payments, usually to take advantage of interest rate movements.

Present value (PV) The present discounted value of future cash flows: For assets, the present discounted value of the future net cash inflows that the asset is expected to generate; for liabilities, the present discounted value of the future net cash outflows that are expected to be required to settle the liabilities.

Present value models Valuation models that estimate the intrinsic value of a security as the present value of the future benefits expected to be received from the security. Also called *discounted cash flow models*.

Pretax margin A profitability ratio calculated as earnings before taxes divided by revenue.

Price elasticity of demand Measures the percentage change in the quantity demanded, given a percentage change in the price of a given product.

Price index Represents the average prices of a basket of goods and services.

Price limits Limits imposed by a futures exchange on the price change that can occur from one day to the next.

Price multiple A ratio that compares the share price with some sort of monetary flow or value to allow evaluation of the relative worth of a company's stock.

Price priority The principle that the highest priced buy orders and the lowest priced sell orders execute first.

Price relative A ratio of an ending price over a beginning price; it is equal to 1 plus the holding period return on the asset.

Price return Measures *only* the price appreciation or percentage change in price of the securities in an index or portfolio.

Price return index An index that reflects *only* the price appreciation or percentage change in price of the constituent securities. Also called *price index*.

Price-setting option The option to adjust prices when demand varies from what is forecast.

Price stability In economics, refers to an inflation rate that is low on average and not subject to wide fluctuation.

Price takers Producers that must accept whatever price the market dictates.

Price to book value A valuation ratio calculated as price per share divided by book value per share.

Price to cash flow A valuation ratio calculated as price per share divided by cash flow per share.

Price to earnings ratio (P/E ratio or P/E) The ratio of share price to earnings per share.

Price to sales A valuation ratio calculated as price per share divided by sales per share.

Price value of a basis point A version of money duration, it is an estimate of the change in the full price of a bond given a 1 basis point change in the yield-to-maturity.

Price weighting An index weighting method in which the weight assigned to each constituent security is determined by dividing its price by the sum of all the prices of the constituent securities.

Priced risk Risk for which investors demand compensation for bearing (e.g., equity risk, company-specific factors, macroeconomic factors).

Primary bond market A market in which issuers first sell bonds to investors to raise capital.

Primary capital markets (primary markets) The market where securities are first sold and the issuers receive the proceeds.

Primary dealer Financial institution that is authorized to deal in new issues of sovereign bonds and that serves primarily as a trading counterparty of the office responsible for issuing sovereign bonds.

Primary market The market where securities are first sold and the issuers receive the proceeds.

Prime brokers Brokers that provide services that commonly include custody, administration, lending, short borrowing, and trading.

Principal The amount of funds originally invested in a project or instrument; the face value to be paid at maturity.

Principal–agent relationship A relationship in which a principal hires an agent to perform a particular task or service; also known as an *agency relationship*.

Principal amount Amount that an issuer agrees to repay the debtholders on the maturity date.

Principal business activity The business activity from which a company derives a majority of its revenues and/or earnings.

Principal value Amount that an issuer agrees to repay the debtholders on the maturity date.

Principle of no arbitrage See *arbitrage-free pricing*.

Prior probabilities Probabilities reflecting beliefs prior to the arrival of new information.

Priority of claims Priority of payment, with the most senior or highest ranking debt having the first claim on the cash flows and assets of the issuer.

Private equity fund A hedge fund that seeks to buy, optimize, and ultimately sell portfolio companies to generate profits. See *venture capital fund*.

Private equity funds Funds that seek to invest in, optimize, and eventually exit portfolio companies to generate profits. See *venture capital funds*.

Private equity securities Securities that are not listed on public exchanges and have no active secondary market. They are issued primarily to institutional investors via non-public offerings, such as private placements.

Private investment in public equity (PIPE) An investment in the equity of a publicly traded firm that is made at a discount to the market value of the firm's shares.

Private placement Typically, a non-underwritten, unregistered offering of securities that are sold only to an investor or a small group of investors. It can be accomplished directly between the issuer and the investor(s) or through an investment bank.

Probability A number between 0 and 1 describing the chance that a stated event will occur.

Probability density function A function with non-negative values such that probability can be described by areas under the curve graphing the function.

Probability distribution A distribution that specifies the probabilities of a random variable's possible outcomes.

Probability function A function that specifies the probability that the random variable takes on a specific value.

Probability sampling A sampling plan that allows every member of the population to have an equal chance of being selected.

Probability tree diagram A diagram with branches emanating from nodes representing either mutually exclusive chance events or mutually exclusive decisions.

Production-flexibility options The options to alter production when demand varies from what is forecast.

Production function Provides the quantitative link between the levels of output that the economy can produce and the inputs used in the production process.

Productivity The amount of output produced by workers during a given period—for example, output per hour worked measures the efficiency of labor.

Profession An occupational group that has specific education, expert knowledge, and a framework of practice and behavior that underpins community trust, respect, and recognition.

Profit The return that owners of a company receive for the use of their capital and the assumption of financial risk when making their investments.

Profit and loss (P&L) statement A financial statement that provides information about a company's profitability over a stated period of time. Also called the *income statement*.

Profit margin An indicator of profitability, calculated as net income divided by revenue; indicates how much of each dollar of revenues is left after all costs and expenses.

Profitability ratios Ratios that measure a company's ability to generate profitable sales from its resources (assets).

Project sequencing To defer the decision to invest in a future project until the outcome of some or all of a current investment is known. Investments are sequenced over time, so that making an investment creates the option to invest in future projects.

Promissory note A written promise to pay a certain amount of money on demand.

Property, plant, and equipment Tangible assets that are expected to be used for more than one period in either the production or supply of goods or services, or for administrative purposes.

Prospectus The document that describes the terms of a new bond issue and helps investors perform their analysis on the issue.

Protective put An option strategy in which a long position in an asset is combined with a long position in a put.

Proxy contest Corporate takeover mechanism in which shareholders are persuaded to vote for a group seeking a controlling position on a company's board of directors.

Proxy voting A process that enables shareholders who are unable to attend a meeting to authorize another individual to vote on their behalf.

Public offer See *public offering*.

Public offering An offering of securities in which any member of the public may buy the securities. Also called *public offer*.

Public–private partnership (PPP) An agreement between the public sector and the private sector to finance, build, and operate public infrastructure, such as hospitals and toll roads.

Pull on liquidity When disbursements are paid too quickly or trade credit availability is limited, requiring companies to expend funds before they receive funds from sales that could cover the liability.

Pure discount bonds See *zero-coupon bond*.

Put An option that gives the holder the right to sell an underlying asset to another party at a fixed price over a specific period of time.

Put–call–forward parity The relationship among puts, calls, and forward contracts.

Put–call parity An equation expressing the equivalence (parity) of a portfolio of a call and a bond with a portfolio of a put and the underlying, which leads to the relationship between put and call prices.

Put/call ratio A technical analysis indicator that evaluates market sentiment based on the volume of put options traded divided by the volume of call options traded for a particular financial instrument.

Put option An option that gives the holder the right to sell an underlying asset to another party at a fixed price over a specific period of time.

Putable bonds Bonds that give the bondholder the right to sell the bond back to the issuer at a predetermined price on specified dates.

Qualitative data see **categorical data**.

Quantile A value at or below which a stated fraction of the data lies. Also referred to as a fractile.

Quantitative data see **numerical data**.

Quantitative easing An expansionary monetary policy based on aggressive open market purchase operations.

Quantity equation of exchange An expression that over a given period, the amount of money used to purchase all goods and services in an economy, $M \times V$, is equal to monetary value of this output, $P \times Y$.

Quantity theory of money Asserts that total spending (in money terms) is proportional to the quantity of money.

Quartiles Quantiles that divide a distribution into four equal parts.

Quasi-fixed cost A cost that stays the same over a range of production but can change to another constant level when production moves outside of that range.

Quasi-government bond A bond issued by an entity that is either owned or sponsored by a national government. Also called *agency bond*.

Quintiles Quantiles that divide a distribution into five equal parts.

Quota rents Profits that foreign producers can earn by raising the price of their goods higher than they would without a quota.

Quotas Government policies that restrict the quantity of a good that can be imported into a country, generally for a specified period of time.

Quote-driven market A market in which dealers acting as principals facilitate trading.

Quoted interest rate A quoted interest rate that does not account for compounding within the year. Also called *stated annual interest rate*.

Quoted margin The specified yield spread over the reference rate, used to compensate an investor for the difference in the credit risk of the issuer and that implied by the reference rate.

Random number An observation drawn from a uniform distribution.

Random number generator An algorithm that produces uniformly distributed random numbers between 0 and 1.

Random variable A quantity whose future outcomes are uncertain.

Range The difference between the maximum and minimum values in a dataset.

Raw data Data available in their original form as collected.

Real exchange rate effect The effect through which changing price level impacts real exchange rate which in turn impacts net exports and aggregate demand.

Real GDP The value of goods and services produced, measured at base year prices.

Real income Income adjusted for the effect of inflation on the purchasing power of money. Also known as the *purchasing power of income*. If income remains constant and a good's price falls, real income is said to rise, even though the number of monetary units (e.g., dollars) remains unchanged.

Real interest rate Nominal interest rate minus the expected rate of inflation.

Real risk-free interest rate The single-period interest rate for a completely risk-free security if no inflation were expected.

Realizable (settlement) value With reference to assets, the amount of cash or cash equivalents that could currently be obtained by selling the asset in an orderly disposal; with reference to liabilities, the undiscounted amount of cash or cash equivalents expected to be paid to satisfy the liabilities in the normal course of business.

Rebalancing Adjusting the weights of the constituent securities in an index.

Rebalancing policy The set of rules that guide the process of restoring a portfolio's asset class weights to those specified in the strategic asset allocation.

Recession A period during which real GDP decreases (i.e., negative growth) for at least two successive quarters, or a period of significant decline in total output, income, employment, and sales usually lasting from six months to a year.

Recognition lag The lag in government response to an economic problem resulting from the delay in confirming a change in the state of the economy.

Recourse loan A loan in which the lender has a claim against the borrower for any shortfall between the outstanding mortgage balance and the proceeds received from the sale of the property.

Redemption yield See *yield-to-maturity*.

Redemptions Withdrawals of funds by investors, as allowed by the notice period and other terms in the partnership agreement.

Refinancing rate A type of central bank policy rate.

Registered bonds Bonds for which ownership is recorded by either name or serial number.

Regression analysis A tool for examining whether a variable is useful for explaining another variable.

Regression coefficients The intercept and slope coefficient of a regression.

Regret The feeling that an opportunity has been missed; typically, an expression of *hindsight bias*.

Regret-aversion bias An emotional bias in which people tend to avoid making decisions that will result in action out of fear that the decision will turn out poorly.

Relative dispersion The amount of dispersion relative to a reference value or benchmark.

Relative frequency The absolute frequency of each unique value of the variable divided by the total number of observations of the variable.

Relative price The price of a specific good or service in comparison with those of other goods and services.

Relative strength analysis A comparison of the performance of one asset with the performance of another asset or a benchmark, based on changes in the ratio of the two assets' prices over time.

Relative strength index (RSI) A technical analysis momentum oscillator that compares a security's gains with its losses over a set period.

Renewable resources Resources that can be replenished, such as a forest.

Rent Payment for the use of property.

Reorganization Agreements made by a company in bankruptcy under which a company's capital structure is altered and/or alternative arrangements are made for debt repayment; US Chapter 11 bankruptcy. The company emerges from bankruptcy as a going concern.

Replication The creation of an asset or portfolio from another asset, portfolio, and/or derivative.

Repo A form of collateralized loan involving the sale of a security with a simultaneous agreement by the seller to buy back the same security from the purchaser at an agreed-on price and future date. The party who sells the

security at the inception of the repurchase agreement and buys it back at maturity is borrowing money from the other party, and the security sold and subsequently repurchased represents the collateral.

Repo margin The difference between the market value of the security used as collateral and the value of the loan. Also called *haircut*.

Repo rate The interest rate on a repurchase agreement.

Representativeness bias A belief perseverance bias in which people tend to classify new information based on past experiences and classifications.

Repurchase agreement A form of collateralized loan involving the sale of a security with a simultaneous agreement by the seller to buy the same security back from the purchaser at an agreed-on price and future date. The party who sells the security at the inception of the repurchase agreement and buys it back at maturity is borrowing money from the other party, and the security sold and subsequently repurchased represents the collateral.

Repurchase date The date when the party who sold the security at the inception of a repurchase agreement buys back the security from the cash lending counterparty.

Repurchase price The price at which the party who sold the security at the inception of the repurchase agreement buys back the security from the cash lending counterparty.

Required margin The yield spread over or under the reference rate such that an FRN is priced at par value on a rate reset date.

Required rate of return See *market discount rate*.

Required yield See *market discount rate*.

Required yield spread The difference between the yield-to-maturity on a new bond and the benchmark rate; additional compensation required by investors for the difference in risk and tax status of a bond relative to a government bond. Sometimes called the *spread over the benchmark*.

Resampling A statistical method that repeatedly draws samples from the original observed data sample for the statistical inference of population parameters.

Reserve accounts Form of internal credit enhancement that relies on creating accounts and depositing in these accounts cash that can be used to absorb losses. Also called *reserve funds*.

Reserve funds See *reserve accounts*.

Reserve requirement The requirement for banks to hold reserves in proportion to the size of deposits.

Residual The difference between an observation and its predicted value, where the predicted value is based on the estimated linear relation between the dependent and independent variables using sample data.

Resistance In technical analysis, a price range in which selling activity is sufficient to stop the rise in the price of a security.

Responsible investing An overall (umbrella) term for several investment strategies—ESG investing, SRI investing, thematic investing, and impact investing—that incorporate ESG analysis in their investment processes.

Restricted payments A bond covenant meant to protect creditors by limiting how much cash can be paid out to shareholders over time.

Retracement In technical analysis, a reversal in the movement of a security's price such that it is counter to the prevailing longer-term price trend.

Return-generating model A model that can provide an estimate of the expected return of a security given certain parameters and estimates of the values of the independent variables in the model.

Return on assets (ROA) A profitability ratio calculated as net income divided by average total assets; indicates a company's net profit generated per dollar invested in total assets.

Return on equity (ROE) A profitability ratio calculated as net income divided by average shareholders' equity.

Return on invested capital A measure of the profitability of a company relative to the amount of capital invested by the equity- and debtholders.

Return on sales An indicator of profitability, calculated as net income divided by revenue; indicates how much of each dollar of revenues is left after all costs and expenses. Also referred to as *net profit margin*.

Return on total capital A profitability ratio calculated as EBIT divided by the sum of short- and long-term debt and equity.

Revaluation model Under IFRS, the process of valuing long-lived assets at fair value, rather than at cost less accumulated depreciation. Any resulting profit or loss is either reported on the income statement and/or through equity under revaluation surplus.

Revenue The amount charged for the delivery of goods or services in the ordinary activities of a business over a stated period; the inflows of economic resources to a company over a stated period.

Reversal pattern A type of pattern used in technical analysis to predict the end of a trend and a change in the direction of a security's price.

Reverse repo A repurchase agreement viewed from the perspective of the cash lending counterparty.

Reverse repurchase agreement A repurchase agreement viewed from the perspective of the cash lending counterparty.

Reverse stock split A reduction in the number of shares outstanding with a corresponding increase in share price, but no change to the company's underlying fundamentals.

Revolving credit agreements (also known as revolvers) The most reliable form of short-term bank borrowing facilities; they are in effect for multiple years (e.g., three to five years) and can have optional medium-term loan features.

Rho The sensitivity of the option price to the risk-free rate.

Ricardian equivalence An economic theory that implies that it makes no difference whether a government finances a deficit by increasing taxes or issuing debt.

Risk Exposure to uncertainty. The chance of a loss or adverse outcome as a result of an action, inaction, or external event.

Risk averse The assumption that an investor will choose the least risky alternative.

Risk aversion The degree of an investor's inability and unwillingness to take risk.

Risk budgeting The establishment of objectives for individuals, groups, or divisions of an organization that takes into account the allocation of an acceptable level of risk.

Risk exposure The state of being exposed or vulnerable to a risk. The extent to which an organization is sensitive to underlying risks.

Risk governance The top-down process and guidance that directs risk management activities to align with and support the overall enterprise.

Risk management The process of identifying the level of risk an organization wants, measuring the level of risk the organization currently has, taking actions that bring the actual

level of risk to the desired level of risk, and monitoring the new actual level of risk so that it continues to be aligned with the desired level of risk.

Risk management framework The infrastructure, process, and analytics needed to support effective risk management in an organization.

Risk-neutral pricing Sometimes said of derivatives pricing, uses the fact that arbitrage opportunities guarantee that a risk-free portfolio consisting of the underlying and the derivative must earn the risk-free rate.

Risk-neutral probabilities Weights that are used to compute a binomial option price. They are the probabilities that would apply if a risk-neutral investor valued an option.

Risk premium An extra return expected by investors for bearing some specified risk.

Risk shifting Actions to change the distribution of risk outcomes.

Risk tolerance The amount of risk an investor is willing and able to bear to achieve an investment goal.

Risk transfer Actions to pass on a risk to another party, often, but not always, in the form of an insurance policy.

Robo-adviser A machine-based analytical tool or service that provides technology-driven investment solutions through online platforms.

Rule of 72 The principle that the approximate number of years necessary for an investment to double is 72 divided by the stated interest rate.

Running yield See *current yield*.

Safety-first rules Rules for portfolio selection that focus on the risk that portfolio value or portfolio return will fall below some minimum acceptable level over some time horizon.

Sales Generally, a synonym for revenue; “sales” is generally understood to refer to the sale of goods, whereas “revenue” is understood to include the sale of goods or services.

Sales risk Uncertainty with respect to the quantity of goods and services that a company is able to sell and the price it is able to achieve; the risk related to the uncertainty of revenues.

Sample A subset of a population.

Sample correlation coefficient A standardized measure of how two variables in a sample move together. It is the ratio of the sample covariance to the product of the two variables’ standard deviations.

Sample covariance A measure of how two variables in a sample move together.

Sample excess kurtosis A sample measure of the degree of a distribution’s kurtosis in excess of the normal distribution’s kurtosis.

Sample mean The sum of the sample observations divided by the sample size.

Sample selection bias Bias introduced by systematically excluding some members of the population according to a particular attribute—for example, the bias introduced when data availability leads to certain observations being excluded from the analysis.

Sample-size neglect A type of representativeness bias in which financial market participants incorrectly assume that small sample sizes are representative of populations (or “real” data).

Sample skewness A sample measure of the degree of asymmetry of a distribution.

Sample standard deviation The positive square root of the sample variance.

Sample statistic A quantity computed from or used to describe a sample.

Sample variance The sum of squared deviations around the mean divided by the degrees of freedom.

Sampling The process of obtaining a sample.

Sampling distribution The distribution of all distinct possible values that a statistic can assume when computed from samples of the same size randomly drawn from the same population.

Sampling error The difference between the observed value of a statistic and the estimate resulting from using subsets of the population.

Sampling plan The set of rules used to select a sample.

Say on pay A process whereby shareholders may vote on executive remuneration (compensation) matters.

Scatter plot A chart in which two variables are plotted along the axis and points on the chart represent pairs of the two variables. In regression, the dependent variable is plotted on the vertical axis and the independent variable is plotted along the horizontal axis. Also known as a scattergram and a *scatter diagram.*

Scatter plot matrix A tool for organizing scatter plots between pairs of variables, making it easy to inspect all pairwise relationships in one combined visual.

Scenario analysis Analysis that shows the changes in key financial quantities that result from given (economic) events, such as the loss of customers, the loss of a supply source, or a catastrophic event; a risk management technique involving examination of the performance of a portfolio under specified situations. Closely related to stress testing.

Screening The application of a set of criteria to reduce a set of potential investments to a smaller set having certain desired characteristics.

Seasoned offering An offering in which an issuer sells additional units of a previously issued security.

Second-degree price discrimination When the monopolist charges different per-unit prices using the quantity purchased as an indicator of how highly the customer values the product.

Second lien A secured interest in the pledged assets that ranks below first lien debt in both collateral protection and priority of payment.

Secondary bond markets Markets in which existing bonds are traded among investors.

Secondary market The market where securities are traded among investors.

Secondary precedence rules Rules that determine how to rank orders placed at the same time.

Sector A group of related industries (GICS definition).

Sector indexes Indexes that represent and track different economic sectors—such as consumer goods, energy, finance, health care, and technology—on either a national, regional, or global basis.

Secured (“asset-based”) loan A loan that is backed by specific, secured company assets.

Secured bonds Bonds secured by assets or financial guarantees pledged to ensure debt repayment in case of default.

Secured debt Debt in which the debtholder has a direct claim—a pledge from the issuer—on certain assets and their associated cash flows.

Securitization A process that involves moving assets into a special legal entity, which then uses the assets as guarantees to secure a bond issue.

Securitized assets Assets that are typically used to create asset-backed bonds; for example, when a bank securitizes a pool of loans, the loans are said to be securitized.

Security characteristic line A plot of the excess return of a security on the excess return of the market.

Security market index A portfolio of securities representing a given security market, market segment, or asset class.

Security market line (SML) The graph of the capital asset pricing model.

Security selection The process of selecting individual securities; typically, security selection has the objective of generating superior risk-adjusted returns relative to a portfolio's benchmark.

Self-attribution bias A bias in which people take too much credit for successes (*self-enhancing*) and assign responsibility to others for failures (*self-protecting*).

Self-control bias A bias in which people fail to act in pursuit of their long-term, overarching goals because of a lack of self-discipline.

Self-investment limits With respect to investment limitations applying to pension plans, restrictions on the percentage of assets that can be invested in securities issued by the pension plan sponsor.

Sell-side firm A broker/dealer that sells securities and provides independent investment research and recommendations to their clients (i.e., buy-side firms).

Semi-strong-form efficient market A market in which security prices reflect all publicly known and available information.

Semiannual bond basis yield An annual rate having a periodicity of two; also known as a *semiannual bond equivalent yield*.

Semiannual bond equivalent yield See *semiannual bond basis yield*.

Seniority ranking Priority of payment of various debt obligations.

Sensitivity analysis Analysis that shows the range of possible outcomes as specific assumptions are changed.

Separately managed account (SMA) An investment portfolio managed exclusively for the benefit of an individual or institution.

Serial maturity structure Structure for a bond issue in which the maturity dates are spread out during the bond's life; a stated number of bonds mature and are paid off each year before final maturity.

Settlement The process that occurs after a trade is completed, the securities are passed to the buyer, and payment is received by the seller.

Settlement date Date when the buyer makes cash payment and the seller delivers the security.

Settlement price The official price, designated by the clearinghouse, from which daily gains and losses will be determined and marked to market.

Share repurchase A transaction in which a company buys back its own shares. Unlike stock dividends and stock splits, share repurchases use corporate cash.

Shareholder activism Strategies used by shareholders to attempt to compel a company to act in a desired manner.

Shareholder engagement The process whereby companies engage with their shareholders.

Shareholders' equity Assets less liabilities; the residual interest in the assets after subtracting the liabilities.

Sharpe ratio The average return in excess of the risk-free rate divided by the standard deviation of return; a measure of the average excess return earned per unit of standard deviation of return.

Shelf registration A type of public offering that allows the issuer to file a single, all-encompassing offering circular that covers a series of bond issues.

Short The seller of an asset or derivative contract. Also refers to the position of being short an asset or derivative contract.

Short position A position in an asset or contract in which one has sold an asset one does not own, or in which a right under a contract can be exercised against oneself.

Short-run average total cost The curve describing average total cost when some costs are considered fixed.

Short selling A transaction in which borrowed securities are sold with the intention to repurchase them at a lower price at a later date and return them to the lender.

Shortfall risk The risk that portfolio value or portfolio return will fall below some minimum acceptable level over some time horizon.

Shutdown point The point at which average revenue is equal to the firm's average variable cost.

Side letters Side agreements created between the GP and specific LPs. These agreements exist *outside* the LPA. These agreements provide additional terms and conditions related to the investment agreement.

Simple interest The interest earned each period on the original investment; interest calculated on the principal only.

Simple linear regression (SLR) A regression that summarizes the relation between the dependent variable and a single independent variable.

Simple random sample A subset of a larger population created in such a way that each element of the population has an equal probability of being selected to the subset.

Simple random sampling The procedure of drawing a sample to satisfy the definition of a simple random sample.

Simple yield The sum of the coupon payments plus the straight-line amortized share of the gain or loss, divided by the flat price.

Simulation Computer-generated sensitivity or scenario analysis that is based on probability models for the factors that drive outcomes.

Simulation trial A complete pass through the steps of a simulation.

Single-step format With respect to the format of the income statement, a format that does not subtotal for gross profit (revenue minus cost of goods sold).

Sinking fund arrangement Provision that reduces the credit risk of a bond issue by requiring the issuer to retire a portion of the bond's principal outstanding each year.

Situational influences External factors, such as environmental or cultural elements, that shape our behavior.

Skewed Not symmetrical.

Skewness A quantitative measure of skew (lack of symmetry); a synonym of skew. It is computed as the average cubed deviation from the mean standardized by dividing by the standard deviation cubed.

Slope coefficient The coefficient of an independent variable that represents the average change in the dependent variable for a one-unit change in the independent variable.

Small country A country that is a price taker in the world market for a product and cannot influence the world market price.

Smart beta Involves the use of simple, transparent, rules-based strategies as a basis for investment decisions.

Smart contract A computer program that is designed to self-execute on the basis of pre-specified terms and conditions agreed to by parties to a contract.

Socially responsible investing An investment approach that excludes investments in companies or industries that deviate from an organization's beliefs and sometimes includes investments with favorable environmental or social profiles.

Soft-bullet covered bonds Covered bonds for which bond default and payment acceleration of bond cash flows may be delayed upon sponsor default until a new final maturity date is reached.

Solvency With respect to financial statement analysis, the ability of a company to fulfill its long-term obligations.

Solvency ratios Ratios that measure a company's ability to meet its long-term obligations.

Solvency risk The risk that an organization does not survive or succeed because it runs out of cash, even though it might otherwise be solvent.

Sovereign bond A bond issued by a national government. Also called "Sovereign."

Spearman rank correlation coefficient A measure of correlation applied to ranked data.

Special dividend A dividend paid by a company that does not pay dividends on a regular schedule, or a dividend that supplements regular cash dividends with an extra payment.

Special purpose entity A non-operating entity created to carry out a specified purpose, such as leasing assets or securitizing receivables; can be a corporation, partnership, trust, or limited liability partnership formed to facilitate a specific type of business activity. Also called *special purpose vehicle*, *special purpose company*, or *variable interest entity*.

Special purpose vehicle See *special purpose entity*.

Specific identification method An inventory accounting method that identifies which specific inventory items were sold and which remained in inventory to be carried over to later periods.

Speculative demand for money The demand to hold speculative money balances based on the potential opportunities or risks that are inherent in other financial instruments. Also called *portfolio demand for money*.

Speculative money balances Monies held in anticipation that other assets will decline in value.

Split coupon bond See *deferred coupon bond*.

Sponsored A type of depository receipt in which the foreign company whose shares are held by the depository has a direct involvement in the issuance of the receipts.

Spot curve A sequence of yields-to-maturity on zero-coupon bonds. Sometimes called *zero* or *strip curve* (because coupon payments are "stripped" off the bonds).

Spot markets Markets in which assets are traded for immediate delivery.

Spot prices The price of an asset for immediately delivery.

Spot rates A sequence of market discount rates that correspond to the cash flow dates; yields-to-maturity on zero-coupon bonds maturing at the date of each cash flow.

Spread In general, the difference in yield between different fixed-income securities. Often used to refer to the difference between the yield-to-maturity and the benchmark.

Spread over the benchmark See *required yield spread*.

Spread risk Bond price risk arising from changes in the yield spread on credit-risky bonds; reflects changes in the market's assessment and/or pricing of credit migration (or downgrade) risk and market liquidity risk.

Spurious correlation Refers to: 1) correlation between two variables that reflects chance relationships in a particular dataset; 2) correlation induced by a calculation that mixes each of two variables with a third variable; and 3) correlation between two variables arising not from a direct relation between them but from their relation to a third variable.

Stacked bar chart An alternative form for presenting the frequency distribution of two categorical variables, where bars representing the sub-groups are placed on top of each other to form a single bar. Each sub-section is shown in a different color to represent the contribution of each sub-group, and the overall height of the stacked bar represents the marginal frequency for the category.

Stackelberg model A prominent model of strategic decision making in which firms are assumed to make their decisions sequentially.

Stagflation The combination of a high inflation rate with a high level of unemployment and a slowdown of the economy.

Staggered boards Election process whereby directors are typically divided into multiple classes that are elected separately in consecutive years—that is, one class every year.

Stakeholder management The identification, prioritization, and understanding of the interests of stakeholder groups and managing the company's relationships with these groups.

Stakeholders Individuals or groups of individuals who may be affected either directly or indirectly by a decision and thus have an interest, or stake, in the decision.

Standard deviation The positive square root of the variance; a measure of dispersion in the same units as the original data.

Standard error of the estimate A measure of the fit of a regression line, calculated as the square root of the mean square error. Also known as the *standard error of the regression* and the *root mean square error*.

Standard error of the forecast A measure of the uncertainty associated with a forecasted value of the dependent variable that depends on the standard error of the estimate, the variability of the independent variable, the deviation of the forecasted independent variable from the mean in the regression, and the number of observations.

Standard error of the slope coefficient The standard error of the slope, which in a simple linear regression is the ratio of the model's standard error of the estimate (s_e) to the square root of the variation of the independent variable.

Standard normal distribution The normal density with mean (μ) equal to 0 and standard deviation (σ) equal to 1.

Standardizing A transformation that involves subtracting the mean and dividing the result by the standard deviation.

Standards of conduct Behaviors required by a group; established benchmarks that clarify or enhance a group's code of ethics.

Standing limit orders A limit order at a price below market and which therefore is waiting to trade.

Stated annual interest rate A quoted interest rate that does not account for compounding within the year. Also called *quoted interest rate*.

Statement of changes in equity (statement of owners' equity) A financial statement that reconciles the beginning-of-period and end-of-period balance sheet values of

shareholders' equity; provides information about all factors affecting shareholders' equity. Also called *statement of owners' equity*.

Statement of financial condition The financial statement that presents an entity's current financial position by disclosing resources the entity controls (its assets) and the claims on those resources (its liabilities and equity claims), as of a particular point in time (the date of the balance sheet).

Statement of financial position The financial statement that presents an entity's current financial position by disclosing resources the entity controls (its assets) and the claims on those resources (its liabilities and equity claims), as of a particular point in time (the date of the balance sheet).

Statement of operations A financial statement that provides information about a company's profitability over a stated period of time.

Static trade-off theory of capital structure A theory pertaining to a company's optimal capital structure. The optimal level of debt is found at the point where additional debt would cause the costs of financial distress to increase by a greater amount than the benefit of the additional tax shield.

Statistic A summary measure of a sample of observations.

Statistically significant A result indicating that the null hypothesis can be rejected; with reference to an estimated regression coefficient, frequently understood to mean a result indicating that the corresponding population regression coefficient is different from zero.

Status quo bias An emotional bias in which people do nothing (i.e., maintain the status quo) instead of making a change.

Statutory voting A common method of voting where each share represents one vote.

Step-up coupon bond Bond for which the coupon, fixed or floating, increases by specified margins at specified dates.

Stochastic oscillator A momentum indicator that compares a particular closing price of a security to a range of the security's prices over a certain period of time.

Stock dividend A type of dividend in which a company distributes additional shares of its common stock to shareholders instead of cash.

Stock split An increase in the number of shares outstanding with a consequent decrease in share price, but no change to the company's underlying fundamentals.

Stop-loss order See *stop order*.

Stop order An order in which a trader has specified a stop price condition. Also called *stop-loss order*.

Store of value The quality of tending to preserve value.

Store of wealth Goods that depend on the fact that they do not perish physically over time, and on the belief that others would always value the good.

Straight-line method A depreciation method that allocates evenly the cost of a long-lived asset less its estimated residual value over the estimated useful life of the asset.

Straight voting A shareholder voting process in which shareholders receive one vote for each share owned.

Strategic analysis Analysis of the competitive environment with an emphasis on the implications of the environment for corporate strategy.

Strategic asset allocation The set of exposures to IPS-permissible asset classes that is expected to achieve the client's long-term objectives given the client's investment constraints.

Stratified random sampling A procedure that first divides a population into subpopulations (strata) based on classification criteria and then randomly draws samples from each stratum in sizes proportional to that of each stratum in the population.

Street convention A yield measure that neglects weekends and holidays; the internal rate of return on cash flows assuming payments are made on the scheduled dates, even when the scheduled date falls on a weekend or holiday.

Stress testing A specific type of scenario analysis that estimates losses in rare and extremely unfavorable combinations of events or scenarios.

Strong-form efficient market A market in which security prices reflect all public and private information.

Structural (or cyclically adjusted) budget deficit The deficit that would exist if the economy was at full employment (or full potential output).

Structural subordination Arises in a holding company structure when the debt of operating subsidiaries is serviced by the cash flow and assets of the subsidiaries before funds can be passed to the holding company to service debt at the parent level.

Structured data Data that are highly organized in a predefined manner, usually with repeating patterns.

Structured financial instrument A financial instrument that shares the common attribute of repackaging risks. Structured financial instruments include asset-backed securities, collateralized debt obligations, and other structured financial instruments such as capital protected, yield enhancement, participation, and leveraged instruments.

Subjective probability A probability drawing on personal or subjective judgment.

Subordinated debt A class of unsecured debt that ranks below a firm's senior unsecured obligations.

Subordination Form of internal credit enhancement that relies on creating more than one bond tranche and ordering the claim priorities for ownership or interest in an asset between the tranches. The ordering of the claim priorities is called a senior/subordinated structure, where the tranches of highest seniority are called senior followed by subordinated or junior tranches. Also called *credit tranching*.

Substitutes Said of two goods or services such that if the price of one increases the demand for the other tends to increase, holding all other things equal (e.g., butter and margarine).

Sum of squares error (SSE) The sum of the squared deviations of (1) the value of the dependent variable and (2) the value of the dependent variable based on the estimated regression line. Also referred to as the *residual sum of squares*.

Sum of squares regression (SSR) The sum of the squared deviations of (1) the value of the dependent variable based on the estimated regression line and (2) the mean of the dependent variable.

Sum of squares total (SST) The sum of the squared deviations of the dependent variable from its mean; the variation of the dependent variable. Also referred to as the *total sum of squares*.

Sunk cost A cost that has already been incurred.

Supervised learning A machine learning approach that makes use of labeled training data.

Supply shock A typically unexpected disturbance to supply.

Support In technical analysis, a price range in which buying activity is sufficient to stop the decline in the price of a security.

Support tranches Classes or tranches in CMOs that protect PAC tranches from prepayment risk.

Supranational bond A bond issued by a supranational agency such as the World Bank.

Surety bond Form of external credit enhancement whereby a rated and regulated insurance company guarantees to reimburse bondholders for any losses incurred up to a maximum amount if the issuer defaults.

Survey approach An estimate of the equity risk premium that is based on estimates provided by a panel of finance experts.

Survivorship bias Relates to the inclusion of only current investment funds in a database. As such, the returns of funds that are no longer available in the marketplace (have been liquidated) are excluded from the database. In addition, *backfill bias* is another problem, whereby certain surviving hedge funds may be added to databases and various hedge fund indexes only after they are initially successful and start to report their returns.

Sustainability linked loans These are any types of loan instruments and/or contingent facilities (such as bonding lines, guarantee lines, or letters of credit) that incentivize the borrower's achievement of ambitious, pre-determined sustainability performance objectives.

Sustainable growth rate The rate of dividend (and earnings) growth that can be sustained over time for a given level of return on equity, keeping the capital structure constant and without issuing additional common stock.

Sustainable investing A term used in a similar context to responsible investing, but its key focus is on factoring in sustainability issues while investing.

Sustainable rate of economic growth The rate of increase in the economy's productive capacity or potential GDP.

Swap contract An agreement between two parties to exchange a series of future cash flows.

Syndicated loan A loan from a group of lenders to a single borrower.

Syndicated offering A bond issue underwritten by a group of investment banks.

Systematic risk Risk that affects the entire market or economy; it cannot be avoided and is inherent in the overall market. Systematic risk is also known as non-diversifiable or market risk.

Systematic sampling A procedure of selecting every *k*th member until reaching a sample of the desired size. The sample that results from this procedure should be approximately random.

Tactical asset allocation The decision to deliberately deviate from the strategic asset allocation in an attempt to add value based on forecasts of the near-term relative performance of asset classes.

Tactical asset allocation (TAA) A portfolio strategy that shifts the percentages of assets held in various asset classes (or categories) to take advantage of market opportunities. Allocation shifts can occur within an asset class or across asset classes.

Tag cloud see **word cloud**.

Target capital structure A company's chosen proportions of debt and equity.

Target independent A bank's ability to determine the definition of inflation that they target, the rate of inflation that they target, and the horizon over which the target is to be achieved.

Target semideviation A measure of downside risk, calculated as the square root of the average of the squared deviations of observations below the target (also called target downside deviation).

Tariffs Taxes that a government levies on imported goods.

Tax base The amount at which an asset or liability is valued for tax purposes.

Tax expense An aggregate of an entity's income tax payable (or recoverable in the case of a tax benefit) and any changes in deferred tax assets and liabilities. It is essentially the income tax payable or recoverable if these had been determined based on accounting profit rather than taxable income.

Tax loss carry forward A taxable loss in the current period that may be used to reduce future taxable income.

Taxable income The portion of an entity's income that is subject to income taxes under the tax laws of its jurisdiction.

Taxable temporary differences Temporary differences that result in a taxable amount in a future period when determining the taxable profit as the balance sheet item is recovered or settled.

Technical analysis A form of security analysis that uses price and volume data, often displayed graphically, in decision making.

Technology The process a company uses to transform inputs into outputs.

Tender offer Corporate takeover mechanism that involves shareholders selling their interests directly to the group seeking to gain control.

Tenor The time-to-maturity for a bond or derivative contract. Also called *term to maturity*.

Term maturity structure Structure for a bond issue in which the bond's notional principal is paid off in a lump sum at maturity.

Term structure See *maturity structure*.

Term structure of credit spreads The relationship between the spreads over the "risk-free" (or benchmark) rates and times-to-maturity.

Term structure of yield volatility The relationship between the volatility of bond yields-to-maturity and times-to-maturity.

Terminal stock value The expected value of a share at the end of the investment horizon—in effect, the expected selling price. Also called *terminal value*.

Terminal value The expected value of a share at the end of the investment horizon—in effect, the expected selling price.

Terms of trade The ratio of the price of exports to the price of imports, representing those prices by export and import price indexes, respectively.

Test of the mean of the differences A statistical test for differences based on paired observations drawn from samples that are dependent on each other.

Text analytics The use of computer programs to analyze and derive meaning from typically large, unstructured text- or voice-based datasets.

Thematic investing An ESG investment approach that focuses on investing in themes or assets specifically relating to ESG factors, such as clean energy, green technology, or sustainable agriculture.

Thin-Tailed Describes a distribution that has relatively less weight in the tails than the normal distribution (also called platykurtic).

Third-degree price discrimination When the monopolist segregates customers into groups based on demographic or other characteristics and offers different pricing to each group.

Time-period bias The possibility that when we use a time-series sample, our statistical conclusion may be sensitive to the starting and ending dates of the sample.

Time-series data A sequence of observations for a single observational unit of a specific variable collected over time and at discrete and typically equally spaced intervals of time (such as daily, weekly, monthly, annually, or quarterly).

Time tranching The creation of classes or tranches in an ABS/MBS that possess different (expected) maturities.

Time value The difference between the market price of the option and its intrinsic value.

Time value decay Said of an option when, at expiration, no time value remains and the option is worth only its exercise value.

Time value of money The principles governing equivalence relationships between cash flows with different dates.

Time-weighted rate of return The compound rate of growth of one unit of currency invested in a portfolio during a stated measurement period; a measure of investment performance that is not sensitive to the timing and amount of withdrawals or additions to the portfolio.

Tokenization The process of representing ownership rights to physical assets on a blockchain or distributed ledger.

Top-down analysis An investment selection approach that begins with consideration of macroeconomic conditions and then evaluates markets and industries based upon such conditions.

Total comprehensive income The change in equity during a period resulting from transaction and other events, other than those changes resulting from transactions with owners in their capacity as owners.

Total cost The summation of all costs, for which costs are classified as fixed or variable.

Total factor productivity A scale factor that reflects the portion of growth unaccounted for by explicit factor inputs (e.g., capital and labor).

Total fixed cost The summation of all expenses that do not change as the level of production varies.

Total invested capital The sum of market value of common equity, book value of preferred equity, and face value of debt.

Total probability rule A rule explaining the unconditional probability of an event in terms of probabilities of the event conditional on mutually exclusive and exhaustive scenarios.

Total probability rule for expected value A rule explaining the expected value of a random variable in terms of expected values of the random variable conditional on mutually exclusive and exhaustive scenarios.

Total return Measures the price appreciation, or percentage change in price of the securities in an index or portfolio, plus any income received over the period.

Total return index An index that reflects the price appreciation or percentage change in price of the constituent securities plus any income received since inception.

Total return swap A swap in which one party agrees to pay the total return on a security. Often used as a credit derivative, in which the underlying is a bond.

Total variable cost The summation of all variable expenses.

Tracking error The standard deviation of the differences between a portfolio's returns and its benchmark's returns; a synonym of active risk.

Tracking risk The standard deviation of the differences between a portfolio's returns and its benchmarks returns. Also called *tracking error*.

Trade creation When regional integration results in the replacement of higher cost domestic production by lower cost imports from other members.

Trade credit A spontaneous form of credit in which a purchaser of the goods or service is financing its purchase by delaying the date on which payment is made.

Trade diversion When regional integration results in lower-cost imports from non-member countries being replaced with higher-cost imports from members.

Trade payables Amounts that a business owes to its vendors for goods and services that were purchased from them but which have not yet been paid.

Trade protection Government policies that impose restrictions on trade, such as tariffs and quotas.

Trade surplus (deficit) When the value of exports is greater (less) than the value of imports.

Trading securities Under US GAAP, a category of debt securities held by a company with the intent to trade them. Also called *held-for-trading securities*.

Traditional investment markets Markets for traditional investments, which include all publicly traded debts and equities and shares in pooled investment vehicles that hold publicly traded debts and/or equities.

Transactions money balances Money balances that are held to finance transactions.

Transfer payments Welfare payments made through the social security system that exist to provide a basic minimum level of income for low-income households.

Transparency Said of something (e.g., a market) in which information is fully disclosed to the public and/or regulators.

Treasury stock method A method for accounting for the effect of options (and warrants) on earnings per share (EPS) that specifies what EPS would have been if the options and warrants had been exercised and the company had used the proceeds to repurchase common stock.

Tree-Map Another graphical tool for displaying categorical data. It consists of a set of colored rectangles to represent distinct groups, and the area of each rectangle is proportional to the value of the corresponding group.

Trend A long-term pattern of movement in a particular direction.

Treynor ratio A measure of risk-adjusted performance that relates a portfolio's excess returns to the portfolio's beta.

Triangle pattern In technical analysis, a continuation chart pattern that forms as the range between high and low prices narrows, visually forming a triangle.

Trimmed mean A mean computed after excluding a stated small percentage of the lowest and highest observations.

Trimodal A distribution that has the three most frequently occurring values.

Triple bottom In technical analysis, a reversal pattern that results when the price forms three troughs at roughly the same price level. A triple bottom is used to predict a change from a downtrend to an uptrend.

Triple top In technical analysis, a reversal pattern that results when the price forms three peaks at roughly the same price level. A triple top is used to predict a change from an uptrend to a downtrend.

True yield The internal rate of return on cash flows using the actual calendar, including weekends and bank holidays.

Trust deed The governing legal credit agreement, typically incorporated by reference in the prospectus. Also called *bond indenture*.

Turn-of-the-year effect Calendar anomaly that stock market returns in January are significantly higher compared to the rest of the months of the year, with most of the abnormal returns reported during the first five trading days in January.

Two-dimensional rectangular array A popular form for organizing data for processing by computers or for presenting data visually. It is comprised of columns and rows to hold multiple variables and multiple observations, respectively (also called a **data table**).

Two-fund separation theorem The theory that all investors regardless of taste, risk preferences, and initial wealth will hold a combination of two portfolios or funds: a risk-free asset and an optimal portfolio of risky assets.

Two-sided hypothesis test A test in which the null hypothesis is rejected in favor of the alternative hypothesis if the evidence indicates that the population parameter is either smaller or larger than a hypothesized value; occurs when the alternative hypothesis is stated as not equal to the hypothesized population parameters.

Two-way table See *contingency table*.

Two-week repo rate The interest rate on a two-week repurchase agreement; may be used as a policy rate by a central bank.

Type I error The error of rejecting a true null hypothesis; a false positive.

Type II error The error of not rejecting a false null hypothesis; false negative.

Unanticipated (unexpected) inflation The component of inflation that is a surprise.

Uncommitted lines of credit The least reliable form of bank borrowing in which a bank offers, without formal commitment, a line of credit for an extended period of time but reserves the right to refuse any request for its use.

Unconditional probability The probability of an event *not* conditioned on another event.

Underemployed A person who has a job but has the qualifications to work a significantly higher-paying job.

Underlying An asset that trades in a market in which buyers and sellers meet, decide on a price, and the seller then delivers the asset to the buyer and receives payment. The underlying is the asset or other derivative on which a particular derivative is based. The market for the underlying is also referred to as the *spot market*.

Underwriter A firm, usually an investment bank, that takes the risk of buying the newly issued securities from the issuer and then reselling them to investors or to dealers, thus guaranteeing the sale of the securities at the offering price negotiated with the issuer.

Underwritten offering A type of securities issue mechanism in which the investment bank guarantees the sale of the securities at an offering price that is negotiated with the issuer. Also known as *firm commitment offering*.

Unearned revenue A liability account for money that has been collected for goods or services that have not yet been delivered; payment received in advance of providing a good or service. Also called *deferred revenue* or *deferred income*.

Unemployed People who are actively seeking employment but are currently without a job.

Unemployment rate The ratio of unemployed to the labor force.

Unexpected inflation The component of inflation that is a surprise.

Unimodal A distribution with a single value that is most frequently occurring.

Unit elastic An elasticity with a magnitude of negative one. Also called *unitary elastic*.

Unit labor cost The average labor cost to produce one unit of output.

Unit normal distribution The normal density with mean (μ) equal to 0 and standard deviation (σ) equal to 1.

Unitranche debt Consists of a hybrid or blended loan structure that combines different tranches of secured and unsecured debt into a single loan with a single, blended interest rate.

Units-of-production method A depreciation method that allocates the cost of a long-lived asset based on actual usage during the period.

Univariate distribution A distribution that specifies the probabilities for a single random variable.

Universal owners Long-term investors, such as pension funds, that have significant assets invested in globally diversified portfolios.

Unlimited funds An unlimited funds environment assumes that the company can raise the funds it wants for all profitable investments simply by paying the required rate of return.

Unsecured debt Debt that gives the debtholder only a general claim on an issuer's assets and cash flow.

Unsponsored A type of depository receipt in which the foreign company whose shares are held by the depository has no involvement in the issuance of the receipts.

Unstructured data Data that do not follow any conventionally organized forms.

Unsupervised learning A machine learning approach that does not make use of labeled training data.

Up transition probability The probability that an asset's value moves up.

Uptrend A pattern that occurs when the price of an asset moves higher over a period of time.

Validity instructions Instructions which indicate when the order may be filled.

Valuation allowance A reserve created against deferred tax assets, based on the likelihood of realizing the deferred tax assets in future accounting periods.

Valuation ratios Ratios that measure the quantity of an asset or flow (e.g., earnings) in relation to the price associated with a specified claim (e.g., a share or ownership of the enterprise).

Value at risk A money measure of the minimum value of losses expected during a specified time period at a given level of probability.

Value investors With reference to equity investors, investors who are focused on paying a relatively low share price in relation to earnings or assets per share.

VaR See *value at risk*.

Variable A characteristic or quantity that can be measured, counted, or categorized and that is subject to change (also called a field, an attribute, or a feature).

Variable costs Costs that fluctuate with the level of production and sales.

Variance The expected value (the probability-weighted average) of squared deviations from a random variable's expected value.

Variation margin Additional margin that must be deposited in an amount sufficient to bring the balance up to the initial margin requirement.

Veblen goods Goods that increase in desirability with increasing price.

Vega A measure of the sensitivity of an option's price to changes in the underlying's volatility.

Venture capital Investments that provide "seed" or startup capital, early-stage financing, or later-stage financing (including mezzanine-stage financing) to companies that are in early development stages and require additional capital for expansion or preparation for an initial public offering.

Venture capital fund A hedge fund that seeks to buy, optimize, and ultimately sell portfolio companies to generate profits. See *private equity fund*.

Venture capital funds Funds that seek to invest in, optimize, and eventually exit portfolio companies to generate profits. See *private equity funds.*

Vertical analysis Common-size analysis using only one reporting period or one base financial statement; for example, an income statement in which all items are stated as percentages of sales.

Vertical demand schedule Implies that some fixed quantity is demanded, regardless of price.

Visual technique The most common and readily available method of initial data assessment. Experts in pattern recognition maintain that the visual (or "eyeball") technique is still the most effective way of searching for recognizable patterns.

Visualization The presentation of data in a pictorial or graphical format for the purpose of increasing understanding and for gaining insights into the data.

Volatility The standard deviation of the continuously compounded returns on the underlying asset.

Voluntarily unemployed A person voluntarily outside the labor force, such as a jobless worker refusing an available vacancy.

Voluntary export restraint A trade barrier under which the exporting country agrees to limit its exports of the good to its trading partners to a specific number of units.

Vote by proxy A mechanism that allows a designated party—such as another shareholder, a shareholder representative, or management—to vote on the shareholder's behalf.

Warrant Attached option that gives its holder the right to buy the underlying stock of the issuing company at a fixed exercise price until the expiration date.

Waterfall Represents the distribution method that defines the order in which allocations are made to LPs and GPs. There are two major types of waterfall: *deal by deal* (or *American*) and *whole of fund* (or *European*).

Weak-form efficient market hypothesis The belief that security prices fully reflect all past market data, which refers to all historical price and volume trading information.

Wealth effect An increase (decrease) in household wealth increases (decreases) consumer spending out of a given level of current income.

Web-based lender A lender that operates primarily on the internet, offering loans in relatively small amounts, typically to small businesses in need of cash.

Weighted average cost method An inventory accounting method that averages the total cost of available inventory items over the total units available for sale.

Weighted average cost of capital A weighted average of the after-tax required rates of return on a company's common stock, preferred stock, and long-term debt, where the weights are the fraction of each source of financing in the company's target capital structure.

Weighted average cost of capital (WACC) A weighted average of the after-tax required rates of return on a company's common stock, preferred stock, and long-term debt, where the weights are the fraction of each source of financing in the company's target capital structure.

Weighted average coupon rate Weighting the mortgage rate of each mortgage loan in the pool by the percentage of the mortgage outstanding relative to the outstanding amount of all the mortgages in the pool.

Weighted average life A measure that gives investors an indication of how long they can expect to hold the MBS before it is paid off; the convention-based average time to receipt of all principal repayments. Also called *average life*.

Weighted average maturity Weighting the remaining number of months to maturity for each mortgage loan in the pool by the amount of the outstanding mortgage balance.

Weighted mean An average in which each observation is weighted by an index of its relative importance.

Winsorized mean A mean computed after assigning a stated percentage of the lowest values equal to one specified low value and a stated percentage of the highest values equal to one specified high value.

Word cloud A visual device for representing textual data, which consists of words extracted from a source of textual data. The size of each distinct word is proportional to the frequency with which it appears in the given text (also known as **tag cloud**).

Working capital The difference between current assets and current liabilities.

Working capital management The management of a company's short-term assets (such as inventory) and short-term liabilities (such as money owed to suppliers).

World price The price prevailing in the world market.

Yield duration The sensitivity of the bond price with respect to the bond's own yield-to-maturity.

Yield to maturity Annual return that an investor earns on a bond if the investor purchases the bond today and holds it until maturity. It is the discount rate that equates the present value of the bond's expected cash flows until maturity with the bond's price. Also called *yield to redemption* or *redemption yield*.

Yield-to-maturity Annual return that an investor earns on a bond if the investor purchases the bond today and holds it until maturity. It is the discount rate that equates the present value of the bond's expected cash flows until maturity with the bond's price. Also called *yield-to-redemption* or *redemption yield*.

Yield-to-redemption See *yield-to-maturity*.

Yield-to-worst The lowest of the sequence of yields-to-call and the yield-to-maturity.

Zero-coupon bond A bond that does not pay interest during its life. It is issued at a discount to par value and redeemed at par. Also called *pure discount bond*.

Zero-volatility spread (Z-spread) Calculates a constant yield spread over a government (or interest rate swap) spot curve.

Glossary **G-1**

How to Use the CFA Program Curriculum

Congratulations on your decision to enter the Chartered Financial Analyst (CFA®) Program. This exciting and rewarding program of study reflects your desire to become a serious investment professional. You are embarking on a program noted for its high ethical standards and the breadth of knowledge, skills, and abilities (competencies) it develops. Your commitment should be educationally and professionally rewarding.

The credential you seek is respected around the world as a mark of accomplishment and dedication. Each level of the program represents a distinct achievement in professional development. Successful completion of the program is rewarded with membership in a prestigious global community of investment professionals. CFA charterholders are dedicated to life-long learning and maintaining currency with the ever-changing dynamics of a challenging profession. CFA Program enrollment represents the first step toward a career-long commitment to professional education.

The CFA exam measures your mastery of the core knowledge, skills, and abilities required to succeed as an investment professional. These core competencies are the basis for the Candidate Body of Knowledge (CBOK™). The CBOK consists of four components:

- A broad outline that lists the major CFA Program topic areas (www.cfainstitute.org/programs/cfa/curriculum/cbok);
- Topic area weights that indicate the relative exam weightings of the top-level topic areas (www.cfainstitute.org/programs/cfa/curriculum);
- Learning outcome statements (LOS) that advise candidates about the specific knowledge, skills, and abilities they should acquire from readings covering a topic area (LOS are provided in candidate study sessions and at the beginning of each reading); and
- CFA Program curriculum that candidates receive upon exam registration.

Therefore, the key to your success on the CFA exams is studying and understanding the CBOK. The following sections provide background on the CBOK, the organization of the curriculum, features of the curriculum, and tips for designing an effective personal study program.

BACKGROUND ON THE CBOK

CFA Program is grounded in the practice of the investment profession. CFA Institute performs a continuous practice analysis with investment professionals around the world to determine the competencies that are relevant to the profession, beginning with the Global Body of Investment Knowledge (GBIK®). Regional expert panels and targeted surveys are conducted annually to verify and reinforce the continuous feedback about the GBIK. The practice analysis process ultimately defines the CBOK. The CBOK reflects the competencies that are generally accepted and applied by investment professionals. These competencies are used in practice in a generalist context and are expected to be demonstrated by a recently qualified CFA charterholder.

© 2021 CFA Institute. All rights reserved.

The CFA Institute staff—in conjunction with the Education Advisory Committee and Curriculum Level Advisors, who consist of practicing CFA charterholders—designs the CFA Program curriculum in order to deliver the CBOK to candidates. The exams, also written by CFA charterholders, are designed to allow you to demonstrate your mastery of the CBOK as set forth in the CFA Program curriculum. As you structure your personal study program, you should emphasize mastery of the CBOK and the practical application of that knowledge. For more information on the practice analysis, CBOK, and development of the CFA Program curriculum, please visit www.cfainstitute.org.

ORGANIZATION OF THE CURRICULUM

The Level I CFA Program curriculum is organized into 10 topic areas. Each topic area begins with a brief statement of the material and the depth of knowledge expected. It is then divided into one or more study sessions. These study sessions should form the basic structure of your reading and preparation. Each study session includes a statement of its structure and objective and is further divided into assigned readings. An outline illustrating the organization of these study sessions can be found at the front of each volume of the curriculum.

The readings are commissioned by CFA Institute and written by content experts, including investment professionals and university professors. Each reading includes LOS and the core material to be studied, often a combination of text, exhibits, and in-text examples and questions. End of Reading Questions (EORQs) followed by solutions help you understand and master the material. The LOS indicate what you should be able to accomplish after studying the material. The LOS, the core material, and the EORQs are dependent on each other, with the core material and EORQs providing context for understanding the scope of the LOS and enabling you to apply a principle or concept in a variety of scenarios.

The entire readings, including the EORQs, are the basis for all exam questions and are selected or developed specifically to teach the knowledge, skills, and abilities reflected in the CBOK.

You should use the LOS to guide and focus your study because each exam question is based on one or more LOS and the core material and practice problems associated with the LOS. As a candidate, you are responsible for the entirety of the required material in a study session.

We encourage you to review the information about the LOS on our website (www.cfainstitute.org/programs/cfa/curriculum/study-sessions), including the descriptions of LOS “command words” on the candidate resources page at www.cfainstitute.org.

FEATURES OF THE CURRICULUM

End of Reading Questions/Solutions *All End of Reading Questions (EORQs) as well as their solutions are part of the curriculum and are required material for the exam.* In addition to the in-text examples and questions, these EORQs help demonstrate practical applications and reinforce your understanding of the concepts presented. Some of these EORQs are adapted from past CFA exams and/or may serve as a basis for exam questions.

Glossary For your convenience, each volume includes a comprehensive Glossary. Throughout the curriculum, a **bolded** word in a reading denotes a term defined in the Glossary.

Note that the digital curriculum that is included in your exam registration fee is searchable for key words, including Glossary terms.

LOS Self-Check We have inserted checkboxes next to each LOS that you can use to track your progress in mastering the concepts in each reading.

Source Material The CFA Institute curriculum cites textbooks, journal articles, and other publications that provide additional context or information about topics covered in the readings. As a candidate, you are not responsible for familiarity with the original source materials cited in the curriculum.

Note that some readings may contain a web address or URL. The referenced sites were live at the time the reading was written or updated but may have been deactivated since then.

Some readings in the curriculum cite articles published in the *Financial Analysts Journal*®, which is the flagship publication of CFA Institute. Since its launch in 1945, the *Financial Analysts Journal* has established itself as the leading practitioner-oriented journal in the investment management community. Over the years, it has advanced the knowledge and understanding of the practice of investment management through the publication of peer-reviewed practitioner-relevant research from leading academics and practitioners. It has also featured thought-provoking opinion pieces that advance the common level of discourse within the investment management profession. Some of the most influential research in the area of investment management has appeared in the pages of the *Financial Analysts Journal*, and several Nobel laureates have contributed articles.

Candidates are not responsible for familiarity with *Financial Analysts Journal* articles that are cited in the curriculum. But, as your time and studies allow, we strongly encourage you to begin supplementing your understanding of key investment management issues by reading this, and other, CFA Institute practice-oriented publications through the Research & Analysis webpage (www.cfainstitute.org/en/research).

Errata The curriculum development process is rigorous and includes multiple rounds of reviews by content experts. Despite our efforts to produce a curriculum that is free of errors, there are times when we must make corrections. Curriculum errata are periodically updated and posted by exam level and test date online (www.cfainstitute.org/en/programs/submit-errata). If you believe you have found an error in the curriculum, you can submit your concerns through our curriculum errata reporting process found at the bottom of the Curriculum Errata webpage.

DESIGNING YOUR PERSONAL STUDY PROGRAM

Create a Schedule An orderly, systematic approach to exam preparation is critical. You should dedicate a consistent block of time every week to reading and studying. Complete all assigned readings and the associated problems and solutions in each study session. Review the LOS both before and after you study each reading to ensure that

you have mastered the applicable content and can demonstrate the knowledge, skills, and abilities described by the LOS and the assigned reading. Use the LOS self-check to track your progress and highlight areas of weakness for later review.

Successful candidates report an average of more than 300 hours preparing for each exam. Your preparation time will vary based on your prior education and experience, and you will probably spend more time on some study sessions than on others.

You should allow ample time for both in-depth study of all topic areas and additional concentration on those topic areas for which you feel the least prepared.

CFA INSTITUTE LEARNING ECOSYSTEM (LES)

As you prepare for your exam, we will email you important exam updates, testing policies, and study tips. Be sure to read these carefully.

Your exam registration fee includes access to the CFA Program Learning Ecosystem (LES). This digital learning platform provides access, even offline, to all of the readings and End of Reading Questions found in the print curriculum organized as a series of shorter online lessons with associated EORQs. This tool is your one-stop location for all study materials, including practice questions and mock exams.

The LES provides the following supplemental study tools:

Structured and Adaptive Study Plans The LES offers two ways to plan your study through the curriculum. The first is a structured plan that allows you to move through the material in the way that you feel best suits your learning. The second is an adaptive study plan based on the results of an assessment test that uses actual practice questions.

Regardless of your chosen study path, the LES tracks your level of proficiency in each topic area and presents you with a dashboard of where you stand in terms of proficiency so that you can allocate your study time efficiently.

Flashcards and Game Center The LES offers all the Glossary terms as Flashcards and tracks correct and incorrect answers. Flashcards can be filtered both by curriculum topic area and by action taken—for example, answered correctly, unanswered, and so on. These Flashcards provide a flexible way to study Glossary item definitions.

The Game Center provides several engaging ways to interact with the Flashcards in a game context. Each game tests your knowledge of the Glossary terms a in different way. Your results are scored and presented, along with a summary of candidates with high scores on the game, on your Dashboard.

Discussion Board The Discussion Board within the LES provides a way for you to interact with other candidates as you pursue your study plan. Discussions can happen at the level of individual lessons to raise questions about material in those lessons that you or other candidates can clarify or comment on. Discussions can also be posted at the level of topics or in the initial Welcome section to connect with other candidates in your area.

Practice Question Bank The LES offers access to a question bank of hundreds of practice questions that are in addition to the End of Reading Questions. These practice questions, only available on the LES, are intended to help you assess your mastery of individual topic areas as you progress through your studies. After each practice question, you will receive immediate feedback noting the correct response and indicating the relevant assigned reading so you can identify areas of weakness for further study.

Mock Exams The LES also includes access to three-hour Mock Exams that simulate the morning and afternoon sessions of the actual CFA exam. These Mock Exams are intended to be taken after you complete your study of the full curriculum and take practice questions so you can test your understanding of the curriculum and your readiness for the exam. If you take these Mock Exams within the LES, you will receive feedback afterward that notes the correct responses and indicates the relevant assigned readings so you can assess areas of weakness for further study. We recommend that you take Mock Exams during the final stages of your preparation for the actual CFA exam. For more information on the Mock Exams, please visit www.cfainstitute.org.

PREP PROVIDERS

You may choose to seek study support outside CFA Institute in the form of exam prep providers. After your CFA Program enrollment, you may receive numerous solicitations for exam prep courses and review materials. When considering a prep course, make sure the provider is committed to following the CFA Institute guidelines and high standards in its offerings.

Remember, however, that there are no shortcuts to success on the CFA exams; reading and studying the CFA Program curriculum *is* the key to success on the exam. The CFA Program exams reference only the CFA Institute assigned curriculum; no prep course or review course materials are consulted or referenced.

SUMMARY

Every question on the CFA exam is based on the content contained in the required readings and on one or more LOS. Frequently, an exam question is based on a specific example highlighted within a reading or on a specific practice problem and its solution. To make effective use of the CFA Program curriculum, please remember these key points:

1. All pages of the curriculum are required reading for the exam.
2. All questions, problems, and their solutions are part of the curriculum and are required study material for the exam. These questions are found at the end of the readings in the print versions of the curriculum. In the LES, these questions appear directly after the lesson with which they are associated. The LES provides immediate feedback on your answers and tracks your performance on these questions throughout your study.
3. We strongly encourage you to use the CFA Program Learning Ecosystem. In addition to providing access to all the curriculum material, including EORQs, in the form of shorter, focused lessons, the LES offers structured and adaptive study planning, a Discussion Board to communicate with other candidates, Flashcards, a Game Center for study activities, a test bank of practice questions, and online Mock Exams. Other supplemental study tools, such as eBook and PDF versions of the print curriculum, and additional candidate resources are available at www.cfainstitute.org.
4. Using the study planner, create a schedule and commit sufficient study time to cover the study sessions. You should also plan to review the materials, answer practice questions, and take Mock Exams.
5. Some of the concepts in the study sessions may be superseded by updated rulings and/or pronouncements issued after a reading was published. Candidates are expected to be familiar with the overall analytical framework contained in the assigned readings. Candidates are not responsible for changes that occur after the material was written.

FEEDBACK

At CFA Institute, we are committed to delivering a comprehensive and rigorous curriculum for the development of competent, ethically grounded investment professionals. We rely on candidate and investment professional comments and feedback as we work to improve the curriculum, supplemental study tools, and candidate resources.

Please send any comments or feedback to info@cfainstitute.org. You can be assured that we will review your suggestions carefully. Ongoing improvements in the curriculum will help you prepare for success on the upcoming exams and for a lifetime of learning as a serious investment professional.

Corporate Issuers

STUDY SESSION

Study Session 9	Corporate Issuers (1)
Study Session 10	Corporate Issuers (2)

TOPIC LEVEL LEARNING OUTCOME

The candidate should be able to evaluate a company's corporate governance; to demonstrate methods used to make capital investment; to evaluate the management of working capital; estimate a company's cost of capital; and to evaluate a company's operating and financial leverage.

Some academic studies have shown that well governed companies may perform better in financial terms. Increasingly, investment approaches that consider environmental, social, and governance factors, known as ESG, are being adopted. In addition to good governance practices, management decisions regarding investment and financing also play a central role in corporate profitability and performance. To remain in business as a going concern and to increase shareholder value over time, a company's management must consistently identify and invest in profitable long-term capital projects relative to cost of capital (financing) and make optimal use of leverage and working capital in day to day operations.

CORPORATE ISSUERS

STUDY SESSION

10

Corporate Issuers (2)

This study session begins with practical techniques to estimate a company's, or project's, cost of capital, a key input used in both corporate decision-making and investor analysis. Methods to estimate the costs of the various sources of capital are covered. Next, capital structure considerations and the Modigliani-Miller propositions are discussed, including factors affecting the use of leverage by companies. Examples of potential stakeholder conflicts that arise with financing decisions are also examined. The session concludes with coverage of the various types of leverage (operating, financial, total), measures of leverage, and the impact that leverage may have on a company's earnings and financial ratios.

READING ASSIGNMENTS

Reading 30	Cost of Capital-Foundational Topics by Yves Courtois, CMT, MRICS, CFA, Gene C. Lai, PhD, and Pamela Peterson Drake, PhD, CFA
Reading 31	Capital Structure Raj Aggarwal, PhD, CFA, Glen D. Campbell, MBA, Pamela Peterson Drake, PhD, CFA, Adam Kobor, PhD, CFA, and Gregory Noronha, PhD, CFA
Reading 32	Measures of Leverage by Pamela Peterson Drake, PhD, CFA, Raj Aggarwal, PhD, CFA, Cynthia Harrington, CFA, and Adam Kobor, PhD, CFA

READING

30

Cost of Capital-Foundational Topics

by Yves Courtois, CMT, MRICS, CFA, Gene C. Lai, PhD, and
Pamela Peterson Drake, PhD, CFA

Yves Courtois, CMT, MRICS, CFA, is at KPMG (Luxembourg). Gene C. Lai, PhD, is at the University of North Carolina at Charlotte (USA). Pamela Peterson Drake, PhD, CFA, is at James Madison University (USA).

LEARNING OUTCOMES

Mastery	*The candidate should be able to:*
☐	**a.** calculate and interpret the weighted average cost of capital (WACC) of a company;
☐	**b.** describe how taxes affect the cost of capital from different capital sources;
☐	**c.** calculate and interpret the cost of debt capital using the yield-to-maturity approach and the debt-rating approach;
☐	**d.** calculate and interpret the cost of noncallable, nonconvertible preferred stock;
☐	**e.** calculate and interpret the cost of equity capital using the capital asset pricing model approach and the bond yield plus risk premium approach;
☐	**f.** explain and demonstrate beta estimation for public companies, thinly traded public companies, and nonpublic companies;
☐	**g.** explain and demonstrate the correct treatment of flotation costs.

INTRODUCTION

1

A company grows by making investments that are expected to increase revenues and profits. It acquires the capital or funds necessary to make such investments by borrowing (i.e., using debt financing) or by using funds from the owners (i.e., equity financing). By applying this capital to investments with long-term benefits, the company is producing value today. How much value? The answer depends not only on the investments' expected future cash flows but also on the cost of the funds. Borrowing is not costless, nor is using owners' funds.

© 2021 CFA Institute. All rights reserved.

The cost of this capital is an important ingredient in both investment decision making by the company's management and the valuation of the company by investors. If a company invests in projects that produce a return in excess of the cost of capital, the company has created value; in contrast, if the company invests in projects whose returns are less than the cost of capital, the company has destroyed value. Therefore, the estimation of the cost of capital is a central issue in corporate financial management and for an analyst seeking to evaluate a company's investment program and its competitive position.

Cost of capital estimation is a challenging task. As we have already implied, the cost of capital is not observable but, rather, must be estimated. Arriving at a cost of capital estimate requires a multitude of assumptions and estimates. Another challenge is that the cost of capital that is appropriately applied to a specific investment depends on the characteristics of that investment: The riskier the investment's cash flows, the greater its cost of capital. In reality, a company must estimate project-specific costs of capital. What is often done, however, is to estimate the cost of capital for the company as a whole and then adjust this overall corporate cost of capital upward or downward to reflect the risk of the contemplated project relative to the company's average project.

This reading is organized as follows: In Section 2, we introduce the cost of capital and its basic computation. Section 3 presents a selection of methods for estimating the costs of the various sources of capital: debt, preferred stock, and common equity. For the latter, two approaches for estimating the equity risk premium are mentioned. Section 4 discusses beta estimation, a key input in using the CAPM to calculate the cost of equity, and Section 5 examines the correct treatment of flotation, or capital issuance, costs. Section 6 highlights methods used by corporations, and a summary concludes the reading.

2

COST OF CAPITAL

a calculate and interpret the weighted average cost of capital (WACC) of a company

The **cost of capital** is the rate of return that the suppliers of capital—lenders and owners—require as compensation for their contribution of capital. Another way of looking at the cost of capital is that it is the opportunity cost of funds for the suppliers of capital: A potential supplier of capital will not voluntarily invest in a company unless its return meets or exceeds what the supplier could earn elsewhere in an investment of comparable risk. In other words, to raise new capital, the issuer must price the security to offer a level of expected return that is competitive with the expected returns being offered by similarly risky securities.

A company typically has several alternatives for raising capital, including issuing equity, debt, and hybrid instruments that share characteristics of both debt and equity, such as preferred stock and convertible debt. Each source selected becomes a component of the company's funding and has a cost (required rate of return) that may be called a **component cost of capital**. Because we are using the cost of capital in the evaluation of investment opportunities, we are dealing with a *marginal* cost—what it would cost to raise additional funds for the potential investment project. Therefore, the cost of capital that the investment analyst is concerned with is a marginal cost, and the required return on a security is the issuer's marginal cost for raising additional capital of the same type.

The cost of capital of a company is the required rate of return that investors demand for the average-risk investment of a company. A company with higher-than-average-risk investments must pay investors a higher rate of return, competitive with other securities of similar risk, which corresponds to a higher cost of capital. Similarly, a company with lower-than-average-risk investments will have lower rates of return demanded by investors, resulting in a lower associated cost of capital. The most common way to estimate this required rate of return is to calculate the marginal cost of each of the various sources of capital and then calculate a weighted average of these costs. You will notice that the debt and equity costs of capital and the tax rate are all understood to be "marginal" rates: the cost or tax rate for additional capital.

The weighted average is referred to as the **weighted average cost of capital** (WACC). The WACC is also referred to as the marginal cost of capital (MCC) because it is the cost that a company incurs for additional capital. Further, this is the current cost: what it would cost the company today.

The weights are the proportions of the various sources of capital that the company uses to support its investment program. It is important to note that the weights should represent the company's **target capital structure**, not the current capital structure. A company's target capital structure is its chosen (or targeted) proportions of debt and equity, whereas its current capital structure is the company's actual weighting of debt and equity. For example, suppose the current capital structure is one-third debt, one-third preferred stock, and one-third common stock. Now suppose the new investment will be financed by issuing more debt so that capital structure changes to one-half debt, one-fourth preferred stock, and one-fourth common stock. Those new weights (i.e., the target weights) should be used to calculate the WACC.

Taking the sources of capital to be common stock, preferred stock, and debt and allowing for the fact that in some jurisdictions, interest expense may be tax deductible, the expression for WACC is

$$\text{WACC} = w_d r_d(1 - t) + w_p r_p + w_e r_e, \tag{1}$$

where

w_d = the target proportion of debt in the capital structure when the company raises new funds

r_d = the before-tax marginal cost of debt

t = the company's marginal tax rate

w_p = the target proportion of preferred stock in the capital structure when the company raises new funds

r_p = the marginal cost of preferred stock

w_e = the target proportion of common stock in the capital structure when the company raises new funds

r_e = the marginal cost of common stock

Note that preferred stock is also referred to as preferred equity, and common stock is also referred to as common equity, or equity.

EXAMPLE 1

Computing the Weighted Average Cost of Capital

Assume that ABC Corporation has the following capital structure: 30% debt, 10% preferred stock, and 60% common stock, or equity. Also assume that interest expense is tax deductible. ABC Corporation wishes to maintain these proportions as it raises new funds. Its before-tax cost of debt is 8%, its cost of preferred stock is 10%, and its cost of equity is 15%. If the company's marginal tax rate is 40%, what is ABC's weighted average cost of capital?

Solution:

The weighted average cost of capital is

$$\text{WACC} = (0.3)(0.08)(1 - 0.40) + (0.1)(0.1) + (0.6)(0.15)$$

$$= 11.44\%.$$

The cost for ABC Corporation to raise new funds while keeping its current capital structure is 11.44%.

Self reflection:

Maintaining its current capital structure, what happens to ABC's weighted average cost of capital if component costs increase or decrease? What happens if the company's marginal tax rate increases or decreases?

There are important points concerning the calculation of the WACC as shown in Equation 1 that the analyst must be familiar with. The next section addresses the key issue of taxes.

2.1 Taxes and the Cost of Capital

b describe how taxes affect the cost of capital from different capital sources

The marginal cost of debt financing is the cost of debt after considering the allowable deduction for interest on debt based on the country's tax law. If interest cannot be deducted for tax purposes, the tax rate applied is zero, so the effective marginal cost of debt is equal to r_d in Equation 1. If interest can be deducted in full, the tax deductibility of debt reduces the effective marginal cost of debt to reflect the income shielded from taxation (often referred to as the tax shield) and the marginal cost of debt is $r_d(1 - t)$. For example, suppose a company pays €1 million in interest on its €10 million of debt. The cost of this debt is not €1 million, because this interest expense reduces taxable income by €1 million, resulting in a lower tax. If the company has a marginal tax rate of 40%, this €1 million of interest costs the company (€1 million)(1 – 0.4) = €0.6 million because the interest reduces the company's tax bill by €0.4 million. In this case, the before-tax cost of debt is 10%, whereas the after-tax cost of debt is (€0.6 million)/(€10 million) = 6%, which can also be calculated as 10%(1 – 0.4).

In jurisdictions in which a tax deduction for a business's interest expense is allowed, there may be reasons why additional interest expense is not tax deductible (e.g., not having sufficient income to offset with interest expense). If the above company with €10 million in debt were in that position, its effective marginal cost of debt would be 10% rather than 6% because any additional interest expense would not be deductible for tax purposes. In other words, if the limit on tax deductibility is reached, the marginal cost of debt is the cost of debt without any adjustment for a tax shield.

EXAMPLE 2

Incorporating the Effect of Taxes on the Costs of Capital

Jorge Ricard, a financial analyst, is estimating the costs of capital for the Zeale Corporation. In the process of this estimation, Ricard has estimated the before-tax costs of capital for Zeale's debt and equity as 4% and 6%, respectively. What are the after-tax costs of debt and equity if there is no limit to the tax deductibility of interest and Zeale's marginal tax rate is:

1 30%?

2 48%?

	Marginal Tax Rate	After-Tax Cost of Debt	After-Tax Cost of Equity
Solution to 1:	30%	0.04(1 – 0.30) = 2.80%.	6%
Solution to 2:	48%	0.04(1 – 0.48) = 2.08%.	6%

Note: There is no adjustment for taxes in the case of equity; the before-tax cost of equity is equal to the after-tax cost of equity.

COSTS OF THE VARIOUS SOURCES OF CAPITAL

3

Each source of capital has a different cost because of the differences among the sources, such as risk, seniority, contractual commitments, and potential value as a tax shield. We focus on the costs of three primary sources of capital: debt, preferred stock, and common equity.

3.1 Cost of Debt

c calculate and interpret the cost of debt capital using the yield-to-maturity approach and the debt-rating approach

The **cost of debt** is the cost of debt financing to a company when it issues a bond or takes out a bank loan. That cost is equal to the risk-free rate plus a premium for risk. A company that is perceived to be very risky would have a higher cost of debt than one that presents little investment risk. Factors that might affect the level of investment risk include profitability, stability of profits, and the degree of financial leverage. In general, the cost of debt would be higher for companies that are unprofitable, whose profits are not stable, or that are already using a lot of debt in their capital structure. We discuss two methods to estimate the before-tax cost of debt, r_d: the yield-to-maturity approach and debt-rating approach.

3.1.1 *Yield-to-Maturity Approach*

The before-tax required return on debt is typically estimated using the expected **yield to maturity** (YTM) of the company's debt based on current market values. YTM is the annual return that an investor earns on a bond if the investor purchases the bond today and holds it until maturity. In other words, it is the yield, r_d, that equates the present value of the bond's promised payments to its market price:

$$P_0 = \frac{PMT_1}{\left(1+\frac{r_d}{2}\right)} + \ldots + \frac{PMT_n}{\left(1+\frac{r_d}{2}\right)^n} + \frac{FV}{\left(1+\frac{r_d}{2}\right)^n} = \left[\sum_{t=1}^{n}\frac{PMT_t}{\left(1+\frac{r_d}{2}\right)^t}\right] + \frac{FV}{\left(1+\frac{r_d}{2}\right)^n}, \qquad (2)$$

where

P_0 = the current market price of the bond
PMT_t = the interest payment in period t
r_d = the yield to maturity
n = the number of periods remaining to maturity
FV = the maturity value of the bond

In this valuation equation, the constant 2 reflects the assumption that the bond pays interest semi-annually (which is the case in many but not all countries) and that any intermediate cash flows (i.e., the interest payments prior to maturity) are reinvested at the rate $r_d/2$ semi-annually.

Example 3a illustrates the calculation of the after-tax cost of debt.

EXAMPLE 3A

Calculating the After-Tax Cost of Debt

Valence Industries issues a bond to finance a new project. It offers a 10-year, $1,000 face value, 5% semi-annual coupon bond. Upon issue, the bond sells at $1,025. What is Valence's before-tax cost of debt? If Valence's marginal tax rate is 35%, what is Valence's after-tax cost of debt?

Solution:

The following are given:

$$PV = \$1{,}025.$$

$$FV = \$1{,}000.$$

$$PMT = 5\% \text{ of } 1{,}000 \div 2 = \$25.$$

$$n = 10 \times 2 = 20.$$

$$\$1{,}025 = \left[\sum_{t=1}^{20} \frac{\$25}{(1+i)^t}\right] + \frac{\$1{,}000}{(1+i)^{20}}.$$

Before proceeding to solve the problem, we already know that the before-tax cost of debt must be less than 5% because the present value of the bond is greater than the face value. We can use a financial calculator to solve for i, the six-month yield. Because $i = 2.342\%$, the before-tax cost of debt is $r_d = 2.342\% \times 2 = 4.684\%$, and Valence's after-tax cost of debt is $r_d(1 - t) = 0.04684(1 - 0.35) = 0.03045$, or 3.045%.

3.1.2 *Debt-Rating Approach*

When a reliable current market price for a company's debt is not available, the **debt-rating approach** can be used to estimate the before-tax cost of debt. Based on a company's debt rating, we estimate the before-tax cost of debt by using the yield on comparably rated bonds for maturities that closely match that of the company's existing debt.

Suppose a company's capital structure includes debt with an average maturity of 10 years and the company's marginal tax rate is 35%. If the company's rating is AAA and the yield on debt with the same debt rating and similar maturity is 4%, the company's after-tax cost of debt is

$$r_d(1 - t) = 0.04(1 - 0.35) = 2.6\%.$$

EXAMPLE 3B

Calculating the After-Tax Cost of Debt

Elttaz Company's capital structure includes debt with an average maturity of 15 years. The company's rating is A1, and it has a marginal tax rate of 18%. If the yield on comparably rated A1 bonds with similar maturity is 6.1%, what is Elttaz's after-tax cost of debt?

Solution:

Elttaz's after-tax cost of debt is

$$r_d(1 - t) = 0.061(1 - 0.18) = 5.0\%.$$

A consideration when using this approach is that debt ratings are ratings of the debt issue itself, with the issuer being only one of the considerations. Other factors, such as debt seniority and security, also affect ratings and yields, so care must be taken to consider the likely type of debt to be issued by the company in determining the comparable debt rating and yield. The debt-rating approach is a simple example of pricing on the basis of valuation-relevant characteristics, which in bond markets has been known as evaluated pricing or **matrix pricing**.

3.1.3 *Issues in Estimating the Cost of Debt*

There are other issues to consider when estimating the cost of debt. Among these are whether the debt is fixed rate or floating rate, whether it has option-like features, whether it is unrated, and whether the company uses leases instead of typical debt.

3.1.3.1 Fixed-Rate Debt vs. Floating-Rate Debt Up to now, we have assumed that the interest on debt is a fixed amount each period. We can observe market yields of the company's existing debt or market yields of debt of similar risk in estimating the before-tax cost of debt. However, the company may also issue floating-rate debt, in which the interest rate adjusts periodically according to a prescribed index, such as the prime rate, over the life of the instrument.

Estimating the cost of a floating-rate security is difficult because the cost of this form of capital over the long term depends not only on the current yields but also on the future yields. The analyst may use the current term structure of interest rates and term structure theory to assign an average cost to such instruments.

3.1.3.2 Debt with Optionlike Features How should an analyst determine the cost of debt when the company uses debt with option-like features, such as call, conversion, or put provisions? Clearly, options affect the value of debt. For example, a callable bond would have a yield greater than a similar noncallable bond of the same issuer because bondholders want to be compensated for the call risk associated with the bond. In a similar manner, the put feature of a bond, which provides the investor with an option to sell the bond back to the issuer at a predetermined price, has the effect of lowering the yield on a bond below that of a similar nonputable bond. Likewise, convertible bonds, which give investors the option of converting the bonds into common stock, lower the yield on the bonds below that of similar nonconvertible bonds.

If the company already has debt outstanding incorporating optionlike features that the analyst believes are representative of the future debt issuance of the company, the analyst may simply use the yield to maturity on such debt in estimating the cost of debt.

If the analyst believes that the company will add or remove option features in future debt issuance, the analyst can make market value adjustments to the current YTM to reflect the value of such additions or deletions. The technology for such adjustments is an advanced topic that is outside the scope of this coverage.

3.1.3.3 Nonrated Debt If a company does not have any debt outstanding or if the yields on the company's existing debt are not available, the analyst may not always be able to use the yield on similarly rated debt securities. It may be the case that the company does not have rated bonds. Although researchers offer approaches for estimating a company's "synthetic" debt rating based on financial ratios, these methods are imprecise because debt ratings incorporate not only financial ratios but also information about the particular bond issue and the issuer that are not captured in financial ratios. A further discussion of these methods is outside the scope of this reading.

3.1.3.4 Leases A lease is a contractual obligation that can substitute for other forms of borrowing. This is true whether the lease is an **operating lease** or a **finance lease** (also called a capital lease). If the company uses leasing as a source of capital, the cost of these leases should be included in the cost of capital. The cost of this form of borrowing is similar to that of the company's other long-term borrowing.

3.2 Cost of Preferred Stock

d calculate and interpret the cost of noncallable, nonconvertible preferred stock

The **cost of preferred stock** is the cost that a company has committed to pay preferred stockholders as a preferred dividend when it issues preferred stock. In the case of nonconvertible, noncallable preferred stock that has a fixed dividend rate and no maturity date (**fixed-rate perpetual preferred stock**), we can use the formula for the value of a preferred stock:

$$P_p = \frac{D_p}{r_p},$$

where

P_p = the current preferred stock price per share
D_p = the preferred stock dividend per share
r_p = the cost of preferred stock

We can rearrange this equation to solve for the cost of preferred stock:

$$r_p = \frac{D_p}{P_p}. \tag{3}$$

Therefore, the cost of preferred stock is the preferred stock's dividend per share divided by the current preferred stock's price per share. Unlike interest on debt, the dividend on preferred stock is not tax-deductible by the company; therefore, there is no adjustment to the cost for taxes.

A preferred stock may have a number of features that affect its yield and hence its cost. These features include a call option, cumulative dividends, participating dividends, adjustable-rate dividends, and convertibility into common stock. When estimating a yield based on current yields of the company's preferred stock, we must make appropriate adjustments for the effects of these features on the yield of an issue. For example, if the company has callable, convertible preferred stock outstanding yet it is expected that the company will issue only noncallable, nonconvertible preferred stock in the future, we would have to either use the current yields on comparable companies' noncallable, nonconvertible preferred stock or estimate the yield on preferred equity using methods outside the scope of this coverage.

EXAMPLE 4

Calculating the Cost of Preferred Stock

Consider a company that has one issue of preferred stock outstanding with a $3.75 cumulative dividend. If the price of this stock is $80, what is the estimate of its cost of preferred stock?

Solution:

Cost of preferred stock = $3.75/$80 = 4.6875%.

EXAMPLE 5

Choosing the Best Estimate of the Cost of Preferred Stock

Wim Vanistendael is finance director of De Gouden Tulip N.V., a leading Dutch flower producer and distributor. He has been asked by the CEO to calculate the cost of preferred stock and has recently obtained the following information:

- The issue price of preferred stock was €3.5 million, and the preferred dividend is 5%.
- If the company issued new preferred stock today, the preferred dividend yield would be 6.5%.
- The company's marginal tax rate is 30.5%.

What is the cost of preferred stock for De Gouden Tulip N.V.?

Solution:

If De Gouden Tulip were to issue new preferred stock today, the dividend yield would be close to 6.5%. The current terms thus prevail over the past terms when evaluating the actual cost of preferred stock. The cost of preferred stock for De Gouden Tulip is, therefore, 6.5%. Because preferred dividends offer no tax shield, there is no adjustment made on the basis of the marginal tax rate.

3.3 Cost of Common Equity

e calculate and interpret the cost of equity capital using the capital asset pricing model approach and the bond yield plus risk premium approach

The cost of common equity, r_e, usually referred to simply as the **cost of equity**, is the rate of return required by a company's common stockholders. A company may increase common equity through the reinvestment of earnings—that is, retained earnings—or through the issuance of new shares of stock.

The estimation of the cost of equity is challenging because of the uncertain nature of the future cash flows in terms of the amount and timing. Commonly used approaches for estimating the cost of equity include the capital asset pricing model (CAPM) method and the bond yield plus risk premium (BYPRP) method. In practice, analysts may use more than one approach to develop the cost of equity. A survey of analysts showed that the CAPM approach is used by 68% of respondents, whereas a build-up approach (bond yield plus a premium) is used by 43% of respondents (Pinto, Robinson, and Stowe 2019).

3.3.1 *Capital Asset Pricing Model Approach*

In the CAPM approach, we use the basic relationship from the capital asset pricing model theory that the expected return on a stock, $E(R_i)$, is the sum of the risk-free rate of interest, R_F, and a premium for bearing the stock's market risk, $\beta_i(R_M - R_F)$. Note that this premium incorporates the stock's return sensitivity to changes in the market return, or market-related risk, known as β_i, or beta:

$$E(R_i) = R_F + \beta_i\left[E(R_M) - R_F\right], \tag{4}$$

where

β_i = the return sensitivity of stock *i* to changes in the market return
$E(R_M)$ = the expected return on the market
$E(R_M) - R_F$ = the expected market risk premium

A risk-free asset is defined here as an asset that has no default risk. A common proxy for the risk-free rate is the yield on a default-free government debt instrument. In general, the selection of the appropriate risk-free rate should be guided by the duration of projected cash flows. For example, for the evaluation of a project with an estimated useful life of 10 years, the rate on the 10-year Treasury bond would be an appropriate proxy to use.

USING THE CAPM TO ESTIMATE THE COST OF EQUITY

1. Valence Industries wants to know its cost of equity. Its chief financial officer (CFO) believes the risk-free rate is 5%, the market risk premium is 7%, and Valence's equity beta is 1.5. What is Valence's cost of equity using the CAPM approach?

Solution:

The cost of equity for Valence is 5% + 1.5(7%) = 15.5%.

2. Exxon Mobil Corporation, BP p.l.c., and Total S.A. are three "super major" integrated oil and gas companies headquartered, respectively, in the United States, the United Kingdom, and France. An analyst estimates that the market risk premium in the United States, the United Kingdom, and the eurozone are, respectively, 4.4%, 5.5%, and 5.9%. Other information is summarized in Exhibit 1.

Exhibit 1. ExxonMobil, BP, and Total

Company	Beta	Estimated Market Risk Premium (%)	Risk-Free Rate (%)
Exxon Mobil Corporation	0.90	4.4	2.8
BP p.l.c.	0.78	5.5	2.0
Total S.A.	0.71	5.9	1.7

Source: Bloomberg; Fernandez, Pershn, and Acin (2018) survey.

Using the capital asset pricing model, calculate the cost of equity for:

1. Exxon Mobil Corporation.
2. BP p.l.c.
3. Total S.A.

Solution to 1:

The cost of equity for ExxonMobil is 2.8% + 0.90(4.4%) = 6.76%.

Solution to 2:

The cost of equity for BP is 2.0% + 0.78(5.5%) = 6.29%.

Solution to 3:

The cost of equity for Total is 1.7% + 0.71(5.9%) = 5.89%.

The expected market risk premium, or $E(R_M - R_F)$, is the premium that investors demand for investing in a market portfolio relative to the risk-free rate. When using the CAPM to estimate the cost of equity, in practice we typically estimate beta relative to an equity market index. In that case, the market premium estimate we are using is actually an estimate of the **equity risk premium** (ERP). Therefore, we are using the terms market risk premium and equity risk premium interchangeably.

An alternative to the CAPM to accommodate risks that may not be captured by the market portfolio alone is a multifactor model that incorporates factors that may be other sources of **priced risk** (risk for which investors demand compensation for bearing), including macroeconomic factors and company-specific factors. In general,

$$\begin{aligned} E(R_i) = R_F &+ \beta_{i1}(\text{Factor risk premium})_1 \\ &+ \beta_{i2}(\text{Factor risk premium})_2 + \ldots \\ &+ \beta_{ij}(\text{Factor risk premium})_j, \end{aligned} \tag{5}$$

where

β_{ij} = stock i's sensitivity to changes in the jth factor

$(\text{Factor risk premium})_j$ = expected risk premium for the jth factor

The basic idea behind these multifactor models is that the CAPM beta may not capture all the risks, especially in a global context, which include inflation, business-cycle, interest rate, exchange rate, and default risks.

There are several ways to estimate the equity risk premium, although there is no general agreement as to the best approach. The two we discuss are the historical equity risk premium approach and the survey approach.

The **historical equity risk premium approach** is a well-established approach based on the assumption that the realized equity risk premium observed over a long period of time is a good indicator of the expected equity risk premium. This approach requires compiling historical data to find the average rate of return of a country's market portfolio and the average rate of return for the risk-free rate in that country. For example, an analyst might use the historical returns to the TOPIX Index to estimate the risk premium for Japanese equities. The exceptional bull market observed during the second half of the 1990s and the bursting of the technology bubble that followed during 2000–2002 remind us that the time period for such estimates should cover complete market cycles.

Elroy Dimson, Paul Marsh, and Mike Staunton (2018) conducted an analysis of the equity risk premiums observed in markets located in 21 countries, including the United States, over the period 1900–2017. These researchers found that the annualized US equity risk premium relative to US Treasury bills was 5.6% (geometric mean) and 7.5% (arithmetic mean). They also found that the annualized US equity risk premium relative to bonds was 4.4% (geometric mean) and 6.5% (arithmetic mean). Jeremy Siegel (2005), covering the period from 1802 through 2004, observed an equity return of 6.82% and an equity risk premium in the range of 3.31%–5.36%. Note that the arithmetic mean is greater than the geometric mean as a result of the significant volatility of the observed market rate of return and the observed risk-free rate. Under the assumption of an unchanging distribution of returns over time, the arithmetic mean is the unbiased estimate of the expected single-period equity risk premium, but the geometric mean better reflects the growth rate over multiple periods. In Exhibit 2, we provide historical estimates of the equity risk premium for a few of the developed markets from Dimson et al. (2018).

Exhibit 2. Selected Equity Risk Premiums Relative to Bonds (1900–2017)

	Mean	
	Geometric	**Arithmetic**
Australia	5.0%	6.6%
Canada	3.5	5.1
France	3.1	5.4
Germany	5.1	8.4
Japan	5.1	9.1
South Africa	5.3	7.1
Switzerland	2.2	3.7
United Kingdom	3.7	5.0
United States	4.4	6.5

Note: Germany excludes 1922–1923.
Source: Dimson, Marsh, and Staunton (2018).

To illustrate the historical method as applied in the CAPM, suppose that we use the historical geometric mean for US equity of 4.4% to value Apple Computer as of early August 2018. According to Yahoo Finance, Apple had a beta of 1.14 at that time. Using a 10-year US Treasury bond yield of 3.0% to represent the risk-free rate, the estimate of the cost of equity for Apple Computer is 3.0% + 1.14(4.4%) = 8.02%.

In general, the equity risk premium can be written as

$$\text{ERP} = \overline{R}_M - \overline{R}_F,$$

where ERP is the equity risk premium, $\overline{R}_M$ is the mean return for equity, and $\overline{R}_F$ the risk-free rate.

The historical premium approach has several limitations. One limitation is that the level of risk of the stock index may change over time. Another is that the risk aversion of investors may change over time. A third limitation is that the estimates are sensitive to the method of estimation and the historical period covered.

EXAMPLE 6

Estimating the Equity Risk Premium Using Historical Rates of Return

Suppose that the arithmetic average T-bond rate observed over the last 90 years is an unbiased estimator for the risk-free rate and is 4.88%. Likewise, suppose the arithmetic average of return on the market observed over the last 90 years is an unbiased estimator for the expected return for the market. The average rate of return of the market was 9.65%. Calculate the equity risk premium.

Solution:

$$\text{ERP} = \overline{R}_M - \overline{R}_F = 9.65\% - 4.88\% = 4.77\%.$$

Another approach to estimate the equity risk premium is quite direct: Ask a panel of finance experts for their estimates, and take the mean response. This is the **survey approach**. For example, a survey of US CFOs in December 2017 found that the average expected US equity risk premium over the next 10 years was 4.42% and the median was 3.63% (Graham and Harvey 2018).

Once we have an estimate of the equity risk premium, we fine-tune this estimate for the particular company or project by adjusting it for the specific systematic risk of the project. We adjust for the specific systematic risk by multiplying the market risk premium by beta to arrive at the company's or project's risk premium, which we then add to the risk-free rate to determine the cost of equity within the framework of the CAPM.

3.3.2 *Bond Yield plus Risk Premium Approach*

For companies with publicly traded debt, the **bond yield plus risk premium approach** provides a quick estimate of the cost of equity. The BYPRP approach is based on the fundamental tenet in financial theory that the cost of capital of riskier cash flows is higher than that of less risky cash flows. In this approach, we sum the before-tax cost of debt, r_d, and a risk premium that captures the additional yield on a company's stock relative to its bonds. The estimate is, therefore,

$$r_e = r_d + \text{Risk premium}. \tag{6}$$

The risk premium compensates for the additional risk of the equity issue compared with the debt issue (recognizing that debt has a prior claim on the cash flows of the company). This risk premium is not to be confused with the equity risk premium. The equity risk premium is the difference between the cost of equity and the risk-free rate of interest. The risk premium in the bond yield plus risk premium approach is the difference between the cost of equity and the cost of debt of the company. Ideally, this risk premium is forward looking, representing the additional risk associated with the equity of the company as compared with the company's debt. However, we often estimate this premium using historical spreads between bond yields and stock yields. In developed country markets, a typical risk premium added is in the range of 3%–5%.

Looking again at Apple Computer, as of early August 2018, the yield to maturity of Apple's 3.35% coupon bonds maturing in 2027 was approximately 3.56%. Adding an arbitrary risk premium of 4.0% produces an estimate of the cost of equity of 3.56% + 4.0% = 7.56%. This estimate contrasts with the higher estimate of 8.026% from the CAPM approach. Such disparities are not uncommon and reflect the difficulty of cost of equity estimation.

4 ESTIMATING BETA

f explain and demonstrate beta estimation for public companies, thinly traded public companies, and nonpublic companies

Beta is an estimate of the company's systematic or market-related risk. It is a critical component of the CAPM, and it can be used to calculate a company's WACC. Therefore, it is essential to have a good understanding of how beta is estimated.

4.1 Estimating Beta for Public Companies

The simplest estimate of beta results from an ordinary least squares regression of the return on the stock on the return on the market. The result is often called an unadjusted or "raw" historical beta. The actual values of beta estimates are influenced by several choices:

- *The choice of the index used to represent the market portfolio*: For US equities, the S&P 500 Index and NYSE Composite have been traditional choices. In Japan, analysts would likely use the Nikkei 225 Index.
- *The length of the data period and the frequency of observations*: The most common choice is five years of monthly data, yielding 60 observations.

Researchers have observed that beta tends to regress toward 1.0. In other words, the value of a stock's beta in a future period is likely to be closer to the mean value of 1.0, the beta of an average-systematic-risk security, than to the value of the calculated raw beta. Because valuation is forward looking, it is logical to adjust the raw beta so that it more accurately predicts a future beta. The most commonly used adjustment was introduced by Blume (1971):

$$\text{Adjusted beta} = (2/3)(\text{Unadjusted beta}) + (1/3)(1.0). \quad (7)$$

For example, if the beta from a regression of an asset's returns on the market return is 1.30, adjusted beta is (2/3)(1.30) + (1/3)(1.0) = 1.20. Equation 7 acts to "smooth" raw betas by adjusting betas above and below 1.0 toward 1.0. Vendors of financial information, such as Bloomberg, often report both raw and adjusted betas.

EXAMPLE 7

Estimating the Adjusted Beta for a Public Company

Betty Lau is an analyst trying to estimate the cost of equity for Singapore Telecommunications Limited. She begins by running an ordinary least squares regression to estimate the beta. Her estimated value is 0.4, which she believes needs adjustment. What is the adjusted beta value she should use in her analysis?

Solution:

$$\text{Adjusted beta} = (2/3)(0.4) + (1/3)(1.0) = 0.6.$$

Arriving at an estimated beta for publicly traded companies is generally not a problem because of the accessibility of stock return data, the ease of use of estimating beta using simple regression, and the availability of estimated betas on publicly traded companies from financial analysis vendors.

The challenge comes in estimating a beta for a company that is thinly traded or nonpublic or for a project that is not the average or typical project of a publicly traded company. Estimating beta in these cases requires proxying for the beta by using information on the project or company combined with the beta of a publicly traded company.

4.2 Estimating Beta for Thinly Traded and Nonpublic Companies

It is not possible to run an ordinary least squares regression to estimate beta if a stock is thinly traded or a company is nonpublic. When a share issue trades infrequently, the most recent transaction price may be stale and may not reflect underlying changes in value. If beta is estimated on the basis of, for example, a monthly data series in which missing values are filled with the most recent transaction price, the estimated beta will be too small. This is because this methodology implicitly assumes that the stock's price is more stable than it really is. As a result, the required return on equity will be understated.

In these cases, a practical alternative is to base the beta estimate on the betas of comparable companies that are publicly traded. A **comparable company**, also called a **peer company**, is a company that has similar business risk. A comparable, or peer, company can be identified by using an industry classification system, such as the MSCI/Standard & Poor's Global Industry Classification Standard (GICS) or the FTSE Industry Classification Benchmark (ICB). The analyst can then indirectly estimate the beta on the basis of the betas of the peer companies.

Because financial leverage can affect beta, an adjustment must be made if the peer company has a substantially different capital structure. First, the peer company's beta must be unlevered to estimate the beta of the assets—reflecting only the systematic risk arising from the fundamentals of the industry. Then, the unlevered beta, often referred to as the **asset beta** because it reflects the business risk of the assets, must be re-levered to reflect the capital structure of the company in question.

Let β_E be the equity beta of the peer company before removing the effects of leverage. Assuming the debt of the peer company is of high quality—so that the debt's beta, or β_D, is approximately equal to zero (that is, it is assumed to have no market risk)—analysts can use the following expression to unlever the beta:

$$\beta_U = \beta_E \left[\frac{1}{1 + (1 - t)\frac{D}{E}} \right], \tag{8}$$

where β_U is the unlevered beta, t is the marginal tax rate of the peer company, and D and E are the market values of debt and equity, respectively, of the peer company.

Now we can re-lever the unlevered beta by rearranging the equation to reflect the capital structure of the thinly traded or nonpublic company in question:

$$\beta_E = \beta_U \left[1 + (1 - t)\frac{D}{E} \right]. \tag{9}$$

where β_E is now the equity beta of the thinly traded or nonpublic company, t is the marginal tax rate of the thinly traded or nonpublic company, and D and E are the debt-to-equity values, respectively, of the thinly traded or nonpublic company.

EXAMPLE 8

Estimating the Adjusted Beta for a Nonpublic Company

Raffi Azadian wants to determine the cost of equity for Elucida Oncology, a privately held company. Raffi realizes that he needs to estimate Elucida's beta before he can proceed. He determines that Merck & Co. is an appropriate publicly traded peer company. Merck has a beta of 0.7, it is 40% funded by debt, and its marginal tax rate is 21%. If Elucida is only 10% funded by debt and its marginal tax rate is also 21%, what is Elucida's beta?

Solution:

Since Merck is 40% funded by debt, it is 60% funded by equity. Therefore,

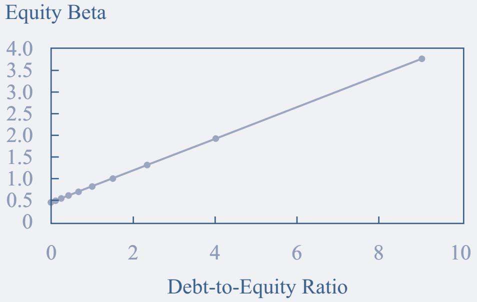
$$\text{Unlevered beta} = (0.7)\left[\frac{1}{1+(1-0.21)\left(\frac{0.4}{0.6}\right)}\right] = 0.46.$$

Now we re-lever the unlevered beta using Elucida's tax rate and capital structure:

$$\text{Elucida's beta} = 0.46\left[1+(1-0.21)\left(\frac{0.1}{0.9}\right)\right] = 0.50.$$

The following table and figure show how Elucida's beta increases as leverage rises.

Debt-to-Equity Ratio	Equity Beta
0.00	0.46
0.11	0.50
0.25	0.55
0.43	0.62
0.67	0.70
1.00	0.82
1.50	1.01
2.33	1.31
4.00	1.91
9.00	3.73



The beta estimate can then be used to determine the component cost of equity and combined with the cost of debt in a weighted average to provide an estimate of the cost of capital for the company.

EXAMPLE 9

Estimating the Weighted Average Cost of Capital

Georg Schrempp is the CFO of Bayern Chemicals KgaA, a German manufacturer of industrial, commercial, and consumer chemical products. Bayern Chemicals is privately owned, and its shares are not listed on an exchange. The CFO has appointed Markus Meier, CFA, a third-party valuator, to perform a stand-alone valuation of Bayern Chemicals. Meier has access to the following information to calculate Bayern Chemicals' weighted average cost of capital:

- The nominal risk-free rate, represented by the yield on the long-term 10-year German bund, was 4.5% at the valuation date.

- The average long-term historical equity risk premium in Germany is assumed to be 5.7%.
- Bayern Chemicals' corporate tax rate is 38%.
- Bayern Chemicals' target debt-to-equity ratio is 0.7. Its capital structure is 41% debt.
- Bayern Chemicals' cost of debt has an estimated spread of 225 bps over the 10-year bund.
- Exhibit 3 supplies additional information on comparables for Bayern Chemicals.

Exhibit 3. Information on Comparables

Comparable Companies	Country	Tax Rate (%)	Market Capitalization in Millions	Net Debt in Millions	D/E	Beta
British Chemicals Ltd.	United Kingdom	30.0	4,500	6,000	1.33	1.45
Compagnie Petrochimique S.A.	France	30.3	9,300	8,700	0.94	0.75
Rotterdam Chemie N.V.	Netherlands	30.5	7,000	7,900	1.13	1.05
Average					1.13	1.08

Based only on the information given, calculate Bayern Chemicals' WACC.

Solution:

To calculate the cost of equity, the first step is to "unlever" the betas of the comparable companies and calculate an average for a company with business risk similar to the average of these companies:

Comparable Companies	Unlevered Beta
British Chemicals Ltd.	$0.75 = \left[\dfrac{1.45}{1 + (1 - 0.30)(1.33)}\right]$
Compagnie Petrochimique S.A.	$0.45 = \left[\dfrac{0.75}{1 + (1 - 0.303)(0.94)}\right]$
Rotterdam Chemie N.V.	$0.59 = \left[\dfrac{1.05}{1 + (1 - 0.305)(1.13)}\right]$
Average*	0.60

*An analyst must apply judgment and experience to determine a representative average for the comparable companies. This example uses a simple average, but in some situations a weighted average based on some factor, such as market capitalization, may be more appropriate.

Levering the average unlevered beta for the peer group average, applying Bayern Chemicals' target debt-to-equity ratio and marginal tax rate, results in a beta of 0.86:

$$\beta_{Bayern\ Chemicals} = 0.60\{1 + [(1 - 0.38)0.7]\} = 0.86.$$

Using CAPM, the cost of equity of Bayern Chemicals (r_e) can be calculated as follows:

$$r_e = 4.5\% + (0.86)(5.7\%) = 9.4\%.$$

The weights for the cost of debt and cost of equity may be calculated as follows:

$$w_d = 0.41, \text{ and } w_e = (1 - 0.41) = 0.59.$$

The before-tax cost of debt of Bayern Chemicals (r_d) is 6.75%:

$$r_d = 4.5\% + 2.25\% = 6.75\%.$$

As a result, Bayern Chemicals' WACC is 7.26%:

$$\text{WACC} = (0.41)(0.0675)(1 - 0.38) + (0.59)(0.094)$$

$$= 0.0726, \text{ or } 7.26\%.$$

5 FLOTATION COSTS

g explain and demonstrate the correct treatment of flotation costs

When a company raises new capital, it generally seeks the assistance of investment bankers. Investment bankers charge the company a fee based on the size and type of offering. This fee is referred to as the **flotation cost**. In general, flotation costs are higher in percentage terms for equity issuances than they are for debt. They are also higher for smaller issuance amounts or for issuances that are perceived to be riskier. In the case of debt and preferred stock, we do not usually incorporate flotation costs in the estimated cost of capital because the amount of these costs is quite small, often less than 1% of the value of the offering.

However, with equity issuance, the flotation costs may be substantial, so we should consider these when estimating the cost of external equity capital. Average flotation costs for new equity have been estimated at 7.11% of the value of the offering in the United States,[1] 1.65% in Germany,[2] 5.78% in the United Kingdom,[3] and 4.53% in Switzerland.[4] A large part of the differences in costs among these studies is likely attributed to the type of offering; cash underwritten offers, typical in the United States, are generally more expensive than rights offerings, which are common in Europe.

[3] Seth Armitage, "The Direct Costs of UK Rights Issues and Open Offers," *European Financial Management* 6 (2000): 57–68.

[4] Christoph Kaserer and Fabian Steiner, "The Cost of Raising Capital—New Evidence from Seasoned Equity Offerings in Switzerland," working paper, Technische Universität München (February 2004).

How should flotation costs be accounted for? There are two views on this topic. One view, which you can find often in textbooks, is to directly incorporate the flotation costs into the cost of capital. The other view is that flotation costs should be incorporated into the valuation analysis as an additional cost. We will argue that the second view is preferred.

Consistent with the first view, we can specify flotation costs in monetary terms as an amount per share or as a percentage of the share price. With flotation costs specified in monetary terms on a per share basis, the cost of external equity is

$$r_e = \left(\frac{D_1}{P_0 - F}\right) + g, \tag{10}$$

where

r_e is the cost of equity
D_1 is the dividend expected at the end of Period 1
P_0 is the current stock price
F is the monetary per share flotation cost
g is the growth rate

As a percentage applied against the price per share, the cost of external equity is

$$r_e = \left[\frac{D_1}{P_0(1 - f)}\right] + g, \tag{11}$$

where f is the flotation cost as a percentage of the issue price.

EXAMPLE 10

Estimating the Cost of Equity with Flotation Costs

A company has a current dividend of \$2 per share, a current price of \$40 per share, and an expected growth rate of 5%.

1 What is the cost of internally generated equity (i.e., stock is not issued and flotation costs are not incurred)?

2 What is the cost of external equity (i.e., new shares are issued and flotation costs are incurred) if the flotation costs are 4% of the issuance?

Solution to 1:

$$r_e = \left[\frac{\$2(1+0.05)}{\$40}\right] + 0.05 = 0.0525 + 0.05 = 0.1025\text{, or } 10.25\%.$$

Solution to 2:

$$r_e = \left[\frac{\$2(1+0.05)}{\$40(1-0.04)}\right] + 0.05 = 0.05469 + 0.05 = 0.1047\text{, or } 10.47\%.$$

Many experts object to this methodology. Flotation costs are a cash flow that occurs at issue and they affect the value of the project only by reducing the initial cash flow. However, by adjusting the cost of capital for flotation costs, we apply a higher cost of capital to determine the present value of the future cash flows. The result is that the calculated net present value of a project is less than its true net present value. As a result, otherwise profitable projects may get rejected when this methodology is used.

An alternative and preferred approach is to make the adjustment for flotation costs to the cash flows in the valuation computation. For example, consider a project that requires a €60,000 initial cash outlay and is expected to produce cash flows of €10,000 each year for 10 years. Suppose the company's marginal tax rate is 40%, the before-tax cost of debt is 5%, and the cost of equity is 10%. Assume the company will finance the project with 40% debt and 60% equity. Exhibit 4 summarizes the information on the component costs of capital.

Exhibit 4. After-Tax Costs of Debt and Equity

Source of Capital	Amount Raised (€)	Proportion	Marginal After-Tax Cost
Debt	24,000	0.40	0.05(1 – 0.4) = 0.03
Equity	36,000	0.60	0.10

The weighted average cost of capital is 7.2%, calculated as 0.40(3%) + 0.60(10%). Ignoring flotation costs for the moment and using a financial calculator, we find that the net present value (NPV) of this project can be expressed as

NPV = Present value of inflows – Present value of the outflows,

or

NPV = €69,591 – €60,000 = €9,591,

where €69,591 is the present value of €10,000 per year for 10 years at 7.2%. Now suppose flotation costs amount to 5% of the new equity capital: (0.05)(€36,000) = €1,800. If flotation costs are not tax deductible, the net present value considering flotation costs is

NPV = €69,591 – €60,000 – €1,800 = €7,791.

If flotation costs are tax deductible, the net present value considering flotation costs is

NPV = €69,591 – €60,000 – €1,800(1-0.4) = €8,511.

Suppose instead of considering the flotation costs as part of the cash flows, we made an adjustment to the cost of equity. Without showing the calculations, the cost of equity increases from 10% to 10.2632%, the cost of capital increases from 7.22% to 7.3579%, and the NPV decreases from €9,591 to €9,089. As you can see, we arrive at different assessments of value using these two methods.

If the preferred method is to deduct the flotation costs as part of the net present value calculation, why do many textbooks highlight the adjustment to the cost of capital? One reason is that it is often difficult to identify specific financing associated with a project. Making the adjustment for flotation costs to the cost of capital is most useful if specific project financing cannot be identified. A second reason is that by adjusting the cost of capital for the flotation costs, it is easier to demonstrate how the costs of financing a company change as a company exhausts internally generated equity (i.e., retained earnings) and switches to externally generated equity (i.e., a new stock issue).

METHODS IN USE

6

We have introduced methods that may be used to estimate the cost of capital for a company or a project, but which methods do companies actually use when making investment decisions? John Graham and Campbell Harvey (2002) surveyed a large number of CFOs to find out which methods they prefer. Their survey revealed the following:

- The most popular method for estimating the cost of equity is the capital asset pricing model.
- Few companies use the dividend discount model (which we did not cover) to estimate the cost of equity.
- Publicly traded companies are more likely to use the capital asset pricing model than are private companies.
- In evaluating projects, the majority of CFOs use a single company cost of capital, but a large portion apply some type of risk adjustment for individual projects.

Their survey also revealed that the single-factor capital asset pricing model is the most popular method for estimating the cost of equity. The second and third most popular methods, respectively, are average stock returns and multifactor return models. The lack of popularity of the dividend discount model indicates that this approach, although once favored, has lost its appeal in practice.

In a survey of publicly traded multinational European companies, Franck Bancel and Usha Mittoo (2004) provided evidence consistent with the Graham and Harvey (2002) survey. They found that over 70% of companies use the CAPM to determine the cost of equity; this finding is similar to the 73.5% of US companies that use the CAPM. In a survey of both publicly traded and private European companies, Dirk Brounen, Abe de Jong, and Kees Koedijk (2004) confirmed the result of Graham and Harvey that larger companies are more likely to use the more sophisticated methods, such as CAPM, in estimating the cost of equity. Brounen, de Jong, and Koedijk found that the use of the CAPM was less popular for their sample (ranging from 34% to 55.6%, depending on the country) than for the other two surveys, which may reflect the inclusion of smaller, private companies in their sample.

We learn from the survey evidence that the CAPM is a popular method for estimating the cost of equity capital and that it is used less often by smaller, private companies. The latter result is not surprising, because of the difficulty in estimating systematic risk in cases in which the company's equity is not publicly traded.

SUMMARY

In this reading, we provided an overview of the techniques used to calculate the cost of capital for companies and projects. We examined the weighted average cost of capital, discussing the methods commonly used to estimate the component costs of capital and the weights applied to these components.

- The weighted average cost of capital is a weighted average of the after-tax marginal costs of each source of capital: WACC = $w_d r_d (1 - t) + w_p r_p + w_e r_e$.
- The before-tax cost of debt is generally estimated by either the yield-to-maturity method or the bond rating method.

- The yield-to-maturity method of estimating the before-tax cost of debt uses the familiar bond valuation equation. Assuming semi-annual coupon payments, the equation is

  $$P_0 = \frac{PMT_1}{\left(1+\frac{r_d}{2}\right)} + \ldots + \frac{PMT_n}{\left(1+\frac{r_d}{2}\right)^n} + \frac{FV}{\left(1+\frac{r_d}{2}\right)^n} = \left[\sum_{t=1}^{n}\frac{PMT_t}{\left(1+\frac{r_d}{2}\right)^t}\right] + \frac{FV}{\left(1+\frac{r_d}{2}\right)^n}.$$

  We solve for the six-month yield ($r_d/2$) and then annualize it to arrive at the before-tax cost of debt, r_d.
- Because interest payments are generally tax deductible, the after-tax cost is the true, effective cost of debt to the company. If a yield to maturity or bond rating is not available, such as in the case of a private company without rated debt or a project, the estimate of the cost of debt becomes more challenging.
- The cost of preferred stock is the preferred stock dividend divided by the current preferred stock price:

  $$r_p = \frac{D_p}{P_p}.$$

- The cost of equity is the rate of return required by a company's common stockholders. We estimate this cost using the CAPM (or its variants).
- The CAPM is the approach most commonly used to calculate the cost of equity. The three components needed to calculate the cost of equity are the risk-free rate, the equity risk premium, and beta:

  $$\mathrm{E}(R_i) = R_F + \beta_i\left[\mathrm{E}(R_M) - R_F\right].$$

- In estimating the cost of equity, an alternative to the CAPM is the bond yield plus risk premium approach. In this approach, we estimate the before-tax cost of debt and add a risk premium that reflects the additional risk associated with the company's equity.
- When estimating the cost of equity capital using the CAPM, if we do not have publicly traded equity, we may be able to use a comparable company operating in the same business line to estimate the unlevered beta for a company with similar business risk, β_U:

  $$\beta_U = \beta_E\left[\frac{1}{1+(1-t)\frac{D}{E}}\right].$$

  Then, we lever this beta to reflect the financial risk of the project or company:

  $$\beta_E = \beta_U\left[1+(1-t)\frac{D}{E}\right].$$

- Flotation costs are costs incurred in the process of raising additional capital. The preferred method of including these costs in the analysis is as an initial cash flow in the valuation analysis.
- Survey evidence tells us that the CAPM method is the most popular method used by companies in estimating the cost of equity. The CAPM method is more popular with larger, publicly traded companies, which is understandable considering the additional analyses and assumptions required in estimating systematic risk for a private company or project.

PRACTICE PROBLEMS

1 The cost of equity is equal to the:

  A expected market return.

  B rate of return required by stockholders.

  C cost of retained earnings plus dividends.

2 Which of the following statements is correct?

  A The appropriate tax rate to use in the adjustment of the before-tax cost of debt to determine the after-tax cost of debt is the average tax rate because interest is deductible against the company's entire taxable income.

  B For a given company, the after-tax cost of debt is generally less than both the cost of preferred equity and the cost of common equity.

  C For a given company, the after-tax cost of debt is generally higher than both the cost of preferred equity and the cost of common equity.

3 An analyst's data source shows that Newmont Mining (NEM) has an estimated beta of –0.2. The risk-free rate of return is 2.5%, and the equity risk premium is estimated to be 4.5%.

  A Using the CAPM, calculate the required rate of return for investors in NEM.

  B The analyst notes that the current yield to maturity on corporate bonds with a credit rating similar to NEM is approximately 3.9%. How should this information affect the analyst's estimate?

4 An analyst assembles the following facts concerning a company's component costs of capital and capital structure. Based on the information given, calculate the company's WACC.

Facts	**(%)**
Cost of equity based on the CAPM	15.60
Pretax cost of debt	8.28
Corporate tax rate	30.00
Capital structure weight	Equity 80, Debt 20

5 Dot.Com has determined that it could issue $1,000 face value bonds with an 8% coupon paid semi-annually and a five-year maturity at $900 per bond. If Dot.Com's marginal tax rate is 38%, its after-tax cost of debt is *closest* to:

  A 6.2%.

  B 6.4%.

  C 6.6%.

6 The cost of debt can be determined using the yield-to-maturity and bond rating approaches. If the bond rating approach is used, the:

  A coupon is the yield.

  B yield is based on the interest coverage ratio.

  C company is rated and the rating can be used to assess the credit default spread of the company's debt.

© 2021 CFA Institute. All rights reserved.

7 Morgan Insurance Ltd. issued a fixed-rate perpetual preferred stock three years ago and placed it privately with institutional investors. The stock was issued at $25 per share with a $1.75 dividend. If the company were to issue preferred stock today, the yield would be 6.5%. The stock's current value is:

- **A** $25.00.
- **B** $26.92.
- **C** $37.31.

8 The Gearing Company has an after-tax cost of debt capital of 4%, a cost of preferred stock of 8%, a cost of equity capital of 10%, and a weighted average cost of capital of 7%. Gearing intends to maintain its current capital structure as it raises additional capital. In making its capital-budgeting decisions for the average-risk project, the relevant cost of capital is:

- **A** 4%.
- **B** 7%.
- **C** 8%.

9 Fran McClure, of Alba Advisers, is estimating the cost of capital of Frontier Corporation as part of her valuation analysis of Frontier. McClure will be using this estimate, along with projected cash flows from Frontier's new projects, to estimate the effect of these new projects on the value of Frontier. McClure has gathered the following information on Frontier Corporation:

	Current Year ($)	Forecasted for Next Year ($)
Book value of debt	50	50
Market value of debt	62	63
Book value of equity	55	58
Market value equity	210	220

The weights that McClure should apply in estimating Frontier's cost of capital for debt and equity are, respectively:

- **A** $w_d = 0.200$ and $w_e = 0.800$.
- **B** $w_d = 0.185$ and $w_e = 0.815$.
- **C** $w_d = 0.223$ and $w_e = 0.777$.

10 Wang Securities had a long-term stable debt-to-equity ratio of 0.65. Recent bank borrowing for expansion into South America raised the ratio to 0.75. The increased leverage has what effect on the asset beta and equity beta of the company?

- **A** The asset beta and the equity beta will both rise.
- **B** The asset beta will remain the same, and the equity beta will rise.
- **C** The asset beta will remain the same, and the equity beta will decline.

11 Brandon Wiene is a financial analyst covering the beverage industry. He is evaluating the impact of DEF Beverage's new product line of flavored waters. DEF currently has a debt-to-equity ratio of 0.6. The new product line would be financed with $50 million of debt and $100 million of equity. In estimating the valuation impact of this new product line on DEF's value, Wiene has estimated the equity beta and asset beta of comparable companies. In calculating the equity beta for the product line, Wiene is intending to use DEF's existing capital structure when converting the asset beta into a project beta. Which of the following statements is correct?

A Using DEF's debt-to-equity ratio of 0.6 is appropriate in calculating the new product line's equity beta.

B Using DEF's debt-to-equity ratio of 0.6 is not appropriate; rather, the debt-to-equity ratio of the new product, 0.5, is appropriate to use in calculating the new product line's equity beta.

C Wiene should use the new debt-to-equity ratio of DEF that would result from the additional $50 million debt and $100 million equity in calculating the new product line's equity beta.

12 Happy Resorts Company currently has 1.2 million common shares of stock outstanding, and the stock has a beta of 2.2. It also has $10 million face value of bonds that have five years remaining to maturity and an 8% coupon with semi-annual payments and are priced to yield 13.65%. If Happy issues up to $2.5 million of new bonds, the bonds will be priced at par and will have a yield of 13.65%; if it issues bonds beyond $2.5 million, the expected yield on the entire issuance will be 16%. Happy has learned that it can issue new common stock at $10 a share. The current risk-free rate of interest is 3%, and the expected market return is 10%. Happy's marginal tax rate is 30%. If Happy raises $7.5 million of new capital while maintaining the same debt-to-equity ratio, its weighted average cost of capital will be *closest* to:

A 14.5%.

B 15.5%.

C 16.5%.

The following information relates to Questions 13–17.

Jurgen Knudsen has been hired to provide industry expertise to Henrik Sandell, CFA, an analyst for a pension plan managing a global large-cap fund internally. Sandell is concerned about one of the fund's larger holdings, auto parts manufacturer Kruspa AB. Kruspa currently operates in 80 countries, with the previous year's global revenues at €5.6 billion. Recently, Kruspa's CFO announced plans for expansion into Trutan, a country with a developing economy. Sandell worries that this expansion will change the company's risk profile and wonders if he should recommend a sale of the position.

Sandell provides Knudsen with the basic information. Kruspa's global annual free cash flow to the firm is €500 million, and earnings are €400 million. Sandell estimates that cash flow will level off at a 2% rate of growth. Sandell also estimates that Kruspa's after-tax free cash flow to the firm on the Trutan project for next three years is, respectively, €48 million, €52 million, and €54.4 million. Kruspa recently announced a dividend of €4.00 per share of stock. For the initial analysis, Sandell requests that Knudsen ignore possible currency fluctuations. He expects the Trutanese plant to sell only to customers within Trutan for the first three years. Knudsen is asked to evaluate Kruspa's planned financing of the required €100 million in Sweden with an €80 million public offering of 10-year debt and the remainder with an equity offering.

Additional information:	
Equity risk premium, Sweden	4.82%
Risk-free rate of interest, Sweden	4.25%
Industry debt-to-equity ratio	0.3
Market value of Kruspa's debt	€900 million

Additional information:	
Market value of Kruspa’s equity	€2.4 billion
Kruspa’s equity beta	1.3
Kruspa’s before-tax cost of debt	9.25%
Trutan credit A2 country risk premium	1.88%
Corporate tax rate	37.5%
Interest payments each year	Level

13 Using the capital asset pricing model, Kruspa’s cost of equity capital for its typical project is *closest* to:

A 7.62%.

B 10.52%.

C 12.40%.

14 Sandell is interested in the weighted average cost of capital of Kruspa AB prior to its investing in the Trutan project. This weighted average cost of capital is *closest* to:

A 7.65%.

B 9.23%.

C 10.17%.

15 In his estimation of the project’s cost of capital, Sandell would like to use the asset beta of Kruspa as a base in his calculations. The estimated asset beta of Kruspa prior to the Trutan project is *closest* to:

A 1.053.

B 1.110.

C 1.327.

16 Sandell is performing a sensitivity analysis of the effect of the new project on the company's cost of capital. If the Trutan project has the same asset risk as Kruspa, the estimated project beta for the Trutan project, if it is financed 80% with debt, is *closest* to:

A 1.300.

B 2.635.

C 3.686.

17 As part of the sensitivity analysis of the effect of the new project on the company's cost of capital, Sandell is estimating the cost of equity of the Trutan project considering that the Trutan project requires a country equity premium to capture the risk of the project. The cost of equity for the project in this case is *closest* to:

A 10.52%.

B 19.91%.

C 28.95%.

The following information relates to Questions 18–21.

Boris Duarte, CFA, covers initial public offerings for Zellweger Analytics, an independent research firm specializing in global small-cap equities. He has been asked to evaluate the upcoming new issue of TagOn, a US-based business intelligence software company. The industry has grown at 26% per year for the previous three years. Large companies dominate the market, but sizable comparable companies, such as Relevant Ltd., ABJ Inc., and Opus Software Pvt. Ltd., also compete. Each of these competitors is domiciled in a different country, but they all have shares of stock that trade on the US NASDAQ. The debt ratio of the industry has risen slightly in recent years.

Company	Sales in Millions ($)	Market Value Equity in Millions ($)	Market Value Debt in Millions ($)	Equity Beta	Tax Rate (%)	Share Price ($)
Relevant Ltd.	752	3,800	0.0	1.702	23	42
ABJ Inc.	843	2,150	6.5	2.800	23	24
Opus Software Pvt. Ltd.	211	972	13.0	3.400	23	13

Duarte uses the information from the preliminary prospectus for TagOn's initial offering. The company intends to issue 1 million new shares. In his conversation with the investment bankers for the deal, he concludes the offering price will be between $7 and $12. The current capital structure of TagOn consists of a $2.4 million five-year noncallable bond issue and 1 million common shares. The following table includes other information that Duarte has gathered:

Currently outstanding bonds	$2.4 million five-year bonds, coupon of 12.5% paying semi-annually with a market value of $2.156 million
Risk-free rate of interest	5.25%
Estimated equity risk premium	7%
Tax rate	23%

18 The asset betas for Relevant, ABJ, and Opus, respectively, are:

A 1.70, 2.52, and 2.73.

B 1.70, 2.79, and 3.37.

C 1.70, 2.81, and 3.44.

19 The average asset beta for comparable players in this industry, Relevant, ABJ, and Opus, weighted by market value of equity is *closest* to:

A 1.67.

B 1.97.

C 2.27.

20 Using the capital asset pricing model, the cost of equity capital for a company in this industry with a debt-to-equity ratio of 0.01, an asset beta of 2.27, and a marginal tax rate of 23% is *closest* to:

A 17%.

B 21%.

C 24%.

21 The marginal cost of capital for TagOn, based on an average asset beta of 2.27 for the industry and assuming that new stock can be issued at $8 per share, is *closest* to:

A 20.5%.

B 21.0%.

C 21.5%.

22 Two years ago, a company issued $20 million in long-term bonds at par value with a coupon rate of 9%. The company has decided to issue an additional $20 million in bonds and expects the new issue to be priced at par value with a coupon rate of 7%. The company has no other debt outstanding and has a tax rate of 40%. To compute the company's weighted average cost of capital, the appropriate after-tax cost of debt is *closest* to:

A 4.2%.

B 4.8%.

C 5.4%.

23 An analyst gathered the following information about a private company and its publicly traded competitor:

Comparable Companies	Tax Rate (%)	Debt/Equity	Equity Beta
Private company	30.0	1.00	na
Public company	35.0	0.90	1.75

The estimated equity beta for the private company is *closest* to:

A 1.029.

B 1.104.

C 1.877.

24 Which of the following statements is *most accurate*? If two equity issues have the same market risk but the first issue has higher leverage, greater liquidity, and a higher required return, the higher required return *is most likely* the result of the first issue's:

A greater liquidity.

B higher leverage.

C higher leverage and greater liquidity.

25 SebCoe plc, a British firm, is evaluating an investment in a £50 million project that will be financed with 50% debt and 50% equity. Management has already determined that the NPV of this project is £5 million if it uses internally generated equity. However, if the company uses external equity, it will incur flotation costs of 5.8%. Assuming flotation costs are not tax deductible, the NPV using external equity would be:

A less than £5 million because we would discount the cash flows using a higher weighted average cost of capital that reflects the flotation costs.

B £3.55 million because flotation costs reduce NPV by $1.45 million.

C £5 million because flotation costs have no impact on NPV.

26 At the time of valuation, the estimated betas for JPMorgan Chase & Co. and the Boeing Company were 1.50 and 0.80, respectively. The risk-free rate of return was 4.35%, and the equity risk premium was 8.04%. Based on these data, calculate the required rates of return for these two stocks using the CAPM.

SOLUTIONS

1 B is correct. The cost of equity is defined as the rate of return required by stockholders.

2 B is correct. Debt is generally less costly than preferred or common stock. The cost of debt is further reduced if interest expense is tax deductible.

3 **A.** The required return is given by

$$r = 0.025 + (-0.2)(0.045) = 2.5\% - 0.9\% = 1.6\%.$$

This example indicates that Newmont Mining has a required return of 1.6%. When beta is negative, the CAPM calculation yields a required rate of return that is below the risk-free rate, which is arguably not meaningful. Cases of equities with negative betas are relatively rare.

B. The fact that the NEM's cost of debt is higher than the calculated required return on equity is another indicator that the return estimated using CAPM is not useful for valuing the company's equity.

4 The company's WACC is 13.64%, calculated as follows:

	Equity		Debt	WACC
Weight	0.80		0.20	
After-Tax Cost	15.6%		(1 – 0.30)8.28%	
Weight × Cost	12.48%	+	1.16%	= 13.64%

5 C is correct. FV = \$1,000, PMT = \$40, N = 10, and PV = \$900.

Solve for i. The six-month yield, i, is 5.3149%.

YTM = 5.3149% × 2 = 10.62985%.

$r_d(1 - t) = 10.62985\%(1 - 0.38) = 6.5905\%$.

6 C is correct. The bond rating approach depends on knowledge of the company's rating and can be compared with yields on bonds in the public market.

7 B is correct. The company can issue preferred stock at 6.5%. Therefore, the calculation of the preferred stock's current value is

$$P_p = \$1.75/0.065 = \$26.92.$$

8 B is correct. The weighted average cost of capital, using weights derived from the current capital structure, is the best estimate of the cost of capital for the average-risk project of a company.

9 C is correct. McClure should use the forecasted or target market values to calculate the weights.

$$w_d = \$63/(\$220 + 63) = 0.223.$$

$$w_e = \$220/(\$220 + 63) = 0.777.$$

10 B is correct. Asset risk does not change with a higher debt-to-equity ratio. Equity risk rises with higher debt.

11 B is correct. The debt-to-equity ratio of the new product should be used when making the adjustment from the asset beta, derived from the comparables, to the equity beta of the new product.

12 B is correct. The capital structure is as follows:

Market value of debt: FV = \$10,000,000, PMT = \$400,000, N = 10, and I/YR = 6.825%. Solving for PV gives \$7,999,688.

Market value of equity: 1.2 million shares outstanding at \$10 = \$12,000,000.

Market value of debt	\$7,999,688	40%
Market value of equity	12,000,000	60%
Total capital	\$19,999,688	100%

To raise \$7.5 million of new capital while maintaining the same capital structure, the company would issue \$7.5 million × 40% = \$3.0 million in bonds, which results in a before-tax rate of 16%.

$r_d(1 - t) = 0.16(1 - 0.3) = 0.112$, or 11.2%.

$r_e = 0.03 + 2.2(0.10 - 0.03) = 0.184$, or 18.4%.

$\text{WACC} = 0.40(0.112) + 0.6(0.184) = 0.0448 + 0.1104 = 0.1552$, or 15.52%.

13 B is correct.

$r_e = 0.0425 + (1.3)(0.0482) = 0.1052$, or 10.52%.

14 B is correct.

$$\begin{aligned}\text{WACC} &= [(€900/€3300)(0.0925)(1 - 0.375)] + [(€2{,}400/€3{,}300)(0.1052)] \\ &= 0.0923, \text{ or } 9.23\%.\end{aligned}$$

15 A is correct.

Asset beta = Unlevered beta = $1.3/\{1 + [(1 - 0.375)(€900/€2{,}400)]\} = 1.053$.

16 C is correct.

Project beta = $1.053\{1 + [(1 - 0.375)(€80/€20)]\} = 1.053(3.5) = 3.686$.

17 C is correct.

$r_e = 0.0425 + 3.686(0.0482 + 0.0188) = 0.2895$, or 28.95%.

18 B is correct.

Asset beta: $\beta_{equity}/[1 + (1 - t)(D/E)]$

Relevant = $1.702/[1 + (0.77)(0)] = 1.702$.

ABJ = $2.8/[1 + (0.77)(0.003)] = 2.7918$.

Opus = $3.4/[1 + (0.77)(0.013)] = 3.3663$.

19 C is correct.

Weights are determined on the basis of relative market values:

Comparables	Market Value of Equity in Millions	Proportion of Total
Relevant	\$3,800	0.5490
ABJ	2,150	0.3106
Opus	972	0.1404
Total	\$6,922	1.0000

Weighted average beta = (0.5490)(1.702) + (0.3106)(2.7918) + (0.1404)(3.3572) = 2.27.

20 B is correct.

Asset beta = 2.27.

Levered beta = 2.27[1 + (1 − 0.23)(0.01)] = 2.2875.

Cost of equity capital = 0.0525 + (2.2875)(0.07) = 0.2126, or 21.26%.

21 C is correct.

For debt: FV = 2,400,000; PV = 2,156,000; n = 10; PMT = 150,000.

Solve for i: i = 0.07748. YTM = 15.5%.

Before-tax cost of debt = 15.5%.

Market value of equity = 1 million shares outstanding + 1 million newly issued shares = 2 million shares at \$8 = \$16 million.

Total market capitalization = \$2.156 million + \$16 million = \$18.156 million.

Levered beta = 2.27[1 + (1 − 0.23)(2.156/16)] = 2.27(1.1038) = 2.5055.

Cost of equity = 0.0525 + 2.5055(0.07) = 0.2279, or 22.79%.

Debt weight = \$2.156/\$18.156 = 0.1187.

Equity weight = \$16/\$18.156 = 0.8813.

TagOn's MCC = (0.1187)(0.155)(1 − 0.23) + (0.8813)(0.2279)
= 0.01417 + 0.20084
= 0.2150. or 21.50%.

22 A is correct. The relevant cost is the marginal cost of debt. The before-tax marginal cost of debt can be estimated by the yield to maturity of the company's expected new issue, which is 7%. After adjusting for tax, the after-tax cost is 7%(1 − 0.4) = 7%(0.6) = 4.2%.

23 C is correct. Inferring the asset beta for the public company: Unlevered beta = 1.75/[1 + (1 − 0.35)(0.90)] = 1.104. Re-levering to reflect the target debt ratio of the private firm: Levered beta = 1.104 × [1 + (1 − 0.30)(1.00)] = 1.877.

24 B is correct. All else equal, the first issue's greater liquidity would tend to make its required return lower than the second issue's. However, the required return on equity increases as leverage increases. The first issue's higher required return must result from its higher leverage, more than offsetting the effect of its greater liquidity, given that both issues have the same market risk.

25 B is correct. Since the project will be financed with 50% equity, the company will issue £25 million of new stock. The flotation cost of external equity is (0.058 × 25,000,000) = 1,450,000. The NPV of the project using external equity is the NPV using internal equity less the flotation cost. Adjusting the cost of capital to reflect the flotation cost is not a preferred way to account for flotation costs.

26 For JPMorgan Chase, the required return is

$$r = R_F + \beta\left[\mathrm{E}\left(R_M\right) - R_F\right] = 4.35\% + 1.50\left(8.04\%\right) = 4.35\% + 12.06\%$$
$$= 16.41\%.$$

For Boeing, the required return is

$$r = R_F + \beta\left[\mathrm{E}\left(R_M\right) - R_F\right] = 4.35\% + 0.80\left(8.04\%\right) = 4.35\% + 6.43\%$$
$$= 10.78\%.$$

LEARNING OUTCOMES

Mastery	*The candidate should be able to:*
☐	**a.** describe how a company's capital structure may change over its life cycle;
☐	**b.** explain the Modigliani–Miller propositions regarding capital structure;
☐	**c.** describe the use of target capital structure in estimating WACC, and calculate and interpret target capital structure weights;
☐	**d.** explain factors affecting capital structure decisions;
☐	**e.** describe competing stakeholder interests in capital structure decisions.

INTRODUCTION

1

Capital structure refers to the specific mix of debt and equity used to finance a company's assets and operations. From a corporate perspective, equity represents a more expensive, permanent source of capital with greater financial flexibility. Debt, on the other hand, represents a cheaper, finite-to-maturity capital source that legally obligates the company to fixed, promised cash outflows with the need to refinance at some future date at an unknown cost.

A company's capital structure is the result of such financing decisions that may be guided by capital structure policies or targets set by management and the board. Capital structure is also the result of such factors as company size and maturity, which influence the financing options a company may have available. Besides equity and debt issuance, capital structure can also be significantly affected by merger and acquisition (M&A) activity, which can be financed by cash, borrowing, share assumption and/or

debt assumption in addition to proceeds from divestitures and asset sales. Capital structure is also affected over time by the company's operations, which might consume or generate cash, and by management decisions regarding dividends and share buybacks.

Since we are considering how a company minimizes its overall cost of capital, the focus here is on the market values of debt and equity. Therefore, capital structure is also affected by changes in the market value of a company's securities over time, particularly the share price.

We tend to think of capital structure as the result of a conscious decision by management, but it is not that simple. For example, unmanageable debt, or financial distress, can arise because a company's capital structure policy was too aggressive, but it can also occur because operating results or prospects deteriorate unexpectedly.

This reading reviews some of the key factors affecting capital structure, including the following:

- **Company life cycle:** Companies typically evolve over time from cash consumers to cash generators, with decreasing business risk and increasing debt capacity.
- **Cost of capital:** From a theoretical perspective, company management seeks to maximize shareholder value and determines an optimal capital structure to minimize the company's **weighted average cost of capital (WACC)**. "Optimal capital structure" involves a trade-off between the benefits of higher leverage, which include the tax deductibility of interest and the lower cost of debt relative to equity, and the costs of higher leverage, which include higher risk for all capital providers and the potential costs of financial distress.
- **Financing considerations:** From a practical perspective, company management may consider several factors in capital structure decisions and the use of leverage.
- **Competing stakeholder interests:** In seeking to maximize shareholder value, company management may make capital structure decisions that are not in the interests of other stakeholders, such as debtholders, suppliers, customers, or employees.

2

CAPITAL STRUCTURE AND COMPANY LIFE CYCLE

a describe how a company's capital structure may change over its life cycle

Many factors influence a company's capital structure and its ability to support debt, including its maturity, capital intensity, the strength of its market position, and the stability and nature of its business.

This section will discuss the typical changes in a company's capital structure as it evolves from a start-up, to a growth business, to a mature business. It will also highlight key variations.

2.1 Background

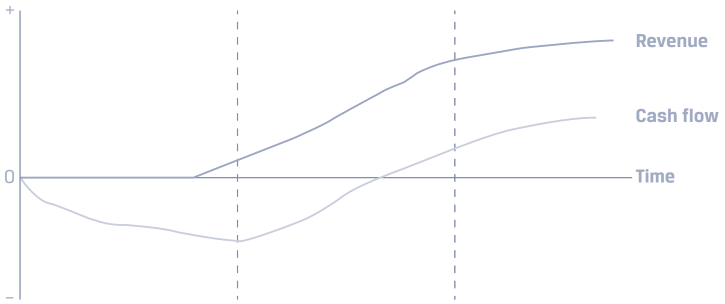
Many financial transactions can be seen in simple terms as the trading of money across time: A party with surplus cash today exchanges it with another party requiring cash in exchange for payments in the future. This is true of everyday consumer financial transactions, such as making a bank deposit, obtaining a loan, or contributing to a pension plan. It is also true of companies accessing the capital markets over their life cycle, from start-up through maturity. Typically, companies begin life as consumers of capital. As they mature, cash flows turn from negative to positive. Capital markets connect them to investors with the opposite requirement, those with cash to invest today in exchange for future payments.

The framework in Exhibit 1 describes the relationship between a company's life-cycle stage, its cash flow characteristics, and its ability to support debt. Life-cycle stage is a principal factor in determining capital structure. Capital not sourced through borrowing must come from equity (including retained earnings). The framework categorizes the stages in life-cycle development as start-up, growth, and mature and shows typical revenue and cash flow characteristics of companies in each stage. As companies mature, business risk typically declines, and their cash flow turns positive and becomes increasingly predictable, allowing for greater use of leverage at more attractive (less costly) financing terms. Debt then becomes a larger component of their capital structure.

Note that the framework references cash flow, which is net of investment. Profitable, high-growth businesses may have negative cash flow once investment is taken into account. Investment includes spending on plant equipment and other fixed assets as well as the expansion of working capital to support and grow the business over time.

Note also that the stages in a company's life cycle—start-up, growth, and mature—are like the evolutionary stages of an industry. However, start-ups and growth companies can often be found in mature industries. Examples include restaurants and apparel (with new concepts, formats, and fashions appearing regularly) and technology-driven disruption of established industries, such as advertising (by Google and Facebook) and even automobiles (by Tesla). This is a very general framework, and there are wide variations between and within sectors.

Exhibit 1 Capital Structure and Company Life Cycle



Stage in life cycle	Start-up	Growth	Mature
Financial management			
Revenue growth	Beginning	Rising	Slowing
Cash flow	Negative	Improving	Positive/Predictable
Business risk	High	Medium	Low
Debt capital/leverage			
Availability	Very limited	Limited/improving	High
Cost	High	Medium	Low
Typical cases	N/A	Secured (by receivables, fixed assets)	Unsecured (bank and public debt)
Typical % of capital structure[1]	Close to 0%	0%–20%	20% +

Note: These ratios are calculated based on the market values of equity and debt.

2.2 Start-Ups

Early in its life, a company is typically a cash consumer. Investment is required to advance concepts through the prototype stage and into commercial production. Revenues are zero or minimal, and risk of business failure is high. The company must raise capital, and since the timing and potential for cash flow generation are highly uncertain, it will generally raise equity rather than debt. Equity for start-ups is generally sourced privately, such as through venture capital rather than in public markets through an IPO, in part because many stock exchange listing requirements include minimum profitability levels, which most start-ups have yet to achieve.

At this early stage, debt capital is typically not available or available but very expensive. Most lenders require stable and positive cash flow to service debt and/or collateral to secure it. An early-stage company often has neither, making it a high-risk prospect to lenders.

From the perspective of an early-stage issuer, debt may be an attractive way to reduce or avoid the dilution associated with equity issuance. However, with cash flows that are negative and unpredictable, a typical start-up would have difficulty making regular debt payments, or "servicing the debt." Even if debt is available, the cost, inflexibility, and risk associated with borrowing are often unattractive to the start-up. As a result, debt is a negligible component in the capital structure of most start-up companies.

EXAMPLE 1

Start-Up Financing

Which of the following are limiting factors in the ability of a start-up company to take on debt?

A Lender requirement for positive cash flows

B Few to no assets that can be used as collateral

C Exchange listing requirements requiring minimum levels of profitability

D (A) and (B) only

E All of the above

Solution:

D is correct. Most lenders require positive and stable cash flows and/or collateral for servicing debt payments. Start-ups often have neither given their early stage in development. With expenditures outpacing revenues, a start-up company's cash flow is negative and unpredictable.

For equity financing, most start-ups fail to meet minimum profitability requirements for exchange listing in public markets and source their capital needs through private equity markets. Therefore, C is incorrect given an exchange listing relates to equity and is not a debt-financing limiting factor.

2.3 Growth Businesses

As a company exits the start-up stage, it is typically generating revenues, providing confirmation of the product concept and evidence of demand. Revenue growth may be rising and/or high, but investment is needed to achieve this growth and scale. This spending includes operating expenses, such as sales and marketing expense, growth related-capital expenditure, and working capital investment. Cash flow is still likely to be negative but may be improving and becoming more predictable. The company begins to establish a customer and supplier base.

As the business progresses through the growth stage, execution and competitive risks decline. Cash flow typically turns positive and then becomes more stable and predictable as the business grows. As a result, the business now becomes more attractive to lenders. Depending on the business model, there may also be assets that can be used to secure debt, such as receivables, inventory, or fixed assets. Both the availability and terms of debt financing improve for the company during this stage.

Many growth companies use debt conservatively in order to preserve operational and financial flexibility and minimize the risk of financial distress. Equity remains the predominant source of capital. Some business models are inherently "**capital light**," that is, they require little incremental investment in fixed assets or working capital to enable revenue growth. As a result, they have no need to borrow or otherwise raise capital to grow, even though they could easily support debt. Software businesses often fit this description.

EXAMPLE 2

Growth Company Financing

A growth retail business that is expected to generate positive operating cash flows in the next 3–5 years would normally be financed with:

A little or no debt.

B significant debt, to minimize equity dilution.

C significant debt, to minimize its weighted average cost of capital.

Solution:

A is correct. A growth retail business expected to generate positive operating cash flows in the next 3-5 years would normally be financed with little to no debt.

While one can often find exceptions, the standard approach to finance a business in such a highly competitive sector as retail with negative and/or unpredictable cash flows would be to rely primarily on equity. Using predominantly equity financing to meet capital needs allows management to preserve operational and financial flexibility while minimizing the risk of financial distress associated with debt.

2.4 Mature Businesses

At the maturity stage, a company's revenue growth may slow or even begin to decline. At this stage, however, a successful business generates reliable and positive cash flow and likely has an established customer and supplier base. There is typically a decline or a deceleration in growth-related investment spending. The company becomes able to support low-cost debt, often on an unsecured basis. From the company's perspective, debt financing is likely to be more attractive than higher-cost equity financing.

In practice, large, mature public companies commonly employ significant leverage, although many seek to maintain an investment-grade rating in order to preserve maximum financial flexibility. An investment-grade rating enables a company to access a very wide pool of potential investors on an unsecured basis without onerous debt covenants, and it minimizes the risk that financing might become unavailable.

Finance theory supports the idea that debt is an important component of the "optimal" capital structure, once the business can support it, due to the tax-deductibility of interest expense. "Optimal" capital structure, however, is a theoretical concept; in practice, there is wide variation in capital structures, even among otherwise similar companies. The prevalence of low interest rates increases the debt-carrying capacity of businesses and the use of corporate debt.

Mature businesses often de-leverage over time, experiencing a reduction in debt as a proportion of total capital. De-leveraging occurs due to continuing cash flow generation and because equity values commonly rise over time from share price appreciation. To offset this de-leveraging, companies may elect to do share buybacks. By using cash to buy back shares, outstanding share count, and therefore equity, is reduced in the capital structure.

Share buybacks are attractive to companies because, compared to dividends, they offer greater flexibility and, in general, are a more tax-efficient means of distributing cash to taxable investors. Buybacks can be done when cash is available and when the share price is seen by management to be attractive. Particularly in North America, investors generally expect dividend levels to be maintained once established. This is not the case with buybacks. Finally, by reducing the share count, buybacks enhance the share price, share option values, and per-share metrics, such as EPS or EPS growth, which may enhance management compensation.

EXAMPLE 3

Mature Business Capital Structure Considerations

Sleepy Mattress Company went public 10 years ago. Since then, the company has seen its revenues and cash flows increase every year. This growth is expected to continue. No dividends have ever been paid. All cash flow has gone toward debt reduction, and the company has recently become debt-free.

There is now a lively debate within the board about the company's capital structure. Board members agree that the company's capital structure should include debt in order to minimize its overall cost of capital, but they do not agree on how to achieve this. We consider each board member's recommendation, its associated scenario and likely impact on Sleepy's capital structure, and what is most likely the best course of action:

A Director TT has argued strongly that the company should initiate a regular annual cash dividend equal to 50% of after-tax cash flow.

B Director DD likes TT's idea but feels that the proposed cash dividend is too low. He recommends an annual stock dividend equal to 75% of after-tax cash flow.

C Director AH advocates making a tender offer to buy back shares at a 50% premium to market price for 50% of the company's shares and issuing debt to finance the offer. Since this would be a very large tender offer (equal to 75% of the company's equity market capitalization), it would be financed using a combination of senior and high-yield debt, carrying a relatively high 6% average interest rate. The company's cash flow will cover the projected interest payments, with operating cash flow equal to 1.1 times interest, and the surplus available for debt reduction. Projected debt/capital would be above 75%.

D Director FF favors a smaller share buyback: 20% of the company's shares at a 20% premium to market price, financed by issuing investment-grade debt with a 3% coupon. The company's cash flow will cover the projected interest payments, with operating cash flow equal to 6.9 times interest, and the surplus available for share repurchases. Projected debt/capital would be 20% to 25%.

Discussion:

Sleepy Mattress is a mature and stable business. It should therefore be able to support significant debt. The optimal capital structure for such a company would normally include debt, with the firm's value enhanced by the tax-deductibility of interest expense. But the company is now debt-free, generating cash flow, and paying no dividend. If no action is taken, cash will accumulate on the company's balance sheet. We look at each recommendation, in turn:

A TT's recommendation to pay a regular cash dividend would slow the cash accumulation on the balance sheet, since some of the company's operating cash flow will now be directed to the payment of a regular dividend. Starting to pay a dividend is probably a good idea for the company, but taking this action does not introduce any debt into the capital structure. The company would continue to have an all-equity capital structure.

B DD's recommendation to pay a stock dividend would also not introduce debt into the capital structure, and the company would continue to have an all-equity capital structure. Since paying a stock dividend does not require cash, cash would accumulate on the balance sheet as quickly as if no action were taken.

C AH's recommendation to buy back shares with debt would increase debt and reduce the equity in the capital structure. This recapitalization plan is a step in the right direction; however, the resulting interest coverage of 1.1 times is extremely low, so taking this action is likely too aggressive for the company. Any profit deterioration, and the company could easily fail to meet its interest obligations. While we are assuming that Sleepy Mattress could raise the debt, it could be challenged in doing this. At over 75%, pro forma debt as a percentage of total capital is very high. For companies with more stable and predictable cash flows, such as regulated utilities or REITS, higher percentages (i.e., above 60%) are common, but they are not common in consumer or industrial companies. Percentages above 75% often indicate that a company may be in financial distress.

D FF's recommendation is a superior course of action. It is a more balanced version of C, resulting in a manageable level of debt in the capital structure (under 25%), with a strong projected interest coverage ratio (6.9 times). It would be reasonable for the board to recommend this recapitalization to address the all-equity capital structure and, in addition, initiate a cash dividend. Doing a regular share buyback combined with a cash dividend would increase debt relative to equity in the capital structure and help counteract the de-leveraging in the business over time.

2.5 Unique Situations

In our discussion of the general relationship between company maturity and capital structure, there are important exceptions to note.

Capital Intensive Businesses with Marketable Assets Some businesses use high levels of leverage regardless of their development stage. For example, in real estate, utilities, shipping, airlines, and certain other highly capital-intensive businesses, the underlying assets can be bought and sold fairly easily, tend to retain their value regardless of who owns them, and can therefore support substantial debt secured by those assets. This would be true of a downtown office building, for example, but would not be true of a highly specialized factory in a remote location.

Note that business models have evolved in some cases to take advantage of this fact. What were once highly capital-intensive and vertically-integrated businesses (e.g., trucking, hotels, retailers, restaurants) have evolved so that many major brands are now owned by marketing or service businesses, which in turn have contractual relationships with the owners of real estate or other fixed assets used in the business. For example, Hilton Worldwide, one of the world's largest hotel companies, operates almost all its hotel rooms through long-term franchise or management agreements; the hotels themselves are owned by others.

Conversely, some relatively large and mature businesses use little debt.

Cyclical Industries In cyclical sectors, such as mining and materials, and many industrials, revenues and cash flows vary widely through the economic cycle, which limits debt capacity. As a result, businesses in cyclical sectors may have less debt in their capital structures than companies in other less cyclical industries.

"Capital-Light" Businesses Some business models, regardless of their development stage, notably software-based technology businesses, have minimal fixed investments or working capital needs. They tend to have little debt in their capital structures and in many cases have substantial net cash. This reflects several factors:

- With little or no fixed assets or capital expenditure required to support growth, these businesses are often cash flow positive from an early stage, never needing to raise large amounts of capital.
- Many companies in rapidly evolving industries see the need to accumulate cash for potential acquisitions.
- If they are rapidly growing and successful, companies may not face typical pressure to pay dividends or repurchase shares.
- A rapidly rising share price can cause the market value of the company's equity to dwarf the value of any debt that might have been raised.

EXAMPLE 4

Debt Use: Industry Variations

Green Company and Black Company are each achieving 15% annual revenue growth and have recently started to generate positive cash flow. Green Company owns and acquires renewable energy generation projects. Black Company is a cloud-based software company with a dominant market position, serving auto dealers. Which is more likely to have greater debt in its capital structure, and why?

A Black Company, because it serves a cyclical business

B Black Company, because of the strength of its market position

C Green Company, because its underlying assets can be financed with debt

Solution:

C is correct. Green Company has fixed assets, for which there is likely to be a ready and liquid market, and stable cash flows, which are supportive of debt financing. Black Company, a cloud-based software technology company, is an example of a capital "light" business, with few fixed assets. Its assets are more likely to be human capital. Additionally, servicing a cyclical industry is also likely to lead to Black Company having low debt.

MODIGLIANI–MILLER PROPOSITIONS

3

b explain the Modigliani–Miller propositions regarding capital structure

In a now-classic paper, Nobel Prize-winning economists Franco Modigliani and Merton Miller (1958) argued that given certain assumptions, a company's choice of capital structure does not affect its value. In short, managers cannot change firm value simply by changing the company's capital structure. In their work, Modigliani and Miller (MM) used simplifying assumptions to show the irrelevance of capital structure to firm value, and then they relaxed the assumptions to show the impact of taxes and financial distress costs on capital structure. Modigliani and Miller's work provides us with a starting point and allows us to examine what happens when the assumptions are relaxed to accommodate real-world considerations.

Their assumptions are shown in Exhibit 2.

Exhibit 2 Modigliani–Miller Assumptions

1. Homogenous expectations.
Investors agree on a given investment's expected cash flows.

2. Perfect capital markets.
No transaction costs, no taxes, no bankruptcy costs. Everyone has the same information.

3. Risk-free rate.
Investors can borrow and lend at the risk-free rate.

4. No agency costs.
Managers always act to maximize shareholder wealth.

5. Independent decisions.
Financing and investment decisions are independent of each other.

Let's begin by imagining a company's capital structure as a pie, with each slice of the pie representing a specific type of capital (e.g., common equity or debt) and the size of the pie representing the company's total value. We can slice the pie in any number of ways, yet the total size remains the same. This is equivalent to saying that the company's value, or present value of expected cash flows, remains the same no matter how the capital slices are allocated as long as the future cash flow stream is expected to remain the same and the risk of that cash flow stream, as reflected by the company's cost of capital, remains the same.

3.1 MM Proposition I without Taxes: Capital Structure Irrelevance

Given their assumptions, Modigliani and Miller proved that changing the capital structure does not affect firm value in part because individual investors can create any capital structure they prefer for the company by borrowing and lending in their own accounts in addition to holding shares in the company.

As an example, suppose that a company has a capital structure consisting of 50% debt and 50% equity and that an individual investor would prefer that the company's capital structure be 70% debt and 30% equity. That investor can borrow money to finance their share purchases so that their ownership of company assets reflects their preferred 70% debt financing. This would be equivalent to buying stock on margin. This action has no effect on the company's expected operating cash flows and no impact on company value.

Modigliani and Miller use the concept of arbitrage to demonstrate their point: If the value of an unlevered company (i.e., a company without any debt) is not equal to that of a levered company, investors could make a riskless arbitrage profit at no cost by selling shares of the overvalued company and using the proceeds to buy shares in the undervalued company, forcing their values to become equal.

MM Proposition I without taxes:
The market value of a company is not affected by the capital structure of the company.

In other words, the value of the levered company (V_L) is equal to the value of the unlevered company (V_U), or $V_L = V_U$. A crucial implication is that in the absence of taxes, the weighted average cost of capital is unaffected by capital structure. Note, however, that this proposition holds only under the restrictive assumptions of Modigliani and Miller.

The importance of the Modigliani and Miller result is that it demonstrates that managers cannot create firm value simply by changing the company's capital structure. In other words, the value of a company is determined solely by its cash flows, not by its relative reliance on debt and equity capital.

Adding leverage increases the risk to equityholders because greater debt increases the probability of bankruptcy. As a result, equityholders will demand a higher return as leverage increases in order to offset the increase in risk. However, overall cost of capital does not change, so there is no change in the value of the company. Note that Modigliani and Miller did not assume away the possibility of bankruptcy. They simply assumed there is no cost to bankruptcy. Given their assumptions of **perfect capital markets**—in which there are no taxes, transaction costs, or bankruptcy costs, and in which all investors have equal ("symmetric") information—capital structure does not affect the value of the company and is irrelevant. This forms the basis of the Modigliani and Miller Proposition I—and II, which follows.

3.2 MM Proposition II without Taxes: Higher Financial Leverage Raises the Cost of Equity

According to MM Proposition I, the value of the company remains unchanged or constant as the capital structure changes. Therefore, the weighted average cost of capital must also remain constant as capital structure changes. Since the cost of debt is lower than the cost of equity because debtholders have a priority in claims, it holds that as the company uses more debt, its risk goes up and the cost of equity must increase. MM Proposition II holds that the increase in the cost of equity must exactly offset the greater use of lower cost debt.

MM Proposition II without taxes:
The cost of equity is a linear function of the company's debt-to-equity ratio.

In their analysis, Modigliani and Miller prove that in the absence of corporate taxes, the cost of equity is equal to

$$r_e = r_0 + (r_0 - r_d)\frac{D}{E}, \tag{1}$$

where r_e is the cost of equity, r_o is the cost of capital for a company financed only with equity (i.e., an all-equity company), r_d is the cost of debt, D is market value of debt, and E is the market value of equity. Equation 1 is a linear function with intercept equal to r_0 and slope equal to the quantity $(r_0 - r_d)$. In short, higher leverage raises the cost of equity but does not change firm value.

Consider the example of the Leverkin Company, which currently has an all-equity capital structure. Leverkin has expected annual cash flows to equityholders (which we denote as "CF_e") of \$5,000 and a cost of equity, which is also its WACC, of 10%. For simplicity, we assume that all cash flows are perpetual. Therefore, Leverkin's value is equal to

$$V = \frac{\text{CF}_e}{r_{wacc}} = \frac{\$5{,}000}{0.10} = \$50{,}000$$

Now suppose that Leverkin plans to issue \$15,000 in debt at a cost of 5% and use the proceeds to buy back \$15,000 worth of its equity.

Under MM Proposition I, $V_L = V_U$, so the value of Leverkin must remain the same at \$50,000. Under MM Proposition II, the cost of Leverkin's equity when it has \$15,000 debt and \$35,000 equity is

$$r_e = 0.10 + (0.10 - 0.05)\frac{\$15{,}000}{\$35{,}000} \approx 0.12143 = 12.143\%$$

Furthermore, the value of Leverkin must equal the sum of the present value of cash flows to debtholders and equityholders. With \$15,000 debt at a cost of 5%, Leverkin makes annual interest payments of \$750 to debtholders, leaving \$5,000 – \$750 = \$4,250 for equityholders. Therefore, the total value of the company is:

$$V = D + E = \frac{\$750}{0.05} + \frac{\$4{,}250}{0.12143} = \$15{,}000 + \$34{,}999.59 \approx \$50{,}000$$

The more debt the company uses, the greater the cost of equity, but the total value of the company does not change and neither does the weighted average cost of capital. With its new capital structure, the company's WACC remains at 10%:

$$r_{wacc} = \left(\frac{\$15{,}000}{\$50{,}000}\right)0.05 + \left(\frac{\$35{,}000}{\$50{,}000}\right)0.12143 = 0.10 = 10\%$$

Now let's consider a company's systematic risk. Portfolio managers know that the beta of an investment portfolio is a market-value-weighted average of the betas of the investments in that portfolio. Similarly, the beta (or systematic risk) of a company's assets is a weighted average of the systematic risks of its sources of capital. This concept is explained by the Hamada equation, which does not account for default risk (see Hamada 1972):

$$\beta_a = \left(\frac{D}{V}\right)\beta_d + \left(\frac{E}{V}\right)\beta_e \tag{2}$$

where β_a is the asset's systematic risk, or **asset beta**, β_d is the beta of debt, and β_e is the equity beta. According to Modigliani and Miller, the company's cost of capital does not depend on its capital structure but rather on its business risk. As the level of debt rises, however, the risk of the company defaulting on its debt increases. This risk is borne by the equityholders. So, as the proportionate use of debt rises, the equity's beta, β_e, also rises. By reordering the terms of Equation 2, we get

$$\beta_e = \beta_a + (\beta_a - \beta_d)\left(\frac{D}{E}\right) \tag{3}$$

We have learned that under Modigliani and Miller's restrictive assumptions, when there are no taxes, leverage does not affect the value of the company or the weighted average cost of capital. However, leverage does cause the risk of equity to increase and therefore the cost of equity to increase as well.

EXAMPLE 5

Value of Firm in Perfect Capital Markets

Company A has 25% debt and 75% equity in its capital structure. Management decides to increase leverage, so it issues more debt and buys back company stock. As a result, the new capital structure is 50% debt and 50% equity. Which of the following statements is true in perfect capital markets?

A Post refinancing, the company is worth more because leverage has increased.

B Post refinancing, the company is worth less because there is a greater chance of bankruptcy.

Solution:

Neither answer is correct. In perfect capital markets, a change in capital structure has no impact on the value of the company.

EXAMPLE 6

Effect of Leverage on Equity Beta

The Chang Shou Noodle Company is financed with 10% debt and 90% equity.

1. If the asset beta is 0.8 and the beta of the debt is 0.2, what is the equity beta?
2. How does the equity beta change if management increases leverage to 30% debt?

Solution:

We use Equation 3 to solve this problem.

1 Prior to the change in capital structure, the equity beta is

$$\beta_e = 0.8 + (0.8 - 0.2)(10/90) = 0.87.$$

2 After the capital structure change, the equity beta is higher because more debt increases the risk to equityholders. The new equity beta is

$$\beta_e = 0.8 + (0.8 - 0.2)(30/70) = 1.06.$$

3.3 MM Propositions with Taxes: Taxes, Cost of Capital, and Value of the Company

Now let's explore what happens when we take a more realistic assumption, that of corporate taxes.

In most countries, interest paid on debt is deductible from income for tax purposes. In other words, debt provides a tax shield for companies that are earning profits. The money saved in taxes enhances the value of the company. Ignoring other realities, such as the costs of financial distress and bankruptcy, the value of the company increases with increasing levels of debt. The actual cost of debt is reduced by the amount of the tax benefit:

After-tax cost of debt = Before-tax cost of debt × (1 − Marginal tax rate).

Modigliani and Miller show that in the presence of corporate taxes (but not personal taxes), the value of the levered company is greater than that of the all-equity company by an amount equal to the tax rate multiplied by the value of the debt, also termed the **debt tax shield**.

> *MM Proposition I with corporate taxes:*
> *The market value of a levered company is equal to the value of an unlevered company plus the value of the debt tax shield.*

$$V_L = V_U + tD, \tag{4}$$

where t is the marginal tax rate and tD is the debt tax shield. When there are corporate taxes, a profitable company can increase its value by using debt financing.

If the value of the company (V) increases as it uses more debt, the weighted average cost of capital must decrease as it uses more debt:

$$r_{wacc} = \left(\frac{D}{V}\right) r_d (1 - t) + \left(\frac{E}{V}\right) r_e \tag{5}$$

If r_0 represents the cost of equity for an all-equity company, Modigliani and Miller also show that the cost of equity for the same company with debt is:

$$r_e = r_0 + (r_0 - r_d)(1 - t)\frac{D}{E} \tag{6}$$

which leads us to MM Proposition II with corporate taxes:

> *MM Proposition II with corporate taxes:*
> *The cost of equity is a linear function of the company's debt-to-equity ratio with an adjustment for the tax rate.*

Notice that the only difference between Equation 6 and Equation 1 (MM Proposition II with no taxes) is the presence of the term (1 – *t*). When *t* is zero, the two equations are identical. When *t* is not zero, the term (1 – *t*) is less than 1 and serves to reduce the cost of levered equity. The cost of equity rises as the company increases the amount of debt in its capital structure, but it rises at a slower rate than in the no-tax case. As debt increases, the WACC decreases and the company's value increases. This implies that when there are taxes (and no costs to financial distress or bankruptcy), debt financing is highly advantageous. Taken to an extreme, a company's optimal capital structure is to have all debt—a conclusion that is at odds with reality and a direct result of Modigliani and Miller's restrictive assumptions.

Let us return to the example of the Leverkin Company. Recall that annual cash flows to equityholders are \$5,000 and the WACC is 10%. As before, Leverkin is planning to issue \$15,000 of 5% debt in order to buy back an equivalent amount of equity. Now, however, assume that Leverkin pays corporate taxes at a rate of 25%.

Since the company does not currently have debt, the after-tax cash flows are \$5,000(1 – 0.25) or \$3,750. Because the cash flows are assumed to be perpetual, the value of the company at 10% is \$37,500, considerably less than it was when there were no taxes. Now suppose Leverkin issues \$15,000 of debt and uses the proceeds to repurchase common stock. According to MM Proposition I with corporate taxes (i.e., Equation 4), the value of the company is:

$$V_L = V_U + tD = \$37{,}500 + 0.25(\$15{,}000) = \$41{,}250.$$

Since the value of the debt is \$15,000, the value of the equity (after the buyback) must be (\$41,250 – \$15,000) = \$26,250. According to MM Proposition II with corporate taxes (Equation 6), the cost of the levered equity is:

$$r_e = 0.10 + (0.10 - 0.05)(1 - 0.25)\frac{\$15{,}000}{\$26{,}250} = 0.12143 = 12.143\%$$

Note that the value of the company must also equal the present value of cash flows to debt and to equity:

$$V_L = D + E = \frac{r_d D}{r_d} + \frac{(\text{CF}_e - r_d D)(1 - t)}{r_e}$$
$$= \frac{\$750}{0.05} + \frac{(\$5{,}000 - \$750)(1 - 0.25)}{0.12143} \approx \$41{,}250$$

which is the same result that we got from MM Proposition I with corporate taxes. As a further check, using Equation 5, the WACC for the levered Leverkin is:

$$r_{wacc} = \frac{\$15{,}000}{\$41{,}250}(0.05)(1 - 0.25) + \frac{\$26{,}250}{\$41{,}250}(0.12143)$$
$$= 0.09091 = 9.091\%$$

As expected, this is lower than the unlevered WACC of 10%. Furthermore, because debtholders and equityholders are entitled to whatever is left of the cash flows after taxes are paid, we must also have:

$$V_L = \frac{\text{CF}_e(1 - t)}{\text{WACC}} = \frac{\$5{,}000(1 - 0.25)}{0.09091} \approx \$41{,}250$$

Exhibit 3 summarizes the results:

Exhibit 3

Modigliani and Miller Propositions

	Without Taxes	With Taxes
Proposition I	$V_L = V_U$	$V_L = V_U + tD$
Proposition II	$r_e = r_0 + (r_0 - r_d)\frac{D}{E}$	$r_e = r_0 + (r_0 - r_d)(1 - t)\frac{D}{E}$

In an attempt to explain why companies are not financed entirely with debt as the Modigliani and Miller analysis with corporate taxes prescribes, Miller (1977) introduced another aspect into the analysis: personal taxes. Miller argued that the existence of a higher personal tax rate on interest income than on dividend income reduces the advantage of debt financing to the corporation. A higher tax rate on interest income causes investors to demand a higher return on debt than they otherwise would, which drives up the cost of debt financing to the company. In the Miller model, whether or not debt financing adds value to the company depends not only on the corporate tax rate but also on the personal tax rates on interest and dividend income. Depending on the levels of the various tax rates, it is possible for debt to add value, lower value, or have no effect on value. The existence of personal taxes might explain, at least in part, why companies are not financed entirely with debt as MM Proposition I with corporate taxes implies. The existence of investors with differing personal tax rates could explain why corporations often have very different capital structures, even when they have a number of other similarities.

Of course, in the real world, taxes are not the only factor that affect the value of a levered company. The analysis gets more complicated when we allow for such things as the costs of financial distress and other real-world considerations. We consider costs of financial distress next.

3.4 Costs of Financial Distress

Operating and financial leverage can magnify profits and losses. Losses can put companies into **financial distress**, the costs of which can be explicit or implicit. Financial distress refers to the heightened uncertainty regarding a company's ability to meet its various obligations because of diminished earnings power or actual current losses. Even before filing for bankruptcy, companies under financial distress may lose customers, creditors, suppliers, and valuable employees.

EXAMPLE 7

Costs of Financial Distress

The Carillion Plc was a UK-based entity with revenues of almost £4.4 billion. It had a number of contracts with the UK government for the maintenance of roads and for catering and cleaning at hundreds of schools. The share price was £308 at the end of 2015 and £236 at the end of 2016.

In mid-2017, Carillion warned that profits would fall short of expectations due to problems collecting on several construction contracts. Soon after, the share price fell by 30%. Even as it faced collection problems, the company was awarded more contracts, including those for railway and military projects.

Subsequent profit warnings sent the share price further downward. The second profit warning of that year was followed by new credit facilities and deferrals of debt repayments. The third profit warning, which included concerns over violating debt covenants, caused the share price to fall to around £21.

Discussions with creditors in December 2017 and January 2018 did not result in an agreement. Carillion was put in compulsory liquidation on 15 January 2018, and share trading was suspended.

The primary causes of Carillion's problems were its many overreaching, unprofitable projects and its inability to collect payments quickly.

The costs of financial distress included:

- the loss of all shareholder value;
- £44.2 million paid to an accounting firm to manage the insolvency;
- costs to the UK government as it grappled with nationalizing contracts; and
- creditors getting paid only a fraction of what they were owed.

The direct costs of financial distress include actual cash expenses associated with the bankruptcy process, such as legal and administrative fees. Indirect costs include forgone investment opportunities, reputational risk, impaired ability to conduct business, and costs arising from conflicts of interest between managers and debtholders, known as **agency costs of debt**, during periods in which the company is near or in bankruptcy.

The costs associated with financial distress are lower for companies whose assets have a ready secondary market. Airlines, shipping companies, and steel manufacturers typically have tangible assets that can be easily sold. High-tech growth companies, pharmaceutical companies, information technology companies, and companies in the services industry typically have fewer tangible assets that can be sold. These companies have higher costs associated with financial distress.

The probability of financial distress and bankruptcy increases when there is a greater amount of debt in the capital structure, a greater amount of business risk, and fewer reserves available to delay bankruptcy. Other factors that affect the probability of bankruptcy include the company's corporate governance structure and the quality of the management team.

4

OPTIMAL AND TARGET CAPITAL STRUCTURE

c describe the use of target capital structure in estimating WACC, and calculate and interpret target capital structure weights

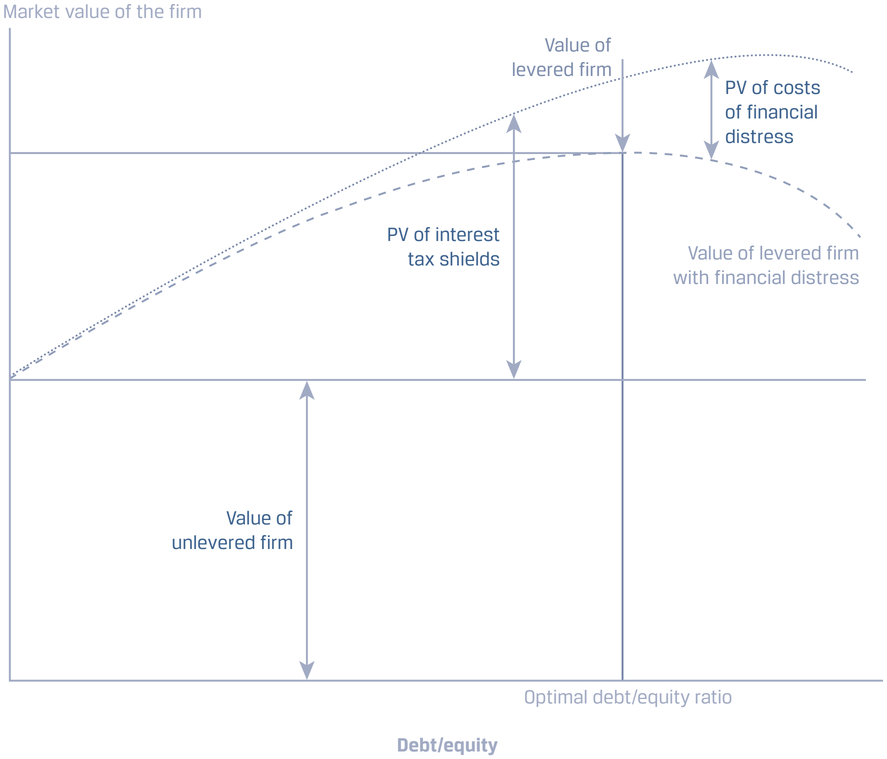
The value-enhancing effects of leverage from the tax deductibility of interest must be weighed against the value-reducing impact of the net present value of the expected (or probability weighted) costs of financial distress or bankruptcy, debt agency costs, debt structuring and issuance fees, etc. Putting the pieces together, we see that the value of the company increases as it uses more debt only up to a point. Beyond that point, the value-enhancing effects of financial leverage are offset by the value-reducing effects. The theoretical point at which the value of the company is maximized is known as the **optimal capital structure**.

Here we consider only the tax shield provided by debt and the costs of financial distress. As a result, we can write the value of a leveraged company as

$$V_L = V_U + tD - PV(\text{Costs of financial distress}), \tag{7}$$

where the last term is the present value of the costs of financial distress. Equation 7 represents the **static trade-off theory of capital structure**, which results in an optimal capital structure that is somewhere less than 100% debt. We diagram this optimum in Exhibit 4.

Exhibit 4 Trade-Off Theory with Taxes and Costs of Financial Distress. Firm Value and the Debt-to-Equity Ratio



In practice, we cannot say precisely where that point is. However, by considering the company's business risk, tax situation, corporate governance, financial accounting information, probable bankruptcy costs, and other factors, management should be able to identify a range that includes the optimal point.

When a company recognizes its optimal capital structure, it may adopt it as its **target capital structure**. This target is the company's chosen proportions of debt and equity as opposed to the actual weightings, which may be different for a number of reasons. For example, management may be able to exploit short-term opportunities in a financing source. A company issuing high-grade debt at attractive rates, for instance, may choose to increase deal size in response to strong investor demand. Or, market-value fluctuations can cause the company's actual capital structure to deviate from the target. In addition, flotation costs may make it impractical for a company to continually adjust its capital structure to keep it on target. Flotation costs are the costs incurred by a publicly traded company when it issues new debt or equity securities. In any case, while optimal capital structure may exist as a specific point in theory, it cannot be determined exactly in practice.

In practice, the optimal and target capital structures should be thought of as being within a range. For example, it would be impossible to determine with certainty that the optimal amount of debt in the capital structure should be exactly 40%. Yet, the company should be able to determine that its target capital structure has between 30% to 50% debt.

When conducting an analysis, how do we determine what WACC weights to use? Ideally, we want to use the proportion of each source of capital that the company would use in the project or company. If we assume that a company has a target capital structure and raises capital consistent with this target, we should use this target capital structure, or the capital structure that a company is striving to obtain. If we know the company's target capital structure, then of course we should use this in our analysis. Individuals outside the company, however, such as analysts, typically do not know the target capital structure and must estimate it using one of several methods:

1. Assume the company's current capital structure, at market value weights for the components, represents the company's target capital structure.
2. Examine trends in the company's capital structure or statements by management regarding capital structure policy to infer the target capital structure.
3. Use averages of comparable companies' capital structures as the target capital structure.

In the absence of knowledge of a company's target capital structure, we may take Method 1 as the baseline. Note that in applying Method 3, we use an unweighted, arithmetic average, as is often done for simplicity. An alternative is to calculate a weighted average, which would give more weight to larger companies.

Suppose we are using the company's current capital structure as a proxy for the target capital structure. In this case, we use the market value of the different capital sources in the calculation of these proportions. For example, suppose a company has the following market values for its capital:

Bonds outstanding	\$5 million
Preferred stock	1 million
Common stock	14 million
Total capital	\$20 million

The weights that we apply would be as follows:

w_d =	0.25
w_p =	0.05
w_e =	0.70

Example 8 illustrates the estimation of weights. Note that a simple way of transforming a debt-to-equity ratio (D/E) into a weight—that is, $D/(D + E)$—is to divide D/E by $1 + D/E$.

EXAMPLE 8

Estimating the Proportions of Capital

Fin Anziell is a financial analyst with Analytiker Firma. Anziell is in the process of estimating the cost of capital of Gewicht GmbH. The following information is provided:

Market value of debt: €50 million

Market value of equity: €60 million

Primary competitors and their capital structures (in millions):

Competitor	Market Value of Debt	Market Value of Equity
A	€25	€50
B	€101	€190
C	£40	£60

What are Gewicht's proportions of debt and equity that Anziell would use if estimating these proportions using the company's:

1. current capital structure?
2. competitors' capital structure?
3. Suppose Gewicht announces that a debt-to-equity ratio of 0.7 reflects its target capital structure. What weights should Anziell use in the cost of capital calculations?

Solution to 1:

Current capital structure

$$w_d = \frac{\text{€}50\text{ million}}{\text{€}50\text{ million} + \text{€}60\text{ million}} = 0.4545$$

$$w_e = \frac{\text{€}60\text{ million}}{\text{€}50\text{ million} + \text{€}60\text{ million}} = 0.5454$$

Solution to 2:

Competitors' capital structure:

$$w_d = \frac{\left(\frac{\text{€}25}{\text{€}25 + \text{€}50}\right) + \left(\frac{\text{€}101}{\text{€}101 + \text{€}190}\right) + \left(\frac{\text{£}40}{\text{£}40 + \text{£}60}\right)}{3} = 0.3601$$

$$w_e = \frac{\left(\frac{\text{€}50}{\text{€}25 + \text{€}50}\right) + \left(\frac{\text{€}190}{\text{€}101 + \text{€}190}\right) + \left(\frac{\text{£}60}{\text{£}40 + \text{£}60}\right)}{3} = 0.6399$$

Solution to 3:

A debt-to-equity ratio of 0.7 represents a weight on debt of 0.7/1.7 = 0.4118, so that $w_d = 0.4118$ and $w_e = 1 - 0.4118 = 0.5882$. These would be the preferred weights to use in a cost of capital calculation.

FACTORS AFFECTING CAPITAL STRUCTURE DECISIONS

5

d explain factors affecting capital structure decisions

In theory, capital structure is an optimal mix of equity and debt, which minimizes the firm's weighted average cost of capital and represents a trade-off between the cost-effectiveness of borrowing relative to higher cost equity and the costs of financial distress. Many practical considerations affect capital structure and the use of leverage by management. These include:

- *capital structure policies and targets*: guidelines set by management and the board that seek to establish sensible borrowing limits for the company based on the company's risk appetite and ability to support debt;
- *capital investment financing:* financing opportunities or requirements associated with acquisitions or other major investments;
- *market conditions:* current share price levels and market interest rates for a company's debt; and
- *asymmetric information:* the unequal information distribution that exists between management and other stakeholders.

We look at each of these in turn.

5.1 Capital Structure Policies and Target Capital Structures

In principle, a company's capital structure policy guides its financing and distribution decisions, with a target capital structure that achieves an optimal mix of equity and debt.

In practice, it is difficult to estimate a company's cost of equity capital or to estimate the costs of financial distress. As a result, it is common for capital structure policies to be debt-oriented, defining reasonable limits for borrowing by the company. Policy limits are often defined in straightforward terms, such as "debt/equity less than 0.5 times"; "debt to operating cash flow less than 2.0 times"; or "debt as a maximum of X% of total capital." Companies differ in the measures and thresholds used, but they frequently start with debt covenants or rating agency thresholds to which they add a cushion, or "margin of safety," to ensure that the debt limits or covenants are not breached or to avoid a rating downgrade.

Not all companies have capital structure policies. Having explicit capital structure policies is important for companies that are significant and frequent borrowers since the risks associated with too much leverage can be severe, while the risks associated with too little leverage generally are not. Companies that have little to no debt, such as start-ups or some technology companies, may not have capital structure policies or targets. In certain industries, capital structures are evaluated by regulators and thus capital structure policies will be determined accordingly.

5.1.1 *Debt Ratings*

Debt ratings are independent, third-party measures of the quality and safety of a company's debt based upon an analysis of the company's ability to pay the promised cash flows. Debt ratings are an important consideration in the practical management of leverage, and maintaining the company's rating at a certain level may also be an explicit policy target for management.

As leverage rises, rating agencies tend to lower the ratings of the company's debt to reflect the higher credit risk and probability of default arising from the increase in leverage. Lower ratings signify higher risk to both equity and debt capital providers, who demand higher returns for supplying capital to the company.

Most large companies pay one or more rating services to provide debt ratings for their bonds. Debt issues are rated for creditworthiness by these credit rating agencies after they perform a financial analysis of the company's ability to pay the promised cash flows as well as an analysis of the bond's indenture (i.e., the set of complex legal documents associated with the issuance of debt instruments).

These agencies evaluate a wealth of information about the issuer and the bond, including the bond's characteristics and indenture agreement, and provide investors with an assessment of the company's ability to pay the interest and principal on the bond as promised.

In practice, most managers consider the company's debt rating in their capital structure policies because the cost of capital is tied so closely to bond ratings. And some companies explicitly target a certain debt rating in their capital structure policy. For example, a company might target an S&P debt rating of A or higher, which is one level above BBB, the minimum investment-grade rating on S&P's scale. The cost of debt increases significantly when a bond's rating drops from investment grade to speculative grade (also called high-yield debt). In economic recessions, these spreads may widen significantly, and borrowing can become more difficult for companies with non-investment-grade ratings.

In addition to lower borrowing costs, highly rated companies have greater borrowing flexibility and better terms. They are able to borrow in debt markets for "general corporate purposes" on an unsecured basis, with very few debt covenants. Similarly, lower-rated, sub-investment-grade companies have higher borrowing costs with more restrictive debt covenants, liens on assets, and differing subordination levels.

In general, firms that are in industries with stable cash flows, greater profitability, shorter asset conversion cycles and/or more liquid assets can support more debt and tend to receive higher debt ratings and have lower borrowing costs. Such companies are often in stable and defensive sectors, such as utilities and consumer staples, and enjoy strong market positions.

On the other hand, companies that require heavy investment in inventory or specialized equipment—with long asset conversion cycles, cyclical or less stable cash flows and/or profitability—have a reduced ability to consistently meet fixed debt payments over time and therefore face lower ratings and higher borrowing costs.

5.1.2 *Market Value vs. Book Value*

While optimal capital structure is calculated using the market value of equity and debt, company capital structure targets often use book value instead for the following reasons:

1. *Market values can fluctuate substantially and seldom impact the appropriate level of borrowing.* On the contrary, a company that has seen a rapid increase in its share price might opportunistically decide to raise equity capital rather than debt to maintain a certain debt-to-equity ratio.
2. *For management, the primary concern is the amount and types of capital invested by the company, not in the company.* This perspective includes how future investment will be funded. It is different from that of a shareholder who has purchased shares at the prevailing market price, for example, and is concerned with generating a return on that investment.
3. *Capital structure policy ensures management's ability to borrow easily and at low cost.* Since lenders, debt investors, and rating agencies generally focus on the book value of debt and equity for their calculation measures, companies and their management will take this into account in their capital structure policies.

EXAMPLE 9

Capital Structure Policy: Abha Software

Abha Software's management believes the company can obtain attractive borrowing terms if debt/EBITDA (earnings before interest, taxes, depreciation, and amortization) is at 2 times or less, which for Abha is the primary criterion used by lenders to assess borrowing capacity and terms. Abha's EBITDA for the latest year is $50 million, and it has a total capitalization of $1.0 billion. Management and the board have agreed that Abha should use leverage if the company can borrow easily at attractive rates. They are seeking a capital structure policy that reflects this objective. Which of the following is *most likely* to be an appropriate capital structure policy for Abha?

A Debt should be a maximum of 25% of total capital in book value terms.

B Debt should be a maximum of 10% of total capital in market value terms.

C The debt-to-EBITDA ratio should be no more than 2 times.

Solution:

C is correct. It is the most appropriate capital structure policy since the debt-to-EBITDA ratio is the primary criterion that lenders and management are using to determine Abha's debt capacity. Note that lending criteria vary by sector, by market, and over time, including the ratios used (as well as the threshold ratios for those ratios).

B is least likely to be appropriate. While useful in calculating the cost of capital for Abha, market value weights are less practical and less commonly used in capital structure targets. Market values of equity can fluctuate a great deal without a corresponding change in the company's borrowing capacity. Increases or decreases in the company's share price would imply increases or decreases in maximum debt that are unlikely to be appropriate.

A is a better policy than B, with 10% debt/capital implying up to $100 million in debt. This ratio is unaffected by fluctuations in the share price. While the implied debt capacity of $100 million happens to equal the amount indicated by the 2.0 times debt/EBITDA that lenders seek, this policy is not the primary criterion used by lenders.

Finally, a company's cash flow generation is almost never entirely predictable and is likely to deviate from management's plan. This will affect the company's borrowing capacity and its financing plans. As management considers their financing plans, they will continually refine their views on the company's cash flow generation as well as its investment needs.

5.2 Financing Capital Investments

In practice, key financing decisions are typically tied to investment spending—and often to a specific investment or acquisition. Management will consider the specific attributes and requirements of the asset or investment at the time of financing in addition to overall capital structure of the business after the investment has been made.

The nature of the investments may be well or poorly suited to leverage, relative to the entire business. Assets suitable to leverage include those that are generally easy to market (i.e., liquid), cash-generative, and typically considered strong collateral by lenders, such as real estate or infrastructure assets. Start-up businesses—those with minimal tangible assets and that are inextricably tied to the parent's operations (for example, a sales/service operation)—are less attractive to lenders for stand-alone financing.

In matching the cash flows and maturity structures of their assets and liabilities, companies reduce risk. A company financing long-term assets with short-term obligations faces rollover risk, which may threaten profitability if short-term financing costs go up over the financing period. Similarly, a company financing short-term assets with long-term financing beyond the term needed faces the risk that the company overpays in financing cost. Asset liability misalignment increases the risk of default and cost of capital for companies as capital suppliers demand higher returns in compensation. In contrast, companies with greater asset liability alignment have lower default risk, higher ratings, and lower borrowing costs.

Some investments may have financing in place. An example would be the acquisition of an established business, with either existing debt or financing provided by the vendor.

It is common for foreign investments to be financed substantially with debt, in order to hedge currency risk by borrowing in the same (foreign) currency as revenues earned or, if tax rates are higher in the foreign jurisdiction, to reduce taxes. More specifically, borrowing in the same (foreign) currency helps to hedge against exchange rate movements on earnings from the foreign investment and on the value of the investment in local currency terms. Higher tax rates enhance the value of the interest tax deduction on new debt.

5.3 Market Conditions

Although it is common to have target capital structures expressed in terms of book values, managers pay close attention to the price of their company's shares and market interest rates for their debt in deciding when, how much, and what type of capital to raise. For this reason, financings are often opportunistic to some degree—and an important reason why capital structures often deviate from target levels defined by management.

An important consideration for corporate issuers is whether their debt or equity issuance meets index provider requirements that allow inclusion in a benchmark index, since this affects the demand for their securities by major investors. Companies reaching a certain market capitalization size in addition to meeting specific index provider requirements may qualify for index membership. Similarly, whether a specific debt issue meets requirements—including issuance size, in particular—for addition to an index is a key factor in debt-financing decisions.

A company's cost of debt is equal to a risk-free rate plus a risk premium specific to the company. The risk premium, or credit spread, above the benchmark risk-free rate reflects issuer-specific risk factors as well as overall credit market conditions. More creditworthy companies—with strong and predictable cash flows, lower risk, and higher debt ratings—have lower costs of debt. Similarly, less profitable companies—with higher cash flow volatility and/or predictability, higher risk, and lower debt ratings—have higher costs of debt.

When a company can issue new debt at a known rate, it is common practice to use that rate as the company's cost of debt. However, if leverage is increasing for the company, the cost of refinancing existing debt in the future is also likely to increase and thus should be included as part of the incremental cost of borrowing. At high levels of leverage, a company's incremental borrowing costs can climb quickly.

Macroeconomic and country-specific factors are reflected in the benchmark rate and in the overall level of credit spreads. They impact the ability to raise debt on attractive terms. Borrowing is less costly when interest rates and inflation rates are low as well as during expansionary stages in the business and credit cycle. Countries with more developed banking systems and capital markets, stronger currencies, and lender-friendly legal systems tend to have lower borrowing costs, supporting higher use of leverage by companies. Companies located in emerging markets often employ lower levels of leverage than those in developed countries.

For a typical company, debt is less expensive than equity, particularly when the tax-deductibility of interest is considered and the company is profitable. Corporate bond spreads over benchmark rates, such as US Treasuries, vary over time and by credit rating, but most investment-grade bonds have historically traded at 0.5% to 2.5% above benchmark bond rates.

In comparison, equity risk premium estimates vary widely, between 3% and 8% depending on the market and period studied. Note that such estimates reflect the returns earned by equity investors, whereas in principle, the equity risk premium refers to the return required by investors on a forward-looking basis. When a company has both debt and equity options, to maximize firm value management should choose the debt–equity combination that minimizes the weighted average cost of capital (WACC).

We next consider information asymmetries and signaling.

5.4 Information Asymmetries and Signaling

Asymmetric information (an unequal distribution of information) arises from the fact that managers have more information about a company's performance and prospects (including future investment opportunities) than do outsiders, such as owners and creditors. Whereas all companies have a certain level of asymmetric information, companies with comparatively high asymmetry in information include those with complex products. These include high-tech companies, companies with little transparency in financial accounting information, or companies with lower levels of institutional ownership. Providers of both debt and equity capital demand higher returns from companies with higher asymmetry in information because there is greater potential for conflicts of interest.

However, investors understand that management has access to more information about a business and its prospects than they do—and that management will take this information into account when raising capital. Investors will be concerned either that a company will issue shares when its shares are expensive or that it will issue debt when its creditworthiness is about to deteriorate, for example due to higher investment or acquisitions.

To address this issue, a common response by the company is to tie financing to the event that requires it or that might cause investor concern, such as an acquisition, investment program, debt retirement, or results announcement. This approach aims to reduce the extent of information asymmetry between managers and investors. In addition, it ties the timing to a specific requirement for capital rather than perceived management opportunism.

Another corporate response is to avoid equity issuance in favor of financing via the company's retained earnings or by issuing debt.

Some degree of asymmetric information always exists because investors never know as much as managers and other insiders. Consequently, investors often closely watch manager behavior for insight into insider opinions on the company's prospects. Aware of this scrutiny, managers consider how their actions might be interpreted by outsiders. The signaling model of capital structure suggests a hierarchy ("pecking order") to managers' selection of methods for financing new investments.

The **pecking order theory**, developed by Myers and Majluf (1984), suggests that managers choose methods of financing according to a hierarchy that gives first preference to methods with the least potential information content (internally generated funds) and lowest preference to the form with the greatest potential information content (public equity offerings). Public equity offerings are, in general, closely scrutinized because investors are typically skeptical that existing owners would share ownership of a company with a great future with other investors. In brief, managers prefer internal financing. If internal financing is insufficient, managers next prefer debt, then equity.

Another implication of the work of Myers and Majluf is that financial managers tend to issue equity when they believe the stock is overvalued, but they are reluctant to issue equity if they believe the stock is undervalued. Thus, additional issuance of stock is often interpreted by investors as a negative signal.

We can read the signals that managers provide in their choice of financing method. Managers can signal to the market their confidence in a company's prospects through the issuance of debt, which commits the company to future obligations (so-called "debt signaling"). For example, commitments to fixed payments, such as dividends and debt service payments, may be interpreted as the company's management having confidence in the company's future prospects of making payments. Such signals are considered too costly for poorly performing companies to afford.

Alternatively, the signal of raising money at the top of the pecking order and issuing equity at the bottom of the pecking order holds other clues. If, for instance, the company's cost of capital increases after an equity issuance, we may interpret this effect as an indication that management needed capital beyond what comes cheaply; in other words, this is a negative signal regarding the company's future prospects. Managers may hesitate to issue new equity when they believe the company's shares are underpriced, because they wish to avoid signaling that they believe the shares are overpriced and also to avoid the cost and effort involved with new equity issuance.

Information asymmetry and "signaling" about the value of a company's shares can also become important factors when there are share sales in a company that has a controlling shareholder. Investors will look for signals about the controlling shareholder's confidence in the value of the shares and reasons for selling shares. For instance, if the company is issuing new equity, is the controlling shareholder participating? If there is no new equity being issued, what is the stated reason for the sale and how convincing is that reason?

When a private equity owner takes a portfolio company public, it is typically assumed that it will eventually sell, often in stages over time. With companies controlled by founders or their families, this is less likely to be the case, although it is common for founders to seek to reduce their stake in order to reduce their exposure to a single business or for succession management reasons. In any case, public investors will assume that controlling shareholders will sell their shares at opportune times, taking advantage of favorable market conditions and/or their superior knowledge of the business.

AGENCY COSTS

6

Agency costs are the costs associated with the fact that all public companies and the larger private companies are managed by non-owners. Agency costs are the incremental costs arising from conflicts of interest when an agent makes decisions for a principal. In the context of a corporation, agency costs arise from conflicts of interest between managers, shareholders, and bondholders. "Perquisite consumption" refers to items that executives may legally authorize for themselves that have a cost to shareholders, such as subsidized dining, a corporate jet fleet, and chauffeured limousines.

The smaller the stake managers have in the company, the less their share in bearing the cost of excessive perquisite consumption—consequently, the less their desire to give their best efforts in running the company to maximize shareholder wealth. The costs arising from this conflict of interest have been called the **agency costs of equity**. Given that outside shareholders are aware of this conflict, they will take actions to monitor management and the board's activities that incur costs, such as requiring audited financial statements and holding annual meetings. Management will also take actions to assure owners they are working in the owners' best interest, such as the use of noncompete employment contracts and insurance to guarantee performance.

The better the company governance, the lower the agency costs. Good governance practices translate into higher shareholder value because managers' interests are better aligned with those of shareholders.

Additionally, agency theory predicts that a reduction in net agency costs of equity results from an increase in the use of debt versus equity. That is, there are savings in the agency costs of equity associated with the use of debt. Similarly, the more financially leveraged a company, the less freedom for managers to either take on more debt or unwisely spend cash. This is the foundation of Michael Jensen's **free cash flow hypothesis**. According to Jensen (1986), higher debt levels discipline managers by forcing them to manage the company efficiently so the company can make its interest and principal payments and by reducing the company's free cash flow and thus management's opportunities to misuse cash. This discipline can be especially important in emerging markets, in which there is a tendency to overinvest.

EXAMPLE 10

Agency Costs, Information Asymmetry, and Signaling

Cloudy Prospects plc, a small pharmaceutical company, is testing the potential for its primary drug, which is already in commercial production, to be used in a new application for which it was not intended: treatment of patients with a widespread virus. The company is managed by a team of medical scientists. Management hopes this new application for the drug could result in a big increase in sales and the value of the company. The company has been consistently profitable and debt-free.

Over the course of three months, the following occurs:

In June, while testing occurs, management monitors the results closely. Results are promising; the share price is stable.

In July, testing results continue to look promising. Anticipating that it might have to scale up production quickly, the company negotiates and announces a large increase in its credit line.

In August, Cloudy announces successful test results. The CEO receives a call from a headhunter, who thinks he might be a good candidate to head a larger competitor. The CEO takes the call and decides to meet the headhunter.

Which, if any of the following, are represented here, and by which event and when?

A Agency costs

B Information asymmetry

C Signaling

Solution:

A Agency costs. The CEO's decision in August to take the headhunter meeting about a possible opportunity with a competitor. If the CEO were acting solely in the interests of the shareholders of Cloudy Prospects, he would not take the meeting.

B Information asymmetry. Management had knowledge of the positive test results in June and July, before they were publicly announced in August.

C Signaling. The company's announcement in July that it is increasing its credit line can reasonably be taken as a signal of its confidence that test results will be positive and that it will need to expand production capacity. Note: This is true whether or not this signaling is intentional.

Next, we address competing stakeholder interests.

STAKEHOLDER INTERESTS

7

e describe competing stakeholder interests in capital structure decisions

In this coverage, we look at how and why stakeholder interests are affected when various capital structure decisions are taken by management. Stakeholder groups we consider include providers of capital, such as shareholders and debtholders, as well as others, such as customers, suppliers, employees, management, and the board.

7.1 Shareholder vs. Stakeholder Theory

In the traditional corporate governance framework, shareholders elect a board of directors, which in turn hires managers to serve the interests of shareholders. The interests of other stakeholders—such as debtholders, employees, customers, and society more broadly—are considered only to the extent that they affect shareholder value. This is referred to as the "shareholder theory" model. More recently, "stakeholder theory" advocates have argued that corporate governance should consider the interests of all stakeholders, not just shareholders. In some countries, stakeholder theory concepts have been put into law.

Stakeholder theory gives more prominence to ESG (environmental, social, and governance) considerations by making them an explicit objective for the board of directors and management. Doing this involves certain challenges: the complexity of balancing multiple objectives; a lack of clarity on how non-shareholder objectives are defined, measured, and balanced; the challenges of competing globally when competitors may not face similar constraints; as well as the direct costs in adhering to higher ESG standards.

Some of the principal stakeholder groups are shown in Exhibit 5.

Exhibit 5 Principal Stakeholder Groups

Providers of Capital

Equity shareholders

- Public (minority) common shareholders
- Controlling shareholders (founders, private equity)

Preferred shareholders

Debtholders

- Public debtholders
- Bank lenders
- Private lenders

Other Stakeholders

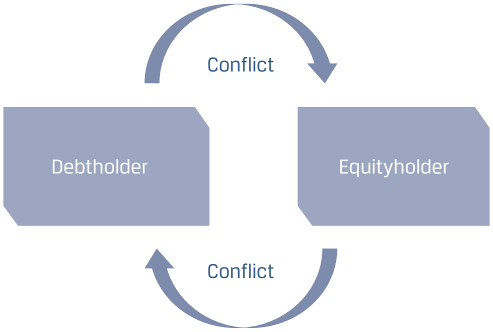
Customers
Suppliers
Employees
Managers
Directors
Regulators, Governments

Capital structure decisions impact stakeholder groups differently. In general, higher financial leverage increases risk for all stakeholders to varying degrees. However, the benefits of increased leverage, primarily through higher returns, accrue almost entirely to shareholders, often including senior management and the board. As a result, shareholders seeking higher returns from the company, and managers acting on their behalf, might prefer decisions that increase the company's financial leverage, while debtholders and other stakeholders in the company generally will not.

Next, we will look at the impact of capital structure decisions on debtholders vs. shareholders and then look more broadly at impacts on other capital providers and other stakeholder groups.

7.2 Debt vs. Equity Conflict

The conflict between equityholders and debtholders reflects their different positions in the capital structure and the different structure of risks and returns for each. Debtholders have a contractual and prior claim to cash flows and firm assets over equityholders. For a holder of debt to maturity, the return or upside is prescribed and limited, while the risk, or downside, is not. In other words, the risk–return profile for debtholders is very asymmetric. In contrast, equityholders typically have more downside risk but much higher upside return potential. As a result, debtholders will almost always favor decisions that reduce a company's leverage and financial risk, while common shareholders often prefer higher leverage levels that offer them greater return potential.



High leverage increases the potential conflict of interest between debtholders and shareholders. At high levels of leverage, the risk–return profile of shareholders becomes more asymmetric. The downside for an equity investor is never more than 100%, or the full value of their investment assuming no leverage or shorting. For highly leveraged companies, the upside reward for shareholders can be multiples of their initial investment. Meanwhile, for a holder of debt to maturity, the return, or upside, remains the face value of debt plus the coupon. However, downside risk for a debtholder increases with higher leverage and the increased probability that the company will be unable to meet its outstanding debt obligations. Similarly, lower leverage levels decrease downside risk for a debtholder as the probability that the company can make its debt obligations increases.

Let's look at a case study.

EXAMPLE 11

Acme Holdings Case Study

Acme Holdings (Acme), a hypothetical company, is planning to make an investment. Three scenarios, each with a different starting leverage for Acme, are compared for impact to Acme's shareholders and debtholders. The scenarios are:

Scenario 1. Normal leverage

Acme has a modest amount of debt, consistent with an investment-grade rating. Debt-to-equity ratio is 1:3.

Scenario 2. High leverage

Acme is highly leveraged, with debt comprising the majority of its capital structure. Debt-to-equity ratio is 9:1.

Scenario 3. Distress scenario

Acme has debt exceeding the value of its business; the intrinsic value of its equity is therefore zero. Debt-to-equity ratio is 1:0.

The case illustrates how the outcomes for shareholders and debtholders are different in each scenario and how management decisions may or may not compromise the interests of debtholders.

It is not necessary that you memorize or be able to replicate the calculations in this example. The purpose is simply to illustrate the debt/equity conflict of interest numerically.

Discussion:

Acme Holdings, with an enterprise value of $1 billion, is considering a $500 million investment to be financed using 50% new debt and 50% equity. The investment has a 50% probability of creating $1.2 billion in value, and a 50% probability of resulting in zero value, for an expected value of $600 million (i.e., 50% × $1.2 billion + 50% × $0). NPV is therefore $100 million (i.e., $600 million – $500 million). Post investment, Acme's enterprise value will either be $2.2 billion ($1.0 billion + $1.2 billion) or $1.0 billion ($1.0 billion + $0), with both outcomes having an equal probability.

Exhibit 6 shows the impact of the investment on equityholder and debtholder value. Columns A, B, C show Acme's pre- and post-investment capital. Columns D, E, F show the company's resulting enterprise value for each if the investment fails or succeeds with corresponding expected value. This value is then compared to the post-capital investment value with the difference being the impact from making the investment. The impact is either positive, negative, or neutral for each group. The last column indicates whether management is likely to proceed or not with the investment based on the expected impact to Acme's equityholders and debtholders.

In short, management is likely to make the investment when equityholders are expected to benefit, even if the impact to debtholders is negative. Management is not likely to make the investment when the impact to equityholders is negative, even if the impact to bondholders and the company is positive.

Exhibit 6 ACME Holdings: Scenarios Summary

	Capital Invested			Enterprise value, ending					
	Pre-investment	New investment	Post-investment	"Failure" (50% prob)	"Success" (50% prob)	Expected value	Impact on Value		Management will likely…
Scenario	A	B	C = A + B	D	E	F = 0.5D + 0.5E	G = F – C		
Scenario 1: Normal leverage									Proceed
Equity	750	250	1,000	500	1,700	1,100	100	Positive	
Debt	250	250	500	500	500	500	—	Neutral	
Total	1,000	500	1,500	1,000	2,200	1,600	100	Positive	
Scenario 2: High leverage									Proceed
Equity	100	250	350	—	1,050	525	175	Positive	
Debt	900	250	1,150	1,000	1,150	1,075	–75	Negative	
Total	1,000	500	1,500	1,000	2,200	1,600	100	Positive	
Scenario 3: Distress									Not proceed
Equity	—	250	250	—	450	225	–25	Negative	

(continued)

Exhibit 6 (Continued)

	Capital Invested			Enterprise value, ending					
	Pre-investment	New investment	Post-investment	“Failure” (50% prob)	“Success” (50% prob)	Expected value	Impact on Value		Management will likely…
Scenario	A	B	C = A + B	D	E	F = 0.5D + 0.5E	G = F – C		
Debt (face value 1,500)	1,000	250	1,250	1,000	1,750	1,375	125	Positive	
Total	1,000	500	1,500	1,000	2,200	1,600	100	Positive	

Scenario 1, 2, 3 “Failure”

D (Debt) = Minimum [Ending Total EV, C(Debt)]

D(Equity) = Ending Total EV – D(Debt)

Scenario 1, 2 “Success”

E(Debt) = Minimum [Ending Total EV, C(Debt)]

Scenario 3 “Success”

E (Debt) = Minimum [Ending Total EV, Face Value Debt + B (Debt)]

Scenario 1, 2, 3 “Success”

D(Equity) = Ending Total EV – D(Debt)

Now we look more closely at the numbers for each scenario:

Scenario 1: Normal Leverage

- Enterprise Value: If the investment fails, Acme is worth $1 billion. Debt capital of $500 million is covered with $500 million residual equity value. If the investment succeeds, Acme is worth $2.2 billion. Debt value remains covered at $500 million, and equityholder residual value is $1.7 billion.
- Outcome: The expected value for equity increases to $1.1 billion from $1.0 billion, so management makes the investment. The expected value of the debt remains unchanged at $500 million, and debtholders are no worse off since the enterprise value of the company ($1.6 billion) exceeds the value of the debt, regardless of whether the new investment succeeds or fails.

Scenario 2: High Leverage

- Enterprise Value: If the investment fails, debtholders lose $150 million ($1 billion – $1.15 billion) and equity value is 0. If the investment succeeds, debt value remains unchanged ($1.15 billion) and equity value increases to $1.05 billion ($2.2 billion – $1.15 billion).
- Outcome: Similar to Scenario 1, equityholders are better off with the investment, with an NPV of negative $350 million if the investment fails, which represents their full post investment value, but $700 million ($1.05 billion – $350 million) if it succeeds. In seeking to maximize equity value, management would make the investment. However, debtholders are worse off, losing $150 million if the investment fails and gaining nothing if it succeeds. In this case, there is a conflict of interest between equity investors and debtholders. Management's decision to make the investment for the benefit of equityholders compromises the interests of the company's debtholders.

Scenario 3: Distress Scenario

- Pre-Investment: Acme has debt with a face value of $1.5 billion and zero equity value.
- Enterprise Value: In this case, equity investors are worse off. If the investment fails, they lose the $250 million they contribute; if it succeeds, there is only $450 million in equity value, or $200 million after deducting the required equity investment, for an expected impact on value of negative $25 million. Debtholders, however, are better off. If the investment succeeds, they have a full recovery on their $250 million investment; if it fails, they lose $500 million ($1.5 billion – $1.0 billion). The expected value of negative $125 million ($1.375 billion – $1.5 billion) is better than without the investment (negative $250 million).
- Outcome: In this case, making the investment would create positive value for Acme, but in seeking to maximize equity value, management would not make the investment because the return to equityholders is negative. Management's decision once again compromises the interests of its bondholders in the interests of equityholders.

Distressed Debt: Observations The Acme Holdings example shows a distress scenario: The value of debt outstanding exceeds the value of the enterprise, and the company's equity has negative intrinsic value. Given this scenario, it would be difficult for Acme to raise new equity capital, and management may decline to make investments that would increase enterprise value.

In this situation, a financial restructuring is often a logical course of action. Restructuring can be involuntary, such as when the company is in default, or voluntary. In either situation, by exchanging debt for equity, the company's capital structure can be repaired, new investments can be financed, and the company can avoid liquidation—which is a very costly type of financial distress.

This situation can arise on a large scale during financial crises. It is particularly problematic in the banking sector given the critical role of banks in sustaining business investment. In such crises, the burden of bad loans on their balance sheets makes banks reluctant to make new loans, even if those new loans would be profitable on a stand-alone basis. In these situations, governments will often intervene to ensure that banks remain solvent and willing to make new loans.

When leverage and financial risk are high, the perspective of debtholders becomes more like that of equityholders. Normally, debt has low default risk and is priced to provide a modest yield to maturity. Return, or upside, is limited, unless the general level of interest rates declines. A holder of debt to maturity will be very focused on minimizing downside risk. However, with higher-risk debt, and particularly with distressed debt, the potential upside can be substantial if the company does not default or if recoveries in default are higher than expected. In these circumstances, the return profile, and thus perspective, of the debtholder becomes closer to that of an equity investor.

Other Debt Considerations

Seniority and Security Debtholder returns are influenced not only by the probability of default but also by the likely recoveries in the event of default. In a default scenario, secured lenders are likely to recover more of their principal than unsecured lenders; likewise, senior debt is likely to recover more than subordinated debt. Recall that senior debt is often secured, but not always. As a result, secured and senior lenders can better tolerate actions by management that increase the probability of default, such as new investment by the company or increasing the level of unsecured or subordinated debt.

Long-Term vs. Short-Term Debt The potential debt/equity conflict is greater in the case of long-term rather than short-term debt because the passage of time exposes debtholders to possible changes in business conditions, strategy, and management behavior.

Safeguards for Debtholders Management generally seeks to maximize equity value and thus may take actions that are unfavorable to debtholders. However, debtholders have the following safeguards to protect their interests:

- Debt covenants can be used to put contractual limits on future borrowing by the company and limit other management actions that would increase risk to debtholders. Positive covenants state what the borrower must do, such as maintaining financial ratios within certain thresholds. Ratios commonly used in debt covenants are drawn from the income and cash flow statements (cash coverage of interest or fixed charges), the balance sheet (minimum net worth, debt-to-equity ratio), or both (debt-to-EBITDA ratio). Negative covenants state what the borrower cannot do, such as additional secured borrowing or dividend payments.
- Companies generally want to preserve favorable access and terms to credit and so will act accordingly to maintain or improve their credit worthiness given they may need to borrow in the future. Management's track record—its statements and actions with respect to capital structure, investment, M&A, dividends, and strategy—will impact the company's future credit rating, banking relationships, and cost of borrowing.
- Financial distress costs can be substantial. Even with a primary focus on maximizing common share value, management will generally seek to keep default risk, and other stakeholder impacts from high leverage, at very low levels.

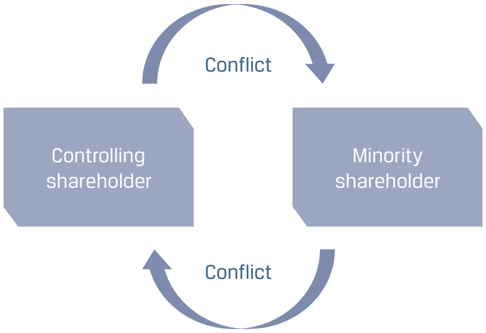
7.3 Preferred Shareholders

Preferred shares are often described as "hybrid" securities since they have both debt-like and equity-like characteristics. Holders of preferred shares rank before common equity shareholders but after debtholders in terms of security and priority of dividend payment. As with common shareholders, preferred shareholders provide long-term capital, with no maturity (repayment) date. Failure to pay a preferred dividend is not an event of default for a company, but it generally prevents the payment of dividends to common shareholders until preferred shareholders are paid. (In the case of cumulative preferred shares, any unpaid preferred dividends from prior periods must also be paid before common dividends can be paid.) The issuance of preferred equity therefore creates less risk for the company's debtholders and common shareholders than if the company were to issue debt. Whether issuing preferred equity is more attractive than issuing debt from a common shareholder perspective depends on the relative after-tax borrowing cost of the company.

Since they are providers of permanent capital and lack covenant protection, preferred shareholders are vulnerable to decisions that increase financial leverage and risk over the long term. For example, a company in a mature business might commit to a long-term policy of dividend growth and share repurchases. This strategy would result in higher financial leverage over the long term. Existing senior secured debtholders might be unconcerned, particularly for debt maturing relatively soon, since there is minimal default risk. However, preferred shareholders might be concerned that the new policy could gradually erode the company's capacity to pay preferred dividends.

7.4 Private Equity Investors/Controlling Shareholders

Not all shareholders have identical financial interests. Where there are one or more large shareholders, the issuance or retirement of common shares affects voting control of the company. Even when one shareholder is clearly in control, with a voting interest of more than 50%, that shareholder may have objectives that are at odds with those of minority shareholders. It is common for private equity majority shareholders to exercise control through the appointment of board members and senior management.



The specific circumstances are important.

- Where controlling shareholders have multiple voting shares, they can pursue expansion strategies and acquisitions that may not increase shareholder value and issue shares to do so, with no risk that minority shareholders or other stakeholders will block their actions. An example might be the acquisition of a sports team by a company in an unrelated business.
- A controlling shareholder seeking to sell its stake, such as a private equity backer, might take a very short-term view on financing, resisting any action that might result in dilution of its equity stake.
- Conversely, some companies that are founder-led and founder-controlled benefit from the fact that founders often take a very long-term perspective on their business, while minority shareholders might not. Amazon is a high-profile example since it has consistently sacrificed short-term profitability in favor of long-term growth and market share. Founder Jeff Bezos has allowed his ownership stake to be diluted as the company has grown.

7.5 Bank and Private Lenders

While the perspectives of lenders are broadly similar, there are stakeholder differences between holders of public debt, private debt, and bank lenders. These differences arise primarily from differences in investment time horizon and stakeholder access to information. Public market debtholders rely on public information and credit rating agency determinations to make their investment decisions. They may not hold debt securities to maturity, so their returns reflect changes in the price of the securities over time—not just the ability of the borrower to pay interest and principal. Bond prices are affected by many factors, including market conditions and shifting perceptions about the company and management, that may or may not impact returns for those who hold the company's debt to maturity.

Bank and private lenders generally hold company debt to maturity. They typically have direct access to company management and non-public information about the company, which in principle reduces information asymmetries. And since an individual bank or private lender can be a critical source of capital, particularly for a small- or mid-sized company, this type of lender has a degree of influence on the company. Such lenders can decide to relax debt covenants, extend more credit, or refuse to do so, which is much more difficult with public debt held by many parties. This is less true for large, "syndicated" loans involving multiple lenders.

Bank lending policies are generally conservative. Like other lenders, a bank will try to balance risk and return, but it must also meet regulatory reserve requirements that are based on the risk profile of their loan book. At the same time, banks generally have a close working relationship with the companies they finance. Banks often provide a range of services, such as payments, foreign currency transactions, and letters of credit, to the companies they finance. This close working relationship provides them with unique and immediate insights into the borrower's current and evolving financial condition and prospects. Bank loan covenants can also be tailored more easily to a borrower's situation than public debt covenants. For these reasons, banks tend to work with borrowers when the latter encounter financing difficulties.

With private lenders, like bank lenders, the general perspective of debtholders applies: Less financial leverage implies less risk and is therefore preferred. However, among private lenders, there is wide variation in their risk appetite, approach, behavior, and relationships with companies to whom they have provided capital. It is therefore difficult to generalize about their particular perspective. Some focus mainly on asset value, such as the collateral supporting their loan; some hold both debt and equity positions in the same company; some have an equity-like focus on the cash flows, value, and prospects of the business; and some lend to businesses they would be interested in owning if the borrowing company were to default on its payments.

7.6 Other Stakeholders

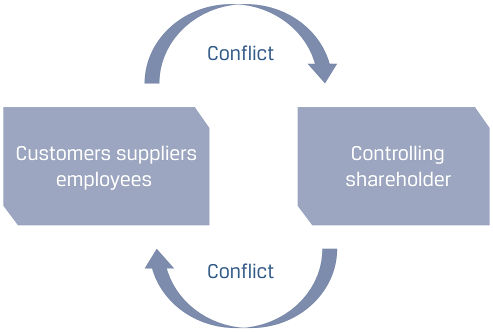
While conflicting interests with respect to capital structure decisions are most apparent with different capital providers, they also arise with other stakeholders.

7.6.1 *Customers and Suppliers*

Suppliers are typically short-term creditors. When companies are in financial distress, their financial position and their willingness to extend additional credit may be affected. However, their interest in the financial health of a customer company is often broader: Customers and suppliers make a substantial investment of time and effort in establishing vendor relationships and have a natural interest in a company's long-term stability. This might not be true for the provider of a commodity product, but it applies when products are specialized and when the customer or supplier makes a significant investment in the relationship—for example, through product design, retooling, training, or software customization. In business strategy terms, such relationships are described as having "switching barriers." Examples include insurance, software, training programs, specialized components, and equipment. In these cases, financial stability can be an important vendor selection criterion, even if there is no actual or anticipated financial distress.

7.6.2 *Employees*

Like suppliers, employees may have both a direct financial stake in their employer company through equity-oriented participation plans (such as profit-sharing, share purchase, or stock option plans) as well as a broader interest in the company's long-term stability, survival, and long-term growth. These are important considerations for companies in attracting and retaining talent. For most employees in most businesses, equity ownership is a minor part of compensation and less important than the company's stability and growth.



The difference in interests between customers, suppliers, employees, and owners is illustrated in the following example.

EXAMPLE 12

Leverage and Other Stakeholders—Mainly Metal Boats, Inc.

Mainly Metal Boats is a small, debt-free manufacturer of welded metal boats and is located in a remote small town. It sells both domestically and internationally in a market that is highly competitive and cyclical. Sales are through a network of dealers, who typically sell three or four different boat brands. Of the company's 50 employees, about half are specialized aluminum welders, with most others in sales and management. The primary purchased input for Mainly's boat production is sheet aluminum. Mainly's sole aluminum supplier is a large multinational company that has many clients. Mainly has not paid dividends previously and now has substantial retained earnings that finance the company's working capital. Mainly's owners have recently decided to borrow heavily to finance working capital so they can pay a large, one-time dividend from the retained earnings.

1. Which of the following stakeholder groups is likely to be most negatively affected by the increase in leverage?
   - **A** The welders employed by the company
   - **B** The company's dealers
   - **C** The supplier of aluminum to the business
2. Is it likely that any of these groups would be impacted positively?

Solution:

1 A is correct. As employees, the welders could face loss of employment if the company were to become financially distressed with the increase in leverage, and since their skills are very specialized, they would probably have difficulty finding another job locally. In a small and remote town, employment opportunities are likely to be limited for specialized workers.

B is incorrect. The dealers might suffer lost sales if Mainly were to fail, but they could likely replace Mainly with a competing brand.

C is incorrect. The aluminum supplier would probably suffer the least impact since it is large and Mainly is not likely a large proportion of its sales.

2 In all cases, impacts are negative. Note that for modest borrowing, these effects would be very minor.

7.6.3 *Management and Directors*

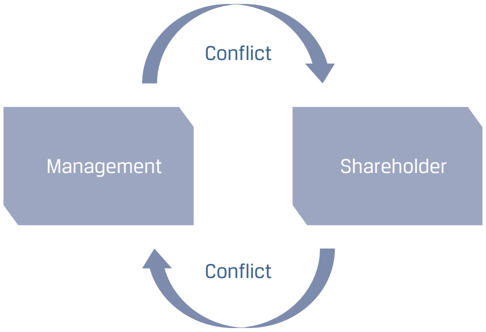
It is critical to consider the interests of management and the board since they make capital structure and business strategy decisions. In principle, management and the board are hired to maximize shareholder wealth, giving rise to the debt/equity conflict described and the risk that their actions will reduce value for debtholders to benefit shareholders.

In practice, compensation is the principal tool used to create alignment of interests between management and directors and shareholders. Equity compensation can be a substantial portion of their total compensation.

In principle, management compensation is intended to motivate managers to work hard to maximize shareholder value. However, the alignment of interests between managers and shareholders is never perfect. For example, the interests of owners are not necessarily identical to the interests of managers, who happen to receive shares and options as part of their compensation.

If we consider the typical elements of management compensation and the typical process by which compensation is determined (e.g., by a compensation committee of the board of directors), we can identify common examples of misalignment or conflicts:

- The overall level of director or executive compensation can be excessive. This is a cost to the company and can lead to "entrenchment," which is the avoidance of taking risk motivated by the desire to keep one's position. Directors, similarly motivated to keep their positions by compensation and prestige, may avoid speaking out against management in the interest of shareholders or other stakeholders.
- Where senior management compensation is high and tied to the size of the business, it can also lead to "growth for growth's sake" or "empire building," with managers motivated to pursue acquisitions and expansion that might not increase shareholder value. It is worth noting that managers two or three tiers below the CEO, whose careers and incomes are tied more to promotions than to the share price, may also be motivated to pursue questionable growth initiatives; it then falls to the CEO and the board to maintain financial and strategic discipline.
- Reliance on management stock options can motivate risk-taking behavior by their holders, particularly with respect to capital structure decisions, since optionholders participate only in upside share price moves.



The following highlights how this can occur.

EXAMPLE 13

Management Stock Options and Leverage

The company Binary Outcomes Ltd. is debt-free and has a share price of $100, with 1 million shares outstanding. Its intrinsic value is $100 million ($100 × 1 million). This is based on a 50% probability of a $110/share value and a 50% probability of a $90/share value. If management has options exercisable at $100, their current expected value is $5.

Is it in management's interest to increase leverage at the company, such as by issuing $50 million of debt to buy back shares?

Discussion:

As shown in Exhibit 7, it would be in management's interest to increase leverage, such as issuing debt to buy back 50% of the company's shares at $100 per share. This would increase debt by $50 million (purchase of 0.5 million shares at $100 per share) and reduce equity value by an equivalent amount, creating a 50% probability of a $120/share value and a 50% probability of an $80/share value. While there is no change in shareholder value, the leverage results in an increase in share value ($120) and corresponding option value ($20) in the upside scenario, while downside option value remains $0, with an average expected option value of $10. The use of leverage doubles the average expected value of management's options from $5 to $10.

Exhibit 7 Binary Outcomes Leverage Scenario

Scenario	Upside	Downside	Expected Value
Probability	50%	50%	
Firm value	$110,000,000	$90,000,000	$100,000,000
No leverage			
Debt	—	—	
Equity value	$110,000,000	$90,000,000	
Shares outstanding	1,000,000	1,000,000	
Share price	$110	$90	$100
Option exercise price	$100	$100	
Option value	$10	—	$5

(continued)

Exhibit 7 (Continued)

Scenario	Upside	Downside	Expected Value
With leverage			
Debt	$50,000,000	$50,000,000	
Equity value	$60,000,000	$40,000,000	
Shares outstanding	500,000	500,000	
Share price	$120	$80	$100
Option exercise price	$100	$100	
Option value	$20	—	$10

With typical management share option schemes, rather than paying dividends, management will be motivated to buy back shares with excess cash. This strategy benefits them by increasing the value of their share options. Similarly, management would be incentivized to retain profits rather than distribute them as a dividend to shareholders.

Continuing this example, if Binary Outcomes earns a profit of $10/share and adds $10/share in cash, retaining that profit would increase its intrinsic value from $100/share to $110/share, thus increasing the intrinsic value of management options by $5 (from $5 to $10). If the entire profit is instead distributed as a dividend, however, there would be no increase in intrinsic value for the shares or management's options.

To mitigate this issue, some companies pay executive performance bonuses in shares rather than options or have minimum share ownership requirements for senior managers and, in some cases, for directors.

In mature or stable businesses, compensation can skew heavily to salaries and bonuses tied to "easy" targets, and management complacency can be a risk. The business may not have enough upside to attract highly talented managers or enough influence to make management aggressively pursue incremental sales or cost efficiencies. In these cases, adding financial leverage is a common strategy, increasing both the incentives and pressure on management to maximize value.

When managers stay in their positions for only a few years, they may be motivated to pursue short-term rather than long-term objectives: They want to demonstrate success and keep their jobs, and they are unsure whether they will be with the company long enough to benefit from longer-term initiatives. From a shareholder perspective, the solution is not to avoid management turnover, but rather to ensure that it is based on performance (i.e., evaluated objectively and carefully) instead of on non-performance-related reasons.

Some of these misalignments offset each other. For example, stock options motivate risk-taking, while high cash compensation can create excessive caution and entrenchment.

7.6.4 *Regulators and Government*

Regulators and the government are often key stakeholders for a company. In some cases, the company's capital structure is an important consideration for regulators. Financial institutions must generally maintain certain levels of solvency or capital adequacy, as defined by regulators. Utilities may have pricing determined based on allowable rates of return, which depend on capital structure. Multinational companies may borrow or retain funds in offshore jurisdictions to minimize taxes, which governments may permit but may also view unfavorably.

Distressed companies may seek government support in order to remain in business, and those governments, in turn, may require new equity investments, block dividends, or otherwise constrain the company's financing decisions.

SUMMARY

- A company's stage in the life cycle, its cash flow characteristics, and its ability to support debt largely dictate its capital structure since capital not sourced through borrowing must come from equity (including retained earnings).
- Generally speaking, as companies mature and move from start-up, through growth, to mature, their business risk declines as operating cash flows turn positive with increasing predictability, allowing for greater use of leverage at more attractive terms.
- Modigliani and Miller's work shows us that managers cannot change firm value simply by changing the firm's capital structure. Firm value is independent of the capital structure decision.
- Given the tax deductibility of interest, adding leverage increases firm value to a point but also increases the risk of default for capital providers who demand higher returns in compensation.
- To maximize firm value, management should target the optimal capital structure that minimizes the company's weighted average cost of capital.
- In practice, financing decisions are typically tied to investment spending and based on the company's ability to support debt given the nature of its business and operating cash flows.
- Managers may provide investors with information ("signaling") through their choice of financing method. For example, commitments to fixed payments can signal management's confidence in the company's future prospects.
- Management's capital structure decisions impact various stakeholder groups differently. In seeking to maximize shareholder wealth or their own, conflicts of interest may arise in which one or more groups are favored at the expense of others.

PRACTICE PROBLEMS

1 Which of the following is *least* likely to affect the capital structure of Longdrive Trucking Company? Longdrive has moderate leverage today.

  A The acquisition of a major competitor for shares

  B A substantial increase in share price

  C The payment of a stock dividend

2 Which of the following is *least* accurate with respect to the market value and book value of a company's equity?

  A Market value is more relevant than book value when measuring a company's cost of capital.

  B Book value is often used by lenders and in financial ratio calculations.

  C Both market value and book value fluctuate with changes in the company's share price.

3 Which of these statements is *most* accurate with respect to the use of debt by a start-up fashion retailer with negative cash flow and uncertain revenue prospects?

  A Debt financing will be unavailable or very costly.

  B The company will prefer to use equity rather than debt given its uncertain cash flow outlook.

  C Both A and B.

4 Which of the following is true of the growth stage in a company's development?

  A Cash flow is negative, by definition, with investment outlays exceeding cash flow from operations.

  B Cash flow may be negative or positive.

  C Cash flow is positive and growing quickly.

5 Which of the following mature companies is *most likely* to employ a high proportion of debt in its capital structure?

  A A mining company with a large, fixed asset base

  B A software company with very stable and predictable revenues and an asset-light business model

  C An electric utility

6 Which of the following is *most likely* to occur as a company evolves from growth stage through maturity and seeks to optimize its capital structure?

  A The company relies on equity to finance its growth.

  B Leverage increases as the company needs more capital to support organic expansion.

  C Leverage increases as the company is able to support more debt.

7 If investors have homogeneous expectations, the market is efficient, and there are no taxes, no transaction costs, and no bankruptcy costs, Modigliani and Miller's Proposition I states that:

  A bankruptcy risk rises with more leverage.

  B managers cannot change the value of the company by changing the amount of debt.

© 2020 CFA Institute. All rights reserved.

  - **C** managers cannot increase the value of the company by employing tax-saving strategies.

8 According to Modigliani and Miller's Proposition II without taxes:

  - **A** the capital structure decision has no effect on the cost of equity.
  - **B** investment and the capital structure decisions are interdependent.
  - **C** the cost of equity increases as the use of debt in the capital structure increases.

9 The current weighted average cost of capital (WACC) for Van der Welde is 10%. The company announced a debt offering that raises the WACC to 13%. The *most likely* conclusion is that for Van der Welde:

  - **A** the company's prospects are improving.
  - **B** equity financing is cheaper than debt financing.
  - **C** the company's debt/equity has moved beyond the optimal range.

10 According to the static trade-off theory:

  - **A** debt should be used only as a last resort.
  - **B** companies have an optimal level of debt.
  - **C** the capital structure decision is irrelevant.

The following information relates to Questions 11–12

Nailah Mablevi is an equity analyst who covers the entertainment industry for Kwame Capital Partners, a major global asset manager. Kwame owns a significant position with a large unrealized capital gain in Mosi Broadcast Group (MBG). On a recent conference call, MBG's management states that they plan to increase the proportion of debt in the company's capital structure. Mablevi is concerned that any changes in MBG's capital structure will negatively affect the value of Kwame's investment.

To evaluate the potential impact of such a capital structure change on Kwame's investment, she gathers the information about MBG given in Exhibit 1.

Exhibit 1 Current Selected Financial Information for MBG

Yield to maturity on debt	8.00%
Market value of debt	$100 million
Number of shares of common stock	10 million
Market price per share of common stock	$30
Cost of capital if all equity-financed	10.3%
Marginal tax rate	35%

11 MBG is *best* described as currently:

  - **A** 25% debt-financed and 75% equity-financed.
  - **B** 33% debt-financed and 66% equity-financed.
  - **C** 75% debt-financed and 25% equity-financed.

12 Holding operating earnings constant, an increase in the marginal tax rate to 40% would:

A result in a lower cost of debt capital.

B result in a higher cost of debt capital.

C not affect the company's cost of capital.

13 Which of the following is *least likely* to be true with respect to optimal capital structure?

A The optimal capital structure minimizes WACC.

B The optimal capital structure is generally close to the target capital structure.

C Debt can be a significant portion of the optimal capital structure because of the tax-deductibility of interest.

14 Fran McClure of Alba Advisers is estimating the cost of capital of Frontier Corporation as part of her valuation analysis of Frontier. McClure will be using this estimate, along with projected cash flows from Frontier's new projects, to estimate the effect of these new projects on the value of Frontier. McClure has gathered the following information on Frontier Corporation:

	Current Year ($)	Forecasted for Next Year ($)
Book value of debt	50	50
Market value of debt	62	63
Book value of shareholders' equity	55	58
Market value of shareholders' equity	210	220

The weights that McClure should apply in estimating Frontier's cost of capital for debt and equity are, respectively:

A $w_d = 0.200$; $w_e = 0.800$.

B $w_d = 0.185$; $w_e = 0.815$.

C $w_d = 0.223$; $w_e = 0.777$.

15 Which of the following is *not* a reason why target capital structure and actual capital structure tend to differ?

A Financing is often tied to a specific investment.

B Companies raise capital when the terms are attractive.

C Target capital structure is set for a particular project, while actual capital structure is measured at the consolidated company level.

16 According to the pecking order theory:

A new debt is preferable to new equity.

B new debt is preferable to internally generated funds.

C new equity is always preferable to other sources of capital.

17 Vega Company has announced that it intends to raise capital next year, but it is unsure as to the appropriate method of raising capital. White, the CFO, has concluded that Vega should apply the pecking order theory to determine the appropriate method of raising capital. Based on White's conclusion, Vega should raise capital in the following order:

A debt, internal financing, equity.

B equity, debt, internal financing.

C internal financing, debt, equity.

18 Which of the following is *least* accurate with respect to debt–equity conflicts?

- **A** Equityholders focus on potential upside and downside, while debtholders focus primarily on downside risk.
- **B** Management attempts to balance the interests of equityholders and debtholders.
- **C** Debt covenants can mitigate the conflict between debtholders and equityholders.

19 Other factors being equal, in which of the following situations are debt–equity conflicts likely to increase?

- **A** Financial leverage is low.
- **B** The company's debt is secured.
- **C** The company's debt is long-term.

20 Which of the following stakeholders are *least likely* to be positively affected by increasing the proportion of debt in the capital structure?

- **A** Senior management
- **B** Non-management employees
- **C** Shareholders

21 Which of the following is an example of agency costs? In each case, management is advocating a substantial acquisition, and management compensation is comprised heavily of stock options.

- **A** Management believes the acquisition will be positive for shareholder value but negative for the value and interests of the company's debtholders.
- **B** Management's stock options are worthless at the current share price. The acquisition has a high (50%) risk of failure (with zero value) but substantial (30%) upside if it works out.
- **C** The acquisition is positive for equityholders and does not significantly impair the position of debtholders. However, the acquisition puts the company into a new business where labor practices are harsh and the production process is environmentally damaging.

22 Which of the following is *least likely* to be true with respect to agency costs and senior management compensation?

- **A** Equity-based incentive compensation is the primary method to address the problem of agency costs.
- **B** A well-designed compensation scheme should eliminate agency costs.
- **C** High cash compensation for senior management, without significant equity-based performance incentives, can lead to excessive caution and complacency.

SOLUTIONS

1 C is correct. Stock dividends, like stock splits, have no impact on the value of a company's equity. Issuing shares to acquire a competitor would increase equity relative to debt in the capital structure. Share price appreciation would also increase the market value of equity, thus increasing equity relative to debt.

2 C is correct. Share price changes will cause the market value of the company's equity to change; book value is unaffected.

Statements A and B are accurate.

3 C is correct. For a start-up company of this nature, debt financing is likely to be unattractive to lenders—and therefore very expensive or difficult to obtain. Debt financing is also unappealing to the company, because it commits the company to interest and principal payments that might be difficult to manage given its uncertain cash flow outlook.

4 B is correct. Cash flow typically turns positive during the growth stage, but it may be negative, particularly at the beginning of this stage.

5 C is correct. An electric utility has the capacity to support substantial debt, with very stable and predictable revenues and cash flows. The software company also has these attributes, but it would have been much less likely to have raised debt during its development and may have raised equity. The mining company has fixed assets, which it would have needed to finance, but the cyclical nature of its business would limit its debt capacity.

6 C is correct. As cash flows become more predictable, the company is able to support more debt in its capital structure; the optimal capital structure includes a higher proportion of debt. While mature companies do borrow to support growth, this would typically not occur because the company is optimizing its capital structure. Likewise, while a mature company might issue equity to finance growth, this would not be the typical approach for a company optimizing its capital structure.

7 B is correct. Proposition I, or the capital structure irrelevance theorem, states that in perfect markets the level of debt versus equity in the capital structure has no effect on company value.

8 C is correct. The cost of equity rises with the use of debt in the capital structure (e.g., with increasing financial leverage).

9 C is correct. If the company's WACC increases as a result of taking on additional debt, the company has moved beyond the optimal capital range. The costs of financial distress may outweigh any tax benefits to the use of debt.

10 B is correct. The static trade-off theory indicates that there is a trade-off between the tax shield from interest on debt and the costs of financial distress, leading to an optimal amount of debt in a company's capital structure.

11 A is correct. The market value of equity is (\$30)(10,000,000) = \$300,000,000. With the market value of debt equal to \$100,000,000, the market value of the company is \$100,000,000 + \$300,000,000 = \$400,000,000. Therefore, the company is \$100,000,000/\$400,000,000 = 0.25 or 25% debt-financed.

12 A is correct. The after-tax cost of debt decreases as the marginal tax rate increases.

13 B is correct. A company's optimal and target capital structures may be very different from one another.

14 C is correct.

w_d = \$63/(\$220 + 63) = 0.223.

w_e = \$220/(\$220 + 63) = 0.777.

Market values should be used in cost of capital calculations, and forecasted market values should be used in this case given that the cost of capital will be applied to *projected* cash flows in McClure's analysis.

15 C is correct. Companies generally raise finance when capital is needed, such as for investment spending or when market pricing and terms are favorable for debt or equity issuance.

16 A is correct. According to the pecking order theory, internally generated funds are preferable to both new equity and new debt. If internal financing is insufficient, managers next prefer new debt, then new equity. Managers prefer forms of financing with the least amount of visibility to outsiders.

17 C is correct. According to the pecking order theory, managers prefer internal financing. If internal financing is insufficient, managers next prefer debt, then equity in order of increasing visibility to outsiders.

18 B is correct. Management is generally focused on maximizing the value of equity.

19 C is correct. Long-term debt is more exposed than short-term debt to the risk of a management decision that is not debtholder-friendly. Secured debt is less exposed than unsecured debt to such a risk, and with low leverage, the risk of debt–equity conflict is reduced, not increased, relative to high leverage.

20 B is correct. While leverage increases risk for all stakeholders, shareholders generally benefit through higher potential returns. Senior management typically benefits through equity-based compensation. For non-management employees, equity-based compensation is likely to be small to non-existent.

21 B is correct. Management is advocating an acquisition that is likely to be positive for the value of the company's options but negative for equityholders given the substantial risk. A is an example of the debt–equity conflict. C is an example of stakeholder interests that are not being considered by management.

22 B is correct. A well-designed management compensation scheme can reduce, but not eliminate, agency costs.

LEARNING OUTCOMES

Mastery	*The candidate should be able to:*
☐	**a.** define and explain leverage, business risk, sales risk, operating risk, and financial risk and classify a risk;
☐	**b.** calculate and interpret the degree of operating leverage, the degree of financial leverage, and the degree of total leverage;
☐	**c.** analyze the effect of financial leverage on a company's net income and return on equity;
☐	**d.** calculate the breakeven quantity of sales and determine the company's net income at various sales levels;
☐	**e.** calculate and interpret the operating breakeven quantity of sales.

INTRODUCTION

1

This reading presents elementary topics in leverage. **Leverage** is the use of fixed costs in a company's cost structure. Fixed costs that are operating costs (such as depreciation or rent) create operating leverage. Fixed costs that are financial costs (such as interest expense) create financial leverage.

Analysts refer to the use of fixed costs as leverage because fixed costs act as a fulcrum for the company's earnings. Leverage can magnify earnings both up and down. The profits of highly leveraged companies might soar with small upturns in revenue. But the reverse is also true: Small downturns in revenue may lead to losses.

Analysts need to understand a company's use of leverage for three main reasons. First, the degree of leverage is an important component in assessing a company's risk and return characteristics. Second, analysts may be able to discern information about a company's business and future prospects from management's decisions about the use of operating and financial leverage. Knowing how to interpret these signals also helps

© 2019 CFA Institute. All rights reserved.

the analyst evaluate the quality of management's decisions. Third, the valuation of a company requires forecasting future cash flows and assessing the risk associated with those cash flows. Understanding a company's use of leverage should help in forecasting cash flows and in selecting an appropriate discount rate for finding their present value.

The reading is organized as follows: Section 2 introduces leverage and defines important terms. Sections 3–8 illustrate and discuss measures of operating leverage and financial leverage, which combine to define a measure of total leverage that gauges the sensitivity of net income to a given percent change in units sold. These sections also cover breakeven points in using leverage and corporate reorganization (a possible consequence of using leverage inappropriately). A summary and practice problems conclude this reading.

2

LEVERAGE

a define and explain leverage, business risk, sales risk, operating risk, and financial risk and classify a risk;

Leverage increases the volatility of a company's earnings and cash flows and increases the risk of lending to or owning a company. Additionally, the valuation of a company and its equity is affected by the degree of leverage: The greater a company's leverage, the greater its risk and, hence, the greater the discount rate that should be applied in its valuation. Further, highly leveraged (levered) companies have a greater chance of incurring significant losses during downturns, thus accelerating conditions that lead to financial distress and bankruptcy.

Consider the simple example of two companies, Impulse Robotics, Inc., and Malvey Aerospace, Inc. These companies have the following performance for the period of study:[1]

Exhibit 1 Impulse Robotics and Malvey Aerospace

	Impulse Robotics	Malvey Aerospace
Revenues	$1,000,000	$1,000,000
Operating costs	700,000	750,000
Operating income	$300,000	$250,000
Financing expense	100,000	50,000
Net income	$200,000	$200,000

These companies have the same net income, but are they identical in terms of operating and financial characteristics? Would we appraise these two companies at the same value? Not necessarily.

The risk associated with future earnings and cash flows of a company are affected by the company's cost structure. The **cost structure** of a company is the mix of variable and fixed costs. **Variable costs** fluctuate with the level of production and sales. Some examples of variable costs are the cost of goods purchased for resale, costs of materials or supplies, shipping charges, delivery charges, wages for hourly employees, sales commissions, and sales or production bonuses. **Fixed costs** are expenses that are the same regardless of the production and sales of the company. These costs include depreciation, rent, interest on debt, insurance, and wages for salaried employees.

---

[1] We are ignoring taxes for this example, but when taxes are included, the general conclusions remain the same.

Suppose that the cost structures of the companies differ in the manner shown in Exhibit 2.

Exhibit 2 Impulse Robotics and Malvey Aerospace

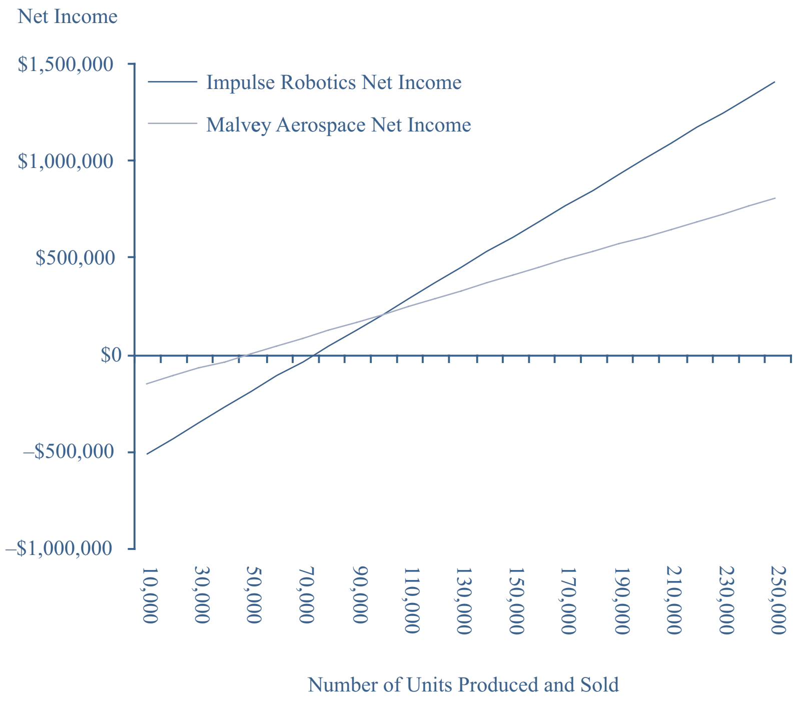
	Impulse Robotics	Malvey Aerospace
Number of units produced and sold	100,000	100,000
Sales price per unit	$10	$10
Variable cost per unit	$2	$6
Fixed operating cost	$500,000	$150,000
Fixed financing expense	$100,000	$50,000

The risk associated with these companies is different, although, as we saw in Exhibit 1, they have the same net income. They have different operating and financing cost structures, resulting in differing volatility of net income.

For example, if the number of units produced and sold is different from 100,000, the net income of the two companies diverges. If 50,000 units are produced and sold, Impulse Robotics has a loss of $200,000 and Malvey Aerospace has $0 earnings. If, on the other hand, the number of units produced and sold is 200,000, Impulse Robotics earns $1 million whereas Malvey Aerospace earns $600,000. In other words, the variability in net income is greater for Impulse Robotics, which has higher fixed costs in terms of both fixed operating costs and fixed financing costs.

Impulse Robotics' cost structure results in more leverage than that of Malvey Aerospace. We can see this effect when we plot the net income of each company against the number of units produced and sold, as in Exhibit 3. The greater leverage of Impulse Robotics is reflected in the greater slope of the line representing net income. This means that as the number of units sold changes, Impulse Robotics experiences a greater change in net income than does Malvey Aerospace for the same change in units sold.

Exhibit 3 Net Income for Different Numbers of Units Produced and Sold



Companies that have more fixed costs relative to variable costs in their cost structures have greater variation in net income as revenues fluctuate and, hence, more risk.

3 BUSINESS AND SALES RISKS

a define and explain leverage, business risk, sales risk, operating risk, and financial risk and classify a risk;

Risk arises from both the operating and financing activities of a company. In the following, we address how that happens and the measures available to the analyst to gauge the risk in each case.

3.1 Business Risk and Its Components

Business risk is the risk associated with operating earnings. Operating earnings are risky because total revenues are risky, as are the costs of producing revenues. Revenues are affected by a large number of factors, including economic conditions, industry dynamics (including the actions of competitors), government regulation, and demographics. Therefore, prices of the company's goods or services or the quantity of sales may be different from what is expected. We refer to the uncertainty with respect to the price and quantity of goods and services as **sales risk**.

Operating risk is the risk attributed to the operating cost structure, in particular the use of fixed costs in operations. The greater the fixed operating costs relative to variable operating costs, the greater the operating risk. Business risk is therefore the combination of sales risk and operating risk. Companies that operate in the same line of business generally have similar business risk.

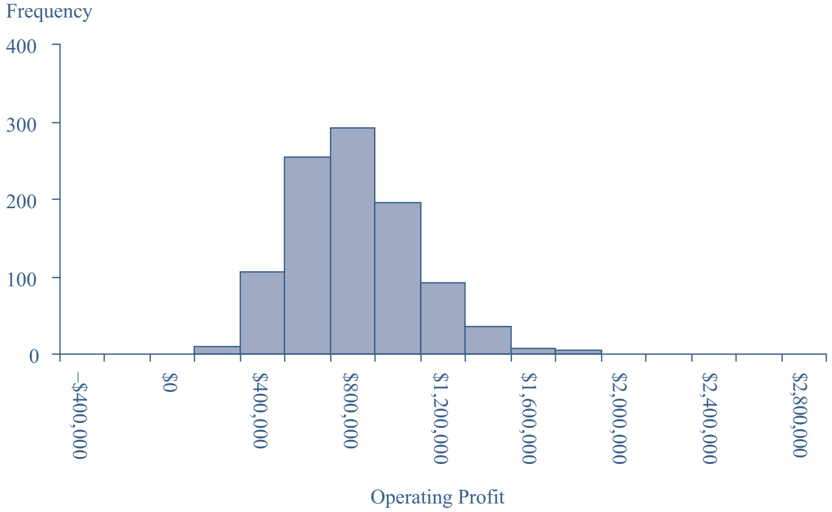
3.2 Sales Risk

Consider Impulse Robotics once again. Suppose that the forecasted number of units produced and sold in the next period is 100,000 but that the standard deviation of the number of units sold is 20,000. And suppose the price that the units sell for is expected to be $10 per unit but the standard deviation is $2. Contrast this situation with that of a company named Tolley Aerospace, Inc., which has the same cost structure but a standard deviation of units sold of 40,000 and a price standard deviation of $4.

If we assume, for simplicity's sake, that the fixed operating costs are known with certainty and that the units sold and price per unit follow a normal distribution, we can see the impact of the different risks on the operating income of the two companies through a simulation; the results are shown in Exhibit 4. Here, we see the differing distributions of operating income that result from the distributions of units sold and price per unit. So, even if the companies have the same cost structure, differing *sales risk* affects the potential variability of the company's profitability. In our example, Tolley Aerospace has a wider distribution of likely outcomes in terms of operating profit. This greater volatility in operating earnings means that Tolley Aerospace has more sales risk than Impulse Robotics.

Exhibit 4 Operating Income Simulations for Impulse Robotics and Tolley Aerospace

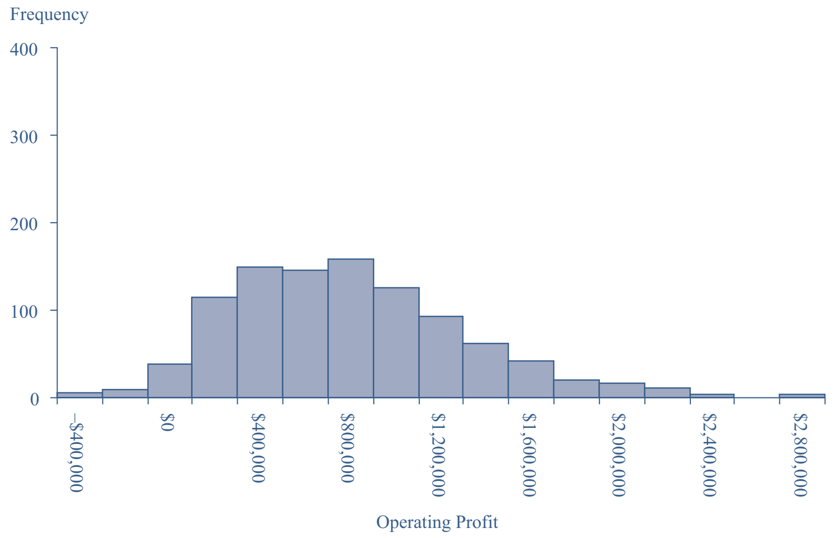
Panel A: Impulse Robotics



(continued)

Exhibit 4 (Continued)

Panel B: Tolley Aerospace



4 OPERATING RISK AND THE DEGREE OF OPERATING LEVERAGE

a define and explain leverage, business risk, sales risk, operating risk, and financial risk and classify a risk;

b calculate and interpret the degree of operating leverage, the degree of financial leverage, and the degree of total leverage;

The greater the fixed component of costs, the more difficult it is for a company to adjust its operating costs to changes in sales. The mixture of fixed and variable costs depends largely on the type of business. Even within the same line of business, companies can vary their fixed and variable costs to some degree. We refer to the risk arising from the mix of fixed and variable costs as **operating risk**. The greater the fixed operating costs relative to variable operating costs, the greater the operating risk.

Next, we look at how operating risk affects the variability of cash flows. A concept taught in microeconomics is **elasticity**, which is simply a measure of the sensitivity of changes in one item to changes in another. We can apply this concept to examine how sensitive a company's operating income is to changes in demand, as measured by unit sales. We will calculate the operating income elasticity, which we refer to as the **degree of operating leverage** (DOL). DOL is a quantitative measure of operating risk as it was defined earlier.

The degree of operating leverage is the ratio of the percentage change in operating income to the percentage change in units sold. We will simplify things and assume that the company sells all that it produces in the same period. Then,

$$\text{DOL} = \frac{\text{Percentage change in operating income}}{\text{Percentage change in units sold}} \quad (1)$$

For example, if DOL at a given level of unit sales is 2.0, a 5 percent increase in unit sales from that level would be expected to result in a (2.0)(5%) = 10 percent increase in operating income. As illustrated later in relation to Exhibit 6, a company's DOL is dependent on the level of unit sales being considered.

Returning to Impulse Robotics, the price per unit is \$10, the variable cost per unit is \$2, and the total fixed operating costs are \$500,000. If Impulse Robotics' output changes from 100,000 units to 110,000 units—an increase of 10 percent in the number of units sold—operating income changes from \$300,000 to \$380,000:[2]

Exhibit 5 Operating Leverage of Impulse Robotics

Item	Selling 100,000 Units	Selling 110,000 Units	Percentage Change
Revenues	\$1,000,000	\$1,100,000	+10.00
Less variable costs	200,000	220,000	+10.00
Less fixed costs	500,000	500,000	0.00
Operating income	\$300,000	\$380,000	+26.67

Operating income increases by 26.67 percent when units sold increases by 10 percent. What if the number of units *decreases* by 10 percent, from 100,000 to 90,000? Operating income is \$220,000, representing a *decline* of 26.67 percent.

What is happening is that for a 1 percent change in units sold, the operating income changes by 2.67 times that percentage, in the same direction. If units sold increases by 10 percent, operating income increases by 26.7 percent; if units sold decreased by 20 percent, operating income would decrease by 53.3 percent.

We can represent the degree of operating leverage as given in Equation 1 in terms of the basic elements of the price per unit, variable cost per unit, number of units sold, and fixed operating costs. Operating income is revenue minus total operating costs (with variable and fixed cost components):

$$\begin{aligned}\begin{matrix}\text{Operating}\\ \text{income}\end{matrix} &= \left[\begin{pmatrix}\text{Price}\\ \text{per unit}\end{pmatrix}\begin{pmatrix}\text{Number of}\\ \text{units sold}\end{pmatrix}\right]\\ &\quad -\left[\begin{pmatrix}\text{Variable cost}\\ \text{per unit}\end{pmatrix}\begin{pmatrix}\text{Number of}\\ \text{units sold}\end{pmatrix}\right]-\begin{bmatrix}\text{Fixed operating}\\ \text{costs}\end{bmatrix}\end{aligned}$$

or

$$\begin{matrix}\text{Operating}\\ \text{income}\end{matrix} = \underbrace{\begin{pmatrix}\text{Number of}\\ \text{units sold}\end{pmatrix}\left[\begin{pmatrix}\text{Price}\\ \text{per unit}\end{pmatrix}-\begin{pmatrix}\text{Variable cost}\\ \text{per unit}\end{pmatrix}\right]}_{\text{Contribution margin}}-\begin{bmatrix}\text{Fixed operating}\\ \text{costs}\end{bmatrix}$$

The **per unit contribution margin** is the amount that each unit sold contributes to covering fixed costs—that is, the difference between the price per unit and the variable cost per unit. That difference multiplied by the quantity sold is the **contribution margin**, which equals revenue minus variable costs.

---

[2] We provide the variable and fixed operating costs for our sample companies used in this reading to illustrate the leverage and breakeven concepts. In reality, however, the financial analyst does not have these breakdowns but rather is faced with interpreting reported account values that often combine variable and fixed costs and costs for different product lines.

How much does operating income change when the number of units sold changes? Fixed costs do not change; therefore, operating income changes by the contribution margin. The percentage change in operating income for a given change in units sold simplifies to

$$\text{DOL} = \frac{Q(P - V)}{Q(P - V) - F} \tag{2}$$

where Q is the number of units, P is the price per unit, V is the variable operating cost per unit, and F is the fixed operating cost. Therefore, $P - V$ is the per unit contribution margin and $Q(P - V)$ is the contribution margin.

Applying the formula for DOL using the data for Impulse Robotics, we can calculate the sensitivity to change in units sold from 100,000 units:

$$\begin{matrix}\text{DOL @} \\ 100{,}000\,\text{units}\end{matrix} = \frac{100{,}000(\$10 - \$2)}{100{,}000(\$10 - \$2) - \$500{,}000} = 2.67$$

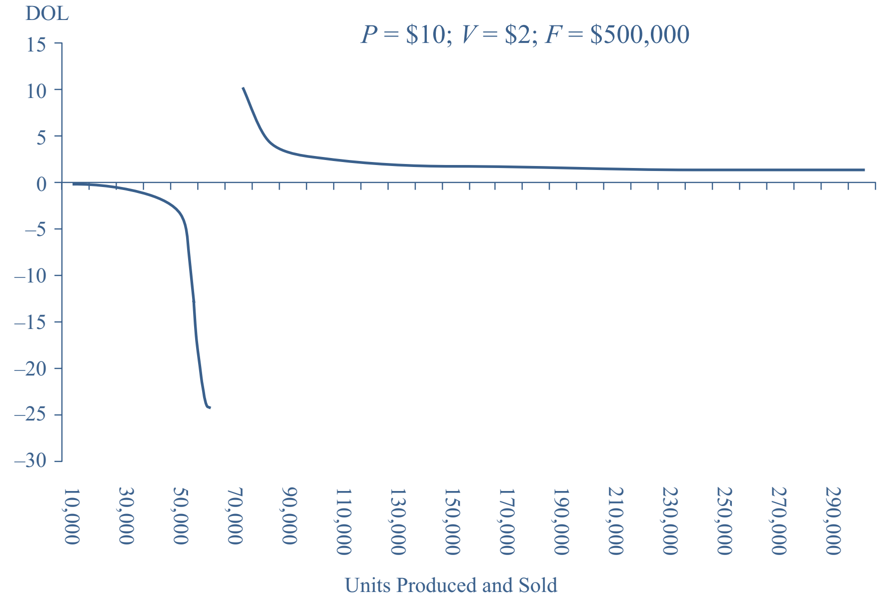
A DOL of 2.67 means that a 1 percent change in units sold results in a 1% × 2.67 = 2.67% change in operating income; a DOL of 5 means that a 1 percent change in units sold results in a 5 percent change in operating income, and so on.

Why do we specify that the DOL is at a particular quantity sold (in this case, 100,000 units)? Because the DOL is different at different numbers of units produced and sold. For example, at 200,000 units,

$$\begin{matrix}\text{DOL @} \\ 200{,}000\,\text{units}\end{matrix} = \frac{200{,}000(\$10 - \$2)}{200{,}000(\$10 - \$2) - \$500{,}000} = 1.45$$

We can see the sensitivity of the DOL for different numbers of units produced and sold in Exhibit 6. When operating profit is negative, the DOL is negative. At positions just below and just above the point where operating income is $0, operating income is at its most sensitive on a percentage basis to changes in units produced and sold. At the point at which operating income is $0 (at 62,500 units produced and sold in this example), the DOL is undefined because the denominator in the DOL calculation is $0. After this point, the DOL gradually declines as more units are produced and sold.

Exhibit 6 Impulse Robotics' Degree of Operating Leverage for Different Number of Units Produced and Sold



We will now look at a similar situation in which the company has shifted some of the operating costs away from fixed costs and into variable costs. Malvey Aerospace has a unit sales price of \$10, a variable cost of \$6 a unit, and \$150,000 in fixed costs. A change in units sold from 100,000 to 110,000 (a 10 percent change) changes operating profit from \$250,000 to \$290,000, or 16 percent. The DOL in this case is 1.6:

$$\begin{matrix}\text{DOL @}\\ 100{,}000\,\text{units}\end{matrix} = \frac{100{,}000(\$10 - \$6)}{100{,}000(\$10 - \$6) - \$150{,}000} = 1.6$$

and the change in operating income is 16 percent:

$$\begin{matrix}\text{Percentage change}\\ \text{in operating income}\end{matrix} = (\text{DOL})\begin{pmatrix}\text{Percentage change}\\ \text{in units sold}\end{pmatrix} = (1.6)(10\%) = 16\%$$

We can see the difference in leverage in the case of Impulse Robotics and Malvey Aerospace companies in Exhibit 7. In Panel A, we see that Impulse Robotics has higher operating income than Malvey Aerospace when both companies produce and sell more than 87,500 units, but lower operating income than Malvey when both companies produce and sell less than 87,500 units.[3]

Exhibit 7 Profitability and the DOL for Impulse Robotics and Malvey Aerospace

Impulse Robotics: P = \$10; V = \$2; F = \$500,000
Malvey Aerospace: P = \$10; V = \$6; F = \$150,000

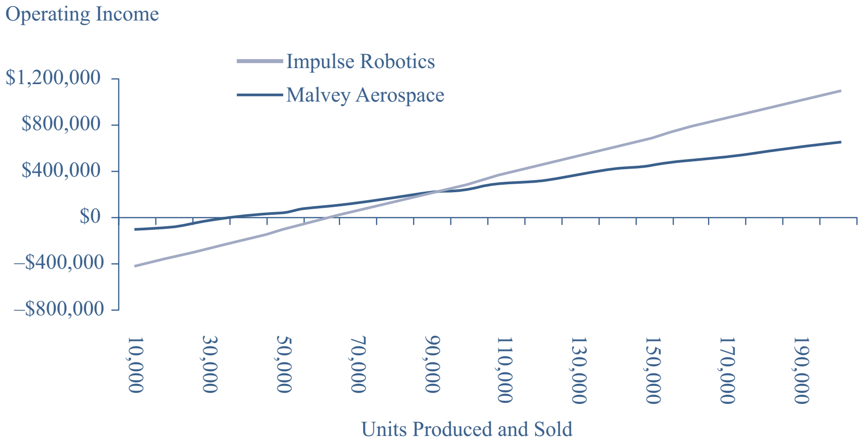
(continued)

---

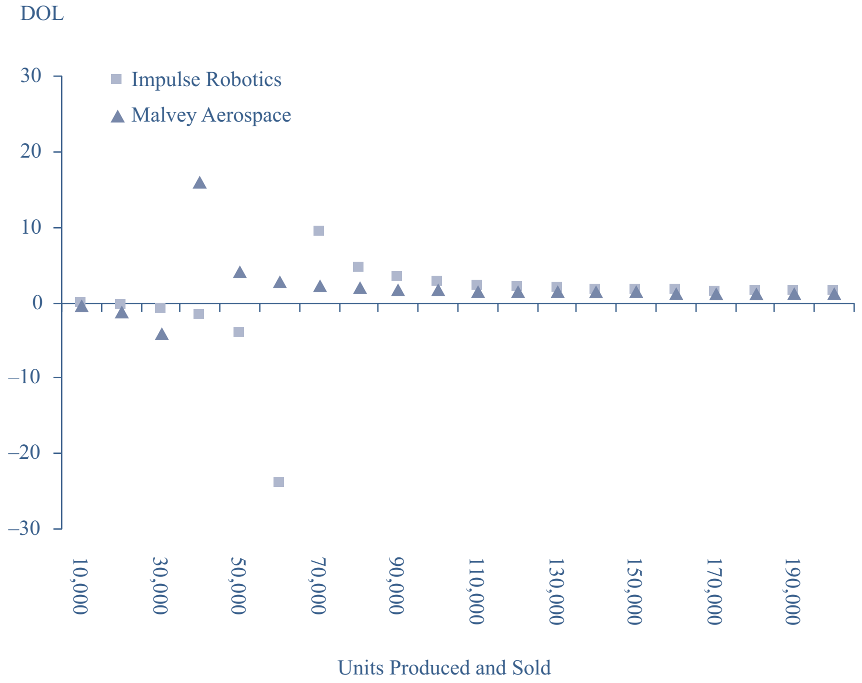
[3] We can calculate the number of units that produce the same operating income for these two companies by equating the operating incomes and solving for the number of units. Let X be the number of units. The X at which Malvey Aerospace and Impulse Robotics generate the same operating income is the X that solves the following: $10X - 2X - 500{,}000 = 10X - 6X - 150{,}000$; that is, $X = 87{,}500$.

Exhibit 7 (Continued)

Panel A: Operating Income and Number of Units Produced and Sold



Panel B: Degree of Operating Leverage (DOL)



This example confirms what we saw earlier in our reasoning of fixed and variable costs: The greater the use of fixed, relative to variable, operating costs, the more sensitive operating income is to changes in units sold and, therefore, the more operating risk. Impulse Robotics has more operating risk because it has more operating leverage. However, as Panel B of Exhibit 7 shows, the degrees of operating leverage are similar for the two companies for larger numbers of units produced and sold.

Both sales risk and operating risk influence a company's business risk. And both sales risk and operating risk are determined in large part by the type of business the company is in. But management has more opportunity to manage and control operating risk than sales risk.

Suppose a company is deciding which equipment to buy to produce a particular product. The sales risk is the same no matter what equipment is chosen to produce the product. But the available equipment may differ in terms of the fixed and variable operating costs of producing the product. Financial analysts need to consider how the operating cost structure of a company affects the company's risk.

EXAMPLE 1

Calculating the Degree of Operating Leverage

Arnaud Kenigswald is analyzing the potential impact of an improving economy on earnings at Global Auto, one of the world's largest car manufacturers. Global is headquartered in Berlin. Global Auto manufactures passenger cars and produces revenues of €168 billion. Kenigswald projects that sales will improve by 10 percent due to increased demand for cars. He wants to see how Global's earnings might respond given that level of increase in sales. He first looks at the degree of leverage at Global, starting with operating leverage.

Global sold 6 million passenger cars in 2017. The average price per car was €28,000, fixed costs associated with passenger car production total €15 billion per year, and variable costs per car are €20,500. What is the degree of operating leverage of Global Auto?

Solution:

$$\begin{array}{c}\text{DOL @}\\ \text{6 million units}\end{array} = \frac{\text{6 million (€28,000} - \text{€20,500)}}{\text{6 million (€28,000} - \text{€20,500)} - \text{€15 billion}} = 1.5$$

Operating income is [6 million × (€28,000 – €20,500)] – €15 billion = €30 billion

For a 10 percent increase in cars sold, operating income increases by 1.50 × 10% = 15.0%.

Industries that tend to have high operating leverage are those that invest up front to produce a product but spend relatively little on making and distributing it. Software developers and pharmaceutical companies fit this description. Alternatively, retailers have low operating leverage because much of the cost of goods sold is variable.

Because most companies produce more than one product, the ratio of variable to fixed costs is difficult to obtain. We can get an idea of the operating leverage of a company by looking at changes in operating income in relation to changes in sales for the entire company. This relation can be estimated by regressing changes in operating income (the variable to be explained) on changes in sales (the explanatory variable) over a recent time period.[4] Although this approach does not provide a precise measure of operating risk, it can help provide a general idea of the amount of operating leverage present. For example, compare the relation between operating earnings and revenues for Delta Air Lines, a transportation company, and Wal-Mart Stores, a discount retailer, as shown in Exhibit 8. Note that the slope of the least-squares regression line is greater for Delta Air Lines (with a slope coefficient of 0.1702) than for Wal-Mart (with a slope coefficient of 0.0493). (A visual comparison of slopes should not be relied upon because the scales of the *x*- and *y*-axes are different in diagrams for the two regressions.) We can see that operating earnings are more sensitive to changes in revenues for the higher-operating-leveraged Delta Air Lines as compared to the lower-operating-leveraged Wal-Mart Stores.

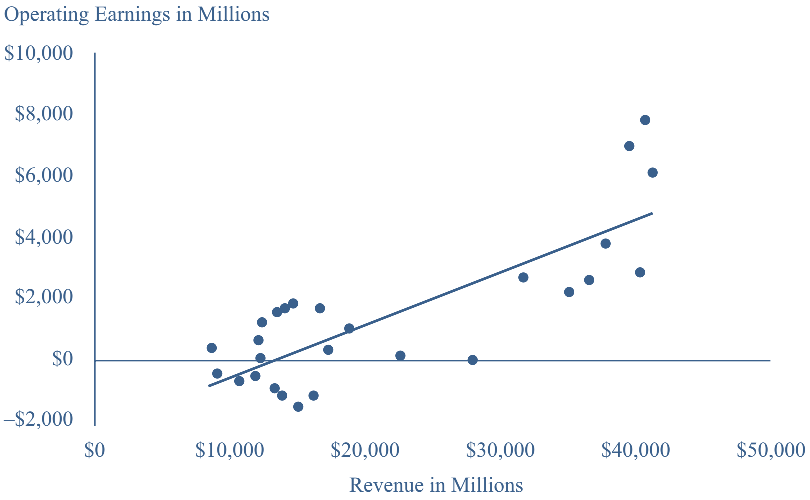
---

[4] A least-squares regression is a procedure for finding the best-fitting line (called the least squares regression line) through a set of data points by minimizing the squared deviations from the line.

Exhibit 8 Relation between Operating Earnings and Revenues

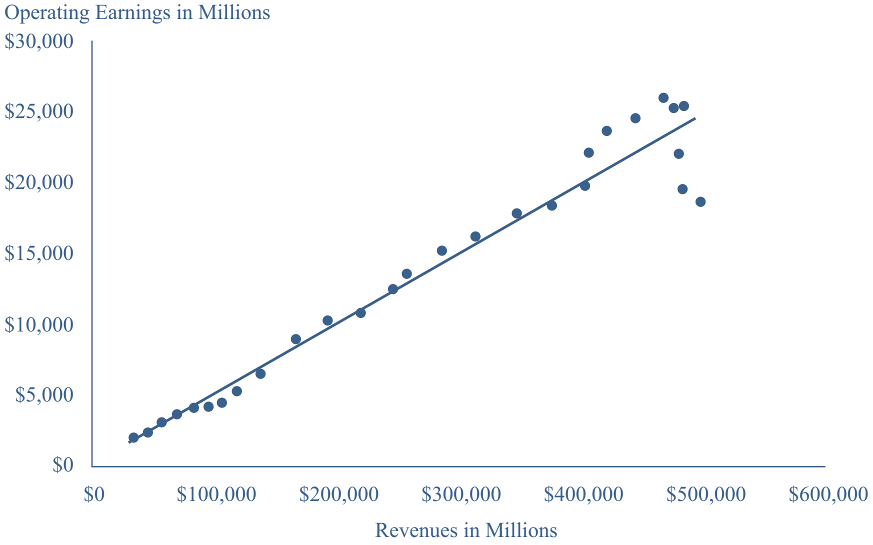
Panel A: Delta Airlines Operating Earnings and Revenues, 1990–2017

Estimated regression: Operating earnings = –$2,249 + 0.1702 Revenues
R^2 = 64.73%



Panel B: Wal-Mart Stores Operating Earnings and Revenues, 1990–2017

Estimated regression: Operating earnings = $253.16 + 0.0493 Revenues
R^2 = 94.89%



Sources: Delta Air Lines 10-K filings and Wal-Mart Stores 10-K filings, various years.

FINANCIAL RISK, THE DEGREE OF FINANCIAL LEVERAGE AND THE LEVERAGING ROLE OF DEBT

5

a define and explain leverage, business risk, sales risk, operating risk, and financial risk and classify a risk;

b calculate and interpret the degree of operating leverage, the degree of financial leverage, and the degree of total leverage;

c analyze the effect of financial leverage on a company's net income and return on equity;

We can expand on the concept of risk to accommodate the perspective of owning a security. A security represents a claim on the income and assets of a business; therefore, the risk of the security goes beyond the variability of operating earnings to include how the cash flows from those earnings are distributed among the claimants—the creditors and owners of the business. The risk of a security is therefore affected by both business risk and financial risk.

Financial risk is the risk associated with how a company finances its operations. If a company finances with debt, it is legally obligated to pay the amounts that make up its debts when due. By taking on fixed obligations, such as debt and long-term leases, the company increases its financial risk. If a company finances its business with common equity, generated either from operations (retained earnings) or from issuing new common shares, it does not incur fixed obligations. The more fixed-cost financial obligations (e.g., debt) incurred by the company, the greater its financial risk.

We can quantify this risk in the same way we did for operating risk, looking at the sensitivity of the cash flows available to owners when operating income changes. This sensitivity, which we refer to as the **degree of financial leverage** (DFL), is

$$\text{DFL} = \frac{\text{Percentage change in net income}}{\text{Percentage change in operating income}} \qquad (3)$$

For example, if DFL at a given level of operating income is 1.1, a 5 percent increase in operating income would be expected to result in a (1.1)(5%) = 5.5 percent increase in net income. A company's DFL is dependent on the level of operating income being considered.

Net income is equal to operating income, less interest and taxes.[5] If operating income changes, how does net income change? Consider Impulse Robotics. Suppose the interest payments are $100,000 and, for simplicity, the tax rate is 0 percent: If operating income changes from $300,000 to $360,000, net income changes from $200,000 to $260,000:

---

[5] More complex entities than we have been using for our examples may also need to account for other income (losses) and extraordinary income (losses) together with operating income as the basis for earnings before interest and taxes.

Exhibit 9 Financial Risk of Impulse Robotics (1)

	Operating Income of $300,000	Operating Income of $360,000	Percentage Change
Operating income	$300,000	$360,000	+20
Less interest	100,000	100,000	0
Net income	$200,000	$260,000	+30

A 20 percent increase in operating income increases net income by $60,000, or 30 percent. What if the fixed financial costs are $150,000? A 20 percent change in operating income results in a 40 percent change in the net income, from $150,000 to $210,000:

Exhibit 10 Financial Risk of Impulse Robotics (2)

	Operating Income of $300,000	Operating Income of $360,000	Percentage Change
Operating income	$300,000	$360,000	+20
Less interest	150,000	150,000	0
Net income	$150,000	$210,000	+40

Using more debt financing, which results in higher fixed costs, increases the sensitivity of net income to changes in operating income. We can represent the sensitivity of net income to a change in operating income, continuing the notation from before and including the fixed financial cost, *C*, and the tax rate, *t*, as

$$\text{DFL} = \frac{\left[Q\left(P - V\right) - F\right]\left(1 - t\right)}{\left[Q\left(P - V\right) - F - C\right]\left(1 - t\right)} = \frac{\left[Q\left(P - V\right) - F\right]}{\left[Q\left(P - V\right) - F - C\right]} \tag{4}$$

As you can see in Equation 4, the factor that adjusts for taxes, (1 – *t*), cancels out of the equation. In other words, the DFL is not affected by the tax rate.

In the case in which operating income is $300,000 and fixed financing costs are $100,000, the degree of financial leverage is

$$\begin{array}{c}\text{DFL @}\\ \text{\$300,000 operating income}\end{array} = \frac{\$300{,}000}{\$300{,}000 - \$100{,}000} = 1.5$$

If, instead, fixed financial costs are $150,000, the DFL is equal to 2.0:

$$\begin{array}{c}\text{DFL @}\\ \text{\$300,000 operating income}\end{array} = \frac{\$300{,}000}{\$300{,}000 - \$150{,}000} = 2.0$$

Again, we need to qualify our degree of leverage by the level of operating income because DFL is different at different levels of operating income.

The greater the use of financing sources that require fixed obligations, such as interest, the greater the sensitivity of net income to changes in operating income.

EXAMPLE 2

Calculating the Degree of Financial Leverage

Global Auto also employs debt financing. If Global can borrow at 8 percent, the interest cost is €18 billion. What is the degree of financial leverage of Global Auto if 6 million cars are produced and sold?

Solution:

At 6 million cars produced and sold, operating income = €30 billion. Therefore:

$$\begin{array}{c}\text{DFL @}\\ \text{€30 billion operating income}\end{array} = \frac{\text{€30 billion}}{\text{€30 billion} - \text{€18 billion}} = 2.5$$

For every 1 percent change in operating income, net income changes 2.5 percent due to financial leverage.

Unlike operating leverage, the degree of financial leverage is most often a choice by the company's management. Whereas operating costs are very similar among companies in the same industry, competitors may decide on differing capital structures.

Companies with relatively high ratios of tangible assets to total assets may be able to use higher degrees of financial leverage than companies with relatively low ratios because the claim on the tangible assets that lenders would have in the event of a default may make lenders more confident in extending larger amounts of credit. In general, businesses with plants, land, and equipment that can be used to collateralize borrowings and businesses whose revenues have below-average business cycle sensitivity may be able to use more financial leverage than businesses without such assets and with relatively high business cycle sensitivity.

Using financial leverage generally increases the variability of return on equity (net income divided by shareholders' equity). In addition, its use by a profitable company may increase the level of return on equity. Example 3 illustrates both effects.

EXAMPLE 3

The Leveraging Role of Debt

Consider the Capital Company, which is expected to generate $1,500,000 in revenues and $500,000 in operating earnings next year. Currently, the Capital Company does not use debt financing and has assets of $2,000,000.

Suppose Capital were to change its capital structure, buying back $1,000,000 of stock and issuing $1,000,000 in debt. If we assume that interest on debt is 5 percent and income is taxed at a rate of 30 percent, what is the effect of debt financing on Capital's net income and return on equity if operating earnings may vary as much as 40 percent from expected earnings?

Exhibit 11 Return on Equity of Capital Company

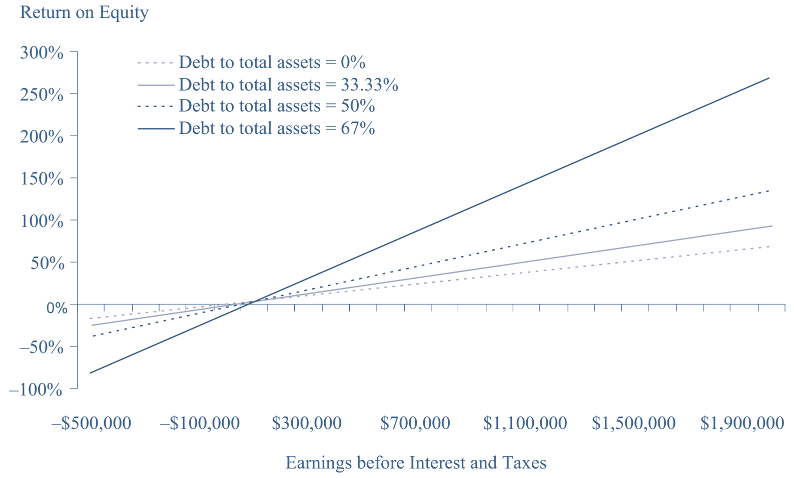
No Debt (Shareholders' Equity = $2 million)	Expected Operating Earnings, Less 40%	Expected Operating Earnings	Expected Operating Earnings, Plus 40%
Earnings before interest and taxes	$300,000	$500,000	$700,000
Interest expense	0	0	0
Earnings before taxes	$300,000	$500,000	$700,000
Taxes	90,000	150,000	210,000
Net income	$210,000	$350,000	$490,000
Return on equity[1]	10.5%	17.5%	24.5%

Debt to Total Assets = 50%; (Shareholders' Equity = $1 million)	Expected Operating Earnings, Less 40%	Expected Operating Earnings	Expected Operating Earnings, Plus 40%
Earnings before interest and taxes	$300,000	$500,000	$700,000
Interest expense	50,000	50,000	50,000
Earnings before taxes	$250,000	$450,000	$650,000
Taxes	75,000	135,000	195,000
Net income	$175,000	$315,000	$455,000
Return on equity	17.5%	31.5%	45.5%

[1] Recall that ROE is calculated as net income/shareholders' equity.

Depicting a broader array of capital structures and operating earnings, ranging from an operating loss of $500,000 to operating earnings of $2,000,000, Exhibit 12 shows the effect of leverage on the return on equity for Capital Company:

Exhibit 12 Return on Equity of Capital Company for Different Levels of Operating Earnings and Different Financing Choices



Business is generally an uncertain venture. Changes in the macroeconomic and competitive environments that influence sales and profitability are typically difficult to discern and forecast. The larger the proportion of debt in the financing mix of a business, the greater is the chance that it will face default. Similarly, the greater the proportion of debt in the capital structure, the more earnings are magnified upward in improving economic times. The bottom line? Financial leverage tends to increase the risk of ownership for shareholders.

TOTAL LEVERAGE AND THE DEGREE OF TOTAL LEVERAGE

6

a define and explain leverage, business risk, sales risk, operating risk, and financial risk and classify a risk;

b calculate and interpret the degree of operating leverage, the degree of financial leverage, and the degree of total leverage;

The degree of operating leverage gives us an idea of the sensitivity of operating income to changes in revenues. And the degree of financial leverage gives us an idea of the sensitivity of net income to changes in operating income. But often we are concerned about the combined effect of both operating leverage and financial leverage. Owners are concerned about the combined effect because both factors contribute to the risk associated with their future cash flows. And financial managers, making decisions intended to maximize owners' wealth, need to be concerned with how investment decisions (which affect the operating cost structure) and financing decisions (which affect the capital structure) affect lenders' and owners' risk.

Look back at the example of Impulse Robotics. The sensitivity of owners' cash flow to a given change in units sold is affected by both operating and financial leverage. Consider using 100,000 units as the base number produced and sold. A 10 percent increase in units sold results in a 27 percent increase in operating income and a 40 percent increase in net income; a like decrease in units sold results in a similar decrease in operating income and net income.

Exhibit 13 Total Leverage of Impulse Robotics

	Units Produced and Sold:		
	90,000	**100,000**	**110,000**
Revenues	\$900,000	\$1,000,000	\$1,100,000
Less variable costs	180,000	200,000	220,000
Less fixed costs	500,000	500,000	500,000
Operating income	\$220,000	\$300,000	\$380,000
Less interest	100,000	100,000	100,000
Net income	\$120,000	\$200,000	\$280,000
Relative to 100,000 units produced and sold			
Percentage change in units sold	–10%		+10%
Percentage change in operating profit	–27%		+27%
Percentage change in net income	–40%		+40%

Combining a company's degree of operating leverage with its degree of financial leverage results in the **degree of total leverage** (DTL), a measure of the sensitivity of net income to changes in the number of units produced and sold. We again make the simplifying assumption that a company sells all that it produces in the same period:

$$\text{DTL} = \frac{\text{Percentage change in net income}}{\text{Percentage change in the number of units sold}} \tag{5}$$

or

$$\begin{aligned}\text{DTL} &= \underbrace{\frac{Q(P-V)}{Q(P-V)-F}}_{\text{DOL}} \times \underbrace{\frac{[Q(P-V)-F]}{[Q(P-V)-F-C]}}_{\text{DFL}} \\ &= \frac{Q(P-V)}{Q(P-V)-F-C}\end{aligned} \tag{6}$$

Suppose

Number of units sold = Q = 100,000
Price per unit = P = \$10
Variable cost per unit = V = \$2
Fixed operating cost = F = \$500,000
Fixed financing cost = C = \$100,000

Then,

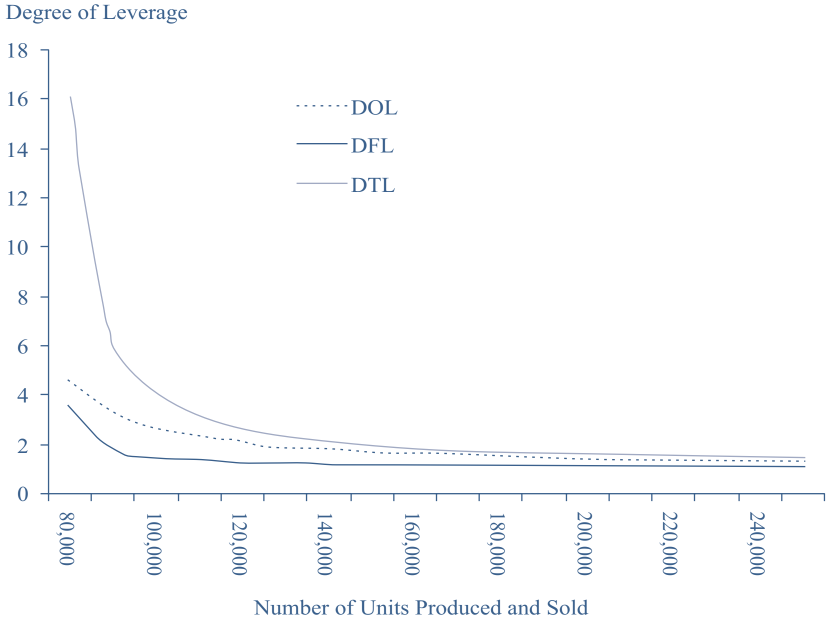
$$\text{DTL} = \frac{100{,}000(\$10-\$2)}{100{,}000(\$10-\$2)-\$500{,}000-\$100{,}000} = 4.0$$

which we could also have determined by multiplying the DOL, 2.67, by the DFL, 1.5. This means that a 1 percent increase in units sold will result in a 4 percent increase in net income; a 50 percent increase in units produced and sold results in a 200 percent increase in net income; a 5 percent decline in units sold results in a 20 percent decline in income to owners; and so on.

Because the DOL is relative to the base number of units produced and sold and the DFL is relative to the base level of operating earnings, DTL is different depending on the number of units produced and sold. We can see the DOL, DFL, and DTL for Impulse Robotics for different numbers of units produced and sold, beginning at the number of units for which the degrees are positive, in Exhibit 14.

Exhibit 14 DOL, DFL, and DTL for Different Numbers of Units Produced and Sold

P = \$10, V = \$2, F = \$500,000, C = \$100,000



In the case of operating leverage, the fixed operating costs act as a fulcrum. The greater the proportion of operating costs that are fixed, the more sensitive operating income is to changes in sales. In the case of financial leverage, the fixed financial costs, such as interest, act as a fulcrum. The greater the proportion of financing with fixed cost sources, such as debt, the more sensitive cash flows available to owners are to changes in operating income. Combining the effects of both types of leverage, we see that fixed operating and financial costs together increase the sensitivity of earnings to owners.

EXAMPLE 4

Calculating the Degree of Total Leverage

Continuing from Examples 1 and 2, Global Auto's total leverage is

$$\begin{matrix}\text{DTL @}\\ \text{6 million units}\end{matrix} = \begin{matrix}\text{DOL @}\\ \text{6 million units}\end{matrix} \times \begin{matrix}\text{DFL @}\\ \text{€30 billion}\end{matrix}$$

$$\begin{matrix}\text{DTL @}\\ \text{6 million units}\end{matrix} = \frac{6\text{ million}\left(€28{,}000 - €20{,}500\right)}{\left[6\text{ million}\left(€28{,}000 - €20{,}500\right) - €15\text{ billion}\right] - €18\text{ billion}}$$

$$= \frac{€45\text{ billion}}{€12\text{ billion}} = 3.75$$

$$\begin{matrix}\text{DTL @}\\ \text{6 million units}\end{matrix} = 1.5 \times 2.5 = 3.75$$

Given Global Auto's operating and financial leverage, a 1 percent change in unit sales changes net income by 3.75 percent.

7 BREAKEVEN POINTS AND OPERATING BREAKEVEN POINTS

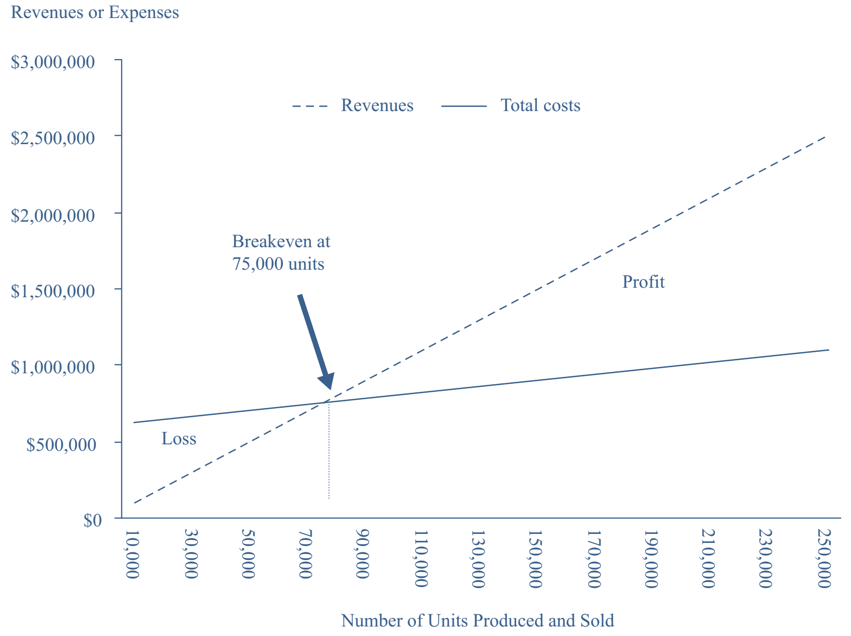
d calculate the breakeven quantity of sales and determine the company's net income at various sales levels;

e calculate and interpret the operating breakeven quantity of sales.

Looking back at Exhibit 3, we see that there is a number of units at which the company goes from being unprofitable to being profitable—that is, the number of units at which the net income is zero. This number is referred to as the breakeven point. The **breakeven point**, Q_{BE}, is the number of units produced and sold at which the company's net income is zero—the point at which revenues are equal to costs.

Plotting revenues and total costs against the number of units produced and sold, as in Exhibit 15, indicates that the breakeven is at 75,000 units. At this number of units produced and sold, revenues are equal to costs and, hence, profit is zero.

Exhibit 15 Impulse Robotics Breakeven



We can calculate this breakeven point for Impulse Robotics and Malvey Aerospace. Consider that net income is zero when the revenues are equal to the expenses. We can represent this equality of revenues and costs (summing variable operating costs, fixed operating costs, and fixed financing costs) by the following equation:

$$PQ = VQ + F + C$$

where

P = the price per unit
Q = the number of units produced and sold
V = the variable cost per unit
F = the fixed operating costs
C = the fixed financial cost

Therefore,

$$PQ_{BE} = VQ_{BE} + F + C$$

and the breakeven number of units, Q_{BE}, is[6]

$$Q_{BE} = \frac{F + C}{P - V} \tag{7}$$

In the case of Impulse Robotics and Malvey Aerospace, Impulse Robotics has a higher breakeven point. Using numbers taken from Exhibit 2:

$$\text{Impulse Robotics: } Q_{BE} = \frac{\$500{,}000 + \$100{,}000}{\$10 - \$2} = 75{,}000 \text{ units}$$

$$\text{Malvey Aerospace: } Q_{BE} = \frac{\$150{,}000 + \$50{,}000}{\$10 - \$6} = 50{,}000 \text{ units}$$

---

[6] You will notice that we did not consider taxes in our calculation of the breakeven point. This is because at the point of breakeven, taxable income is zero.

This means that Impulse Robotics must produce and sell more units to achieve a profit. So, while the higher-leveraged Impulse Robotics has a greater breakeven point relative to Malvey Aerospace, the profit that Impulse Robotics generates beyond this breakeven point is greater than that of Malvey Aerospace. Therefore, leverage has its rewards in terms of potentially greater profit, but it also increases risk.

In addition to the breakeven point specified in terms of net income, Q_{BE}, we can also specify the breakeven point in terms of operating profit, which we refer to as the **operating breakeven** point, Q_{OBE}. Revenues at the operating breakeven point are set equal to operating costs at the operating breakeven point to solve for the operating breakeven number of units, Q_{OBE}. The expression shows Q_{OBE} as equal to fixed operating costs divided by the difference between price per unit and variable cost per unit:

$$PQ_{OBE} = VQ_{OBE} + F$$

$$Q_{OBE} = \frac{F}{P - V}$$

For the two companies in our example, Impulse Robotics and Malvey Aerospace, the operating breakevens are 62,500 and 37,500 units, respectively:

$$\text{Impulse Robotics: } Q_{OBE} = \frac{\$500{,}000}{\$10 - \$2} = 62{,}500 \text{ units}$$

$$\text{Malvey Aerospace: } Q_{OBE} = \frac{\$150{,}000}{\$10 - \$6} = 37{,}500 \text{ units}$$

Impulse Robotics has a higher operating breakeven point in terms of the number of units produced and sold.

EXAMPLE 5

Calculating Operating Breakeven and Breakeven Points

Continuing with his analysis, Kenigswald considers the effect of a possible downturn on Global Auto's earnings. He divides the fixed operating costs of €15 billion by the per unit contribution margin:

$$Q_{OBE} = \frac{\text{€15 billion}}{\text{€28,000} - \text{€20,500}} = 2 \text{ million cars}$$

The operating breakeven for Global is 2,000,000 cars, or €56 billion in revenues. We calculate the breakeven point by dividing fixed operating costs, plus interest costs, by the contribution margin:

$$Q_{BE} = \frac{\text{€15 billion} + \text{€18 billion}}{\text{€28,000} - \text{€20,500}} = 4{,}400{,}000$$

Considering the degree of total leverage, Global's breakeven is 4.4 million cars, or revenues of €123.2 billion.

We can verify these calculations by constructing an income statement for the breakeven sales (in € billions):

	2,000,000 Cars	**4,400,000 Cars**
Revenues (= $P \times Q$)	€56.0	€123.2
Variable operating costs (= $V \times Q$)	41.0	90.2
Fixed operating costs (F)	15.0	15.0
Operating income	**€0**	€18.0
Fixed financial costs (C)	18.0	18.0
Net income	–€18.0	**€0**

As business expands or contracts beyond or below breakeven points, fixed costs do not change. The breakeven points for companies with low operating and financial leverage are less important than those for companies with high leverage. Companies with greater total leverage must generate more revenue to cover fixed operating and financing costs. The farther unit sales are from the breakeven point for high-leverage companies, the greater the magnifying effect of this leverage.

THE RISKS OF CREDITORS AND OWNERS

8

As we discussed earlier, business risk refers to the effect of economic conditions as well as the level of operating leverage. Uncertainty about demand, output prices, and costs are among the many factors that affect business risk. When conditions change for any of these factors, companies with higher business risk experience more volatile earnings. Financial risk is the additional risk that results from the use of debt and preferred stock. The degree of financial risk grows with greater use of debt. Who bears this risk?

The risk for providers of equity and debt capital differs because of the relative rights and responsibilities associated with the use of borrowed money in a business. Lenders have a prior claim on assets relative to shareholders, so they have greater security. In return for lending money to a business, lenders require the payment of interest and principal when due. These contractual payments to lenders must be made regardless of the profitability of the business. A business must satisfy these claims in a timely fashion or face the pain of bankruptcy should it default. In return for their higher priority in claims, lenders get predefined yet limited returns.

In contrast, equity providers claim whatever is left over after all expenses, including debt service, have been paid. So, unlike the fixed and known commitments to the lenders, what is left over for the owners may be a great deal or may be nothing. In exchange for this risk, providers of equity capital exercise the decision-making power over the business, including the right to hire, guide, and if necessary, fire managers. In public companies, ownership rights are usually exercised through an elected board of directors. They undertake the decisions over what portion of the business's earnings should be paid out as dividends for common shareholders.

Legal codes in most countries provide for these rights, as well as conditions for companies to file for bankruptcy (with reference to businesses, often called insolvency). A number of bankruptcy codes provide in some form for two categories of bankruptcies. One form provides for a temporary protection from creditors so that a viable business may reorganize. In the United States, the US Bankruptcy Code sets the terms for the form of negotiated **reorganization** of a company's capital structure that allows it to remain a going concern in Chapter 11.[7] For businesses that are not viable, the second form of bankruptcy process allows for the orderly satisfaction of the creditors' claims. In the United States, this form of bankruptcy is referred to as **liquidation**.[8] Whereas both types of bankruptcy lead to major dislocations in the rights and privileges of owners, lenders, employees, and managers, it is in this latter category of bankruptcy that the original business ceases to exist.

---

[7] US Code, Title 11—Bankruptcy, Chapter 11—Reorganization. Companies filing for bankruptcy under this code are referred to as having filed for Chapter 11 bankruptcy.

[8] US Code, Title 11—Bankruptcy, Chapter 7—Liquidation.

The difference between a company that reorganizes and emerges from bankruptcy and one that is liquidated is often the difference between operating and financial leverage. Companies with high operating leverage have less flexibility in making changes, and bankruptcy protection does little to help reduce operating costs. Companies with high financial leverage use bankruptcy laws and protection to change their capital structure and, once the restructuring is complete, can emerge as ongoing concerns.

EXAMPLE 6

Dow Corning: In and Out of Chapter 11 Bankruptcy

Dow Corning, a leading silicone producer, was a joint venture of Dow Chemical and Corning Inc. Dow Chemical filed for bankruptcy protection using Chapter 11 in 1995 as a result of the lawsuits related to silicone implants. The company was profitable at the time of filing, with more than $500 million in net income in 1994, but the potential liability from lawsuits, initially estimated around $2 billion, was significant when compared to its $4 billion in total assets. In 2004, Dow Corning emerged from bankruptcy, and in 2016 Dow Chemical completed the acquisition of 100 percent of Dow Corning, which currently operates as a wholly owned subsidiary of Dow Chemical Company.

EXAMPLE 7

Retailers Do Not Deliver

Traditional brick-and-mortar retail stores have been challenged with competition from online retailers. Whereas some retailers successfully added online access, others have struggled to compete effectively. A number of US retail stores filed for bankruptcy protection in 2017 and 2018, including Radio Shack, Nine West, Toys R Us, Brookstone, Payless, and hhgregg. Though some of these retailers were “reborn” online (e.g., hhgregg.com), others liquidated (e.g., Toys R Us), and many are closing stores and working closely with creditors to stave off liquidation.

Whereas the ability to file for bankruptcy is important to the economy, the goal of most investors is to avoid ownership of companies that are heading toward this extreme step, as well as to be able to evaluate opportunities among companies already in bankruptcy. Under both Chapter 7 and Chapter 11, providers of equity capital generally lose all value during the bankruptcy. On the other hand, debtholders typically receive at least a portion of their capital, but the payments of principal and interest are delayed during the period of bankruptcy protection.

SUMMARY

In this reading, we have reviewed the fundamentals of business risk, financial risk, and measures of leverage.

- Leverage is the use of fixed costs in a company’s cost structure. Business risk is the risk associated with operating earnings and reflects both sales risk (uncertainty with respect to the price and quantity of sales) and operating risk (the risk related to the use of fixed costs in operations). Financial risk is the risk associated with how a company finances its operations (i.e., the split between equity and debt financing of the business).

- The degree of operating leverage (DOL) is the ratio of the percentage change in operating income to the percentage change in units sold. We can use the following formula to measure the degree of operating leverage:

$$\text{DOL} = \frac{Q(P-V)}{Q(P-V)-F}$$

- The degree of financial leverage (DFL) is the percentage change in net income for a one percent change in operating income. We can use the following formula to measure the degree of financial leverage:

$$\text{DFL} = \frac{\left[Q(P-V)-F\right](1-t)}{\left[Q(P-V)-F-C\right](1-t)} = \frac{\left[Q(P-V)-F\right]}{\left[Q(P-V)-F-C\right]}$$

- The degree of total leverage (DTL) is a measure of the sensitivity of net income to changes in unit sales, which is equivalent to DTL = DOL × DFL.
- The breakeven point, Q_{BE}, is the number of units produced and sold at which the company's net income is zero, which we calculate as

$$Q_{\text{BE}} = \frac{F+C}{P-V}$$

- The operating breakeven point, Q_{OBE}, is the number of units produced and sold at which the company's operating income is zero, which we calculate as

$$Q_{\text{OBE}} = \frac{F}{P-V}$$

PRACTICE PROBLEMS

1 If two companies have identical unit sales volume and operating risk, they are *most likely* to also have identical:

A sales risk.

B business risk.

C sensitivity of operating earnings to changes in the number of units produced and sold.

2 Degree of operating leverage is *best* described as a measure of the sensitivity of:

A net earnings to changes in sales.

B fixed operating costs to changes in variable costs.

C operating earnings to changes in the number of units produced and sold.

3 The Fulcrum Company produces decorative swivel platforms for home televisions. If Fulcrum produces 40 million units, it estimates that it can sell them for $100 each. Variable production costs are $65 per unit and fixed production costs are $1.05 billion. Which of the following statements is *most accurate*? Holding all else constant, the Fulcrum Company would:

A generate positive operating income if unit sales were 25 million.

B have less operating leverage if fixed production costs were 10 percent greater than $1.05 billion.

C generate 20 percent more operating income if unit sales were 5 percent greater than 40 million.

4 The business risk of a particular company is *most accurately* measured by the company's:

A debt-to-equity ratio.

B efficiency in using assets to generate sales.

C operating leverage and level of uncertainty about demand, output prices, and competition.

5 Consider two companies that operate in the same line of business and have the same degree of operating leverage: the Basic Company and the Grundlegend Company. The Basic Company and the Grundlegend Company have, respectively, no debt and 50 percent debt in their capital structure. Which of the following statements is *most accurate*? Compared to the Basic Company, the Grundlegend Company has:

A a lower sensitivity of net income to changes in unit sales.

B the same sensitivity of operating income to changes in unit sales.

C the same sensitivity of net income to changes in operating income.

6 Myundia Motors now sells 1 million units at ¥3,529 per unit. Fixed operating costs are ¥1,290 million and variable operating costs are ¥1,500 per unit. If the company pays ¥410 million in interest, the levels of sales at the operating breakeven and breakeven points are, respectively:

A ¥1,500,000,000 and ¥2,257,612,900.

B ¥2,243,671,760 and ¥2,956,776,737.

C ¥2,975,148,800 and ¥3,529,000,000.

© 2011 CFA Institute. All rights reserved.

7 Juan Alavanca is evaluating the risk of two companies in the machinery industry: The Gearing Company and Hebelkraft, Inc. Alavanca used the latest fiscal year's financial statements and interviews with managers of the respective companies to gather the following information:

	The Gearing Company	**Hebelkraft, Inc.**
Number of units produced and sold	1 million	1.5 million
Sales price per unit	\$200	\$200
Variable cost per unit	\$120	\$100
Fixed operating cost	\$40 million	\$90 million
Fixed financing expense	\$20 million	\$20 million

Based on this information, the breakeven points for The Gearing Company and Hebelkraft, Inc. are:

A 0.75 million and 1.1 million units, respectively.

B 1 million and 1.5 million units, respectively.

C 1.5 million and 0.75 million units, respectively.

The following information relates to Questions 8–16

Mary Benn, CFA, is a financial analyst for Twin Fields Investments, located in Storrs, Connecticut, USA. She has been asked by her supervisor, Bill Cho, to examine two small Japanese cell phone component manufacturers: 4G, Inc. and Qphone Corp. Cho indicates that his clients are most interested in the use of leverage by 4G and Qphone. Benn states, "I will have to specifically analyze each company's respective business risk, sales risk, operating risk, and financial risk." "Fine, I'll check back with you shortly," Cho, answers.

Benn begins her analysis by examining the sales prospects of the two firms. The results of her sales analysis appear in Exhibit 1. She also expects very little price variability for these cell phones. She next gathers more data on these two companies to assist her analysis of their operating and financial risk.

When Cho inquires as to her progress Benn responds, "I have calculated Qphone's degree of operating leverage (DOL) and degree of financial leverage (DFL) at Qphone's 2009 level of unit sales. I have also calculated Qphone's breakeven level for unit sales. I will have 4G's leverage results shortly."

Cho responds, "Good, I will call a meeting of some potential investors for tomorrow. Please help me explain these concepts to them, and the differences in use of leverage by these two companies. In preparation for the meeting, I have a number of questions":

- "You mentioned business risk; what is included in that?"
- "How would you classify the risk due to the varying mix of variable and fixed costs?"
- "Could you conduct an analysis and tell me how the two companies will fare relative to each other in terms of net income if their unit sales increased by 10 percent above their 2009 unit sales levels?"
- "Finally, what would be an accurate verbal description of the degree of total leverage?"

The relevant data for analysis of 4G is contained in Exhibit 2, and Benn's analysis of the Qphone data appears in Exhibit 3:

Exhibit 1 Benn's Unit Sales Estimates for 4G, Inc. and Qphone Corp.

Company	2009 Unit Sales	Standard Deviation of Unit Sales	2010 Expected Unit Sales Growth Rate (%)
4G, Inc.	1,000,000	25,000	15
Qphone Corp.	1,500,000	10,000	15

Exhibit 2 Sales, Cost, and Expense Data for 4G, Inc. (At Unit Sales of 1,000,000)

Number of units produced and sold	1,000,000
Sales price per unit	¥108
Variable cost per unit	¥72
Fixed operating cost	¥22,500,000
Fixed financing expense	¥9,000,000

Exhibit 3 Benn's Analysis of Qphone (At Unit Sales of 1,500,000)

Degree of operating leverage	1.40
Degree of financial leverage	1.15
Breakeven quantity (units)	571,429

8 Based on Benn's analysis, 4G's sales risk relative to Qphone's is *most likely* to be:

A lower.

B equal.

C higher.

9 What is the *most appropriate* response to Cho's question regarding the components of business risk?

A Sales risk and financial risk.

B Operating risk and sales risk.

C Financial risk and operating risk.

10 The *most appropriate* response to Cho's question regarding the classification of risk arising from the mixture of variable and fixed costs is:

A sales risk.

B financial risk.

C operating risk.

11 Based on the information in Exhibit 2, the degree of operating leverage (DOL) of 4G, Inc., at unit sales of 1,000,000, is *closest* to:

A 1.60.

B 2.67.

C 3.20.

12 Based on the information in Exhibit 2, 4G, Inc.'s degree of financial leverage (DFL), at unit sales of 1,000,000, is *closest* to:

A 1.33.

B 2.67.

C 3.00.

13 Based on the information in Exhibit 1 and Exhibit 3, Qphone's expected percentage change in operating income for 2010 is *closest* to:

A 17.25%.

B 21.00%.

C 24.30%.

14 4G's breakeven quantity of unit sales is *closest* to:

A 437,500 units.

B 625,000 units.

C 875,000 units.

15 In response to Cho's question regarding an increase in unit sales above 2009 unit sales levels, it is *most likely* that 4G's net income will increase at:

A a slower rate than Qphone's.

B the same rate as Qphone's.

C a faster rate than Qphone's.

16 The *most appropriate* response to Cho's question regarding a description of the degree of total leverage is that degree of total leverage is:

A the percentage change in net income divided by the percentage change in units sold.

B the percentage change in operating income divided by the percentage change in units sold.

C the percentage change in net income divided by the percentage change in operating income.

SOLUTIONS

1 C is correct. The companies' degree of operating leverage should be the same, consistent with C. Sales risk refers to the uncertainty of the number of units produced and sold and the price at which units are sold. Business risk is the joint effect of sales risk and operating risk.

2 C is correct. The degree of operating leverage is the elasticity of operating earnings with respect to the number of units produced and sold. As an elasticity, the degree of operating leverage measures the sensitivity of operating earnings to a change in the number of units produced and sold.

3 C is correct. Because DOL is 4, if unit sales increase by 5 percent, Fulcrum's operating earnings are expected to increase by 4 × 5% = 20%. The calculation for DOL is:

$$\begin{aligned}\text{DOL} &= \frac{(40\text{ million})(\$100-\$65)}{\left[(40\text{ million})(\$100-\$65)\right]-\$1.05\text{ billion}}\\ &= \frac{\$1.400\text{ billion}}{\$1.400\text{ billion}-\$1.05\text{ billion}} = \frac{\$1.4}{\$0.35} = 4\end{aligned}$$

4 C is correct. Business risk reflects operating leverage and factors that affect sales (such as those given).

5 B is correct. Grundlegend's degree of operating leverage is the same as Basic Company's, whereas Grundlegend's degree of total leverage and degree of financial leverage are higher.

6 B is correct.

$$\text{Operating breakeven units} = \frac{¥1{,}290\text{ million}}{(¥3{,}529-¥1{,}500)} = 635{,}781.173\text{ units}$$

$$\text{Operating breakeven sales} = ¥3{,}529 \times 635{,}781.173\text{ units} = ¥2{,}243{,}671{,}760$$

or

$$\text{Operating breakeven sales} = \frac{¥1{,}290\text{ million}}{1-(¥1{,}500/¥3{,}529)} = ¥2{,}243{,}671{,}760$$

$$\begin{aligned}\text{Total breakeven} &= \frac{¥1{,}290\text{ million}+¥410\text{ million}}{(¥3{,}529-¥1{,}500)} = \frac{¥1{,}700\text{ million}}{¥2{,}029}\\ &= 837{,}851.1582\text{ units}\end{aligned}$$

$$\text{Breakeven sales} = ¥3{,}529 \times 837{,}851.1582\text{ units} = ¥2{,}956{,}776{,}737$$

or

$$\text{Breakeven sales} = \frac{¥1{,}700\text{ million}}{1-(¥1{,}500/¥3{,}529)} = ¥2{,}956{,}776{,}737$$

7 A is correct. For The Gearing Company,

$$Q_{\text{BE}} = \frac{F+C}{P-V} = \frac{\$40\text{ million}+\$20\text{ million}}{\$200-\$120} = 750{,}000$$

For Hebelkraft, Inc.,

$$Q_{\text{BE}} = \frac{F+C}{P-V} = \frac{\$90\text{ million}+\$20\text{ million}}{\$200-\$100} = 1{,}100{,}000$$

8 C is correct. Sales risk is defined as uncertainty with respect to the price or quantity of goods and services sold. 4G has a higher standard deviation of unit sales than Qphone; in addition, 4G's standard deviation of unit sales stated as a fraction of its level of unit sales, at 25,000/1,000,000 = 0.025, is greater than the comparable ratio for Qphone, 10,000/1,500,000 = 0.0067.

9 B is correct. Business risk is associated with operating earnings. Operating earnings are affected by sales risk (uncertainty with respect to price and quantity), and operating risk (the operating cost structure and the level of fixed costs).

10 C is correct. Operating risk refers to the risk arising from the mix of fixed and variable costs.

11 B is correct. $\text{DOL} = \dfrac{Q(P-V)}{Q(P-V)-F}$

$$\begin{array}{c}\text{DOL @}\\ \text{1,000,000 units}\end{array} = \frac{1{,}000{,}000(¥108-¥72)}{1{,}000{,}000(¥108-¥72)-¥22{,}500{,}000} = 2.67$$

12 C is correct. Degree of financial leverage is

$$\begin{aligned}\text{DFL} &= \frac{[Q(P-V)-F]}{[Q(P-V)-F-C]}\\ &= \frac{1{,}000{,}000(¥108-¥72)-¥22{,}500{,}000}{1{,}000{,}000(¥108-¥72)-¥22{,}500{,}000-¥9{,}000{,}000} = 3.00\end{aligned}$$

13 B is correct. The degree of operating leverage of Qphone is 1.4. The percentage change in operating income is equal to the DOL times the percentage change in units sold, therefore:

$$\begin{array}{c}\text{Percentage change}\\ \text{in operating income}\end{array} = (\text{DOL})\begin{pmatrix}\text{Percentage change}\\ \text{in units sold}\end{pmatrix} = (1.4)(15\%) = 21\%$$

14 C is correct. The breakeven quantity is computed

$$Q_{\text{BE}} = \frac{F+C}{P-V} = \frac{(¥22{,}500{,}000+¥9{,}000{,}000)}{(¥108-¥72)} = 875{,}000$$

15 C is correct. 4G, Inc.'s degree of total leverage can be shown to equal 8, whereas Qphone Corp.'s degree of total leverage is only DOL × DFL = 1.4 × 1.15 = 1.61. Therefore, a 10 percent increase in unit sales will mean an 80 percent increase in net income for 4G, but only a 16.1 percent increase in net income for Qphone Corp. The calculation for 4G, Inc.'s DTL is

$$\begin{aligned}\text{DTL} &= \frac{Q(P-V)}{Q(P-V)-F-C}\\ &= \frac{1{,}000{,}000(¥108-¥72)}{1{,}000{,}000(¥108-¥72)-¥22{,}500{,}000-¥9{,}000{,}000} = 8.00\end{aligned}$$

16 A is correct. Degree of total leverage is defined as the percentage change in net income divided by the percentage change in units sold.

Equity Investments

STUDY SESSIONS

Study Session 11	Equity Investments (1)
Study Session 12	Equity Investments (2)

TOPIC LEVEL LEARNING OUTCOME

The candidate should be able to describe characteristics of equity investments, security markets, and indexes. The candidate should also be able to analyze industries, companies, and equity securities and to describe and demonstrate the use of basic equity valuation models.

Global equities are an important asset class for meeting longer term growth and diversification objectives. Global equities also represent a substantial share of capital markets that has been expanding in breadth and depth as developing economies come to market for equity capital. As developed and emerging economies continue to open their markets to investment, their activity is expected to significantly change the composition of world equity markets.

EQUITY INVESTMENTS

STUDY SESSION

11

Equity Investments (1)

This study session provides a structural overview of financial markets and their operating characteristics. Overview markets include equities, fixed income, derivatives, and alternative investments. Various asset types, market participants, and how assets trade within these markets and ecosystems are described. Coverage of these core asset classes continues in subsequent Level I study sessions, laying the foundation for further study in Levels II and III. The study session then turns to the calculation, construction, and use of security market indexes. A discussion of market efficiency and the degree to which market prices may reflect available information concludes the session.

READING

33

Market Organization and Structure

by Larry Harris, PhD, CFA

Larry Harris, PhD, CFA, is at the USC Marshall School of Business (USA).

LEARNING OUTCOMES

Mastery	*The candidate should be able to:*
☐	**a.** explain the main functions of the financial system;
☐	**b.** describe classifications of assets and markets;
☐	**c.** describe the major types of securities, currencies, contracts, commodities, and real assets that trade in organized markets, including their distinguishing characteristics and major subtypes;
☐	**d.** describe types of financial intermediaries and services that they provide;
☐	**e.** compare positions an investor can take in an asset;
☐	**f.** calculate and interpret the leverage ratio, the rate of return on a margin transaction, and the security price at which the investor would receive a margin call;
☐	**g.** compare execution, validity, and clearing instructions;
☐	**h.** compare market orders with limit orders;
☐	**i.** define primary and secondary markets and explain how secondary markets support primary markets;
☐	**j.** describe how securities, contracts, and currencies are traded in quote-driven, order-driven, and brokered markets;
☐	**k.** describe characteristics of a well-functioning financial system;
☐	**l.** describe objectives of market regulation.

1

INTRODUCTION

Financial analysts gather and process information to make investment decisions, including those related to buying and selling assets. Generally, the decisions involve trading securities, currencies, contracts, commodities, and real assets such as real estate. Consider several examples:

- Fixed income analysts evaluate issuer credit-worthiness and macroeconomic prospects to determine which bonds and notes to buy or sell to preserve capital while obtaining a fair rate of return.
- Stock analysts study corporate values to determine which stocks to buy or sell to maximize the value of their stock portfolios.
- Corporate treasurers analyze exchange rates, interest rates, and credit conditions to determine which currencies to trade and which notes to buy or sell to have funds available in a needed currency.
- Risk managers work for producers or users of commodities to calculate how many commodity futures contracts to buy or sell to manage inventory risks.

Financial analysts must understand the characteristics of the markets in which their decisions will be executed. This reading, by examining those markets from the analyst's perspective, provides that understanding.

This reading is organized as follows. Section 2 examines the functions of the financial system. Sections 3–6 introduce assets that investors, information-motivated traders, and risk managers use to advance their financial objectives and presents ways practitioners classify these assets into markets. These assets include such financial instruments as securities, currencies, and some contracts; certain commodities; and real assets. Financial analysts must know the distinctive characteristics of these trading assets.

Sections 7–9 is an overview of financial intermediaries (entities that facilitate the functioning of the financial system). Sections 10–11 discuss the positions that can be obtained while trading assets. You will learn about the benefits and risks of long and short positions, how these positions can be financed, and how the financing affects their risks. Section2 12–13 discuss how market participants order trades and how markets process those orders. These processes must be understood to achieve trading objectives while controlling transaction costs.

Section 14 focuses on describing primary markets. Section 15 describes the structures of secondary markets in securities. Sections 16 and 16 close the reading with discussions of the characteristics of a well-functioning financial system and of how regulation helps make financial markets function better. A summary reviews the reading's major ideas and points, and practice problems conclude.

2

THE FUNCTIONS OF THE FINANCIAL SYSTEM

a explain the main functions of the financial system;

The financial system includes markets and various financial intermediaries that help transfer financial assets, real assets, and financial risks in various forms from one entity to another, from one place to another, and from one point in time to another. These transfers take place whenever someone exchanges one asset or financial contract for another. The assets and contracts that people (people act on behalf of themselves, companies, charities, governments, etc., so the term "people" has a broad definition in this reading) trade include notes, bonds, stocks, exchange-traded funds, currencies, forward contracts, futures contracts, option contracts, swap contracts, and certain commodities. When the buyer and seller voluntarily arrange their trades, as is usually the case, the buyer and the seller both expect to be better off.

People use the financial system for six main purposes:

1. to save money for the future;
2. to borrow money for current use;
3. to raise equity capital;
4. to manage risks;
5. to exchange assets for immediate and future deliveries; and
6. to trade on information.

The main functions of the financial system are to facilitate:

1. the achievement of the purposes for which people use the financial system;
2. the discovery of the rates of return that equate aggregate savings with aggregate borrowings; and
3. the allocation of capital to the best uses.

These functions are extremely important to economic welfare. In a well-functioning financial system, transaction costs are low, analysts can value savings and investments, and scarce capital resources are used well.

Sections 2.1 through 2.3 expand on these three functions. The six subsections of Section 2.1 cover the six main purposes for which people use the financial system and how the financial system facilitates the achievement of those purposes. Sections 2.2 and 2.3 discuss determining rates of return and capital allocation efficiency, respectively.

2.1 Helping People Achieve Their Purposes in Using the Financial System

People often arrange transactions to achieve more than one purpose when using the financial system. For example, an investor who buys the stock of an oil producer may do so to move her wealth from the present to the future, to hedge the risk that she will have to pay more for energy in the future, and to exploit insightful research that she conducted that suggests the company's stock is undervalued in the marketplace. If the investment proves to be successful, she will have saved money for the future, managed her energy risk exposure, and obtained a return on her research.

The separate discussions of each of the six main uses of the financial system by people will help you better identify the reasons why people trade. Your ability to identify the various uses of the financial system will help you avoid confusion that often leads to poor financial decisions. The financial intermediaries that are mentioned in these discussions are explained further in Sections 7–9.

2.1.1 *Saving*

People often have money that they choose not to spend now and that they want available in the future. For example, workers who save for their retirements need to move some of their current earnings into the future. When they retire, they will use their savings to replace the wages that they will no longer be earning. Similarly, companies save money from their sales revenue so that they can pay vendors when their bills come due, repay debt, or acquire assets (for example, other companies or machinery) in the future.

To move money from the present to the future, savers buy notes, certificates of deposit, bonds, stocks, mutual funds, or real assets such as real estate. These alternatives generally provide a better expected rate of return than simply storing money. Savers then sell these assets in the future to fund their future expenditures. When savers commit money to earn a financial return, they commonly are called investors. They invest when they purchase assets, and they divest when they sell them.

Investors require a fair rate of return while their money is invested. The required fair rate of return compensates them for the use of their money and for the risk that they may lose money if the investment fails or if inflation reduces the real value of their investments.

The financial system facilitates savings when institutions create investment vehicles, such as bank deposits, notes, stocks, and mutual funds, that investors can acquire and sell without paying substantial transaction costs. When these instruments are fairly priced and easy to trade, investors will use them to save more.

2.1.2 *Borrowing*

People, companies, and governments often want to spend money now that they do not have. They can obtain money to fund projects that they wish to undertake now by borrowing it. Companies can also obtain funds by selling ownership or equity interests (covered in Section 2.1.3). Banks and other investors provide those requiring funds with money because they expect to be repaid with interest or because they expect to be compensated with future disbursements, such as dividends and capital gains, as the ownership interest appreciates in value.

People may borrow to pay for such items as vacations, homes, cars, or education. They generally borrow through mortgages and personal loans, or by using credit cards. People typically repay these loans with money they earn later.

Companies often require money to fund current operations or to engage in new capital projects. They may borrow the needed funds in a variety of ways, such as arranging a loan or a line of credit with a bank, or selling fixed income securities to investors. Companies typically repay their borrowing with income generated in the future. In addition to borrowing, companies may raise funds by selling ownership interests.

Governments may borrow money to pay salaries and other expenses, to fund projects, to provide welfare benefits to their citizens and residents, and to subsidize various activities. Governments borrow by selling bills, notes, or bonds. Governments repay their debt using future revenues from taxes and in some instances from the projects funded by these debts.

Borrowers can borrow from lenders only if the lenders believe that they will be repaid. If the lenders believe, however, that repayment in full with interest may not occur, they will demand higher rates of interest to cover their expected losses and to compensate them for the discomfit they experience wondering whether they will lose their money. To lower the costs of borrowing, borrowers often pledge assets as collateral for their loans. The assets pledged as collateral often include those that will be purchased by the proceeds of the loan. If the borrowers do not repay their loans, the lenders can sell the collateral and use the proceeds to settle the loans.

Lenders often will not loan to borrowers who intend to invest in risky projects, especially if the borrowers cannot pledge other collateral. Investors may still be willing to supply capital for these risky projects if they believe that the projects will likely produce valuable future cash flows. Rather than lending money, however, they will contribute capital in exchange for equity in the projects.

The financial system facilitates borrowing. Lenders aggregate from savers the funds that borrowers require. Borrowers must convince lenders that they can repay their loans, and that, in the event they cannot, lenders can recover most of the funds lent. Credit bureaus, credit rating agencies, and governments promote borrowing; credit bureaus and credit rating agencies do so by collecting and disseminating information that lenders need to analyze credit prospects and governments do so by establishing bankruptcy codes and courts that define and enforce the rights of borrowers and lenders. When the transaction costs of loans (i.e., the costs of arranging, monitoring, and collecting them) are low, borrowers can borrow more to fund current expenditures with credible promises to return the money in the future.

2.1.3 *Raising Equity Capital*

Companies often raise money for projects by selling (issuing) ownership interests (e.g., corporate common stock or partnership interests). Although these equity instruments legally represent ownership in companies rather than loans to the companies, selling equity to raise capital is simply another mechanism for moving money from the future to the present. When shareholders or partners contribute capital to a company, the company obtains money in the present in exchange for equity instruments that will be entitled to distributions in the future. Although the repayment of the money is not scheduled as it would be for loans, equity instruments also represent potential claims on money in the future.

The financial system facilitates raising equity capital. Investment banks help companies issue equities, analysts value the securities that companies sell, and regulatory reporting requirements and accounting standards attempt to ensure the production of meaningful financial disclosures. The financial system helps promote capital formation by producing the financial information needed to determine fair prices for equity. Liquid markets help companies raise capital. In these markets, shareholders can easily divest their equities as desired. When investors can easily value and trade equities, they are more willing to fund reasonable projects that companies wish to undertake.

EXAMPLE 1

Financing Capital Projects

As a chief financial officer (CFO) of a large industrial firm, you need to raise cash within a few months to pay for a project to expand existing and acquire new manufacturing facilities. What are the primary options available to you?

Solution:

Your primary options are to borrow the funds or to raise the funds by selling ownership interests. If the company borrows the funds, you may have the company pledge some or all of the project as collateral to reduce the cost of borrowing.

2.1.4 *Managing Risks*

Many people, companies, and governments face financial risks that concern them. These risks include default risk and the risk of changes in interest rates, exchange rates, raw material prices, and sale prices, among many other risks. These risks are often managed by trading contracts that serve as hedges for the risks.

For example, a farmer and a food processor both face risks related to the price of grain. The farmer fears that prices will be lower than expected when his grain is ready for sale whereas the food processor fears that prices will be higher than expected when she has to buy grain in the future. They both can eliminate their exposures to these risks if they enter into a binding forward contract for the farmer to sell a specified quantity of grain to the food processor at a future date at a mutually agreed upon price. By entering into a forward contract that sets the future trade price, they both eliminate their exposure to changing grain prices.

In general, hedgers trade to offset or insure against risks that concern them. In addition to forward contracts, they may use futures contracts, option contracts, or insurance contracts to transfer risk to other entities more willing to bear the risks (these contracts will be covered in Section 6). Often the hedger and the other entity face exactly the opposite risks, so the transfer makes both more secure, as in the grain example.

The financial system facilitates risk management when liquid markets exist in which risk managers can trade instruments that are correlated (or inversely correlated) with the risks that concern them without incurring substantial transaction costs. Investment banks, exchanges, and insurance companies devote substantial resources to designing such contracts and to ensuring that they will trade in liquid markets. When such markets exist, people are better able to manage the risks that they face and often are more willing to undertake risky activities that they expect will be profitable.

2.1.5 *Exchanging Assets for Immediate Delivery (Spot Market Trading)*

People and companies often trade one asset for another that they rate more highly or, equivalently, that is more useful to them. They may trade one currency for another currency, or money for a needed commodity or right. Following are some examples that illustrate these trades:

- Volkswagen pays its German workers in euros, but the company receives dollars when it sells cars in the United States. To convert money from dollars to euros, Volkswagen trades in the foreign exchange markets.
- A Mexican investor who is worried about the prospects for peso inflation or a potential devaluation of the peso may buy gold in the spot gold market. (This transaction may hedge against the risk of devaluation of the peso because the value of gold may increase with inflation.)
- A plastic producer must buy carbon credits to emit carbon dioxide when burning fuel to comply with environmental regulations. The carbon credit is a legal right that the producer must have to engage in activities that emit carbon dioxide.

In each of these cases, the trades are considered spot market trades because the instruments trade for immediate delivery. The financial system facilitates these exchanges when liquid spot markets exist in which people can arrange and settle trades without substantial transaction costs.

2.1.6 *Information-Motivated Trading*

Information-motivated traders trade to profit from information that they believe allows them to predict future prices. Like all other traders, they hope to buy at low prices and sell at higher prices. Unlike pure investors, however, they expect to earn a return on their information in addition to the normal return expected for bearing risk through time.

Active investment managers are information-motivated traders who collect and analyze information to identify securities, contracts, and other assets that their analyses indicate are under- or overvalued. They then buy those that they consider undervalued and sell those that they consider overvalued. If successful, they obtain a greater return than the unconditional return that would be expected for bearing the risk in their positions. The return that they expect to obtain is a conditional return earned on the basis of the information in their analyses. Practitioners often call this process active portfolio management.

Note that the distinction between pure investors and information-motivated traders depends on their motives for trading and not on the risks that they take or their expected holding periods. Investors trade to move wealth from the present to the future whereas information-motivated traders trade to profit from superior information about future values. When trading to move wealth forward, the time period may be short or long. For example, a bank treasurer may only need to move money overnight and might use money market instruments trading in an interbank funds market to accomplish that. A pension fund, however, may need to move money 30 years forward and might do that by using shares trading in a stock market. Both are investors although their expected holding periods and the risks in the instruments that they trade are vastly different.

In contrast, information-motivated traders trade because their information-based analyses suggest to them that prices of various instruments will increase or decrease in the future at a rate faster than others without their information or analytical models would expect. After establishing their positions, they hope that prices will change quickly in their favor so that they can close their positions, realize their profits, and redeploy their capital. These price changes may occur almost instantaneously, or they may take years to occur if information about the mispricing is difficult to obtain or understand.

The two categories of traders are not mutually exclusive. Investors also are often information-motivated traders. Many investors who want to move wealth forward through time collect and analyze information to select securities that will allow them to obtain conditional returns that are greater than the unconditional returns expected for securities in their asset classes. If they have rational reasons to expect that their efforts will indeed produce superior returns, they are information-motivated traders. If they consistently fail to produce such returns, their efforts will be futile, and they would have been better off simply buying and holding well-diversified portfolios.

EXAMPLE 2

Investing versus Information-Motivated Trading

The head of a large labor union with a pension fund asks you, a pension consultant, to distinguish between investing and information-motivated trading. You are expected to provide an explanation that addresses the financial problems that she faces. How would you respond?

Solution:

The object of investing for the pension fund is to move the union's pension assets from the present to the future when they will be needed to pay the union's retired pensioners. The pension fund managers will typically do this by buying stocks, bonds, and perhaps other assets. The pension fund managers expect to receive a fair rate of return on the pension fund's assets without paying excessive transaction costs and management fees. The return should compensate the fund for the risks that it bears and for the time that other people are using the fund's money.

The object of information-motivated trading is to earn a return in excess of the fair rate of return. Information-motivated traders analyze information that they collect with the hope that their analyses will allow them to predict better than others where prices will be in the future. They then buy assets that they think will produce excess returns and sell those that they think will underperform. Active investment managers are information-motivated traders.

The characteristic that most distinguishes investors from information-motivated traders is the return that they expect. Although both types of traders hope to obtain extraordinary returns, investors rationally expect to receive only fair returns during the periods of their investments. In contrast, information-motivated traders expect to make returns in excess of required fair rates of return. Of course, not all investing or information-motivated trading is successful (in other words, the actual returns may not equal or exceed the expected returns).

The financial system facilitates information-motivated trading when liquid markets allow active managers to trade without significant transaction costs. Accounting standards and reporting requirements that produce meaningful financial disclosures reduce the costs of being well informed, but do not necessarily help informed traders profit because they often compete with each other. The most profitable well-informed traders are often those that have the most unique insights into future values.

2.1.7 *Summary*

People use the financial system for many purposes, the most important of which are saving, borrowing, raising equity capital, managing risk, exchanging assets in spot markets, and information-motivated trading. The financial system best facilitates these uses when people can trade instruments that interest them in liquid markets, when institutions provide financial services at low cost, when information about assets and about credit risks is readily available, and when regulation helps ensure that everyone faithfully honors their contracts.

2.2 Determining Rates of Return

Saving, borrowing, and selling equity are all means of moving money through time. Savers move money from the present to the future whereas borrowers and equity issuers move money from the future to the present.

Because time machines do not exist, money can travel forward in time only if an equal amount of money is travelling in the other direction. This equality always occurs because borrowers and equity sellers create the securities in which savers invest. For example, the bond sold by a company that needs to move money from the future to the present is the same bond bought by a saver who needs to move money from the present to the future.

The aggregate amount of money that savers will move from the present to the future is related to the expected rate of return on their investments. If the expected return is high, they will forgo current consumption and move more money to the future. Similarly, the aggregate amount of money that borrowers and equity sellers will move from the future to the present depends on the costs of borrowing funds or of giving up ownership. These costs can be expressed as the rate of return that borrowers and equity sellers are expected to deliver in exchange for obtaining current funds. It is the same rate that savers expect to receive when delivering current funds. If this rate is low, borrowers and equity sellers will want to move more money to the present from the future. In other words, they will want to raise more funds.

Because the total money saved must equal the total money borrowed and received in exchange for equity, the expected rate of return depends on the aggregate supply of funds through savings and the aggregate demand for funds. If the rate is too high, savers will want to move more money to the future than borrowers and equity issuers will want to move to the present. The expected rate will have to be lower to discourage the savers and to encourage the borrowers and equity issuers. Conversely, if the rate is too low, savers will want to move less money forward than borrowers and equity issuers will want to move to the present. The expected rate will have to be higher to encourage the savers and to discourage the borrowers and equity issuers. Between rates too high and too low, an expected rate of return exists, in theory, in which the aggregate supply of funds for investing (supply of funds saved) and the aggregate demand for funds through borrowing and equity issuing are equal.

Economists call this rate the equilibrium interest rate. It is the price for moving money through time. Determining this rate is one of the most important functions of the financial system. The equilibrium interest rate is the only interest rate that would exist if all securities were equally risky, had equal terms, and were equally liquid. In fact, the required rates of return for securities vary by their risk characteristics, terms, and liquidity. For a given issuer, investors generally require higher rates of return for equity than for debt, for long-term securities than for short-term securities, and for illiquid securities than for liquid ones. Financial analysts recognize that all required rates of return depend on a common equilibrium interest rate plus adjustments for risk.

EXAMPLE 3

Interest Rates

For a presentation to private wealth clients by your firm's chief economist, you are asked to prepare the audience by explaining the most fundamental facts concerning the role of interest rates in the economy. You agree. What main points should you try to convey?

Solution:

Savers have money now that they will want to use in the future. Borrowers want to use money now that they do not have, but they expect that they will have money in the future. Borrowers are loaned money by savers and promise to repay it in the future.

The interest rate is the return that lenders, the savers, expect to receive from borrowers for allowing borrowers to use the savers' money. The interest rate is the price of using money.

Interest rates depend on the total amount of money that people want to borrow and the total amount of money that people are willing to lend. Interest rates are high when, in aggregate, people value having money now substantially more than they value having money in the future. In contrast, if many people with money want to use it in the future and few people presently need more money than they have, interest rates will be low.

2.3 Capital Allocation Efficiency

Primary capital markets (primary markets) are the markets in which companies and governments raise capital (funds). Companies may raise funds by borrowing money or by issuing equity. Governments may raise funds by borrowing money.

Economies are said to be **allocationally efficient** when their financial systems allocate capital (funds) to those uses that are most productive. Although companies may be interested in getting funding for many potential projects, not all projects are worth funding. One of the most important functions of the financial system is to ensure that only the best projects obtain scarce capital funds; the funds available from savers should be allocated to the most productive uses.

In market-based economies, savers determine, directly or indirectly, which projects obtain capital. Savers determine capital allocations directly by choosing which securities they will invest in. Savers determine capital allocations indirectly by giving funds to financial intermediaries that then invest the funds. Because investors fear the loss of their money, they will lend at lower interest rates to borrowers with the best credit prospects or the best collateral, and they will lend at higher rates to other borrowers with less secure prospects. Similarly, they will buy only those equities that they believe have the best prospects relative to their prices and risks.

To avoid losses, investors carefully study the prospects of the various investment opportunities available to them. The decisions that they make tend to be well informed, which helps ensure that capital is allocated efficiently. The fear of losses by investors and by those raising funds to invest in projects ensures that only the best projects tend to be funded. The process works best when investors are well informed about the prospects of the various projects.

In general, investors will fund an equity project if they expect that the value of the project is greater than its cost, and they will not fund projects otherwise. If the investor expectations are accurate, only projects that should be undertaken will be funded and all such projects will be funded. Accurate market information thus leads to efficient capital allocation.

EXAMPLE 4

Primary Market Capital Allocation

How can poor information about the value of a project result in poor capital allocation decisions?

Solution:

Projects should be undertaken only if their value is greater than their cost. If investors have poor information and overestimate the value of a project in which its true value is less than its cost, a wealth-diminishing project may be undertaken. Alternatively, if investors have poor information and underestimate the value of a project in which its true value is greater than its cost, a wealth-enhancing project may not be undertaken.

3 ASSETS AND CONTRACTS

b describe classifications of assets and markets;

People, companies, and governments use many different assets and contracts to further their financial goals and to manage their risks. The most common assets include financial assets (such as bank deposits, certificates of deposit, loans, mortgages, corporate and government bonds and notes, common and preferred stocks, real estate investment trusts, master limited partnership interests, pooled investment products, and exchange-traded funds), currencies, certain commodities (such as gold and oil), and real assets (such as real estate). The most common contracts are option, futures, forward, swap, and insurance contracts. People, companies, and governments use these assets and contracts to raise funds, to invest, to profit from information-motivated trading, to hedge risks, and/or to transfer money from one form to another.

3.1 Classifications of Assets and Markets

Practitioners often classify assets and the markets in which they trade by various common characteristics to facilitate communications with their clients, with each other, and with regulators.

The most actively traded assets are securities, currencies, contracts, and commodities. In addition, real assets are traded. Securities generally include debt instruments, equities, and shares in pooled investment vehicles. **Currencies** are monies issued by national monetary authorities. Contracts are agreements to exchange securities, currencies, commodities or other contracts in the future. Commodities include precious metals, energy products, industrial metals, and agricultural products. Real assets are tangible properties such as real estate, airplanes, or machinery. Securities, currencies, and contracts are classified as financial assets whereas commodities and real assets are classified as physical assets.

Securities are further classified as debt or equity. Debt instruments (also called fixed-income instruments) are promises to repay borrowed money. Equities represent ownership in companies. Pooled investment vehicle shares represent ownership of an undivided interest in an investment portfolio. The portfolio may include securities, currencies, contracts, commodities, or real assets. Pooled investment vehicles, such as exchange-traded funds, which exclusively own shares in other companies, generally are also considered equities.

Securities are also classified by whether they are public or private securities. Public securities are those registered to trade in public markets, such as on exchanges or through dealers. In most jurisdictions, issuers must meet stringent minimum regulatory standards, including reporting and corporate governance standards, to issue publicly traded securities.

Private securities are all other securities. Often, only specially qualified investors can purchase private equities and private debt instruments. Investors may purchase them directly from the issuer or indirectly through an investment vehicle specifically formed to hold such securities. Issuers often issue private securities when they find public reporting standards too burdensome or when they do not want to conform to the regulatory standards associated with public equity. Venture capital is private equity that investors supply to companies when or shortly after they are founded. Private securities generally are illiquid. In contrast, many public securities trade in liquid markets in which sellers can easily find buyers for their securities.

Contracts are derivative contracts if their values depend on the prices of other underlying assets. Derivative contracts may be classified as physical or financial depending on whether the underlying instruments are physical products or financial securities. Equity derivatives are contracts whose values depend on equities or indexes of equities. Fixed-income derivatives are contracts whose values depend on debt securities or indexes of debt securities.

Practitioners classify markets by whether the markets trade instruments for immediate delivery or for future delivery. Markets that trade contracts that call for delivery in the future are forward or futures markets. Those that trade for immediate delivery are called **spot markets** to distinguish them from forward markets that trade contracts on the same underlying instruments. Options markets trade contracts that deliver in the future, but delivery takes place only if the holders of the options choose to exercise them.

When issuers sell securities to investors, practitioners say that they trade in the **primary market**. When investors sell those securities to others, they trade in the **secondary market**. In the primary market, funds flow to the issuer of the security from the purchaser. In the secondary market, funds flow between traders.

Practitioners classify financial markets as money markets or capital markets. **Money markets** trade debt instruments maturing in one year or less. The most common such instruments are repurchase agreements (defined in Section 4), negotiable certificates of deposit, government bills, and commercial paper. In contrast, **capital markets** trade instruments of longer duration, such as bonds and equities, whose values depend on the credit-worthiness of the issuers and on payments of interest or dividends that will be made in the future and may be uncertain. Corporations generally finance their operations in the capital markets, but some also finance a portion of their operations by issuing short-term securities, such as commercial paper.

Finally, practitioners distinguish between **traditional investment markets** and **alternative investment markets**. Traditional investments include all publicly traded debts and equities and shares in pooled investment vehicles that hold publicly traded debts and/or equities. Alternative investments include **hedge funds**, private equities (including venture capital), commodities, real estate securities and real estate properties, securitized debts, operating leases, machinery, collectibles, and precious gems. Because these investments are often hard to trade and hard to value, they may sometimes trade at substantial deviations from their intrinsic values. The discounts compensate investors for the research that they must do to value these assets and for their inability to easily sell the assets if they need to liquidate a portion of their portfolios.

The remainder of this section describes the most common assets and contracts that people, companies, and governments trade.

EXAMPLE 5

Asset and Market Classification

The investment policy of a mutual fund only permits the fund to invest in public equities traded in secondary markets. Would the fund be able to purchase:

1. Common stock of a company that trades on a large stock exchange?
2. Common stock of a public company that trades only through dealers?
3. A government bond?
4. A single stock futures contract?
5. Common stock sold for the first time by a properly registered public company?
6. Shares in a privately held bank with €10 billion of capital?

Solution to 1:

Yes. Common stock is equity. Those common stocks that trade on large exchanges invariably are public equities that trade in secondary markets.

Solution to 2:

Yes. Dealer markets are secondary markets and the security is a public equity.

Solution to 3:

No. Although government bonds are public securities, they are not equities. They are debt securities.

Solution to 4:

No. Although the underlying instruments for single stock futures are invariably public equities, single stock futures are derivative contracts, not equities.

Solution to 5:

No. The fund would not be able to buy these shares because a purchase from the issuer would be in the primary market. The fund would have to wait until it could buy the shares from someone other than the issuer.

Solution to 6:

No. These shares are private equities, not public equities. The public prominence of the company does not make its securities public securities unless they have been properly registered as public securities.

SECURITIES

4

c describe the major types of securities, currencies, contracts, commodities, and real assets that trade in organized markets, including their distinguishing characteristics and major subtypes;

People, companies, and governments sell securities to raise money. Securities include bonds, notes, commercial paper, mortgages, common stocks, preferred stocks, warrants, mutual fund shares, unit trusts, and depository receipts. These can be classified broadly as fixed-income instruments, equities, and shares in pooled investment vehicles. Note that the legal definition of a security varies by country and may or may not coincide with the usage here. Securities that are sold to the public or that can be resold to the public are called issues. Companies and governments are the most common issuers.

4.1 Fixed Income

Fixed-income instruments contractually include predetermined payment schedules that usually include interest and principal payments. Fixed-income instruments generally are promises to repay borrowed money but may include other instruments with payment schedules, such as settlements of legal cases or prizes from lotteries. The payment amounts may be pre-specified or they may vary according to a fixed formula that depends on the future values of an interest rate or a commodity price. Bonds, notes, bills, certificates of deposit, commercial paper, repurchase agreements, loan agreements, and mortgages are examples of promises to repay money in the future. People, companies, and governments create fixed-income instruments when they borrow money.

Corporations and governments issue bonds and notes. Fixed-income securities with shorter maturities are called "notes," those with longer maturities are called "bonds." The cutoff is usually at 10 years. In practice, however, the terms are generally used interchangeably. Both become short-term instruments when the remaining time until maturity is short, usually taken to be one year or less.

Some corporations issue convertible bonds, which are typically convertible into stock, usually at the option of the holder after some period. If stock prices are high so that conversion is likely, convertibles are valued like stock. Conversely, if stock prices are low so that conversion is unlikely, convertibles are valued like bonds.

Bills, certificates of deposit, and commercial paper are respectively issued by governments, banks, and corporations. They usually mature within a year of being issued; certificates of deposit sometimes have longer initial maturities.

Repurchase agreements (repos) are short-term lending instruments. The term can be as short as overnight. A borrower seeking funds will sell an instrument—typically a high-quality bond—to a lender with an agreement to repurchase it later at a slightly higher price based on an agreed upon interest rate.

Practitioners distinguish between short-term, intermediate-term, and long-term fixed-income securities. No general consensus exists about the definition of short-term, intermediate-term, and long-term. Instruments that mature in less than one to two years are considered short-term instruments whereas those that mature in more than five to ten years are considered long-term instruments. In the middle are intermediate-term instruments.

Instruments trading in money markets are called money market instruments. Such instruments are traded debt instruments maturing in one year or less. Money market funds and corporations seeking a return on their short-term cash balances typically hold money market instruments.

4.2 Equities

Equities represent ownership rights in companies. These include common and preferred shares. Common shareholders own residual rights to the assets of the company. They have the right to receive any dividends declared by the boards of directors, and in the event of liquidation, any assets remaining after all other claims are paid. Acting through the boards of directors that they elect, common shareholders usually can select the managers who run the corporations.

Preferred shares are equities that have preferred rights (relative to common shares) to the cash flows and assets of the company. Preferred shareholders generally have the right to receive a specific dividend on a regular basis. If the preferred share is a cumulative preferred equity, the company must pay the preferred shareholders any previously omitted dividends before it can pay dividends to the common shareholders. Preferred shareholders also have higher claims to assets relative to common shareholders in the event of corporate liquidation. For valuation purposes, financial analysts generally treat preferred stocks as fixed-income securities when the issuers will clearly be able to pay their promised dividends in the foreseeable future.

Warrants are securities issued by a corporation that allow the warrant holders to buy a security issued by that corporation, if they so desire, usually at any time before the warrants expire or, if not, upon expiration. The security that warrant holders can buy usually is the issuer's common stock, in which case the warrants are considered equities because the warrant holders can obtain equity in the company by exercising their warrants. The warrant **exercise price** is the price that the warrant holder must pay to buy the security.

EXAMPLE 6

Securities

What factors distinguish fixed-income securities from equities?

Solution:

Fixed-income securities generate income on a regular schedule. They derive their value from the promise to pay a scheduled cash flow. The most common fixed-income securities are promises made by people, companies, and governments to repay loans.

Equities represent residual ownership in companies after all other claims—including any fixed-income liabilities of the company—have been satisfied. For corporations, the claims of preferred equities typically have priority over the claims of common equities. Common equities have the residual ownership in corporations.

4.3 Pooled Investments

Pooled investment vehicles are mutual funds, trusts, depositories, and hedge funds, that issue securities that represent shared ownership in the assets that these entities hold. The securities created by mutual funds, trusts, depositories, and hedge fund are respectively called *shares*, *units*, *depository receipts*, and *limited partnership interests* but practitioners often use these terms interchangeably. People invest in pooled investment vehicles to benefit from the investment management services of their managers and from diversification opportunities that are not readily available to them on an individual basis.

Mutual funds are investment vehicles that pool money from many investors for investment in a portfolio of securities. They are often legally organized as investment trusts or as corporate investment companies. Pooled investment vehicles may be open-ended or closed-ended. Open-ended funds issue new shares and redeem existing shares on demand, usually on a daily basis. The price at which a fund redeems and sells the fund's shares is based on the net asset value of the fund's portfolio, which is the difference between the fund's assets and liabilities, expressed on a per share basis. Investors generally buy and sell open-ended mutual funds by trading with the mutual fund.

In contrast, closed-end funds issue shares in primary market offerings that the fund or its investment bankers arrange. Once issued, investors cannot sell their shares of the fund back to the fund by demanding redemption. Instead, investors in closed-end funds must sell their shares to other investors in the secondary market. The secondary market prices of closed-end funds may differ—sometimes quite significantly—from their net asset values. Closed-end funds generally trade at a discount to their net asset values. The discount reflects the expenses of running the fund and sometimes investor concerns about the quality of the management. Closed-end funds may also trade at a discount or a premium to net asset value when investors believe that the portfolio securities are overvalued or undervalued. Many financial analysts thus believe that discounts and premiums on closed-end funds measure market sentiment.

Exchange-traded funds (ETFs) and exchange-traded notes (ETNs) are open-ended funds that investors can trade among themselves in secondary markets. The prices at which ETFs trade rarely differ much from net asset values because a class of investors, known as authorized participants (APs), has the option of trading directly with the ETF. If the market price of an equity ETF is sufficiently below its net asset value, APs will buy shares in the secondary market at market price and redeem shares at net asset value with the fund. Conversely, if the price of an ETF is sufficiently above its net asset value, APs will buy shares from the fund at net asset value and sell shares in the secondary market at market price. As a result, the market price and net asset values of ETFs tend to converge.

Many ETFs permit only in-kind deposits and redemptions. Buyers who buy directly from such a fund pay for their shares with a portfolio of securities rather than with cash. Similarly, sellers receive a portfolio of securities. The transaction portfolio generally is very similar—often essentially identical—to the portfolio held by the fund. Practitioners sometimes call such funds "depositories" because they issue depository receipts for the portfolios that traders deposit with them. The traders then trade the receipts in the secondary market. Some warehouses holding industrial materials and precious metals also issue tradable warehouse receipts.

Asset-backed securities are securities whose values and income payments are derived from a pool of assets, such as mortgage bonds, credit card debt, or car loans. These securities typically pass interest and principal payments received from the pool of assets through to their holders on a monthly basis. These payments may depend on formulas that give some classes of securities—called tranches—backed by the pool more value than other classes.

Hedge funds are investment funds that generally organize as limited partnerships. The hedge fund managers are the general partners. The limited partners are qualified investors who are wealthy enough and well informed enough to tolerate and accept substantial losses, should they occur. The regulatory requirements to participate in a hedge fund and the regulatory restrictions on hedge funds vary by jurisdiction. Most hedge funds follow only one investment strategy, but no single investment strategy characterizes hedge funds as a group. Hedge funds exist that follow almost every imaginable strategy ranging from long–short arbitrage in the stock markets to direct investments in exotic alternative assets.

The primary distinguishing characteristic of hedge funds is their management compensation scheme. Almost all funds pay their managers with an annual fee that is proportional to their assets and with an additional performance fee that depends on the wealth that the funds generate for their shareholders. A secondary distinguishing characteristic of many hedge funds is the use of leverage to increase risk exposure and to hopefully increase returns.

5 CURRENCIES, COMMODITIES, AND REAL ASSETS

c describe the major types of securities, currencies, contracts, commodities, and real assets that trade in organized markets, including their distinguishing characteristics and major subtypes;

Currencies are monies issued by national monetary authorities. Approximately 180 currencies are currently in use throughout the world. Some of these currencies are regarded as reserve currencies. Reserve currencies are currencies that national central banks and other monetary authorities hold in significant quantities. The primary reserve currencies are the US dollar and the euro. Secondary reserve currencies include the British pound, the Japanese yen, and the Swiss franc.

Currencies trade in foreign exchange markets. In spot currency transactions, one currency is immediately or almost immediately exchanged for another. The rate of exchange is called the spot exchange rate. Traders typically negotiate institutional trades in multiples of large quantities, such as US$1 million or ¥100 million. Institutional trades generally settle in two business days.

Retail currency trades most commonly take place through commercial banks when their customers exchange currencies at a location of the bank, use ATM machines when travelling to withdraw a different currency than the currency in which their bank accounts are denominated, or use credit cards to buy items priced in different currencies. Retail currency trades also take place at airport kiosks, at store front currency exchanges, or on the street.

5.1 Commodities

Commodities include precious metals, energy products, industrial metals, agricultural products, and carbon credits. Spot commodity markets trade commodities for immediate delivery whereas the forward and futures markets trade commodities for future delivery. Managers seeking positions in commodities can acquire them directly by trading in the spot markets or indirectly by trading forward and futures contracts.

The producers and processors of industrial metals and agricultural products are the primary users of the spot commodity markets because they generally are best able to take and make delivery and to store physical products. They undertake these activities in the normal course of operating their businesses. Their ability to handle physical products and the information that they gather operating businesses also gives them substantial advantages as information-motivated traders in these markets. Many producers employ financial analysts to help them analyze commodity market conditions so that they can best manage their inventories to hedge their operational risks and to speculate on future price changes.

Commodities also interest information-motivated traders and investment managers because they can use them as hedges against risks that they hold in their portfolios or as vehicles to speculate on future price changes. Most such traders take positions in the futures markets because they usually do not have facilities to handle most physical products nor can they easily obtain them. They also cannot easily cope with the normal variation in qualities that characterizes many commodities. Information-motivated traders and investment managers also prefer to trade in futures markets because most futures markets are more liquid than their associated spot markets and forward markets. The liquidity allows them to easily close their positions before delivery so that they can avoid handling physical products.

Some information-motivated traders and investment managers, however, trade in the spot commodity markets, especially when they can easily contract for low-cost storage. Commodities for which delivery and storage costs are lowest are nonperishable products for which the ratio of value to weight is high and variation in quality is low. These generally include precious metals, industrial diamonds, such high-value industrial metals as copper, aluminum, and mercury, and carbon credits.

5.2 Real Assets

Real assets include such tangible properties as real estate, airplanes, machinery, or lumber stands. These assets normally are held by operating companies, such as real estate developers, airplane leasing companies, manufacturers, or loggers. Many institutional investment managers, however, have been adding real assets to their portfolios as direct investments (involving direct ownership of the real assets) and indirect investments (involving indirect ownership, for example, purchase of securities of companies that invest in real assets or real estate investment trusts). Investments in real assets are attractive to them because of the income and tax benefits that they often generate, and because changes in their values may have a low correlation with other investments that the managers hold.

Direct investments in real assets generally require substantial management to ensure that the assets are maintained and used efficiently. Investment managers investing in such assets must either hire personnel to manage them or hire outside management companies. Either way, management of real assets is quite costly.

Real assets are unique properties in the sense that no two assets are alike. An example of a unique property is a real estate parcel. No two parcels are the same because, if nothing else, they are located in different places. Real assets generally differ in their conditions, remaining useful lives, locations, and suitability for various purposes. These differences are very important to the people who use them, so the market for a given real asset may be very limited. Thus, real assets tend to trade in very illiquid markets.

The heterogeneity of real assets, their illiquidity, and the substantial costs of managing them are all factors that complicate the valuation of real assets and generally make them unsuitable for most investment portfolios. These same problems, however, often cause real assets to be misvalued in the market, so astute information-motivated traders may occasionally identify significantly undervalued assets. The benefits from purchasing such assets, however, are often offset by the substantial costs of searching for them and by the substantial costs of managing them.

Many financial intermediaries create entities, such as real estate investment trusts (REITs) and master limited partnerships (MLPs), to securitize real assets and to facilitate indirect investment in real assets. The financial intermediaries manage the assets and pass through the net benefits after management costs to the investors who hold these securities. Because these securities are much more homogenous and divisible than the real assets that they represent, they tend to trade in much more liquid markets. Thus, they are much more suitable as investments than the real assets themselves.

Of course, investors seeking exposure to real assets can also buy shares in corporations that hold and operate real assets. Although almost all corporations hold and operate real assets, many specialize in assets that particularly interest investors seeking exposure to specific real asset classes. For example, investors interested in owning aircraft can buy an aircraft leasing company such as Waha Capital (Abu Dhabi Securities Exchange) and Aircastle Limited (NYSE).

EXAMPLE 7

Assets and Contracts

Consider the following assets and contracts:

Bank deposits
Certificates of deposit
Common stocks
Corporate bonds
Currencies
Exchange-traded funds
Lumber forward contracts
Crude oil futures contracts
Gold
Hedge funds
Master limited partnership interests
Mortgages
Mutual funds
Stock option contracts
Preferred stocks
Real estate parcels
Interest rate swaps
Treasury notes

1. Which of these represent ownership in corporations?
2. Which of these are debt instruments?
3. Which of these are created by traders rather than by issuers?
4. Which of these are pooled investment vehicles?
5. Which of these are real assets?
6. Which of these would a home builder most likely use to hedge construction costs?
7. Which of these would a corporation trade when moving cash balances among various countries?

Solution to 1:

Common and preferred stocks represent ownership in corporations.

Solution to 2:

Bank deposits, certificates of deposit, corporate bonds, mortgages, and Treasury notes are all debt instruments. They respectively represent loans made to banks, corporations, mortgagees (typically real estate owners), and the Treasury.

Solution to 3:

Lumber forward contracts, crude oil futures contracts, stock option contracts, and interest rate swaps are created when the seller sells them to a buyer.

Solution to 4:

Exchange-traded funds, hedge funds, and mutual funds are pooled investment vehicles. They represent shared ownership in a portfolio of other assets.

Solution to 5:

Real estate parcels are real assets.

Solution to 6:

A builder would buy lumber forward contracts to lock in the price of lumber needed to build homes.

Solution to 7:

Corporations often trade currencies when moving cash from one country to another.

CONTRACTS

6

c describe the major types of securities, currencies, contracts, commodities, and real assets that trade in organized markets, including their distinguishing characteristics and major subtypes;

A contract is an agreement among traders to do something in the future. Contracts include forward, futures, swap, option, and insurance contracts. The values of most contracts depend on the value of an **underlying** asset. The underlying asset may be a commodity, a security, an index representing the values of other instruments, a currency pair or basket, or other contracts.

Contracts provide for some physical or cash settlement in the future. In a physically settled contract, settlement occurs when the parties to the contract physically exchange some item, such as avocados, pork bellies, or gold bars. Physical settlement also includes the delivery of such financial instruments as bonds, equities, or futures contracts even though the delivery is electronic. In contrast, cash settled contracts settle through cash payments. The amount of the payment depends on formulas specified in the contracts.

Financial analysts classify contracts by whether they are physical or financial based on the nature of the underlying asset. If the underlying asset is a physical product, the contract is a physical; otherwise, the contract is a financial. Examples of assets classified as physical include contracts for the delivery of petroleum, lumber, and gold. Examples of assets classified as financial include option contracts, and contracts on interest rates, stock indexes, currencies, and credit default swaps.

Contracts that call for immediate delivery are called spot contracts, and they trade in spot markets. Immediate delivery generally is three days or less, but depends on each market. All other contracts involve what practitioners call futurity. They derive their values from events that will take place in the future.

EXAMPLE 8

Contracts for Difference

Contracts for difference (CFD) allow people to speculate on price changes for an underlying asset, such as a common stock or an index. Dealers generally sell CFDs to their clients. When the clients sell the CFDs back to their dealer, they receive any appreciation in the underlying asset's price between the time of purchase and sale (open and close) of the contract. If the underlying asset's price drops over this interval, the client pays the dealer the difference.

1 Are contracts for difference derivative contracts?

2 Are contracts for difference based on copper prices cash settled or physically settled?

Solution to 1:

Contracts for difference are derivative contracts because their values are derived from changes in the prices of the underlying asset on which they are based.

Solution to 2:

All contracts for difference are cash settled contracts regardless of the underlying asset on which they are based because they settle in cash and not in the underlying asset.

6.1 Forward Contracts

A **forward contract** is an agreement to trade the underlying asset in the future at a price agreed upon today. For example, a contract for the sale of wheat after the harvest is a forward contract. People often use forward contracts to reduce risk. Before planting wheat, farmers like to know the price at which they will sell their crop. Similarly, before committing to sell flour to bakers in the future, millers like to know the prices that they will pay for wheat. The farmer and the miller both reduce their operating risks by agreeing to trade wheat forward.

Practitioners call such traders hedgers because they use their contractual commitments to hedge their risks. If the price of wheat falls, the wheat farmer's crop will drop in value on the spot market but he has a contract to sell wheat in the future at a higher fixed price. The forward contract has become more valuable to the farmer. Conversely, if the price of wheat rises, the miller's future obligation to sell flour will become more burdensome because of the high price he would have to pay for wheat on the spot market, but the miller has a contract to buy wheat at a lower fixed price. The forward contract has become more valuable to the miller. In both cases, fluctuations in the spot price are hedged by the forward contract. The forward contract offsets the operating risks that the hedgers face.

Consider a simple example of hedging. An avocado farmer in Mexico expects to harvest 15,000 kilograms of avocados and that the price at harvest will be 60 pesos per kilogram. That price, however, could fluctuate significantly before the harvest. If the price of avocados drops to 50 pesos, the farmer would lose 10 pesos per kilogram (60 pesos − 50 pesos) relative to his expectations, or a total of 150,000 pesos. Now, suppose that the farmer can sell avocados forward to Del Rey Avocado at 58 pesos for delivery at the harvest. If the farmer sells 15,000 kilograms forward, and the price of avocados drops to 50 pesos, the farmer would still be able to sell his avocados for 58 pesos, and thus would not suffer from the drop in the price of avocados below this level.

EXAMPLE 9

Hedging Gold Production

A Zimbabwean gold producer invests in a mine expansion project on the expectation that gold prices will remain at or above $1,200 USD per ounce when the new project starts producing ore.

1 What risks does the gold producer face with respect to the price of gold?
2 How might the gold producer hedge its gold price risk?

Solution to 1:

The gold producer faces the risk that the price of gold could fall below $1,200 USD before it can sell its new production. If so, the investment in the expansion project will be less profitable than expected, and may even generate losses for the mine.

Solution to 2:

The gold producer could hedge the gold price risk by selling gold forward, hopefully at a price near $1,200 USD. Even if the price of gold falls, the gold producer would get paid the contract price.

Forward contracts are very common, but two problems limit their usefulness for many market participants. The first problem is counterparty risk. **Counterparty risk** is the risk that the other party to a contract will fail to honor the terms of the contract. Concerns about counterparty risk ensure that generally only parties who have long-standing relationships with each other execute forward contracts. Trustworthiness is critical when prices are volatile because, after a large price change, one side or the other may prefer not to settle the contract.

The second problem is liquidity. Trading out of a forward contract is very difficult because it can only be done with the consent of the other party. The liquidity problem ensures that forward contracts tend to be executed only among participants for whom delivery is economically efficient and quite certain at the time of contracting so that both parties will want to arrange for delivery.

The counterparty risk problem and the liquidity problem often make it difficult for market participants to obtain the hedging benefits associated with forward contracting. Fortunately, futures contracts have been developed to mitigate these problems.

6.2 Futures Contracts

A **futures contract** is a standardized forward contract for which a clearinghouse guarantees the performance of all traders. The buyer of a futures contract is the side that will take physical delivery or its cash equivalent. The seller of a futures contract is the side that is liable for the delivery or its cash equivalent. A **clearinghouse** is an organization that ensures that no trader is harmed if another trader fails to honor the contract. In effect, the clearinghouse acts as the buyer for every seller and as the seller for every buyer. Buyers and sellers, therefore, can trade futures without worrying whether their counterparties are creditworthy. Because futures contracts are standardized, a buyer can eliminate his obligation to buy by selling his contract to anyone. A seller similarly can eliminate her obligation to deliver by buying a contact from anyone. In either case, the clearinghouse will release the trader from all future obligations if his or her long and short positions exactly offset each other.

To protect against defaults, futures clearinghouses require that all participants post with the clearinghouse an amount of money known as **initial margin** when they enter a contract. The clearinghouse then settles the margin accounts on a daily basis. All participants who have lost on their contracts that day will have the amount of their losses deducted from their margin by the clearinghouse. The clearinghouse similarly increases margins for all participants who gained on that day. Participants whose margins drop below the required **maintenance margin** must replenish their accounts. If a participant does not provide sufficient additional margin when required, the participant's broker will immediately trade to offset the participant's position. These **variation margin** payments ensure that the liabilities associated with futures contracts do not grow large.

EXAMPLE 10

Futures Margin

NYMEX's Light Sweet Crude Oil futures contract specifies the delivery of 1,000 barrels of West Texas Intermediate Crude Oil when the contract finally settles. A broker requires that its clients post an initial overnight margin of $7,763 per contract and an overnight maintenance margin of $5,750 per contract. A client buys ten contracts at $75 per barrel through this broker. On the next day, the contract settles for $72 per barrel. How much additional margin will the client have to provide to his broker?

Solution:

The client lost three dollars per barrel (he is the side committed to take delivery or its cash equivalent at $75 per barrel). This results in a $3,000 loss on each of his 10 contracts, and a total loss of $30,000. His initial margin of $77,630 is reduced by $30,000 leaving $47,630 in his margin account. Because his account has dropped below the maintenance margin requirement of $57,500, the client will get a margin call. The client must provide an additional $30,000 = $77,630 – $47,630 to replenish his margin account; the account is replenished to the amount of the initial margin. The client will only receive another margin call if his account drops to below $57,500 again.

Futures contracts have vastly improved the efficiency of forward contracting markets. Traders can trade standardized futures contracts with anyone without worrying about counterparty risk, and they can close their positions by arranging offsetting trades. Hedgers for whom the terms of the standard contract are not ideal generally still use the futures markets because the contracts embody most of the price risk that concerns them. They simply offset (close out) their futures positions, at the same time they enter spot contracts on which they make or take ultimate delivery.

EXAMPLE 11

Forward and Futures Contracts

What feature most distinguishes futures contracts from forward contracts?

Solution:

A futures contract is a standardized forward contract for which a clearinghouse guarantees the performance of all buyers and sellers. The clearinghouse reduces the counterparty risk problem. The clearinghouse allows a buyer who has bought a contract from one person and sold the same contract to another person to net out the two obligations so that she is no longer liable for either side of the contract; the positions are closed. The ability to trade futures contracts provides liquidity in futures contracts compared with forward contracts.

6.3 Swap Contracts

A **swap contract** is an agreement to exchange payments of periodic cash flows that depend on future asset prices or interest rates. For example, in a typical **interest rate swap**, at periodic intervals, one party makes fixed cash payments to the counterparty in exchange for variable cash payments from the counterparty. The variable payments are based on a pre-specified variable interest rate such as the London Interbank Offered Rate (Libor). This swap effectively exchanges fixed interest payments for variable interest payments. Because the variable rate is set in the future, the cash flows for this contract are uncertain when the parties enter the contract.

Investment managers often enter interest rate swaps when they own a fixed long-term income stream that they want to convert to a cash flow that varies with current short-term interest rates, or vice versa. The conversion may allow them to substantially reduce the total interest rate risk to which they are exposed. Hedgers often use swap contracts to manage risks.

In a **commodity swap**, one party typically makes fixed payments in exchange for payments that depend on future prices of a commodity such as oil. In a **currency swap**, the parties exchange payments denominated in different currencies. The payments may be fixed, or they may vary depending on future interest rates in the two countries. In an **equity swap**, the parties exchange fixed cash payments for payments that depend on the returns to a stock or a stock index.

EXAMPLE 12

Swap and Forward Contracts

What feature most distinguishes a swap contract from a cash-settled forward contract?

Solution:

Both contracts provide for the exchange of cash payments in the future. A forward contract only has a single cash payment at the end that depends on an underlying price or index at the end. In contrast, a swap contract has several scheduled periodic payments, each of which depends on an underlying price or index at the time of the payment.

6.4 Option Contracts

An **option contract** allows the holder (the purchaser) of the **option** to buy or sell, depending on the type of option, an underlying instrument at a specified price at or before a specified date in the future. Those that do buy or sell are said to **exercise** their contracts. An option to buy is a **call option**, and an option to sell is a **put** option. The specified price is called the strike price (exercise price). If the holders can exercise their contracts only when they mature, they are **European-style** contracts. If they can exercise the contracts earlier, they are **American-style** contracts. Many exchanges list standardized option contracts on individual stocks, stock indexes, futures contracts, currencies, swaps, and precious metals. Institutions also trade many customized option contracts with dealers in the over-the-counter derivative market.

Option holders generally will exercise call options if the strike price is below the market price of the underlying instrument, in which case, they will be able to buy at a lower price than the market price. Similarly, they will exercise put options if the strike price is above the underlying instrument price so that they sell at a higher price than the market price. Otherwise, option holders allow their options to expire as worthless.

The price that traders pay for an option is the option premium. Options can be quite expensive because, unlike forward and futures contracts, they do not impose any liability on the holder. The premium compensates the sellers of options—called option writers—for giving the call option holders the right to potentially buy below market prices and put option holders the right to potentially sell above market prices. Because the writers must trade if the holders exercise their options, option contracts may impose substantial liabilities on the writers.

EXAMPLE 13

Option and Forward Contracts

What feature most distinguishes option contracts from forward contracts?

Solution:

The holder of an option contract has the right, but not the obligation, to buy (for a call option) or sell (for a put option) the underlying instrument at some time in the future. The writer of an option contract must trade the underlying instrument if the holder exercises the option.

In contrast, the two parties to a forward contract must trade the underlying instrument (or its equivalent value for a cash-settled contract) at some time in the future if either party wants to settle the contract.

6.5 Other Contracts

Insurance contracts pay their beneficiaries a cash benefit if some event occurs. Life, liability, and automobile insurance are examples of insurance contracts sold to retail clients. People generally use insurance contracts to compensate for losses that they will experience if bad things happen unexpectedly. Insurance contracts allow them to hedge risks that they face.

Credit default swaps (CDS) are insurance contracts that promise payment of principal in the event that a company defaults on its bonds. Bondholders use credit default swaps to convert risky bonds into more secure investments. Other creditors of the company may also buy them to hedge against the risk they will not be paid if the company goes bankrupt.

Well-informed traders who believe that a corporation will default on its bonds may buy credit default swaps written on the corporation's bonds if the swap prices are sufficiently low. If they are correct, the traders will profit if the payoff to the swap is more than the cost of buying and maintaining the swap position.

People sometimes also buy insurance contracts as investments, especially in jurisdictions where payouts from insurance contracts are not subject to as much taxation as are payouts to other investment vehicles. They may buy these contracts directly from insurance companies, or they may buy already issued contracts from their owners. For example, the life settlements market trades life insurance contracts that people sell to investors when they need cash.

FINANCIAL INTERMEDIARIES

7

d describe types of financial intermediaries and services that they provide;

Financial intermediaries help entities achieve their financial goals. These intermediaries include commercial, mortgage, and investment banks; credit unions, credit card companies, and various other finance corporations; brokers and exchanges; dealers and arbitrageurs; clearinghouses and depositories; mutual funds and hedge funds; and insurance companies. The services and products that financial intermediaries provide allow their clients to solve the financial problems that they face more efficiently than they could do so by themselves. Financial intermediaries are essential to well-functioning financial systems.

Financial intermediaries are called intermediaries because the services and products that they provide help connect buyers to sellers in various ways. Whether the connections are easy to identify or involve complex financial structures, financial intermediaries stand between one or more buyers and one or more sellers and help them transfer capital and risk between them. Financial intermediaries' activities allow buyers and sellers to benefit from trading, often without any knowledge of the other.

This section introduces the main financial intermediaries that provide services and products in well-developed financial markets. The discussion starts with those intermediaries whose services most obviously connect buyers to sellers and then proceeds to those intermediaries whose services create more subtle connections. Because many financial intermediaries provide many different types of services, some are mentioned more than once. The section concludes with a general characterization of the various ways in which financial intermediaries add value to the financial system.

7.1 Brokers, Exchanges, and Alternative Trading Systems

Brokers are agents who fill orders for their clients. They do not trade with their clients. Instead, they search for traders who are willing to take the other side of their clients' orders. Individual brokers may work for large brokerage firms, the brokerage arm of banks, or at exchanges. Some brokers match clients to clients personally. Others use specialized computer systems to identify potential trades and help their clients fill their orders. Brokers help their clients trade by reducing the costs of finding counterparties for their trades.

Block brokers provide brokerage service to large traders. Large orders are hard to fill because finding a counterparty willing to do a large trade is often quite difficult. A large buy order generally will trade at a premium to the current market price, and a large sell order generally will trade at a discount to the current market price. These price concessions encourage other traders to trade with the large traders. They also make large traders reluctant, however, to expose their orders to the public before their trades are arranged because they do not want to move the market. Block brokers, therefore, carefully manage the exposure of the orders entrusted to them, which makes filling them difficult.

Investment banks provide advice to their mostly corporate clients and help them arrange transactions such as initial and seasoned securities offerings. Their corporate finance divisions help corporations finance their business by issuing securities, such as common and preferred shares, notes, and bonds. Another function of corporate finance divisions is to help companies identify and acquire other companies (i.e., in mergers and acquisitions).

Exchanges provide places where traders can meet to arrange their trades. Historically, brokers and dealers met on an exchange floor to negotiate trades. Increasingly, exchanges arrange trades for traders based on orders that brokers and dealers submit to them. Such exchanges essentially act as brokers. The distinction between exchanges and brokers has become quite blurred. Exchanges and brokers that use electronic order matching systems to arrange trades among their clients are functionally indistinguishable in this respect. Examples of exchanges include the NYSE, Eurex, Frankfurt Stock Exchange, the Chicago Mercantile Exchange, the Tokyo Stock Exchange, and the Singapore Exchange.

Exchanges are easily distinguished from brokers by their regulatory operations. Most exchanges regulate their members' behavior when trading on the exchange, and sometimes away from the exchange.

Many securities exchanges regulate the issuers that list their securities on the exchange. These regulations generally require timely financial disclosure. Financial analysts use this information to value the securities traded at the exchange. Without such disclosure, valuing securities could be very difficult and market prices might not reflect the fundamental values of the securities. In such situations, well-informed participants may profit from less-informed participants. To avoid such losses, the less-informed participants may withdraw from the market, which can greatly increase corporate costs of capital.

Some exchanges also prohibit issuers from creating capital structures that would concentrate voting rights in the hands of a few owners who do not own a commensurate share of the equity. These regulations attempt to ensure that corporations are run for the benefit of all shareholders and not to promote the interests of controlling shareholders who do not have significant economic stakes in the company.

Exchanges derive their regulatory authority from their national or regional governments, or through the voluntary agreements of their members and issuers to subject themselves to the exchange regulations. In most countries, government regulators oversee the exchange rules and the regulatory operations. Most countries also impose financial disclosure standards on public issuers. Examples of government regulatory bodies include the Japanese Financial Services Agency, the British Financial Conduct Authority, the German Federal Financial Supervisory Authority (BaFin), the US Securities and Exchange Commission, the Ontario Securities Commission, and the Argentine National Securities Commission (CNV).

Alternative trading systems (ATSs), also known as **electronic communications networks** (ECNs) or **multilateral trading facilities** (MTFs) are trading venues that function like exchanges but that do not exercise regulatory authority over their subscribers except with respect to the conduct of their trading in their trading systems. Some ATSs operate electronic trading systems that are otherwise indistinguishable from the trading systems operated by exchanges. Others operate innovative trading systems that suggest trades to their customers based on information that their customers share with them or that they obtain through research into their customers' preferences. Many ATSs are known as **dark pools** because they do not display the orders that their clients send to them. Large investment managers especially like these systems because market prices often move to their disadvantage when other traders know about their large orders. ATSs may be owned and operated by broker–dealers, exchanges, banks, or by companies organized solely for this purpose, many of which may be owned by a consortia of brokers–dealers and banks. Examples of ATSs include MATCHNow (Canada), BATS (United States), POSIT (United States), Liquidnet (United States), Baxter-FX (Ireland), and Turquoise (Europe). Many of these ATSs provide services in many markets besides the ones in which they are domiciled.

7.2 Dealers

Dealers fill their clients' orders by trading with them. When their clients want to sell securities or contracts, dealers buy the instruments for their own accounts. If their clients want to buy securities, dealers sell securities that they own or have borrowed.

After completing a transaction, dealers hope to reverse the transaction by trading with another client on the other side of the market. When they are successful, they effectively connect a buyer who arrived at one point in time with a seller who arrived at another point in time.

The service that dealers provide is liquidity. **Liquidity** is the ability to buy or sell with low transactions costs when you want to trade. By allowing their clients to trade when they want to trade, dealers provide liquidity to them. In over-the-counter markets, dealers offer liquidity when their clients ask them to trade with them. In exchange markets, dealers offer liquidity to anyone who is willing to trade at the prices that the dealers offer at the exchange. Dealers profit when they can buy at prices that on average are lower than the prices at which they sell.

Dealers may organize their operations within proprietary trading houses, investment banks, and hedge funds, or as sole proprietorships. Some dealers are traditional dealers in the sense that individuals make trading decisions. Others use computerized trading to make all trading decisions. Examples of companies with large dealing operations include Deutsche Bank (Germany), RBC Capital Markets (Canada), Nomura Securities (Japan), Timber Hill (United States), Goldman Sachs (United States), and IG Group (United Kingdom). Almost all investment banks have large dealing operations.

Most dealers also broker orders, and many brokers deal to their customers. Accordingly, practitioners often use the term **broker–dealer** to refer to dealers and brokers. Broker–dealers have a conflict of interest with respect to how they fill their customers' orders. When acting as a broker, they must seek the best price for their customers' orders. When acting as dealers, however, they profit most when they sell to their customers at high prices or buy from their customers at low prices. The problem is most serious when the customer allows the broker–dealer to decide whether to trade the order with another trader or to fill it as a dealer. Consequently, when trading with a broker–dealer, some customers specify how they want their orders filled. They may also trade only with pure agency brokers who do not also deal.

Primary dealers are dealers with whom central banks trade when conducting monetary policy. They buy bills, notes, and bonds when the central banks sell them to decrease the money supply. The dealers then sell these instruments to their clients. Similarly, when the central banks want to increase the money supply, the primary dealers buy these instruments from their clients and sell them to the central banks.

EXAMPLE 14

Brokers and Dealers

What characteristic *most likely* distinguishes brokers from dealers?

Solution:

Brokers are agents that arrange trades on behalf of their clients. They do not trade with their clients. In contrast, dealers are proprietary traders who trade with their clients.

7.3 Arbitrageurs

Arbitrageurs trade when they can identify opportunities to buy and sell identical or essentially similar instruments at different prices in different markets. They profit when they can buy in one market for less than they sell in another market. Arbitrageurs are financial intermediaries because they connect buyers in one market to sellers in another market.

The purest form of arbitrage involves buying and selling the same instrument in two different markets. Arbitrageurs who do such trades sell to buyers in one market and buy from sellers in the other market. They provide liquidity to the markets because they make it easier for buyers and sellers to trade when and where they want to trade.

Because dealers and arbitrageurs both provide liquidity to other traders, they compete with each other. The dealers connect buyers and sellers who arrive in the same market at different times whereas the arbitrageurs connect buyers and sellers who arrive at the same time in different markets. In practice, traders who profit from offering liquidity rarely are purely dealers or purely arbitrageurs. Instead, most traders attempt to identify and exploit every opportunity they can to manage their inventories profitably.

If information about prices is readily available to market participants, pure arbitrages involving the same instrument will be quite rare. Traders who are well informed about market conditions usually route their orders to the market offering the best price so that arbitrageurs will have few opportunities to match traders across markets when they want to trade the exact same instrument.

Arbitrageurs often trade securities or contracts whose values depend on the same underlying factors. For example, dealers in equity option contracts often sell call options in the contract market and buy the underlying shares in the stock market. Because the values of the call options and of the underlying shares are closely correlated (the value of the call increases with the value of the shares), the long stock position hedges the risk in the short call position so that the dealer's net position is not too risky.

Similar to the pure arbitrage that involves the same instrument in different markets, these arbitrage trades connect buyers in one market to sellers in another market. In this case, however, the buyers and sellers are interested in different instruments whose values are closely related. In the example, the buyer is interested in buying a call options contract, the value of which is a nonlinear function of the value of the underlying stock; the seller is interested in selling the underlying stock.

Options dealers buy stock and sell calls when calls are overpriced relative to the underlying stocks. They use complicated financial models to value options in relation to underlying stock values, and they use financial engineering techniques to control the risk of their portfolios. Successful arbitrageurs must know valuation relations well and they must manage the risk in their portfolios well to trade profitably. They profit by buying the relatively undervalued instrument and selling the relatively overvalued instrument.

Buying a risk in one form and selling it another form involves a process called replication. Arbitrageurs use various trading strategies to replicate the returns to securities and contracts. If they can substantially replicate those returns, they can use the replication trading strategy to offset the risk of buying or selling the actual securities and contracts. The combined effect of their trading is to transform risk from one form to another. This process allows them to create or eliminate contracts in response to the excess demand for, and supply of, contracts.

For example, when traders want to buy more call contracts than are presently available, they push the call contract prices up so that calls become overvalued relative to the underlying stock. The arbitrageurs replicate calls by using a particular financial engineering strategy to buy the underlying stock, and then create the desired call option contracts by selling them short. In contrast, if more calls have been created than traders want to hold, call prices will fall so that calls become undervalued relative to the underlying stock. The arbitrageurs will trade stocks and contracts to absorb the excess contracts. Arbitrageurs who use these strategies are financial intermediaries because they connect buyers and sellers who want to trade the same underlying risks but in different forms.

EXAMPLE 15

Dealers and Arbitrageurs

With respect to providing liquidity to market participants, what characteristics most clearly distinguish dealers from arbitrageurs?

Solution:

Dealers provide liquidity to buyers and sellers who arrive at the same market at different times. They move liquidity through time. Arbitrageurs provide liquidity to buyers and sellers who arrive at different markets at the same time. They move liquidity across markets.

SECURITIZERS, DEPOSITORY INSTITUTIONS AND INSURANCE COMPANIES

8

d describe types of financial intermediaries and services that they provide;

Banks and investment companies create new financial products when they buy and repackage securities or other assets. For example, mortgage banks commonly originate hundreds or thousands of residential mortgages by lending money to homeowners. They then place the mortgages in a pool and sell shares of the pool to investors as mortgage pass-through securities, which are also known as mortgage-backed securities. All payments of principal and interest are passed through to the investors each month, after deducting the costs of servicing the mortgages. Investors who purchase these pass-through securities obtain securities that in aggregate have the same net cash flows and associated risks as the pool of mortgages.

The process of buying assets, placing them in a pool, and then selling securities that represent ownership of the pool is called securitization.

Mortgage-backed securities have the advantage that default losses and early repayments are much more predictable for a diversified portfolio of mortgages than they are for individual mortgages. They are also attractive to investors who cannot efficiently service mortgages but wish to invest in mortgages. By securitizing mortgage pools, the mortgage banks allow investors who are not large enough to buy hundreds of mortgages to obtain the benefits of diversification and economies of scale in loan servicing.

Securitization greatly improves liquidity in the mortgage markets because it allows investors in the pass-through securities to buy mortgages indirectly that they otherwise would not buy. Because the financial risks associated with mortgage-backed securities (debt securities with specified claims on the cash flows of a portfolio of mortgages) are much more predictable than those of individual mortgages, mortgage-backed securities are easier to price and thus easier to sell when investors need to raise cash. These characteristics make the market for mortgage-backed securities much more liquid than the market for individual mortgages. Because investors value liquidity—the ability to sell when they want to—they will pay more for securitized mortgages than for individual mortgages. The homeowners benefit because higher mortgage prices imply lower interest rates.

The mortgage bank is a financial intermediary because it connects investors who want to buy mortgages to homeowners who want to borrow money. The homeowners sell mortgages to the bank when the bank lends them money.

Some mortgage banks form mortgage pools from mortgages that they buy from other banks that originate the loans. These mortgage banks are also financial intermediaries because they connect sellers of mortgages to buyers of mortgage-backed securities. Although the sellers of the mortgages are the originating lenders and not the borrowers, the benefits of creating liquid mortgage-backed securities ultimately flow back to the borrowers.

The creation of the pass-through securities generally takes place on the accounts of the mortgage bank. The bank buys mortgages and sells pass-through securities whose values depend on the mortgage pool. The mortgages appear on the bank's accounts as assets and the mortgage-backed securities appear as liabilities.

In many securitizations, the financial intermediary avoids placing the assets and liabilities on its balance sheet by setting up a special corporation or trust that buys the assets and issues the securities. That corporation or trust is called a **special purpose vehicle** (SPV) or alternatively a **special purpose entity** (SPE). Conducting a securitization through a special purpose vehicle is advantageous to investors because their interests in the asset pool are better protected in an SPV than they would be on the balance sheet of the financial intermediary if the financial intermediary were to go bankrupt.

Financial intermediaries securitize many assets. Besides mortgages, banks securitize car loans, credit card receivables, bank loans, and airplane leases, to name just a few assets. As a class, these securities are called asset-backed securities.

When financial intermediaries securitize assets, they often create several classes of securities, called tranches, that have different rights to the cash flows from the asset pool. The tranches are structured so that some produce more predictable cash flows than do others. The senior tranches have first rights to the cash flow from the asset pool. Because the overall risk of a given asset pool cannot be changed, the more junior tranches bear a disproportionate share of the risk of the pool. Practitioners often call the most junior tranche toxic waste because it is so risky. The complexity associated with slicing asset pools into tranches can make the resulting securities difficult to value. Mistakes in valuing these securities contributed to the financial crisis that started in 2007.

Investment companies also create pass-through securities based on investment pools. For example, an exchange-traded fund is an asset-backed security that represents ownership in the securities and contracts held by the fund. The shareholders benefit from the securitization because they can buy or sell an entire portfolio in a single transaction. Because the transaction cost savings are quite substantial, exchange-traded funds often trade in very liquid markets. The investment companies (and sometimes the arbitrageurs) that create exchange-traded funds are financial intermediaries because they connect the buyers of the funds to the sellers of the assets that make up the fund portfolios.

More generally, the creators of all pooled investment vehicles are financial intermediaries that transform portfolios of securities and contracts into securities that represent undivided ownership of the portfolios. The investors in these funds thus indirectly invest in the securities held by the fund. They benefit from the expertise of the investment manager and from obtaining a portfolio that may be more diversified than one they might otherwise be able to hold.

8.1 Depository Institutions and Other Financial Corporations

Depository institutions include commercial banks, savings and loan banks, credit unions, and similar institutions that raise funds from depositors and other investors and lend it to borrowers. The banks give their depositors interest and transaction services, such as check writing and check cashing, in exchange for using their money. They may also raise funds by selling bonds or equity in the bank.

These banks are financial intermediaries because they transfer funds from their depositors and investors to their borrowers. The depositors and investors benefit because they obtain a return (in interest, transaction services, dividends, or capital appreciation) on their funds without having to contract with the borrowers and manage their loans. The borrowers benefit because they obtain the funds that they need without having to search for investors who will trust them to repay their loans.

Many other financial corporations provide credit services. For example, acceptance corporations, discount corporations, payday advance corporations, and factors provide credit to borrowers by lending them money secured by such assets as consumer loans, machinery, future paychecks, or accounts receivables. They finance these loans by selling commercial paper, bonds, and shares to investors. These corporations are intermediaries because they connect investors to borrowers. The investors obtain investments secured by a diversified portfolio of loans while the borrowers obtain funds without having to search for investors.

Brokers also act as financial intermediaries when they lend funds to clients who want to buy securities on margin. They generally obtain the funds from other clients who deposit them in their accounts. Brokers who provide these services to hedge funds and other similar institutions are called prime brokers.

Banks, financial corporations, and brokers can only raise money from depositors and other lenders because their equity owners retain residual interests in the performance of the loans that they make. If the borrowers default, the depositors and other lenders have priority claims over the equity owners. If insufficient money is collected from the borrowers, shareholders' equity is used to pay their depositors and other lenders. The risk of losing capital focuses the equity owners' and management's attention so that credit is not offered foolishly.

Because the ability of these companies to cover their credit losses is limited by the capital that their owners invest in them, the depositors and other investors who lend them money pay close attention to how much money the owners have at risk. For example, if a finance corporation is poorly capitalized, its shareholders will lose little if its clients default on the loans that the finance corporation makes to them. In that case, the finance corporation will have little incentive to lend only to creditworthy borrowers and to effectively manage collection on those loans once they have been made. Worse, it may even choose to lend to borrowers with poor credit because the interest rates that they can charge such borrowers are higher. Until those loans default, the higher income will make the corporation appear to be more profitable than it actually is. Depositors and other investors are aware of these problems and generally pay close attention to them. Accordingly, poorly capitalized financial institutions cannot easily borrow money to finance their operations at favorable rates.

Depository banks and financial corporations are similar to securitized asset pools that issue pass-through securities. Their depositors and investors own securities that ultimately are backed by an asset pool consisting of their loan portfolios. The depositors generally hold the most senior tranche, followed by the other creditors. The shareholders hold the most junior tranche. In the event of bankruptcy, they are paid only if everyone else is paid.

EXAMPLE 16

Commercial Banks

What services do commercial banks provide that make them financial intermediaries?

Solution:

Commercial banks collect deposits from investors and lend them to borrowers. They are intermediaries because they connect lenders to borrowers. Commercial banks also provide transaction services that make it easier for the banks' depository customers to pay bills and collect funds from their own customers.

8.2 Insurance Companies

Insurance companies help people and companies offset risks that concern them. They do this by creating insurance contracts (policies) that provide a payment in the event that some loss occurs. The insured buy these contracts to hedge against potential losses. Common examples of insurance contracts include auto, fire, life, liability, medical, theft, and disaster insurance contracts.

Credit default swaps are also insurance contracts, but historically they have not been subject to the same reserve requirements that most governments apply to more traditional insurance contracts. They may be sold by insurance companies or by other financial entities, such as investment banks or hedge funds.

Insurance contracts transfer risk from those who buy the contracts to those who sell them. Although insurance companies occasionally broker trades between the insured and the insurer, they more commonly provide the insurance themselves. In that case, the insurance company's owners and creditors become the indirect insurers of the risks that the insurance company assumes. Insurance companies also often transfer risks that they do not wish to bear by buying reinsurance policies from reinsurers.

Insurers are financial intermediaries because they connect the buyers of their insurance contracts with investors, creditors, and reinsurers who are willing to bear the insured risks. The buyers benefit because they can easily obtain the risk transfers that they seek without searching for entities that would be willing to assume those risks.

The owners, creditors, and reinsurers of the insurance company benefit because the company allows them to sell their tolerance for risk easily without having to manage the insurance contracts. Instead, the company manages the relationships with the insured—primarily collections and claims—and hopefully controls the various problems—fraud, moral hazard, and adverse selection—that often plague insurance markets. Fraud occurs when people deliberately cause or falsely report losses to collect on insurance. Moral hazard occurs when people are less careful about avoiding insured losses than they would be if they were not insured so that losses occur more often than they would otherwise. Adverse selection occurs when only those who are most at risk buy insurance so that insured losses tend to be greater than average.

Everyone benefits because insurance companies hold large diversified portfolios of policies. Loss rates for well-diversified portfolios of insurance contracts are much more predictable than for single contracts. For such contracts as auto insurance in which losses are almost uncorrelated across policies, diversification ensures that the financial performance of a large portfolio of contracts will be quite predictable and so holding the portfolio will not be very risky. The insured benefit because they do not have to pay the insurers much to compensate them for bearing risk (the expected loss is quite predictable so the risk is relatively low). Instead, their insurance premiums primarily reflect the expected loss rate in the portfolio plus the costs of running and financing the company.

SETTLEMENT AND CUSTODIAL SERVICES AND SUMMARY

9

d describe types of financial intermediaries and services that they provide;

In addition to connecting buyers to sellers through a variety of direct and indirect means, financial intermediaries also help their customers settle their trades and ensure that the resulting positions are not stolen or pledged more than once as collateral.

Clearinghouses arrange for final settlement of trades. In futures markets, they guarantee contract performance. In other markets, they may act only as escrow agents, transferring money from the buyer to the seller while transferring securities from the seller to the buyer.

The members of a clearinghouse are the only traders for whom the clearinghouse will settle trades. To ensure that their members settle the trades that they present to the clearinghouse, clearinghouses require that their members have adequate capital and post-performance bonds (margins). Clearinghouses also limit the aggregate net (buy minus sell) quantities that their members can settle.

Brokers and dealers who are not members of the clearinghouse must arrange to have a clearinghouse member settle their trades. To ensure that the non-member brokers and dealers can settle their trades, clearinghouse members require that their customers (the non-member brokers and dealers) have adequate capital and post-margins. They also limit the aggregate net quantities that their customers can settle and they monitor their customers' trading to ensure that they do not arrange trades that they cannot settle.

Brokers and dealers similarly monitor the trades made by their retail and institutional customers, and regulate their customers to ensure that they do not arrange trades that they cannot settle.

This hierarchical system of responsibility generally ensures that traders settle their trades. The brokers and dealers guarantee settlement of the trades they arrange for their retail and institutional customers. The clearinghouse members guarantee settlement of the trades that their customers present to them, and clearinghouses guarantee settlement of all trades presented to them by their members. If a clearinghouse member fails to settle a trade, the clearinghouse settles the trade using its own capital or capital drafted from the other members.

Reliable settlement of all trades is extremely important to a well-functioning financial system because it allows strangers to confidently contract with each other without worrying too much about **counterparty risk**, the risk that their counterparties will not settle their trades. A secure clearinghouse system thus greatly increases liquidity because it greatly increases the number of counterparties with whom a trader can safely arrange a trade.

In many national markets, clearinghouses clear all securities trades so that traders can trade securities through any exchange, broker, alternative trading system, or dealer. These clearinghouse systems promote competition among these exchange service providers.

In contrast, most futures exchanges have their own clearinghouses. These clearinghouses usually will not accept trades arranged away from their exchanges so that a competing exchange cannot trade another exchange's contracts. Competing exchanges may create similar contracts, but moving traders from one established market to a new market is extraordinarily difficult because traders prefer to trade where other traders trade.

Depositories or custodians hold securities on behalf of their clients. These services, which are often offered by banks, help prevent the loss of securities through fraud, oversight, or natural disaster. Broker–dealers also often hold securities on behalf of their customers so that the customers do not have to hold the securities in certificate form. To avoid problems with lost certificates, securities increasingly are issued only in electronic form.

EXAMPLE 17

Financial Intermediaries

As a relatively new member of the business community, you decide it would be advantageous to join the local lunch club to network with businessmen. Upon learning that you are a financial analyst, club members soon enlist you to give a lunch speech. During the question and answer session afterwards, a member of the audience asks, “I keep reading in the newspaper about the need to regulate ‘financial intermediaries,’ but really don’t understand exactly what they are. Can you tell me?” How do you answer?

Solution:

Financial intermediaries are companies that help their clients achieve their financial goals. They are called intermediaries because, in some way or another, they stand between two or more people who would like to trade with each other, but for various reasons find it difficult to do so directly. The intermediary arranges the trade for them, or more often, trades with both sides.

For example, a commercial bank is an intermediary that connects investors with money to borrowers who need money. The investors buy certificates of deposit from the bank, buy bonds or stock issued by the bank, or simply are depositors in the bank. The borrowers borrow this money from the bank when they arrange loans. Without the bank’s intermediation, the investors would have to find trustworthy borrowers themselves, which would be difficult, and the borrowers would have to find trusting lenders, which would also be difficult.

Similarly, an insurance company is an intermediary because it connects customers who want to insure risks with investors who are willing to bear those risks. The investors own shares or bonds issued by the insurance company, or they have sold reinsurance contracts to the insurance company. The insured benefit because they can more easily buy a policy from an insurance company than they can find counterparties who would be willing to bear their risks. The investors benefit because the insurance company creates a diversified portfolio of risks by selling insurance to thousands or millions of customers. Diversification ensures that the net risk borne by the insurance company and its investors will be predictable and thus financially manageable.

In both cases, the financial intermediary also manages the relationships with its customers and investors so that neither side has to worry about the credit-worthiness or trust-worthiness of its counterparties. For example, the bank manages credit quality and collections on its loans and the insurance company manages risk exposure and collections on its policies. These services benefit both sides by reducing the costs of connecting investors to borrowers or of insured to insurers.

These are only two examples of financial intermediation. Many others involve firms engaged in brokerage, dealing, arbitrage, securitization, investment management, and the clearing and settlement of trades. In all cases, the financial intermediary stands between a buyer and a seller, offering them services that allow them to better achieve their financial goals in a cost effective and efficient manner.

9.1 Summary

By facilitating transactions among buyers and sellers, financial intermediaries provide services essential to a well-functioning financial system. They facilitate transactions the following ways:

1. Brokers, exchanges, and various alternative trading systems match buyers and sellers interested in trading the same instrument at the same place and time. These financial intermediaries specialize in discovering and organizing information about who wants to trade.
2. Dealers and arbitrageurs connect buyers to sellers interested in trading the same instrument but who are not present at the same place and time. Dealers connect buyers to sellers who are present at the same place but at different times whereas arbitrageurs connect buyers to sellers who are present at the same time but in different places. These financial intermediaries trade for their own accounts when providing these services. Dealers buy or sell with one client and hope to do the offsetting transaction later with another client. Arbitrageurs buy from a seller in one market while simultaneously selling to a buyer in another market.
3. Many financial intermediaries create new instruments that depend on the cash flows and associated financial risks of other instruments. The intermediaries provide these services when they securitize assets, manage investment funds, operate banks and other finance corporations that offer investments to investors and loans to borrowers, and operate insurance companies that pool risks. The instruments that they create generally are more attractive to their clients than the instruments on which they are based. The new instruments also may be differentiated to appeal to diverse clienteles. Their efforts connect buyers of one or more instruments to sellers of other instruments, all of which in aggregate provide the same cash flows and risk exposures. Financial intermediaries thus effectively arrange trades among traders who otherwise would not trade with each other.
4. Arbitrageurs who conduct arbitrage among securities and contracts whose values depend on common factors convert risk from one form to another. Their trading connects buyers and sellers who want to trade similar risks expressed in different forms.
5. Banks, clearinghouses, and depositories provide services that ensure traders settle their trades and that the resulting positions are not stolen or pledged more than once as collateral.

POSITIONS AND SHORT POSITIONS

10

e compare positions an investor can take in an asset;

People generally solve their financial and risk management problems by taking positions in various assets or contracts. A **position** in an asset is the quantity of the instrument that an entity owns or owes. A portfolio consists of a set of positions.

People have **long positions** when they own assets or contracts. Examples of long positions include ownership of stocks, bonds, currencies, contracts, commodities, or real assets. Long positions benefit from an appreciation in the prices of the assets or contracts owned.

People have **short positions** when they have sold assets that they do not own, or when they write and sell contracts. Short positions benefit from a decrease in the prices of the assets or contracts sold. Short sellers profit by selling at high prices and repurchasing at lower prices. Information-motivated traders sell assets and contracts short positions when they believe that prices will fall.

Hedgers also often sell instruments short. They short securities and contracts when the financial risks inherent in the instruments are positively correlated with the risks to which they are exposed. For example, to hedge the risk associated with holding copper inventories, a wire manufacturer would sell short copper futures. If the price of copper falls, the manufacturer will lose on his copper inventories but gain on his short futures position. (If the risk in an instrument is inversely correlated with a risk to which hedgers are exposed, the hedgers will hedge with long positions.)

Contracts have long sides and short sides. The long side of a forward or futures contract is the side that will take physical delivery or its cash equivalent. The short side of such contracts is the side that is liable for the delivery. The long side of a futures contract increases in value when the value of the underlying asset increases in value.

The identification of the two sides can be confusing for option contracts. The long side of an option contract is the side that holds the right to exercise the option. The short side is the side that must satisfy the obligation. Practitioners say that that the long side *holds* the option and the short side *writes* the option, so the long side is the holder and the short side is the writer. The put contracts are the source of the potential confusion. The put contract holder has the right to sell the underlying to the writer. The holder will benefit if the price of the underlying falls, in which case the price of the put contract will rise. The holder is long the put contract and has an indirect short position in the underlying instrument. Analysts call the indirect short position short exposure to the underlying. The put contract holders have long exposure to their option contract and short exposure to the underlying instrument.

Exhibit 1 Option Positions and Their Associated Underlying Risk Exposures

Type of Option	Option Position	Exposure to Underlying Risk
Call	Long	Long
Call	Short	Short
Put	Long	Short
Put	Short	Long

The identification of the long side in a swap contract is often arbitrary because swap contracts call for the exchange of contractually determined cash flows rather than for the purchase (or the cash equivalent) of some underlying instrument. In general, the side that benefits from an increase in the quoted price is the long side.

The identification of the long side in currency contracts also may be confusing. In this case, the confusion stems from symmetry in the contracts. The buyer of one currency is the seller of the other currency, and vice versa for the seller. Thus, a long forward position in one currency is a short forward position in the other currency. When practitioners describe a position, they generally will say, “I’m long the dollar against the yen,” which means they have bought dollars and sold yen.

10.1 Short Positions

Short sellers create short positions in contracts by selling contracts that they do not own. In a sense, they become the issuers of the contract when they create the liabilities associated with their contracts. This analogy will also help you better understand risk when you study corporate finance: Corporations create short positions in their bonds when they issue bonds in exchange for cash. Although bonds are generally considered to be securities, they are also contracts between the issuer and the bondholder.

Short sellers create short positions in securities by borrowing securities from security lenders who are long holders. The short sellers then sell the borrowed securities to other traders. Short sellers close their positions by repurchasing the securities and returning them to the security lenders. If the securities drop in value, the short sellers profit because they repurchase the securities at lower prices than the prices at which they sold the securities. If the securities rise in value, they will lose. Short sellers who buy to close their positions are said to cover their positions.

The potential gains in a long position generally are unbounded. For example, the stock prices of such highly successful companies as Yahoo! have increased more than 50-fold since they were first publicly traded. The potential losses on long positions, however, are limited to no more than 100 percent—a complete loss—for long positions without any associated liabilities.

In contrast, the potential gains on a short position are limited to no more than 100 percent whereas the potential losses are unbounded. The unbounded potential losses on short positions make short positions very risky in volatile instruments. As an extreme example of this, if you had shorted 100 shares of Yahoo! in July 1996 at $20 and kept the position open for four years, you would have lost $148,000 on your $2,000 initial short position. During this period, Yahoo! rose 75-fold to $1,500 on a split-adjusted equivalent basis.

Although security lenders generally believe that they are long the securities that they lend, in fact, they do not actually own the securities during the periods of their loans. Instead, they own promises made by the short sellers to return the securities. These promises are memorialized in security lending agreements. These agreements specify that the short sellers will pay the long sellers all dividends or interest that they otherwise would have received had they not lent their securities. These payments are called payments-in-lieu of dividends (or of interest), and they may have different tax treatments than actual dividends and interest. The security lending agreements also protect the lenders in the event of a stock split.

To secure the security loans, lenders require that the short seller leave the proceeds of the short sale on deposit with them as collateral for the stock loan. They invest the collateral in short-term securities, and they rebate the interest to the short sellers at rates called short rebate rates. The short rebate rates are determined in the market and generally are available only to institutional short-sellers and some large retail traders. If a security is hard to borrow, the rebate rate may be very small or even negative. Such securities are said to be “on special”. Most security lending agreements require various margin payments to keep the credit risk among the parties from growing when prices change.

Securities lenders lend their securities because the short rebate rates they pay on the collateral are lower than the interest rates they receive from investing the collateral. The difference is because of the implicit loan fees that they receive from the borrowers for borrowing the stock. The difference also compensates lenders for risks that the lenders take when investing the collateral and for the risk that the borrowers will default if prices rise significantly.

EXAMPLE 18

Short Positions in Securities and Contracts

How is the process of short selling shares of Siemens different from that of short selling a Siemens equity call option contract?

Solution:

To short sell shares of Siemens, the seller (or his broker) must borrow the shares from a long holder so that he can deliver them to the buyer. To short sell a Siemens equity call option contract, the seller simply creates the contract when he sells it to the buyer.

11 LEVERAGED POSITIONS

f calculate and interpret the leverage ratio, the rate of return on a margin transaction, and the security price at which the investor would receive a margin call;

In many markets, traders can buy securities by borrowing some of the purchase price. They usually borrow the money from their brokers. The borrowed money is called the **margin loan**, and they are said to buy on margin. The interest rate that the buyers pay for their margin loan is called the **call money rate**. The call money rate is above the government bill rate and is negotiable. Large buyers generally obtain more favorable rates than do retail buyers. For institutional-size buyers, the call money rate is quite low because the loans are generally well secured by securities held as collateral by the lender.

Trader's equity is that portion of the security price that the buyer must supply. Traders who buy securities on margin are subject to minimum margin requirements. The **initial margin requirement** is the minimum fraction of the purchase price that must be trader's equity. This requirement may be set by the government, the exchange, or the exchange clearinghouse. For example, in the United States, the Federal Reserve Board sets the initial margin requirement through Regulation T. In Hong Kong SAR, the Securities and Futures Commission sets the margin requirements. In all markets, brokers often require more equity than the government-required minimum from their clients when lending to them.

Many markets allow brokers to lend their clients more money if the brokers use risk models to measure and control the overall risk of their clients' portfolios. This system is called portfolio margining.

Buying securities on margin can greatly increase the potential gains or losses for a given amount of equity in a position because the trader can buy more securities on margin than he could otherwise. The buyer thus earns greater profits when prices rise and suffers greater losses when prices fall. The relation between risk and borrowing is called **financial leverage** (often simply called leverage). Traders leverage their positions when they borrow to buy more securities. A highly leveraged position is large relative to the equity that supports it.

The leverage ratio is the ratio of the value of the position to the value of the equity investment in it. The leverage ratio indicates how many times larger a position is than the equity that supports it. The maximum leverage ratio associated with a position financed by the minimum margin requirement is one divided by the minimum margin requirement. If the requirement is 40 percent, then the maximum leverage ratio is 2.5 = 100% position ÷ 40% equity.

The leverage ratio indicates how much more risky a leveraged position is relative to an unleveraged position. For example, if a stock bought on 40 percent margin rises 10 percent, the buyer will experience a 25 percent (2.5 × 10%) return on the equity investment in her leveraged position. But if the stock falls by 10 percent, the return on the equity investment will be −25 percent (before the interest on the margin loan and before payment of commissions).

Financial analysts must be able to compute the total return to the equity investment in a leveraged position. The total return depends on the price change of the purchased security, the dividends or interest paid by the security, the interest paid on the margin loan, and the commissions paid to buy and sell the security. The following example illustrates the computation of the total return to a leveraged purchase of stock that pays a dividend.

EXAMPLE 19

Computing Total Return to a Leveraged Stock Purchase

A buyer buys stock on margin and holds the position for exactly one year, during which time the stock pays a dividend. For simplicity, assume that the interest on the loan and the dividend are both paid at the end of the year.

Purchase price	$20/share
Sale price	$15/share
Shares purchased	1,000
Leverage ratio	2.5
Call money rate	5%
Dividend	$0.10/share
Commission	$0.01/share

1 What is the total return on this investment?

2 Why is the loss greater than the 25 percent decrease in the market price?

Solution to 1:

To find the return on this investment, first determine the initial equity and then determine the equity remaining after the sale. The total purchase price is $20,000. The leverage ratio of 2.5 indicates that the buyer's equity financed 40 percent = (1 ÷ 2.5) of the purchase price. Thus, the equity investment is $8,000 = 40% of $20,000. The $12,000 remainder is borrowed. The actual investment is slightly higher because the buyer must pay a commission of $10 = $0.01/share × 1,000 shares to buy the stock. The total initial investment is $8,010.

At the end of the year, the stock price has declined by $5/share. The buyer lost $5,000 = $5/share × 1,000 shares as a result of the price change. In addition, the buyer has to pay interest at 5 percent on the $12,000 loan, or $600. The buyer also receives a dividend of $0.10/share, or $100. The trader's equity remaining after the sale is computed from the initial equity investment as follows:

Initial investment	$8,010
Purchase commission	−10
Trading gains/losses	−5,000
Margin interest paid	−600
Dividends received	100

(continued)

Sales commission paid	–10
Remaining equity	$2,490

or

Proceeds on sale	$15,000
Payoff loan	–12,000
Margin interest paid	–600
Dividends received	100
Sales commission paid	–10
Remaining equity	$2,490

so that the return on the initial investment of $8,010 is (2,490 – 8,010)/8,010 = –68.9%.

Solution to 2:

The realized loss is substantially greater than the stock price return of ($15 – $20)/$20 = –25%. Most of the difference is because of the leverage with the remainder primarily the result of the interest paid on the loan. Based on the leverage alone and ignoring the other cash flows, we would expect that the return on the equity would be –62.5% = 2.5 leverage times the –25% stock price return.

In the above example, if the stock dropped more than the buyer's original 40 percent margin (ignoring commissions, interest, and dividends), the trader's equity would have become negative. In that case, the investor would owe his broker more than the stock is worth. Brokers often lose money in such situations if the buyer does not repay the loan out of other funds.

To prevent such losses, brokers require that margin buyers always have a minimum amount of equity in their positions. This minimum is called the **maintenance margin requirement**. It is usually 25 percent of the current value of the position, but it may be higher or lower depending on the volatility of the instrument and the policies of the broker.

If the value of the equity falls below the maintenance margin requirement, the buyer will receive a **margin call**, or request for additional equity. If the buyer does not deposit additional equity with the broker in a timely manner, the broker will close the position to prevent further losses and thereby secure repayment of the margin loan.

When you buy securities on margin, you must know the price at which you will receive a margin call if prices drop. The answer to this question depends on your initial equity and on the maintenance margin requirement.

EXAMPLE 20

Margin Call Price

A trader buys stock on margin posting 40 percent of the initial stock price of $20 as equity. The maintenance margin requirement for the position is 25 percent. Below what price will a margin call occur?

Solution:

The trader's initial equity is 40 percent of the initial stock price of $20, or $8 per share. Subsequent changes in equity per share are equal to the share price change so that equity per share is equal to $8 + ($P$ – 20) where P is the current share price. The margin call takes place when equity drops below the 25 percent maintenance margin requirement. The price below which a margin call will take place is the solution to the following equation:

$$\frac{\text{Equity/share}}{\text{Price/share}} = \frac{\$8 + P - 20}{P} = 25\%$$

which occurs at P = 16. When the price drops below \$16, the equity will be under \$4/share, which is less than 25 percent of the price.

Traders who sell securities short are also subject to margin requirements because they have borrowed securities. Initially, the trader's equity supporting the short position must be at least equal to the margin requirement times the initial value of the short position. If prices rise, equity will be lost. At some point, the short seller will have to contribute additional equity to meet the maintenance margin requirement. Otherwise, the broker will buy the security back to cover the short position to prevent further losses and thereby secure repayment of the stock loan.

ORDERS AND EXECUTION INSTRUCTIONS

12

g compare execution, validity, and clearing instructions;

h compare market orders with limit orders;

Buyers and sellers communicate with the brokers, exchanges, and dealers that arrange their trades by issuing **orders**. All orders specify what instrument to trade, how much to trade, and whether to buy or sell. Most orders also have other instructions attached to them. These additional instructions may include execution instructions, validity instructions, and clearing instructions. **Execution instructions** indicate how to fill the order, **validity instructions** indicate when the order may be filled, and **clearing instructions** indicate how to arrange the final settlement of the trade.

In this section, we introduce various order instructions and explain how traders use them to achieve their objectives. We discuss execution mechanisms—how exchanges, brokers and dealers fill orders—in the next section. To understand the concepts in this section, however, you need to know a little about order execution mechanisms.

In most markets, dealers and various other proprietary traders often are willing to buy from, or sell to, other traders seeking to sell or buy. The prices at which they are willing to buy are called **bid** prices and those at which they are willing to sell are called **ask** prices, or sometimes **offer** prices. The ask prices are invariably higher than the bid prices.

The traders who are willing to trade at various prices may also indicate the quantities that they will trade at those prices. These quantities are called **bid sizes** and **ask sizes** depending on whether they are attached to bids or offers.

Practitioners say that the traders who offer to trade make a market. Those who trade with them take the market.

The highest bid in the market is the **best bid**, and the lowest ask in the market is the **best offer**. The difference between the best bid and the best offer is the **market bid–ask spread**. When traders ask, "What's the market?" they want to know the best bid and ask prices and their associated sizes. Bid–ask spreads are an implicit cost of trading. Markets with small bid–ask spreads are markets in which the costs of trading are small, at least for the sizes quoted. Dealers often quote both bid and ask prices, and in that case, practitioners say that they quote a two-sided market. The market spread is never more than any dealer spread.

12.1 Execution Instructions

Market and limit orders convey the most common execution instructions. A **market order** instructs the broker or exchange to obtain the best price immediately available when filling the order. A **limit order** conveys almost the same instruction: Obtain the best price immediately available, but in no event accept a price higher than a specified limit price when buying or accept a price lower than a specified limit price when selling.

Many people mistakenly believe that limit orders specify the prices at which the orders will trade. Although limit orders do often trade at their limit prices, remember that the first instruction is to obtain the best price available. If better prices are available than the limit price, brokers and exchanges should obtain those prices for their clients.

Market orders generally execute immediately if other traders are willing to take the other side of the trade. The main drawback with market orders is that they can be expensive to execute, especially when the order is placed in a market for a thinly traded security, or more generally, when the order is large relative to the normal trading activity in the market. In that case, a market buy order may fill at a high price, or a market sell order may fill at a low price if no traders are willing to trade at better prices. High purchase prices and low sale prices represent price concessions given to other traders to encourage them to take the other side of the trade. Because the sizes of price concessions can be difficult to predict, and because prices often change between when a trader submits an order and when the order finally fills, the execution prices for market orders are often uncertain.

Buyers and sellers who are concerned about the possibility of trading at unacceptable prices add limit price instructions to their orders. The main problem with limit orders is that they may not execute. Limit orders do not execute if the limit price on a buy order is too low, or if the limit price on a sell order is too high. For example, if an investment manager submits a limit order to buy at the limit price of 20 (buy limit 20) and nobody is willing to sell at or below 20, the order will not trade. If prices never drop to 20, the manager will never buy. If the price subsequently rises, the manager will have lost the opportunity to profit from the price rise.

Whether traders use market orders or limit orders when trying to arrange trades depends on their concerns about price, trading quickly, and failing to trade. On average, limit orders trade at better prices than do market orders, but they often do not trade. Traders generally regret when their limit orders fail to trade because they usually would have profited if they had traded. Limit buy orders do not fill when prices are rising, and limit sell orders do not fill when prices are falling. In both cases, traders would be better off if their orders had filled.

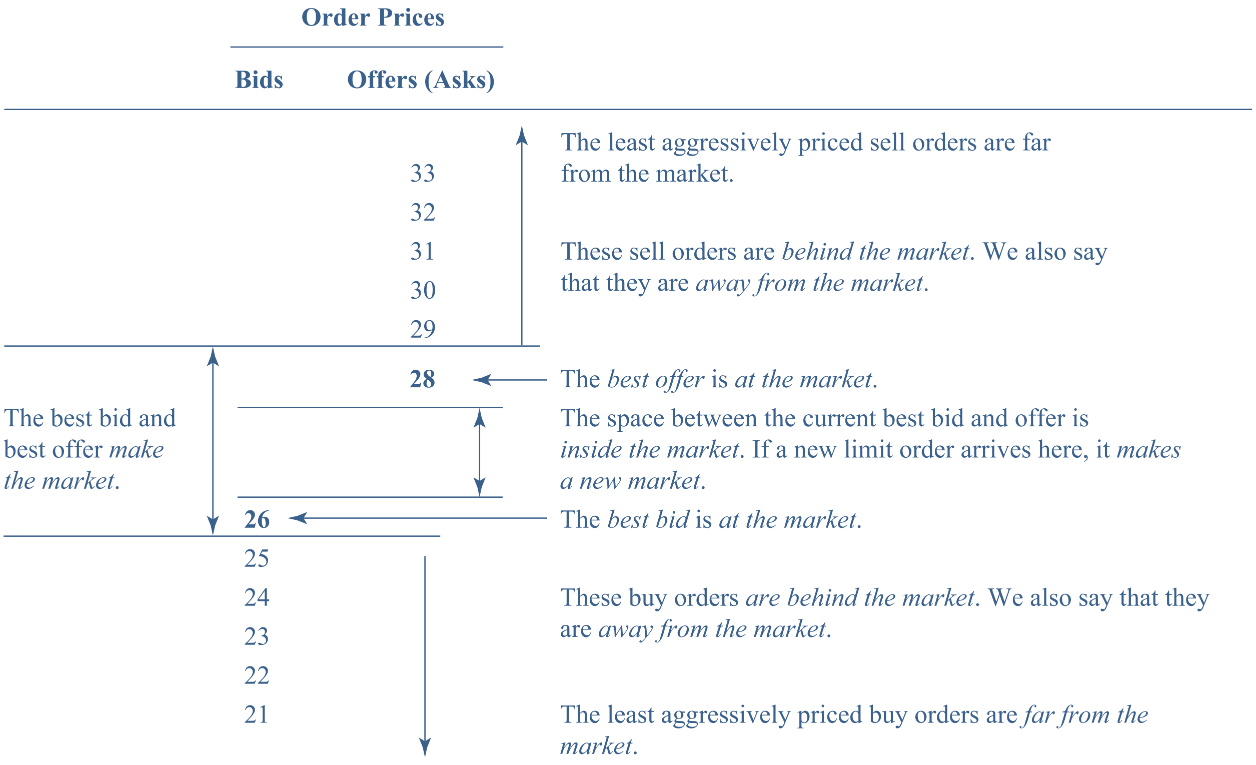
The probability that a limit order will execute depends on where the order is placed relative to market prices. An aggressively priced order is more likely to trade than is a less aggressively priced order. A limit buy order is aggressively priced when the limit price is high relative to the market bid and ask prices. If the limit price is placed above the best offer, the buy order generally will partially or completely fill at the best offer price, depending on the size available at the best offer. Such limit orders are called **marketable limit orders** because at least part of the order can trade immediately. A limit buy order with a very high price relative to the market is essentially a market order.

If the buy order is placed above the best bid but below the best offer, traders say the order makes a new market because it becomes the new best bid. Such orders generally will not immediately trade, but they may attract sellers who are interested in trading. A buy order placed at the best bid is said to make market. It may have to wait until all other buy orders at that price trade first. Finally, a buy order placed below the best bid is **behind the market**. It will not execute unless market prices drop. Traders call limit orders that are waiting to trade **standing limit orders**.

Sell limit orders are aggressively priced if the limit price is low relative to market prices. The limit price of a marketable sell limit order is below the best bid. A limit sell order placed between the best bid and the best offer makes a new market on the sell side, one placed at the best offer makes market, and one placed above the best offer is behind the market.

Exhibit 2 presents a simplified **limit order book** in which orders are presented ranked by their limit prices for a hypothetical market. The market is "26 bid, offered at 28" because the best bid is 26 and the best offer (ask) is 28.

Exhibit 2 Terms Traders Use to Describe Standing Limit Orders



The least aggressively priced sell orders are far from the market.

These sell orders are *behind the market*. We also say that they are *away from the market*.

The *best offer* is *at the market*.

The best bid and best offer *make the market*.

The space between the current best bid and offer is *inside the market*. If a new limit order arrives here, it *makes a new market*.

The *best bid* is *at the market*.

These buy orders *are behind the market*. We also say that they are *away from the market*.

The least aggressively priced buy orders are *far from the market*.

EXAMPLE 21

Making and Taking

1. What is the difference between making a market and taking a market?
2. What order types are most likely associated with making a market and taking a market?

Solution to 1:

A trader makes a market when the trader offers to trade. A trader takes a market when the trader accepts an offer to trade.

Solution to 2:

Traders place standing limit orders to give other traders opportunities to trade. Standing limit orders thus make markets. In contrast, traders use market orders or marketable limit orders to take offers to trade. These marketable orders take the market.

A trade-off exists between how aggressively priced an order is and the ultimate trade price. Although aggressively priced orders fill faster and with more certainty then do less aggressively priced limit orders, the prices at which they execute are inferior. Buyers seeking to trade quickly must pay higher prices to increase the probability of trading quickly. Similarly, sellers seeking to trade quickly must accept lower prices to increase the probability of trading quickly.

Some order execution instructions specify conditions on size. For example, **all-or-nothing (AON) orders** can only trade if their entire sizes can be traded. Traders can similarly specify minimum fill sizes. This specification is common when settlement costs depend on the number of trades made to fill an order and not on the aggregate size of the order.

Exposure instructions indicate whether, how, and perhaps to whom orders should be exposed. **Hidden orders** are exposed only to the brokers or exchanges that receive them. These agencies cannot disclose hidden orders to other traders until they can fill them. Traders use hidden orders when they are afraid that other traders might behave strategically if they knew that a large order was in the market. Traders can discover hidden size only by submitting orders that will trade with that size. Thus, traders can only learn about hidden size after they have committed to trading with it.

Traders also often indicate a specific **display size** for their orders. Brokers and exchanges then expose only the display size for these orders. Any additional size is hidden from the public but can be filled if a suitably large order arrives. Traders sometimes call such orders **iceberg orders** because most of the order is hidden. Traders specify display sizes when they do not want to display their full sizes, but still want other traders to know that someone is willing to trade at the displayed price. Traders on the opposite side who wish to trade additional size at that price can discover the hidden size only if they trade the displayed size, at which point the broker or exchange will display any remaining size up to the display size. They also can discover the hidden size by submitting large orders that will trade with that size.

EXAMPLE 22

Market versus Limit and Hidden versus Displayed Orders

You are the buy-side trader for a very clever investment manager. The manager has hired a commercial satellite firm to take regular pictures of the parking lots in which new car dealers store their inventories. It has also hired some part-time workers to count the cars on the lots. With this information and some econometric analyses, the manager can predict weekly new car sale announcements more accurately than can most analysts. The manager typically makes a quarter percent each week on this strategy. Once a week, a day before the announcements are made, the manager gives you large orders to buy or sell car manufacturers based on his insights into their dealers' sales. What primary issues should you consider when deciding whether to:

1 use market or limit orders to fill his orders?

2 display the orders or hide them?

Solution to 1:

The manager's information is quite perishable. If his orders are not filled before the weekly sales are reported to the public, the manager will lose the opportunity to profit from the information as prices immediately adjust to the news. The manager, therefore, needs to get the orders filled quickly. This consideration suggests that the orders should be submitted as market orders. If submitted as limit orders, the orders might not execute and the firm would lose the opportunity to profit.

Large market orders, however, can be very expensive to execute, especially if few people are willing to trade significant size on the other side of the market. Because transaction costs can easily exceed the expected quarter percent return, you should submit limit orders to limit the execution prices that you are willing to accept. It is better to fail to trade than to trade at losing prices.

Solution to 2:

Your large orders could easily move the market if many people were aware of them, and even more so if others were aware that you are trading on behalf of a successful information-motivated trader. You thus should consider submitting hidden orders. The disadvantage of hidden orders is that they do not let people know that they can trade the other side if they want to.

VALIDITY INSTRUCTIONS AND CLEARING INSTRUCTIONS

13

g compare execution, validity, and clearing instructions;

Validity instructions indicate when an order may be filled. The most common validity instruction is the **day order**. A day order is good for the day on which it is submitted. If it has not been filled by the close of business, the order expires unfilled.

Good-till-cancelled orders (GTC) are just that. In practice, most brokers limit how long they will manage an order to ensure that they do not fill orders that their clients have forgotten. Such brokers may limit their GTC orders to a few months.

Immediate or cancel orders (IOC) are good only upon receipt by the broker or exchange. If they cannot be filled in part or in whole, they cancel immediately. In some markets these orders are also known as **fill or kill** orders. When searching for hidden liquidity, electronic algorithmic trading systems often submit thousands of these IOC orders for every order that they fill.

Good-on-close orders can only be filled at the close of trading. These orders often are market orders, so traders call them **market-on-close** orders. Traders often use on-close orders when they want to trade at the same prices that will be published as the closing prices of the day. Mutual funds often like to trade at such prices because they value their portfolios at closing prices. Many traders also use **good-on-open** orders.

13.1 Stop Orders

A **stop order** is an order in which a trader has specified a stop price condition. The stop order may not be filled until the stop price condition has been satisfied. For a sell order, the stop price condition suspends execution of the order until a trade occurs at or below the stop price. After that trade, the stop condition is satisfied and the order becomes valid for execution, subject to all other execution instructions attached to it. If the market price subsequently rises above the sell order's stop price before the order trades, the order remains valid. Similarly, a buy order with a stop condition becomes valid only after a price rises above the specified stop price.

Traders often call stop orders **stop-loss orders** because many traders use them with the hope of stopping losses on positions that they have established. For example, a trader who has bought stock at 40 may want to sell the stock if the price falls below 30. In that case, the trader might submit a "GTC, stop 30, market sell" order. If the price falls to or below 30, the market order becomes valid and it should immediately execute at the best price then available in the market. That price may be substantially lower than 30 if the market is falling quickly. The stop-loss order thus does not guarantee a stop to losses at the stop price. If potential sellers are worried about trading at too low of a price, they can attach stop instructions to limit orders instead of market orders. In this example, if the trader is unwilling to sell below 25, the trader would submit a "GTC, stop 30, limit 25 sell" order.

If a trader wants to guarantee that he can sell at 30, the trader would buy a put option contract struck at 30. The purchase price of the option would include a premium for the insurance that the trader is buying. Option contracts can be viewed as limit orders for which execution is guaranteed at the strike price. A trader similarly might use a stop-buy order or a call option to limit losses on a short position.

A portfolio manager might use a stop-buy order when the manager believes that a security is undervalued but is unwilling to trade without market confirmation. For example, suppose that a stock currently trades for 50 RMB and a manager believes that it should be worth 100 RMB. Further, the manager believes that the stock will much more likely be worth 100 RMB if other traders are willing to buy it above 65 RMB. To best take advantage of this information, the manager would consider issuing a "GTC, stop 65 RMB, limit 100 RMB buy" order. Note that if the manager relies too much on the market when making this trading decision, however, he may violate CFA Standard of Professional Conduct V.A.2, which requires that all investment actions have a reasonable and adequate basis supported by appropriate research and investigation.

Because stop-sell orders become valid when prices are falling and stop-buy orders become valid when prices are rising, traders using stop orders contribute to market momentum as their sell orders push prices down further and their buy orders push prices up. Execution prices for stop orders thus are often quite poor.

EXAMPLE 23

Limit and Stop Instructions

In what ways do limit and stop instructions differ?

Solution:

Although both limit and stop instructions specify prices, the role that these prices play in the arrangement of a trade are completely different. A limit price places a limit on what trade prices will be acceptable to the trader. A buyer will accept prices only at or lower than the limit price whereas a seller will accept prices only at or above the limit price.

In contrast, a stop price indicates when an order can be filled. A buy order can only be filled once the market has traded at a price at or above the stop price. A sell order can only be filled once the market has traded at a price at or below the stop price.

Both order instructions may delay or prevent the execution of an order. A buy limit order will not execute until someone is willing to sell at or below the limit price. Similarly, a sell limit order will not execute until someone is willing to buy at or above the limit sell price. In contrast, a stop-buy order will not execute if the market price never rises to the stop price. Similarly, a stop-sell order will not execute if the market price never falls to the stop price.

13.2 Clearing Instructions

Clearing instructions tell brokers and exchanges how to arrange final settlement of trades. Traders generally do not attach these instructions to each order—instead they provide them as standing instructions. These instructions indicate what entity is responsible for clearing and settling the trade. For retail trades, that entity is the customer's broker. For institutional trades, that entity may be a custodian or another broker. When a client uses one broker to arrange trades and another broker to settle trades, traders say that the first broker gives up the trade to the other broker, who is often known as the prime broker. Institutional traders provide these instructions so they can obtain specialized execution services from different brokers while maintaining a single account for custodial services and other prime brokerage services, such as margin loans.

An important clearing instruction that must appear on security sale orders is an indication of whether the sale is a long sale or a short sale. In either case, the broker representing the sell order must ensure that the trader can deliver securities for settlement. For a long sale, the broker must confirm that the securities held are available for delivery. For a short sale, the broker must either borrow the security on behalf of the client or confirm that the client can borrow the security.

PRIMARY SECURITY MARKETS

14

i. define primary and secondary markets and explain how secondary markets support primary markets;

When issuers first sell their securities to investors, practitioners say that the trades take place in the **primary markets**. An issuer makes an **initial public offering** (IPO)—sometimes called a placing—of a security issue when it sells the security to the public for the first time. A seasoned security is a security that an issuer has already issued. If the issuer wants to sell additional units of a previously issued security, it makes a **seasoned offering** (sometimes called a secondary offering). Both types of offerings occur in the **primary market** where issuers sell their securities to investors. Later, if investors trade these securities among themselves, they trade in **secondary markets**. This section discusses primary markets and the procedures that issuers use to offer their securities to the public.

14.1 Public Offerings

Corporations generally contract with an investment bank to help them sell their securities to the public. The investment bank then lines up subscribers who will buy the security. Investment bankers call this process **book building**. In London, the book builder is called the book runner. The bank tries to build a book of orders to which they can sell the offering. Investment banks often support their book building by providing investment information and opinion about the issuer to their clients and to the public. Before the offering, the issuer generally makes a very detailed disclosure of its business, of the risks inherent in it, and of the uses to which the new funds will be placed.

When time is of the essence, issuers in Europe may issue securities through an **accelerated book build**, in which the investment bank arranges the offering in only one or two days. Such sales often occur at discounted prices.

The first public offering of common stock in a company consists of newly issued shares to be sold by the company. It may also include shares that the founders and other early investors in the company seek to sell. The initial public offering provides these investors with a means of liquidating their investments.

In an **underwritten offering**—the most common type of offering—the investment bank guarantees the sale of the issue at an offering price that it negotiates with the issuer. If the issue is undersubscribed, the bank will buy whatever securities it cannot sell at the offering price. In the case of an IPO, the underwriter usually also promises to make a market in the security for about a month to ensure that the secondary market will be liquid and to provide price support, if necessary. For large issues, a syndicate of investment banks and broker–dealers helps the **lead underwriter** build the book. The issuer usually pays an underwriting fee of about 7 percent for these various services. The underwriting fee is a placement cost of the offering.

In a **best effort offering**, the investment bank acts only as broker. If the offering is undersubscribed, the issuer will not sell as much as it hoped to sell.

For both types of offerings, the issuer and the bank usually jointly set the offering price following a negotiation. If they set a price that buyers consider too high, the offering will be undersubscribed, and they will fail to sell the entire issue. If they set the price too low, the offering will be oversubscribed, in which case the securities are often allocated to preferred clients or on a pro-rata basis.

(Note that CFA Standard of Professional Conduct III.B—fair dealing—requires that the allocation be based on a written policy disclosed to clients and suggests that the securities be offered on a pro-rata basis among all clients who have comparable relationships with their broker–dealers.)

Investment banks have a conflict of interest with respect to the offering price in underwritten offerings. As agents for the issuers, they generally are supposed to select the offering price that will raise the most money. But as underwriters, they have strong incentives to choose a low price. If the price is low, the banks can allocate valuable shares to benefit their clients and thereby indirectly benefit the banks. If the price is too high, the underwriters will have to buy overvalued shares in the offering and perhaps also during the following month if they must support the price in the secondary market, which directly costs the banks. These considerations tend to lower initial offering prices so that prices in the secondary market often rise immediately following an IPO. They are less important in a seasoned offering because trading in the secondary market helps identify the proper price for the offering.

First time issuers generally accept lower offering prices because they and many others believe that an undersubscribed IPO conveys very unfavorable information to the market about the company's prospects at a time when it is most vulnerable to public opinion about its prospects. They fear that an undersubscribed initial public offering will make it substantially harder to raise additional capital in subsequent seasoned offerings.

EXAMPLE 24

The Healthybots Initial Public Offering

Healthybots is a health care company that treats diseases using artificial intelligence–based solutions. Healthybots raised approximately £265 million gross through an initial public offering of 103,142,466 ordinary shares at £2.57 per ordinary share. After the initial public offering, Healthybots had 213,333,333 ordinary shares issued and outstanding.

Healthybots received gross proceeds of approximately £34.3 million and net proceeds of £31.8 million. The ordinary shares that were sold to the public represented approximately 48 percent of Healthybots' total issued ordinary shares.

The shares commenced trading at 8:00 a.m. on the AIM market of the London Stock Exchange, where Healthybots opened at £2.74, traded 37 million shares between £2.68 and £2.74, and closed at £2.73.

1. Approximately how many new shares were issued by the company and how many shares were sold by the company's founders? What fraction of their holdings in the company did the founders sell?
2. Approximately what return did the subscribers who participated in the IPO make on the first day it traded?
3. Approximately how much did Healthybots pay in placement costs as a percentage of the new funds raised?

Solution to 1:

Healthybots received gross proceeds of £34.3 million at £2.57 per share, so the company issued and sold 13,346,304 shares (= £34.3 million/£2.57 per share). The total placement was for 103,142,466 shares, so the founders sold 89,796,162 shares (= 103,142,466 shares − 13,346,304 shares). Because approximately 200 million shares (= 213.3 million shares – 13.3 million shares) were outstanding before the placement, the founders sold approximately 45 percent (= 90 million shares/200 million shares) of the company.

Solution to 2:

The subscribers bought the stock for £2.57 per share, and it closed at £2.73. The first day return thus was $6.2\% = \frac{2.73 - 2.57}{2.57} \times 100$.

Solution to 3:

Healthybots obtained gross proceeds of £34.3 million but only raised net proceeds of £31.8 million. The £2.5 million difference was the total cost of the placement to the firm, which is 7.9 percent of net proceeds, or new funds raised (£2.5 million/£31.8 million).

14.2 Private Placements and Other Primary Market Transactions

Corporations sometimes issue their securities in private placements. In a **private placement**, corporations sell securities directly to a small group of qualified investors, usually with the assistance of an investment bank. Qualified investors have sufficient knowledge and experience to recognize the risks that they assume, and sufficient wealth to assume those risks responsibly. Most countries allow corporations to do private placements without nearly as much public disclosure as is required for public offerings. Private placements, therefore, may be cheaper than public offerings, but the buyers generally require higher returns (lower purchase prices) because they cannot subsequently trade the securities in an organized secondary market.

Corporations sometimes sell new issues of seasoned securities directly to the public on a piecemeal basis via a shelf registration. In a **shelf registration**, the corporation makes all public disclosures that it would for a regular offering, but it does not sell the shares in a single transaction. Instead, it sells the shares directly into the secondary market over time, generally when it needs additional capital. Shelf registrations provide corporations with flexibility in the timing of their capital transactions, and they can alleviate the downward price pressures often associated with large secondary offerings.

Many corporations may also issue shares via dividend reinvestment plans (DRPs or DRIPs, for short) that allow their shareholders to reinvest their dividends in newly issued shares of the corporation (in particular, DRPs specify that the corporation issue new shares for the plan rather than purchase them on the open market). These plans sometimes also allow existing shareholders and other investors to buy additional stock at a slight discount to current prices.

Finally, corporations can issue new stock via a rights offering. In a rights offering, the corporation distributes rights to buy stock at a fixed price to existing shareholders in proportion to their holdings. Because the rights need not be exercised, they are options. The exercise price, however, is set below the current market price of the stock so that buying stock with the rights is immediately profitable. Consequently, shareholders will experience dilution in the value of their existing shares. They can offset the dilution loss by exercising their rights or by selling the rights to others who will exercise them. Shareholders generally do not like rights offerings because they must provide additional capital (or sell their rights) to avoid losses through dilution. Financial analysts recognize that these securities, although called rights, are actually short-term stock warrants and value them accordingly.

The national governments of financially strong countries generally issue their bonds, notes, and bills in public auctions organized by a government agency (usually associated with the finance ministry). They may also sell them directly to dealers.

Smaller and less financially secure national governments and most regional governments often contract with investment banks to help them sell and distribute their securities. The laws of many governments, however, require that they auction their securities.

EXAMPLE 25

Private and Public Placements

In what ways do private placements differ from public placements?

Solution:

Issuers make private placements to a limited number of investors that generally are financially sophisticated and well informed about risk. The investors generally have some relationship to the issuer. Issuers make public placements when they sell securities to the general public. Public placements generally require substantially more financial disclosure than do private placements.

14.3 Importance of Secondary Markets to Primary Markets

Corporations and governments can raise money in the primary markets at lower cost when their securities will trade in liquid secondary markets. In a **liquid market**, traders can buy or sell with low transaction costs and small price concessions when they want to trade. Buyers value liquidity because they may need to sell their securities to meet liquidity needs. Investors thus will pay more for securities that they can easily sell than for those that they cannot easily sell. Higher prices translate into lower costs of capital for the issuers.

SECONDARY SECURITY MARKET AND CONTRACT MARKET STRUCTURES

15

i. define primary and secondary markets and explain how secondary markets support primary markets;

j. describe how securities, contracts, and currencies are traded in quote-driven, order-driven, and brokered markets;

Trading is the successful outcome to a bilateral search in which buyers look for sellers and sellers look for buyers. Many market structures have developed to reduce the costs of this search. Markets are liquid when the costs of finding a suitable counterparty to a trade are low.

Trading in securities and contracts takes place in a variety of market structures. The structures differ by when trades can be arranged, who arranges the trades, how they do so, and how traders learn about possible trading opportunities and executed trades. This section introduces the various market structures used to trade securities and contracts. We first consider trading sessions, then execution mechanisms, and finally market information systems.

15.1 Trading Sessions

Markets are organized as call markets or as continuous trading markets. In a **call market**, trades can be arranged only when the market is called at a particular time and place. In contrast in a **continuous trading market**, trades can be arranged and executed anytime the market is open.

Buyers can easily find sellers and vice versa in call markets because all traders interested in trading (or orders representing their interests) are present at the same time and place. Call markets thus have the potential to be very liquid when they are called. But they are completely illiquid between trading sessions. In contrast, traders can arrange and execute their trades at any time in continuous trading markets, but doing so can be difficult if the buyers and sellers (or their orders) are not both present at the same time.

Most call markets use single price auctions to match buyers to sellers. In these auctions, the market constructs order books representing all buy orders and all seller orders. The market then chooses a single trade price that will maximize the total volume of trade. The order books are supply and demand schedules, and the point at which they cross determines the trade price.

Call markets usually are organized just once a day, but some markets organize calls at more frequent intervals.

Many continuous trading markets start their trading with a call market auction. During a pre-opening period, traders submit their orders for the market call. At the opening, any possible trades are arranged and then trading continues in the continuous trading session. Some continuous trading markets also close their trading with a call. In these markets, traders who are only interested in trading in the closing call submit market- or limit-on-close orders.

EXAMPLE 26

Call Markets and Continuous Trading Markets

1 What is the main advantage of a call market compared with a continuous trading market?

2 What is the main advantage of a continuous trading market compared with a call market?

Solution to 1:

By gathering all traders to the same place at the same time, a call market makes it easier for buyers to find sellers and vice versa. In contrast, if buyers and sellers (or their orders) are not present at the same time in a continuous market, they cannot trade.

Solution to 2:

In a continuous trading market, a willing buyer and seller can trade at any time the market is open. In contrast, in a call market trading can take place only when the market is called.

15.2 Execution Mechanisms

The three main types of market structures are quote-driven markets (sometimes called price-driven or dealer markets), order-driven markets, and brokered markets. In **quote-driven markets**, customers trade with dealers. In **order-driven markets**, an order matching system run by an exchange, a broker, or an alternative trading system uses rules to arrange trades based on the orders that traders submit. Most exchanges and ECNs organize order-driven markets. In **brokered markets**, brokers arrange trades between their customers. Brokered markets are common for transactions of unique instruments, such as real estate properties, intellectual properties, or large blocks of securities. Many trading systems use more than one type of market structure.

15.2.1 *Quote-Driven Markets*

Worldwide, most trading, other than in stocks, takes place in quote-driven markets. Almost all bonds and currencies and most spot commodities trade in quote-driven markets. Traders call them quote-driven (or price-driven or dealer) because customers trade at the prices quoted by dealers. Depending on the instrument traded, the dealers work for commercial banks, for investment banks, for broker–dealers, or for proprietary trading houses.

Quote-driven markets also often are called over-the-counter (OTC) markets because securities used to be literally traded over the dealer's counter in the dealer's office. Now, most trades in OTC markets are conducted over proprietary computer communications networks, by telephone, or sometimes over instant messaging systems.

15.2.2 *Order-Driven Markets*

Order-driven markets arrange trades using rules to match buy orders to sell orders. The orders may be submitted by customers or by dealers. Almost all exchanges use order-driven trading systems, and every automated trading system is an order-driven system.

Because rules match buyers to sellers, traders often trade with complete strangers. Order-driven markets thus must have procedures to ensure that buyers and sellers perform on their trade contracts. Otherwise, dishonest traders would enter contracts that they would not settle if a change in market conditions made settlement unprofitable.

Two sets of rules characterize order-driven market mechanisms: Order matching rules and trade pricing rules. The order matching rules match buy orders to sell orders. The trade pricing rules determine the prices at which the matched trades take place.

15.2.2.1 Order Matching Rules Order-driven trading systems match buyers to sellers using rules that rank the buy orders and the sell orders based on price, and often along with other secondary criteria. The systems then match the highest-ranking buy order with the highest-ranking sell order. If the buyer is willing to pay at least as much as the seller is willing to receive, the system will arrange a trade for the minimum of the buy and sell quantities. The remaining size, if any, is then matched with the next order on the other side and the process continues until no further trades can be arranged.

The **order precedence hierarchy** determines which orders go first. The first rule is **price priority**: The highest priced buy orders and the lowest priced sell orders go first. They are the most aggressively priced orders. **Secondary precedence rules** determine how to rank orders at the same price. Most trading systems use time precedence to rank orders at the same price. The first order to arrive has precedence over other orders. In trading systems that permit hidden and partially hidden orders, displayed quantities at a given price generally have precedence over the undisplayed quantities. So the complete precedence hierarchy is given by price priority, display precedence at a given price, and finally time precedence among all orders with the same display status at a given price. These rules give traders incentives to improve price, display their orders, and arrive early if they want to trade quickly. These incentives increase market liquidity.

15.2.2.2 Trade Pricing Rules After the orders are matched, the trading system then uses its trade pricing rule to determine the trade price. The three rules that various order-driven markets use to price their trades are the uniform pricing rule, the discriminatory pricing rule, and the derivative pricing rule.

Call markets commonly use the uniform pricing rule. Under this rule, all trades execute at the same price. The market chooses the price that maximizes the total quantity traded.

Continuous trading markets use the **discriminatory pricing rule**. Under this rule, the limit price of the order or quote that first arrived—the standing order—determines the trade price. This rule allows a large arriving trader to discriminate among standing limit orders by filling the most aggressively priced orders first at their limit prices and then filling less aggressively priced orders at their less favorable (from the point of view of the arriving trader) limit prices. If trading systems did not use this pricing rule, large traders would break their orders into pieces to price discriminate on their own.

EXAMPLE 27

Filling a Large Order in a Continuous Trading Market

Before the arrival of a large order, the Tokyo Stock Exchange has the following limit orders standing on its book:

Buyer	Bid Size	Limit Price(¥)	Offer Size	Seller
Takumi	15	100.1		
Hiroto	8	100.2		
Shou	10	100.3		
		100.4	4	Hina
		100.5	6	Sakura
		100.6	12	Miku

Tsubasa submits a day order to buy 15 contracts, limit ¥100.5. With whom does he trade, what is his average trade price, and what does the limit order book look like afterward?

Solution:

Tsubasa's buy order first fills with the most aggressively priced sell order, which is Hina's order for four contracts. A trade takes place at ¥100.4 for four contracts, Hina's order fills completely, and Tsubasa still has 11 more contracts remaining.

The next most aggressively priced sell order is Sakura's order for six contracts. A second trade takes place at ¥100.5 for six contracts, Sakura's order fills completely, and Tsubasa still has five more contracts remaining.

The next most aggressively priced sell order is Miku's order at ¥100.6. No further trade is possible, however, because her limit sell price is above Tsubasa's limit buy price. Tsubasa's average trade price is $¥100.46 = \frac{4 \times ¥100.4 + 6 \times ¥100.5}{4 + 6}$.

Because Tsubasa issued a day order, the remainder of his order is placed on the book on the buy side at ¥100.5. The following orders are then on the book:

Buyer	Bid Size	Limit Price (¥)	Offer Size	Seller
Takumi	15	100.1		
Hiroto	8	100.2		
Shou	10	100.3		
		100.4		
Tsubasa	5	100.5		
		100.6	12	Miku

If Tsubasa had issued an immediate-or-cancel order, the remaining five contracts would have been cancelled.

Crossing networks use the derivative pricing rule. **Crossing networks** are trading systems that match buyers and sellers who are willing to trade at prices obtained from other markets. Most systems cross their trades at the midpoint of the best bid and ask quotes published by the exchange at which the security primarily trades. This pricing rule is called a **derivative pricing rule** because the price is derived from another market. In particular, the price does not depend on the orders submitted to the crossing network. Some crossing networks are organized as call markets and others as continuously trading markets. The most important crossing market is the equity trading system POSIT.

15.2.3 *Brokered Markets*

The third execution mechanism is the **brokered market**, in which brokers arrange trades among their clients. Brokers organize markets for instruments for which finding a buyer or a seller willing to trade is difficult because the instruments are unique and thus of interest only to a limited number of people or institutions. These instruments generally are also infrequently traded and expensive to carry in inventory. Examples of such instruments include very large blocks of stock, real estate properties, fine art masterpieces, intellectual properties, operating companies, liquor licenses, and taxi medallions. Because dealers generally are unable or unwilling to hold these assets in their inventories, they will not make markets in them. Organizing order-driven markets for these instruments is not sensible because too few traders would submit orders to them.

Successful brokers in these markets try to know everyone who might now or in the future be willing to trade. They spend most of their time on the telephone and in meetings building their networks.

EXAMPLE 28

Quote-Driven, Order-Driven, and Brokered Markets

What are the primary advantages of quote-driven, order-driven, and brokered markets?

Solution:

In a quote-driven market, dealers generally are available to supply liquidity. In an order-driven market, traders can supply liquidity to each other. In a brokered market, brokers help find traders who are willing to trade when dealers would not be willing to make markets and when traders would not be willing to post orders.

15.3 Market Information Systems

Markets vary in the type and quantity of data that they disseminate to the public. Traders say that a market is pre-trade transparent if the market publishes real-time data about quotes and orders. Markets are post-trade transparent if the market publishes trade prices and sizes soon after trades occur.

Buy-side traders value transparency because it allows them to better manage their trading, understand market values, and estimate their prospective and actual transaction costs. In contrast, dealers prefer to trade in opaque markets because, as frequent traders, they have an information advantage over those who know less than they do. Bid–ask spreads tend to be wider and transaction costs tend to be higher in opaque markets because finding the best available price is harder for traders in such markets.

WELL-FUNCTIONING FINANCIAL SYSTEMS

16

k describe characteristics of a well-functioning financial system;

The financial system allows traders to solve financing and risk management problems. In a well-functioning financial system:

- investors can easily move money from the present to the future while obtaining a fair rate of return for the risks that they bear;
- borrowers can easily obtain funds that they need to undertake current projects if they can credibly promise to repay the funds in the future;
- hedgers can easily trade away or offset the risks that concern them; and
- traders can easily trade currencies for other currencies or commodities that they need.

If the assets or contracts needed to solve these problems are available to trade, the financial system has **complete markets**. If the costs of arranging these trades are low, the financial system is **operationally efficient**. If the prices of the assets and contracts reflect all available information related to fundamental values, the financial system is informationally efficient.

Well-functioning financial systems are characterized by:

- the existence of well-developed markets that trade instruments that help people solve their financial problems (complete markets);
- liquid markets in which the costs of trading—commissions, bid–ask spreads, and order price impacts—are low (operationally efficient markets);
- timely financial disclosures by corporations and governments that allow market participants to estimate the fundamental values of securities (support **informationally efficient markets**); and
- prices that reflect fundamental values so that prices vary primarily in response to changes in fundamental values and not to demands for liquidity made by uninformed traders (informationally efficient markets).

Such complete and operationally efficient markets are produced by financial intermediaries who:

- organize exchanges, brokerages, and alternative trading systems that match buyers to sellers;
- provide liquidity on demand to traders;
- securitize assets to produce investment instruments that are attractive to investors and thereby lower the costs of funds for borrowers;
- run banks that match investors to borrowers by taking deposits and making loans;
- run insurance companies that pool uncorrelated risks;
- provide investment advisory services that help investors manage and grow their assets at low cost;
- organize clearinghouses that ensure everyone settles their trades and contracts; and
- organize depositories that ensure nobody loses their assets.

The benefits of a well-functioning financial system are huge. In such systems, investors who need to move money to the future can easily connect with entrepreneurs who need money now to develop new products and services. Similarly, producers who would otherwise avoid valuable projects because they are too risky can easily transfer those risks to others who can better bear them. Most importantly, these transactions generally can take place among strangers so that the benefits from trading can be derived from an enormous number of potential matches.

In contrast, economies that have poorly functioning financial systems have great difficulties allocating capital among the many companies who could use it. Financial transactions tend to be limited to arrangements within families when people cannot easily find trustworthy counterparties who will honor their contracts. In such economies, capital is allocated inefficiently, risks are not easily shared, and production is inefficient.

An extraordinarily important byproduct of an operationally efficient financial system is the production of informationally efficient prices. Prices are informationally efficient when they reflect all available information about fundamental values. Informative prices are crucially important to the welfare of an economy because they help ensure that resources go where they are most valuable. Economies that use resources where they are most valuable are allocationally efficient. Economies that do not use resources where they are most valuable waste their resources and consequently often are quite poor.

Well-informed traders make prices informationally efficient. When they buy assets and contracts that they think are undervalued, they tend to push the assets' prices up. Similarly, when they sell assets and contracts that they think are overvalued, they tend to push the assets' prices down. The effect of their trading thus causes prices to reflect their information about values.

How accurately prices reflect fundamental information depends on the costs of obtaining fundamental information and on the liquidity available to well-informed traders. Accounting standards and reporting requirements that produce meaningful and timely financial disclosures reduce the costs of obtaining fundamental information and thereby allow analysts to form more accurate estimates of fundamental values. Liquid markets allow well-informed traders to fill their orders at low cost. If filling orders is very costly, informed trading may not be profitable. In that case, information-motivated traders will not commit resources to collect and analyze data and they will not trade. Without their research and their associated trading, prices would be less informative.

EXAMPLE 29

Well-Functioning Financial Systems

As a financial analyst specializing in emerging market equities, you understand that a well-functioning financial system contributes to the economic prosperity of a country. You are asked to start covering a new small market country. What factors will you consider when characterizing the quality of its financial markets?

Solution:

In general, you will consider whether:

- the country has markets that allow its companies and residents to finance projects, save for the future, and exchange risk;
- the costs of trading in those markets is low; and
- prices reflect fundamental values.

You may specifically check to see whether:

- fixed income and stock markets allow borrowers to easily obtain capital from investors;
- corporations disclose financial and operating data on a timely basis in conformity to widely respected reporting standards, such as IFRS;
- forward, futures, and options markets trade instruments that companies need to hedge their risks;
- dealers and arbitrageurs allow traders to trade when they want to;
- bid–ask spreads are small;
- trades and contracts invariably settle as expected;
- investment managers provide high-quality management services for reasonable fees;
- banks and other financing companies are well capitalized and thus able to help investors provide capital to borrowers;
- securitized assets are available and represent reasonable credit risks;

- insurance companies are well capitalized and thus able to help those exposed to risks insure against them; and
- price volatility appears consistent with changes in fundamental values.

17 MARKET REGULATION

l. describe objectives of market regulation.

Government agencies and practitioner organizations regulate many markets and the financial intermediaries that participate in them. The regulators generally seek to promote fair and orderly markets in which traders can trade at prices that accurately reflect fundamental values without incurring excessive transaction costs. This section identifies the problems that financial regulators hope to solve and the objectives of their regulations.

Regrettably, some people will steal from each other if given a chance, especially if the probability of detection is low or if the penalty for being caught is low. The number of ways that people can steal or misappropriate wealth generally increases with the complexity of their relationships and with asymmetries in their knowledge. Because financial markets tend to be complex, and because customers are often much less sophisticated than the professionals that serve them, the potential for losses through various frauds can be unacceptably high in unregulated markets.

Regulators thus ensure that systems are in place to protect customers from fraud. In principle, the customers themselves would demand such systems as a condition of doing business. When customers are unsophisticated or poorly informed, however, they may not know how to protect themselves. When the costs of learning are large—as they often are in complex financial markets—having regulators look out for the public interest can be economically efficient.

More customer money is probably lost in financial markets through negligence than through outright fraud. Most customers in financial markets use various agents to help them solve problems that they do not understand well. These agents include securities brokers, financial advisers, investment managers, and insurance agents. Because customers generally do not have much information about market conditions, they find it extremely difficult to measure the added value they obtain from their agents. This problem is especially challenging when performance has a strong random component. In that case, determining whether agents are skilled or lucky is very difficult. Moreover, if the agent is a good salesman, the customer may not critically evaluate their agent's performance. These conditions, which characterize most financial markets, ensure that customers cannot easily determine whether their agents are working faithfully for them. They tend to lose if their agents are unqualified or lazy, or if they unconsciously favor themselves and their friends over their clients, as is natural for even the most honest people.

Regulators help solve these agency problems by setting minimum standards of competence for agents and by defining and enforcing minimum standards of practice. CFA Institute provides significant standard setting leadership in the areas of investment management and investment performance reporting through its Chartered Financial Analyst Program, in which you are studying, and its Global Investment Performance Standards. In principle, regulation would not be necessary if customers could identify competent agents and effectively measure their performance. In the financial markets, doing so is very difficult.

Regulators often act to level the playing field for market participants. For example, in many jurisdictions, insider trading in securities is illegal. The rule prevents corporate insiders and others with access to corporate information from trading on material information that has not been released to the public. The purpose of the rule is to reduce the profits that insiders could extract from the markets. These profits would come from other traders who would lose when they trade with well-informed insiders. Because traders tend to withdraw from markets when they lose, rules against insider trading help keep markets liquid. They also keep corporate insiders from hoarding information.

Many situations arise in financial markets in which common standards benefit everyone involved. For example, having all companies report financial results on a common basis allows financial analysts to easily compare companies. Accordingly, the International Accounting Standards Board (IASB) and the US-based Financial Accounting Standards Board (FASB), among many others, promulgate common financial standards to which all companies must report. The benefits of having common reporting standards has led to a very successful and continuing effort to converge all accounting standards to a single worldwide standard. Without such regulations, investors might eventually refuse to invest in companies that do not report to a common standard, but such market-based discipline is a very slow regulator of behavior, and it would have little effect on companies that do not need to raise new capital.

Regulators generally require that financial firms maintain minimum levels of capital. These capital requirements serve two purposes. First, they ensure that the companies will be able to honor their contractual commitments when unexpected market movements or poor decisions cause them to lose money. Second, they ensure that the owners of financial firms have substantial interest in the decisions that they make. Without a substantial financial interest in the decisions that they make, companies often take too many risks and exercise poor judgment about extending credit to others. When such companies fail, they impose significant costs on others. Minimum capital requirements reduce the probability that financial firms will fail and they reduce the disruptions associated with those failures that do occur. In principle, a firm's customers and counterparties could require minimum capital levels as a condition of doing business with the firm, but they have more difficulty enforcing their contracts than do governments who can imprison people.

Regulators similarly regulate insurance companies and pension funds that make long-term promises to their clients. Such entities need to maintain adequate reserves to ensure that they can fund their liabilities. Unfortunately, their managers have a tendency to underestimate these reserves if they will not be around when the liabilities come due. Again, in principle, policyholders and employees could regulate the behavior of their insurance funds and their employers by refusing to contract with them if they do not promise to adequately fund their liabilities. In practice, however, the sophistication, information, and time necessary to write and enforce contracts that control these problems are beyond the reach of most people. The government thus is a sensible regulator of such problems.

Many regulators are self-regulating organizations (SROs) that regulate their members. Exchanges, clearinghouses, and dealer trade organizations are examples of self-regulating organizations. In some cases, the members of these organizations voluntarily subject themselves to the SRO's regulations to promote the common good. In other cases, governments delegate regulatory and enforcement authorities to SROs, usually subject to the supervision of a government agency, such as a national securities and exchange authority. Exchanges, dealer associations, and clearing agencies often regulate their members with these delegated powers.

By setting high standards of behavior, SROs help their members obtain the confidence of their customers. They also reduce the chance that members of the SRO will incur losses when dealing with other members of the SRO.

When regulators fail to solve the problems discussed here, the financial system does not function well. People who lose money stop saving and borrowers with good ideas cannot fund their projects. Similarly, hedgers withdraw from markets when the costs of hedging are high. Without the ability to hedge, producers become reluctant to specialize because specialization generally increases risk. Because specialization also decreases costs, however, production becomes less efficient as producers chose safer technologies. Economies that cannot solve the regulatory problems described in this section tend to operate less efficiently than do better regulated economies, and they tend to be less wealthy.

To summarize, the objectives of market regulation are to:

1 control fraud;
2 control agency problems;
3 promote fairness;
4 set mutually beneficial standards;
5 prevent undercapitalized financial firms from exploiting their investors by making excessively risky investments; and
6 ensure that long-term liabilities are funded.

Regulation is necessary because regulating certain behaviors through market-based mechanisms is too costly for people who are unsophisticated and uninformed. Effectively regulated markets allow people to better achieve their financial goals.

EXAMPLE 30

Bankrupt Traders

You are the chief executive officer of a brokerage that is a member of a clearinghouse. A trader who clears through your firm is bankrupt at midday, but you do not yet know it even though your clearing agreement with him explicitly requires that he immediately report significant losses. The trader knows that if he takes a large position, prices might move in his favor so that he will no longer be bankrupt. The trader attempts to do so and succeeds. You find out about this later in the evening.

1 Why does the clearinghouse regulate its members?
2 What should you do about the trader?
3 Why would the clearinghouse allow you to keep his trading profits?

Solution to 1:

The clearinghouse regulates its members to ensure that no member imposes costs on another member by failing to settle a trade.

Solution to 2:

You should immediately end your clearing relationship with the trader and confiscate his trading profits. The trader was trading with your firm's capital after he became bankrupt. Had he lost, your firm would have borne the loss.

Solution to 3:

If the clearinghouse did not permit you to keep his trading profits, other traders similarly situated might attempt the same strategy.

SUMMARY

This reading introduces how the financial system operates and explains how well-functioning financial systems lead to wealthy economies. Financial analysts need to understand how the financial system works because their analyses often lead to trading decisions.

The financial system consists of markets and the financial intermediaries that operate in them. These institutions allow buyers to connect with sellers. They may trade directly with each other when they trade the same instrument or they only may trade indirectly when a financial intermediary connects the buyer to the seller through transactions with each that appear on the intermediary's balance sheet. The buyer and seller may exchange instruments, cash flows, or risks.

The following points, among others, were made in this reading:

- The financial system consists of mechanisms that allow strangers to contract with each other to move money through time, to hedge risks, and to exchange assets that they value less for those that they value more.
- Investors move money from the present to the future when they save. They expect a normal rate of return for bearing risk through time. Borrowers move money from the future to the present to fund current projects and expenditures. Hedgers trade to reduce their exposure to risks they prefer not to take. Information-motivated traders are active investment managers who try to identify under- and overvalued instruments.
- Securities are first sold in primary markets by their issuers. They then trade in secondary markets.
- People invest in pooled investment vehicles to benefit from the investment management services of their managers.
- Forward contracts allow buyers and sellers to arrange for future sales at predetermined prices. Futures contracts are forward contracts guaranteed by clearinghouses. The guarantee ensures that strangers are willing to trade with each other and that traders can offset their positions by trading with anybody. These features of futures contract markets make them highly attractive to hedgers and information-motivated traders.
- Many financial intermediaries connect buyers to sellers in a given instrument, acting directly as brokers and exchanges or indirectly as dealers and arbitrageurs.
- Financial intermediaries create instruments when they conduct arbitrage, securitize assets, borrow to lend, manage investment funds, or pool insurance contracts. These activities all transform cash flows and risks from one form to another. Their services allow buyers and sellers to connect with each other through instruments that meet their specific needs.
- Financial markets work best when strangers can contract with each other without worrying about whether their counterparts are able and willing to honor their contract. Clearinghouses, variation margins, maintenance margins, and settlement guarantees made by creditworthy brokers on behalf of their clients help manage credit risk and ultimately allow strangers to contract with each other.
- Information-motivated traders short sell when they expect that prices will fall. Hedgers short sell to reduce the risks of a long position in a related contract or commodity.

- Margin loans allow people to buy more securities than their equity would otherwise permit them to buy. The larger positions expose them to more risk so that gains and losses for a given amount of equity will be larger. The leverage ratio is the value of a position divided by the value of the equity supporting it. The returns to the equity in a position are equal to the leverage ratio times the returns to the unleveraged position.
- To protect against credit losses, brokers demand maintenance margin payments from their customers who have borrowed cash or securities when adverse price changes cause their customer's equity to drop below the maintenance margin ratio. Brokers close positions for customers who do not satisfy these margin calls.
- Orders are instructions to trade. They always specify instrument, side (buy or sell), and quantity. They usually also provide several other instructions.
- Market orders tend to fill quickly but often at inferior prices. Limit orders generally fill at better prices if they fill, but they may not fill. Traders choose order submission strategies on the basis of how quickly they want to trade, the prices they are willing to accept, and the consequences of failing to trade.
- Stop instructions are attached to other orders to delay efforts to fill them until the stop condition is satisfied. Although stop orders are often used to stop losses, they are not always effective.
- Issuers sell their securities using underwritten public offerings, best efforts public offerings, private placements, shelf registrations, dividend reinvestment programs, and rights offerings. Investment banks have a conflict of interests when setting the initial offering price in an IPO.
- Well-functioning secondary markets are essential to raising capital in the primary markets because investors value the ability to sell their securities if they no longer want to hold them or if they need to disinvest to raise cash. If they cannot trade their securities in a liquid market, they will not pay as much for them.
- Matching buyers and sellers in call markets is easy because the traders (or their orders) come together at the same time and place.
- Dealers provide liquidity in quote-driven markets. Public traders as well as dealers provide liquidity in order-driven markets.
- Order-driven markets arrange trades by ranking orders using precedence rules. The rules generally ensure that traders who provide the best prices, display the most size, and arrive early trade first. Continuous order-driven markets price orders using the discriminatory pricing rule. Under this rule, standing limit orders determine trade prices.
- Brokers help people trade unique instruments or positions for which finding a buyer or a seller is difficult.
- Transaction costs are lower in transparent markets than in opaque markets because traders can more easily determine market value and more easily manage their trading in transparent markets.
- A well-functioning financial system allows people to trade instruments that best solve their wealth and risk management problems with low transaction costs. Complete and liquid markets characterize a well-functioning financial system. Complete markets are markets in which the instruments needed to solve investment and risk management problems are available to trade. Liquid markets are markets in which traders can trade when they want to trade at low cost.
- The financial system is operationally efficient when its markets are liquid. Liquid markets lower the costs of raising capital.

- A well-functioning financial system promotes wealth by ensuring that capital allocation decisions are well made. A well-functioning financial system also promotes wealth by allowing people to share the risks associated with valuable products that would otherwise not be undertaken.
- Prices are informationally efficient when they reflect all available information about fundamental values. Information-motivated traders make prices informationally efficient. Prices will be most informative in liquid markets because information-motivated traders will not invest in information and research if establishing positions based on their analyses is too costly.
- Regulators generally seek to promote fair and orderly markets in which traders can trade at prices that accurately reflect fundamental values without incurring excessive transaction costs. Governmental agencies and self-regulating organizations of practitioners provide regulatory services that attempt to make markets safer and more efficient.
- Mandated financial disclosure programs for the issuers of publicly traded securities ensure that information necessary to estimate security values is available to financial analysts on a consistent basis.

PRACTICE PROBLEMS

1 Akihiko Takabe has designed a sophisticated forecasting model, which predicts the movements in the overall stock market, in the hope of earning a return in excess of a fair return for the risk involved. He uses the predictions of the model to decide whether to buy, hold, or sell the shares of an index fund that aims to replicate the movements of the stock market. Takabe would *best* be characterized as a(n):

A hedger.

B investor.

C information-motivated trader.

2 James Beach is young and has substantial wealth. A significant proportion of his stock portfolio consists of emerging market stocks that offer relatively high expected returns at the cost of relatively high risk. Beach believes that investment in emerging market stocks is appropriate for him given his ability and willingness to take risk. Which of the following labels *most appropriately* describes Beach?

A Hedger.

B Investor.

C Information-motivated trader.

3 Lisa Smith owns a manufacturing company in the United States. Her company has sold goods to a customer in Brazil and will be paid in Brazilian real (BRL) in three months. Smith is concerned about the possibility of the BRL depreciating more than expected against the US dollar (USD). Therefore, she is planning to sell three-month futures contracts on the BRL. The seller of such contracts generally gains when the BRL depreciates against the USD. If Smith were to sell these future contracts, she would *most appropriately* be described as a(n):

A hedger.

B investor.

C information-motivated trader.

4 Which of the following is *not* a function of the financial system?

A To regulate arbitrageurs' profits (excess returns).

B To help the economy achieve allocational efficiency.

C To facilitate borrowing by businesses to fund current operations.

5 An investor primarily invests in stocks of publicly traded companies. The investor wants to increase the diversification of his portfolio. A friend has recommended investing in real estate properties. The purchase of real estate would *best* be characterized as a transaction in the:

A derivative investment market.

B traditional investment market.

C alternative investment market.

6 A hedge fund holds its excess cash in 90-day commercial paper and negotiable certificates of deposit. The cash management policy of the hedge fund is *best described* as using:

A capital market instruments.

© 2019 CFA Institute. All rights reserved.

B money market instruments.

C intermediate-term debt instruments.

7 An oil and gas exploration and production company announces that it is offering 30 million shares to the public at $45.50 each. This transaction is *most likely* a sale in the:

A futures market.

B primary market.

C secondary market.

8 Consider a mutual fund that invests primarily in fixed-income securities that have been determined to be appropriate given the fund's investment goal. Which of the following is *least likely* to be a part of this fund?

A Warrants.

B Commercial paper.

C Repurchase agreements.

9 A friend has asked you to explain the differences between open-end and closed-end funds. Which of the following will you *most likely* include in your explanation?

A Closed-end funds are unavailable to new investors.

B When investors sell the shares of an open-end fund, they can receive a discount or a premium to the fund's net asset value.

C When selling shares, investors in an open-end fund sell the shares back to the fund whereas investors in a closed-end fund sell the shares to others in the secondary market.

10 The usefulness of a forward contract is limited by some problems. Which of the following is *most likely* one of those problems?

A Once you have entered into a forward contract, it is difficult to exit from the contract.

B Entering into a forward contract requires the long party to deposit an initial amount with the short party.

C If the price of the underlying asset moves adversely from the perspective of the long party, periodic payments must be made to the short party.

11 Tony Harris is planning to start trading in commodities. He has heard about the use of futures contracts on commodities and is learning more about them. Which of the following is Harris *least likely* to find associated with a futures contract?

A Existence of counterparty risk.

B Standardized contractual terms.

C Payment of an initial margin to enter into a contract.

12 A German company that exports machinery is expecting to receive $10 million in three months. The firm converts all its foreign currency receipts into euros. The chief financial officer of the company wishes to lock in a minimum fixed rate for converting the $10 million to euro but also wants to keep the flexibility to use the future spot rate if it is favorable. What hedging transaction is *most likely* to achieve this objective?

A Selling dollars forward.

B Buying put options on the dollar.

C Selling futures contracts on dollars.

13 A book publisher requires substantial quantities of paper. The publisher and a paper producer have entered into an agreement for the publisher to buy and the producer to supply a given quantity of paper four months later at a price agreed upon today. This agreement is a:

- **A** futures contract.
- **B** forward contract.
- **C** commodity swap.

14 The Standard & Poor's Depositary Receipts (SPDRs) is an investment that tracks the S&P 500 stock market index. Purchases and sales of SPDRs during an average trading day are *best* described as:

- **A** primary market transactions in a pooled investment.
- **B** secondary market transactions in a pooled investment.
- **C** secondary market transactions in an actively managed investment.

15 The Standard & Poor's Depositary Receipts (SPDRs) is an exchange-traded fund in the United States that is designed to track the S&P 500 stock market index. The latest price of a share of SPDRs is $290. A trader has just bought call options on shares of SPDRs for a premium of $3 per share. The call options expire in six months and have an exercise price of $305 per share. On the expiration date, the trader will exercise the call options (ignore any transaction costs) if and only if the shares of SPDRs are trading:

- **A** below $305 per share.
- **B** above $305 per share.
- **C** above $308 per share.

16 Which of the following statements about exchange-traded funds is *most correct*?

- **A** Exchange-traded funds are not backed by any assets.
- **B** The investment companies that create exchange-traded funds are financial intermediaries.
- **C** The transaction costs of trading shares of exchange-traded funds are substantially greater than the combined costs of trading the underlying assets of the fund.

17 Jason Schmidt works for a hedge fund and he specializes in finding profit opportunities that are the result of inefficiencies in the market for convertible bonds—bonds that can be converted into a predetermined amount of a company's common stock. Schmidt tries to find convertibles that are priced inefficiently relative to the underlying stock. The trading strategy involves the simultaneous purchase of the convertible bond and the short sale of the underlying common stock. The above process could best be described as:

- **A** hedging.
- **B** arbitrage.
- **C** securitization.

18 Pierre-Louis Robert just purchased a call option on shares of the Michelin Group. A few days ago he wrote a put option on Michelin shares. The call and put options have the same exercise price, expiration date, and number of shares underlying. Considering both positions, Robert's exposure to the risk of the stock of the Michelin Group is:

- **A** long.
- **B** short.
- **C** neutral.

19 An online brokerage firm has set the minimum margin requirement at 55 percent. What is the maximum leverage ratio associated with a position financed by this minimum margin requirement?

A 1.55.

B 1.82.

C 2.22.

20 A trader has purchased 200 shares of a non-dividend-paying firm on margin at a price of $50 per share. The leverage ratio is 2.5. Six months later, the trader sells these shares at $60 per share. Ignoring the interest paid on the borrowed amount and the transaction costs, what was the return to the trader during the six-month period?

A 20 percent.

B 33.33 percent.

C 50 percent.

21 Jason Williams purchased 500 shares of a company at $32 per share. The stock was bought on 75 percent margin. One month later, Williams had to pay interest on the amount borrowed at a rate of 2 percent per month. At that time, Williams received a dividend of $0.50 per share. Immediately after that he sold the shares at $28 per share. He paid commissions of $10 on the purchase and $10 on the sale of the stock. What was the rate of return on this investment for the one-month period?

A –12.5 percent.

B –15.4 percent.

C –50.1 percent.

22 Caroline Rogers believes the price of Gamma Corp. stock will go down in the near future. She has decided to sell short 200 shares of Gamma Corp. at the current market price of €47. The initial margin requirement is 40 percent. Which of the following is an appropriate statement regarding the margin requirement that Rogers is subject to on this short sale?

A She will need to contribute €3,760 as margin.

B She will need to contribute €5,640 as margin.

C She will only need to leave the proceeds from the short sale as deposit and does not need to contribute any additional funds.

23 The current price of a stock is $25 per share. You have $10,000 to invest. You borrow an additional $10,000 from your broker and invest $20,000 in the stock. If the maintenance margin is 30 percent, at what price will a margin call first occur?

A $9.62.

B $17.86.

C $19.71.

24 You have placed a sell market-on-open order—a market order that would automatically be submitted at the market's open tomorrow and would fill at the market price. Your instruction, to sell the shares at the market open, is a(n):

A execution instruction.

B validity instruction.

C clearing instruction.

25 A market has the following limit orders standing on its book for a particular stock. The bid and ask sizes are number of shares in hundreds.

Bid Size	Limit Price (€)	Offer Size
5	9.73	
12	9.81	
4	9.84	
6	9.95	
	10.02	5
	10.10	12
	10.14	8

What is the market?

A 9.73 bid, offered at 10.14.

B 9.81 bid, offered at 10.10.

C 9.95 bid, offered at 10.02.

26 Consider the following limit order book for a stock. The bid and ask sizes are number of shares in hundreds.

Bid Size	Limit Price (¥)	Offer Size
3	122.80	
8	123.00	
4	123.35	
	123.80	7
	124.10	6
	124.50	7

A new buy limit order is placed for 300 shares at ¥123.40. This limit order is said to:

A take the market.

B make the market.

C make a new market.

27 Currently, the market in a stock is "$54.62 bid, offered at $54.71." A new sell limit order is placed at $54.62. This limit order is said to:

A take the market.

B make the market.

C make a new market.

28 Jim White has sold short 100 shares of Super Stores at a price of $42 per share. He has also simultaneously placed a "good-till-cancelled, stop 50, limit 55 buy" order. Assume that if the stop condition specified by White is satisfied and the order becomes valid, it will get executed. Excluding transaction costs, what is the maximum possible loss that White can have?

A $800.

B $1,300.

C Unlimited.

29 You own shares of a company that are currently trading at $30 a share. Your technical analysis of the shares indicates a support level of $27.50. That is, if the price of the shares is going down, it is more likely to stay above this level rather than fall below it. If the price does fall below this level, however, you believe that the price may continue to decline. You have no immediate intent to sell the shares but are concerned about the possibility of a huge loss if the share price declines below the support level. Which of the following types of orders could you place to most appropriately address your concern?

A Short sell order.

B Good-till-cancelled stop sell order.

C Good-till-cancelled stop buy order.

30 In an underwritten offering, the risk that the entire issue may not be sold to the public at the stipulated offering price is borne by the:

A issuer.

B investment bank.

C buyers of the part of the issue that is sold.

31 A British company listed on AIM (formerly the Alternative Investment Market) of the London Stock Exchange announced the sale of 6,686,665 shares to a small group of qualified investors at £0.025 per share. Which of the following *best describes* this sale?

A Shelf registration.

B Private placement.

C Initial public offering.

32 A German publicly traded company, to raise new capital, gave its existing shareholders the opportunity to subscribe for new shares. The existing shareholders could purchase two new shares at a subscription price of €4.58 per share for every 15 shares held. This is an example of a(n):

A rights offering.

B private placement.

C initial public offering.

33 Consider an order-driven system that allows hidden orders. The following four sell orders on a particular stock are currently in the system's limit order book. Based on the commonly used order precedence hierarchy, which of these orders will have precedence over others?

Order	Time of Arrival (HH:MM:SS)	Limit Price (€)	Special Instruction (If any)
I	9:52:01	20.33	
II	9:52:08	20.29	Hidden order
III	9:53:04	20.29	
IV	9:53:49	20.29	

A Order I (time of arrival of 9:52:01).

B Order II (time of arrival of 9:52:08).

C Order III (time of arrival of 9:53:04).

34 Zhenhu Li has submitted an immediate-or-cancel buy order for 500 shares of a company at a limit price of CNY 74.25. There are two sell limit orders standing in that stock's order book at that time. One is for 300 shares at a limit price of CNY 74.30 and the other is for 400 shares at a limit price of CNY 74.35. How many shares in Li's order would get cancelled?

A None (the order would remain open but unfilled).

B 200 (300 shares would get filled).

C 500 (there would be no fill).

35 A market has the following limit orders standing on its book for a particular stock:

Buyer	Bid Size (Number of Shares)	Limit Price (£)	Offer Size (Number of Shares)	Seller
Keith	1,000	19.70		
Paul	200	19.84		
Ann	400	19.89		
Mary	300	20.02		
		20.03	800	Jack
		20.11	1,100	Margaret
		20.16	400	Jeff

Ian submits a day order to sell 1,000 shares, limit £19.83. Assuming that no more buy orders are submitted on that day after Ian submits his order, what would be Ian's average trade price?

A £19.70.

B £19.92.

C £20.05.

36 A financial analyst is examining whether a country's financial market is well functioning. She finds that the transaction costs in this market are low and trading volumes are high. She concludes that the market is quite liquid. In such a market:

A traders will find it hard to make use of their information.

B traders will find it easy to trade and their trading will make the market less informationally efficient.

C traders will find it easy to trade and their trading will make the market more informationally efficient.

37 The government of a country whose financial markets are in an early stage of development has hired you as a consultant on financial market regulation. Your first task is to prepare a list of the objectives of market regulation. Which of the following is *least likely* to be included in this list of objectives?

A Minimize agency problems in the financial markets.

B Ensure that financial markets are fair and orderly.

C Ensure that investors in the stock market achieve a rate of return that is at least equal to the risk-free rate of return.

SOLUTIONS

1 C is correct. Takabe is best characterized as an information-motivated trader. Takabe believes that his model provides him superior information about the movements in the stock market and his motive for trading is to profit from this information.

2 B is correct. Beach is an investor. He is simply investing in risky assets consistent with his level of risk aversion. Beach is not hedging any existing risk or using information to identify and trade mispriced securities. Therefore, he is not a hedger or an information-motivated trader.

3 A is correct. Smith is a hedger. The short position on the BRL futures contract offsets the BRL long position in three months. She is hedging the risk of the BRL depreciating against the USD. If the BRL depreciates, the value of the cash inflow goes down in USD terms but there is a gain on the futures contracts.

4 A is correct. Regulation of arbitrageurs' profits is not a function of the financial system. The financial system facilitates the allocation of capital to the best uses and the purposes for which people use the financial system, including borrowing money.

5 C is correct. The purchase of real estate properties is a transaction in the alternative investment market.

6 B is correct. The 90-day commercial paper and negotiable certificates of deposit are money market instruments.

7 B is correct. This transaction is a sale in the primary market. It is a sale of shares from the issuer to the investor and funds flow to the issuer of the security from the purchaser.

8 A is correct. Warrants are least likely to be part of the fund. Warrant holders have the right to buy the issuer's common stock. Thus, warrants are typically classified as equity and are least likely to be a part of a fixed-income mutual fund. Commercial paper and repurchase agreements are short-term fixed-income securities.

9 C is correct. When investors want to sell their shares, investors of an open-end fund sell the shares back to the fund whereas investors of a closed-end fund sell the shares to others in the secondary market. Closed-end funds are available to new investors but they must purchase shares in the fund in the secondary market. The shares of a closed-end fund trade at a premium or discount to net asset value.

10 A is correct. Once you have entered into a forward contract, it is difficult to exit from the contract. As opposed to a futures contract, trading out of a forward contract is quite difficult. There is no exchange of cash at the origination of a forward contract. There is no exchange on a forward contract until the maturity of the contract.

11 A is correct. Harris is least likely to find counterparty risk associated with a futures contract. There is limited counterparty risk in a futures contract because the clearinghouse is on the other side of every contract.

12 B is correct. Buying a put option on the dollar will ensure a minimum exchange rate but does not have to be exercised if the exchange rate moves in a favorable direction. Forward and futures contracts would lock in a fixed rate but would not allow for the possibility to profit in case the value of the dollar three months later in the spot market turns out to be greater than the value in the forward or futures contract.

13 B is correct. The agreement between the publisher and the paper supplier to respectively buy and supply paper in the future at a price agreed upon today is a forward contract.

14 B is correct. SPDRs trade in the secondary market and are a pooled investment vehicle.

15 B is correct. The holder of the call option will exercise the call options if the price is above the exercise price of \$305 per share. Note that if the stock price is above \$305 but less than \$308, the option would be exercised even though the net result for the option buyer after considering the premium is a loss. For example, if the stock price is \$307, the option buyer would exercise the option to make \$2 = \$307 – \$305 per share, resulting in a loss of \$1 = \$3 – \$2 after considering the premium. It is better to exercise and have a loss of only \$1, however, rather than not exercise and lose the entire \$3 premium.

16 B is correct. The investment companies that create exchange-traded funds (ETFs) are financial intermediaries. ETFs are securities that represent ownership in the assets held by the fund. The transaction costs of trading shares of ETFs are substantially lower than the combined costs of trading the underlying assets of the ETF.

17 B is correct. The process can best be described as arbitrage because it involves buying and selling instruments, whose values are closely related, at different prices in different markets.

18 A is correct. Robert's exposure to the risk of the stock of the Michelin Group is long. The exposure as a result of the long call position is long. The exposure as a result of the short put position is also long. Therefore, the combined exposure is long.

19 B is correct. The maximum leverage ratio is 1.82 = 100% position ÷ 55% equity. The maximum leverage ratio associated with a position financed by the minimum margin requirement is one divided by the minimum margin requirement.

20 C is correct. The return is 50 percent. If the position had been unleveraged, the return would be 20% = (60 – 50)/50. Because of leverage, the return is 50% = 2.5 × 20%.

Another way to look at this problem is that the equity contributed by the trader (the minimum margin requirement) is 40% = 100% ÷ 2.5. The trader contributed \$20 = 40% of \$50 per share. The gain is \$10 per share, resulting in a return of 50% = 10/20.

21 B is correct. The return is –15.4 percent.

Total cost of the purchase = \$16,000 = 500 × \$32

Equity invested = \$12,000 = 0.75 × \$16,000

Amount borrowed = \$4,000 = 16,000 – 12,000

Interest paid at month end = \$80 = 0.02 × \$4,000

Dividend received at month end = \$250 = 500 × \$0.50

Proceeds on stock sale = \$14,000 = 500 × \$28

Total commissions paid = \$20 = \$10 + \$10

Net gain/loss = –\$1,850 = –16,000 – 80 + 250 + 14,000 – 20

Initial investment including commission on purchase = \$12,010

Return = –15.4% = –\$1,850/\$12,010

22 A is correct. She will need to contribute €3,760 as margin. In view of the possibility of a loss, if the stock price goes up, she will need to contribute €3,760 = 40% of €9,400 as the initial margin. Rogers will need to leave the proceeds from the short sale (€9,400 = 200 × €47) on deposit.

23 B is correct. A margin call will first occur at a price of $17.86. Because you have contributed half and borrowed the remaining half, your initial equity is 50 percent of the initial stock price, or $12.50 = 0.50 × $25. If P is the subsequent price, your equity would change by an amount equal to the change in price. So, your equity at price P would be 12.50 + (P – 25). A margin call will occur when the percentage margin drops to 30 percent. So, the price at which a margin call will occur is the solution to the following equation.

$$\frac{\text{Equity/Share}}{\text{Price/Share}} = \frac{12.50 + P - 25}{P} = 30\%$$

The solution is P = $17.86.

24 B is correct. An instruction regarding when to fill an order is considered a validity instruction.

25 C is correct. The market is 9.95 bid, offered at 10.02. The best bid is at €9.95 and the best offer is €10.02.

26 C is correct. This order is said to make a new market. The new buy order is at ¥123.40, which is better than the current best bid of ¥123.35. Therefore, the buy order is making a new market. Had the new order been at ¥123.35, it would be said to make the market. Because the new buy limit order is at a price less than the best offer of ¥123.80, it will not immediately execute and is not taking the market.

27 A is correct. This order is said to take the market. The new sell order is at $54.62, which is at the current best bid. Therefore, the new sell order will immediately trade with the current best bid and is taking the market.

28 B is correct. The maximum possible loss is $1,300. If the stock price crosses $50, the stop buy order will become valid and will get executed at a maximum limit price of $55. The maximum loss per share is $13 = $55 – $42, or $1,300 for 100 shares.

29 B is correct. The most appropriate order is a good-till-cancelled stop sell order. This order will be acted on if the stock price declines below a specified price (in this case, $27.50). This order is sometimes referred to as a good-till-cancelled stop loss sell order. You are generally bullish about the stock, as indicated by no immediate intent to sell, and would expect a loss on short selling the stock. A stop buy order is placed to buy a stock when the stock is going up.

30 B is correct. The investment bank bears the risk that the issue may be undersubscribed at the offering price. If the entire issue is not sold, the investment bank underwriting the issue will buy the unsold securities at the offering price.

31 B is correct. This sale is a private placement. As the company is already publicly traded, the share sale is clearly not an initial public offering. The sale also does not involve a shelf registration because the company is not selling shares to the public on a piecemeal basis.

32 A is correct. This offering is a rights offering. The company is distributing rights to buy stock at a fixed price to existing shareholders in proportion to their holdings.

33 C is correct. Order III (time of arrival of 9:53:04) has precedence. In the order precedence hierarchy, the first rule is price priority. Based on this rule, sell orders II, III, and IV get precedence over order I. The next rule is display precedence at a given price. Because order II is a hidden order, orders III and IV get precedence. Finally, order III gets precedence over order IV based on time priority at same price and same display status.

34 C is correct. The order for 500 shares would get cancelled; there would be no fill. Li is willing to buy at CNY 74.25 or less but the minimum offer price in the book is CNY 74.30; therefore, no part of the order would be filled. Because Li's order is immediate-or-cancel, it would be cancelled.

35 B is correct. Ian's average trade price is:

$$\text{£}19.92 = \frac{300 \times \text{£}20.02 + 400 \times \text{£}19.89 \ + \ 200 \times \text{£}19.84}{300 + 400 + 200}$$

Ian's sell order first fills with the most aggressively priced buy order, which is Mary's order for 300 shares at £20.02. Ian still has 700 shares for sale. The next most aggressively priced buy order is Ann's order for 400 shares at £19.89. This order is filled. Ian still has 300 shares for sale. The next most aggressively priced buy order is Paul's order for 200 shares at £19.84. A third trade takes place. Ian still has 100 shares for sale.

The next buy order is Keith's order for 1,000 shares at £19.70. However, this price is below Ian's limit price of £19.83. Therefore, no more trade is possible.

36 C is correct. In such a market, well-informed traders will find it easy to trade and their trading will make the market more informationally efficient. In a liquid market, it is easier for informed traders to fill their orders. Their trading will cause prices to incorporate their information and the prices will be more in line with the fundamental values.

37 C is correct. Ensure that investors in the stock market achieve a rate of return that is at least equal to the risk-free rate of return is least likely to be included as an objective of market regulation. Stocks are risky investments and there would be occasions when a stock market investment would not only have a return less than the risk-free rate but also a negative return. Minimizing agency costs and ensuring that financial markets are fair and orderly are objectives of market regulation.

Security Market Indexes

by Paul D. Kaplan, PhD, CFA, and Dorothy C. Kelly, CFA

Paul D. Kaplan, PhD, CFA, is at Morningstar (Canada). Dorothy C. Kelly, CFA, is at McIntire School of Commerce, University of Virginia (USA).

LEARNING OUTCOMES

Mastery	*The candidate should be able to:*
☐	**a.** describe a security market index;
☐	**b.** calculate and interpret the value, price return, and total return of an index;
☐	**c.** describe the choices and issues in index construction and management;
☐	**d.** compare the different weighting methods used in index construction;
☐	**e.** calculate and analyze the value and return of an index given its weighting method;
☐	**f.** describe rebalancing and reconstitution of an index;
☐	**g.** describe uses of security market indexes;
☐	**h.** describe types of equity indexes;
☐	**i.** describe types of fixed-income indexes;
☐	**j.** describe indexes representing alternative investments;
☐	**k.** compare types of security market indexes.

INTRODUCTION

1

Investors gather and analyze vast amounts of information about security markets on a continual basis. Because this work can be both time consuming and data intensive, investors often use a single measure that consolidates this information and reflects the performance of an entire security market.

© 2019 CFA Institute. All rights reserved.

Security market indexes were first introduced as a simple measure to reflect the performance of the US stock market. Since then, security market indexes have evolved into important multi-purpose tools that help investors track the performance of various security markets, estimate risk, and evaluate the performance of investment managers. They also form the basis for new investment products.

in·dex, *noun* (*pl.* **in·dex·es** *or* **in·di·ces**) Latin *indic-, index,* from *indicare* to indicate: an indicator, sign, or measure of something.

ORIGIN OF MARKET INDEXES

Investors had access to regularly published data on individual security prices in London as early as 1698, but nearly 200 years passed before they had access to a simple indicator to reflect security market information. To give readers a sense of how the US stock market in general performed on a given day, publishers Charles H. Dow and Edward D. Jones introduced the Dow Jones Average, the world's first security market index, in 1884. The index, which appeared in *The Customers' Afternoon Letter*, consisted of the stocks of nine railroads and two industrial companies. It eventually became the Dow Jones Transportation Average. Convinced that industrial companies, rather than railroads, would be "the great speculative market" of the future, Dow and Jones introduced a second index in May 1896—the Dow Jones Industrial Average (DJIA). It had an initial value of 40.94 and consisted of 12 stocks from major US industries. Today, investors can choose from among thousands of indexes to measure and monitor different security markets and asset classes.

This reading is organized as follows. Section 2 defines a security market index and explains how to calculate the price return and total return of an index for a single period and over multiple periods. Sections 3–4 describe how indexes are constructed and managed. Section 5 discusses the use of market indexes. Sections 6, 7, and 8 discuss various types of indexes, and the final section summarizes the reading. Practice problems follow the conclusions and summary.

2

INDEX DEFINITION AND CALCULATIONS OF VALUE AND RETURNS

a describe a security market index;

b calculate and interpret the value, price return, and total return of an index;

A **security market index** represents a given security market, market segment, or asset class. Most indexes are constructed as portfolios of marketable securities.

The value of an index is calculated on a regular basis using either the actual or estimated market prices of the individual securities, known as **constituent securities**, within the index. For each security market index, investors may encounter two versions of the same index (i.e., an index with identical constituent securities and weights): one version based on price return and one version based on total return. As the name suggests, a **price return index**, also known as a **price index**, reflects *only* the prices of the constituent securities within the index. A **total return index**, in contrast, reflects not only the prices of the constituent securities but also the reinvestment of all income received since inception.

At inception, the values of the price and total return versions of an index are equal. As time passes, however, the value of the total return index, which includes the reinvestment of all dividends and/or interest received, will exceed the value of the price return index by an increasing amount. A look at how the values of each version are calculated over multiple periods illustrates why.

The value of a price return index is calculated as:

$$V_{PRI} = \frac{\sum_{i=1}^{N} n_i P_i}{D} \tag{1}$$

where

V_{PRI} = the value of the price return index

n_i = the number of units of constituent security i held in the index portfolio

N = the number of constituent securities in the index

P_i = the unit price of constituent security i

D = the value of the divisor

The **divisor** is a number initially chosen at inception. It is frequently chosen so that the price index has a convenient initial value, such as 1,000. The index provider then adjusts the value of the divisor as necessary to avoid changes in the index value that are unrelated to changes in the prices of its constituent securities. For example, when changing index constituents, the index provider may adjust the divisor so that the value of the index with the new constituents equals the value of the index prior to the changes.

Index return calculations, like calculations of investment portfolio returns, may measure price return or total return. **Price return** measures only price appreciation or percentage change in price. **Total return** measures price appreciation plus interest, dividends, and other distributions.

2.1 Calculation of Single-Period Returns

For a security market index, price return can be calculated in two ways: either the percentage change in value of the price return index, or the weighted average of price returns of the constituent securities. The price return of an index can be expressed as:

$$\text{PR}_I = \frac{V_{PRI1} - V_{PRI0}}{V_{PRI0}} \tag{2}$$

where

PR_I = the price return of the index portfolio (as a decimal number, i.e., 12 percent is 0.12)

V_{PRI1} = the value of the price return index at the end of the period

V_{PRI0} = the value of the price return index at the beginning of the period

Similarly, the price return of each constituent security can be expressed as:

$$\text{PR}_i = \frac{P_{i1} - P_{i0}}{P_{i0}} \tag{3}$$

where

PR_i = the price return of constituent security i (as a decimal number)
P_{i1} = the price of constituent security i at the end of the period
P_{i0} = the price of constituent security i at the beginning of the period

Because the price return of the index equals the weighted average of price returns of the individual securities, we can write:

$$\text{PR}_I = \sum_{i=1}^{N} \text{w}_i \text{PR}_i = \sum_{i=1}^{N} \text{w}_i \left(\frac{P_{i1} - P_{i0}}{P_{i0}} \right) \tag{4}$$

where:

PR_I = the price return of index portfolio (as a decimal number)
PR_i = the price return of constituent security i (as a decimal number)
N = the number of individual securities in the index
w_i = the weight of security i (the fraction of the index portfolio allocated to security i)
P_{i1} = the price of constituent security i at the end of the period
P_{i0} = the price of constituent security i at the beginning of the period

Equation 4 can be rewritten simply as:

$$\text{PR}_I = \text{w}_1\text{PR}_1 + \text{w}_2\text{PR}_2 + \ldots + \text{w}_N\text{PR}_N \tag{5}$$

where

PR_I = the price return of index portfolio (as a decimal number)
PR_i = the price return of constituent security i (as a decimal number)
w_i = the weight of security i (the fraction of the index portfolio allocated to security i)
N = the number of securities in the index

Total return measures price appreciation plus interest, dividends, and other distributions. Thus, the **total return** of an index is the price appreciation, or change in the value of the price return index, plus income (dividends and/or interest) over the period, expressed as a percentage of the beginning value of the price return index. The total return of an index can be expressed as:

$$\text{TR}_I = \frac{V_{PRI1} - V_{PRI0} + Inc_I}{V_{PRI0}} \tag{6}$$

where

TR_I = the total return of the index portfolio (as a decimal number)
V_{PRI1} = the value of the price return index at the end of the period
V_{PRI0} = the value of the price return index at the beginning of the period
Inc_I = the total income (dividends and/or interest) from all securities in the index held over the period

The total return of an index can also be calculated as the weighted average of total returns of the constituent securities. The total return of each constituent security in the index is calculated as:

$$\text{TR}_i = \frac{P_{1i} - P_{0i} + Inc_i}{P_{0i}} \tag{7}$$

where

TR_i = the total return of constituent security i (as a decimal number)
P_{1i} = the price of constituent security i at the end of the period
P_{0i} = the price of constituent security i at the beginning of the period
Inc_i = the total income (dividends and/or interest) from security i over the period

Because the total return of an index can be calculated as the weighted average of total returns of the constituent securities, we can express total return as:

$$\mathrm{TR}_I = \sum_{i=1}^{N} \mathrm{w}_i \mathrm{TR}_i = \sum_{i=1}^{N} \mathrm{w}_i \left(\frac{P_{1i} - P_{0i} + Inc_i}{P_{0i}} \right) \quad (8)$$

Equation 8 can be rewritten simply as

$$\mathrm{TR}_I = \mathrm{w}_1\mathrm{TR}_1 + \mathrm{w}_2\mathrm{TR}_2 + \ldots + \mathrm{w}_N\mathrm{TR}_N \quad (9)$$

where

TR_I = the total return of the index portfolio (as a decimal number)
TR_i = the total return of constituent security i (as a decimal number)
w_i = the weight of security i (the fraction of the index portfolio allocated to security i)
N = the number of securities in the index

2.2 Calculation of Index Values over Multiple Time Periods

The calculation of index values over multiple time periods requires geometrically linking the series of index returns. With a series of price returns for an index, we can calculate the value of the price return index with the following equation:

$$\mathrm{V}_{PRIT} = \mathrm{V}_{PRI0}(1 + \mathrm{PR}_{I1})(1 + \mathrm{PR}_{I2})\ldots(1 + \mathrm{PR}_{IT}) \quad (10)$$

where

V_{PRI0} = the value of the price return index at inception
V_{PRIT} = the value of the price return index at time t
PR_{IT} = the price return (as a decimal number) on the index over period t, t = 1, 2, …, T

For an index with an inception value set to 1,000 and price returns of 5 percent and 3 percent for Periods 1 and 2 respectively, the values of the price return index would be calculated as follows:

Period	Return (%)	Calculation	Ending Value
0		1,000(1.00)	1,000.00
1	5.00	1,000(1.05)	1,050.00
2	3.00	1,000(1.05)(1.03)	1,081.50

Similarly, the series of total returns for an index is used to calculate the value of the total return index with the following equation:

$$\mathrm{V}_{TRIT} = \mathrm{V}_{TRI0}(1 + \mathrm{TR}_{I1})(1 + \mathrm{TR}_{I2})\ldots(1 + \mathrm{TR}_{IT}) \quad (11)$$

where

V_{TRI0} = the value of the index at inception
V_{TRIT} = the value of the total return index at time t
TR_{IT} = the total return (as a decimal number) on the index over period t, t = 1, 2, …, T

Suppose that the same index yields an additional 1.5 percent return from income in Period 1 and an additional 2.0 percent return from income in Period 2, bringing the total returns for Periods 1 and 2, respectively, to 6.5 percent and 5 percent. The values of the total return index would be calculated as follows:

Period	Return (%)	Calculation	Ending Value
0		1,000(1.00)	1,000.00
1	6.50	1,000(1.065)	1,065.00
2	5.00	1,000(1.065)(1.05)	1,118.25

As illustrated above, as time passes, the value of the total return index, which includes the reinvestment of all dividends and/or interest received, exceeds the value of the price return index by an increasing amount.

3

INDEX CONSTRUCTION

c describe the choices and issues in index construction and management;

d compare the different weighting methods used in index construction;

e calculate and analyze the value and return of an index given its weighting method;

Constructing and managing a security market index is similar to constructing and managing a portfolio of securities. Index providers must decide the following:

1. Which target market should the index represent?
2. Which securities should be selected from that target market?
3. How much weight should be allocated to each security in the index?
4. When should the index be rebalanced?
5. When should the security selection and weighting decision be re-examined?

3.1 Target Market and Security Selection

The first decision in index construction is identifying the target market, market segment, or asset class that the index is intended to represent. The target market may be defined very broadly or narrowly. It may be based on asset class (e.g., equities, fixed income, real estate, commodities, hedge funds); geographic region (e.g., Japan, South Africa, Latin America, Europe); the exchange on which the securities are traded (e.g., Shanghai, Toronto, Tokyo), and/or other characteristics (e.g., economic sector, company size, investment style, duration, or credit quality).

The target market determines the investment universe and the securities available for inclusion in the index. Once the investment universe is identified, the number of securities and the specific securities to include in the index must be determined. The constituent securities could be nearly all those in the target market or a representative sample of the target market. Some equity indexes, such as the S&P 500 Index and the FTSE 100, fix the number of securities included in the index and indicate this number in the name of the index. Other indexes allow the number of securities to vary to reflect changes in the target market or to maintain a certain percentage of the target market. For example, the Tokyo Stock Price Index (TOPIX) represents and includes all of the largest stocks, known as the First Section, listed on the Tokyo Stock Exchange. To be included in the First Section—and thus the TOPIX—stocks must meet certain criteria, such as the number of shares outstanding, the number of shareholders, and market capitalization. Stocks that no longer meet the criteria are removed from the First Section and also the TOPIX. Objective or mechanical rules determine the constituent securities of most, but not all, indexes. The S&P Bombay Stock Exchange Sensitive Index, also called the S&P BSE SENSEX and the S&P 500, for example, use a selection committee and more subjective decision-making rules to determine constituent securities.

3.2 Index Weighting

The weighting decision determines how much of each security to include in the index and has a substantial impact on an index's value. Index providers use a number of methods to weight the constituent securities in an index. Indexes can be price weighted, equal weighted, market-capitalization weighted, or fundamentally weighted. Each weighting method has its advantages and disadvantages.

3.2.1 *Price Weighting*

The simplest method to weight an index and the one used by Charles Dow to construct the Dow Jones Industrial Average is **price weighting**. In price weighting, the weight on each constituent security is determined by dividing its price by the sum of all the prices of the constituent securities. The weight is calculated using the following formula:

$$w_i^P = \frac{P_i}{\sum_{i=1}^{N} P_i} \tag{12}$$

Exhibit 1 illustrates the values, weights, and single-period returns following inception of a price-weighted equity index with five constituent securities. The value of the price-weighted index is determined by dividing the sum of the security values (101.50) by the divisor, which is typically set at inception to equal the initial number of securities in the index. Thus, in our example, the divisor is 5 and the initial value of the index is calculated as 101.50 ÷ 5 = 20.30.

As illustrated in this exhibit, Security A, which has the highest price, also has the highest weighting and thus will have the greatest impact on the return of the index. Note how both the price return and the total return of the index are calculated on the basis of the corresponding returns on the constituent securities.

A property unique to price-weighted indexes is that a stock split on one constituent security changes the weights on all the securities in the index.[1] To prevent the stock split and the resulting new weights from changing the value of the index, the index provider must adjust the value of the divisor as illustrated in Exhibit 2. Given a 2-for-1 split in Security A, the divisor is adjusted by dividing the sum of the constituent prices *after* the split (77.50) by the value of the index *before* the split (21.00). This adjustment results in changing the divisor from 5 to 3.69 so that the index value is maintained at 21.00.

---

[1] A stock split is an increase in the number of shares outstanding and a proportionate decrease in the price per share such that the total market value of equity, as well as investors' proportionate ownership in the company, does not change.

Exhibit 1 Example of a Price-Weighted Equity Index

Security	Shares in Index	BOP Price	Value (Shares × BOP Price)	BOP Weight (%)	EOP Price	Dividends Per Share	Value (Shares × EOP Price)	Total Dividends	Price Return (%)	Total Return (%)	BOP Weight × Price Return (%)	BOP Weight × Total Return (%)	EOP Weight (%)
A	1	50.00	50.00	49.26	55.00	0.75	55.00	0.75	10.00	11.50	4.93	5.66	52.38
B	1	25.00	25.00	24.63	22.00	0.10	22.00	0.10	−12.00	−11.60	−2.96	−2.86	20.95
C	1	12.50	12.50	12.32	8.00	0.00	8.00	0.00	−36.00	−36.00	−4.43	−4.43	7.62
D	1	10.00	10.00	9.85	14.00	0.05	14.00	0.05	40.00	40.50	3.94	3.99	13.33
E	1	4.00	4.00	3.94	6.00	0.00	6.00	0.00	50.00	50.00	1.97	1.97	5.72
Total			**101.50**	**100.00**			**105.00**	**0.90**			**3.45**	**4.33**	**100.00**
Index Value			**20.30**				**21.00**	**0.18**	**3.45**	**4.33**			

Divisor = 5

BOP = Beginning of period

EOP = End of period

Type of Index	BOP Value	Return (%)	EOP Value
Price Return	20.30	3.45	21.00
Total Return	20.30	4.33	21.18

The primary advantage of price weighting is its simplicity. The main disadvantage of price weighting is that it results in arbitrary weights for each security. In particular, a stock split in any one security causes arbitrary changes in the weights of all the constituents' securities.

Exhibit 2 Impact of 2-for-1 Split in Security A

Security	Price before Split	Weight before Split (%)	Price after Split	Weight after Split (%)
A	55.00	52.38	27.50	35.48
B	22.00	20.95	22.00	28.39
C	8.00	7.62	8.00	10.32
D	14.00	13.33	14.00	18.07
E	6.00	5.72	6.00	7.74
Total	105.00	100.00	77.50	100.00
Divisor	5.00		3.69	
Index Value	21.00		21.00	

3.2.2 *Equal Weighting*

Another simple index weighting method is **equal weighting**. This method assigns an equal weight to each constituent security at inception. The weights are calculated as:

$$w_i^E = \frac{1}{N} \tag{13}$$

where

w_i = fraction of the portfolio that is allocated to security *i* or weight of security *i*

N = number of securities in the index

To construct an equal-weighted index from the five securities in Exhibit 1, the index provider allocates one-fifth (20 percent) of the value of the index (at the beginning of the period) to each security. Dividing the value allocated to each security by each security's individual share price determines the number of shares of each security to include in the index. Unlike a price-weighted index, where the weights are arbitrarily determined by the market prices, the weights in an equal-weighted index are arbitrarily assigned by the index provider.

Exhibit 3 illustrates the values, weights, and single-period returns following inception of an equal-weighted index with the same constituent securities as those in Exhibit 1. This example assumes a beginning index portfolio value of 10,000 (i.e., an investment of 2,000 in each security). To set the initial value of the index to 1,000, the divisor is set to 10 (10,000 ÷ 10 = 1,000).

Exhibits 1 and 3 demonstrate how different weighting methods result in different returns. The 10.4 percent price return of the equal-weighted index shown in Exhibit 3 differs significantly from the 3.45 percent price return of the price-weighted index in Exhibit 1.

Like price weighting, the primary advantage of equal weighting is its simplicity. Equal weighting, however, has a number of disadvantages. First, securities that constitute the largest fraction of the target market value are underrepresented, and securities that constitute a small fraction of the target market value are overrepresented.

Exhibit 3 Example of an Equal-Weighted Equity Index

Security	Shares in Index	BOP Price	Value (Shares × BOP Price)	Weight (%)	EOP Price	Dividends Per Share	Value (Shares × EOP Price)	Total Dividends	Price Return (%)	Total Return (%)	Weight × Price Return (%)	Weight × Total Return (%)	EOP Weight (%)
A	40	50.00	2,000	20.00	55.00	0.75	2,200	30	10.00	11.50	2.00	2.30	19.93
B	80	25.00	2,000	20.00	22.00	0.10	1,760	8	−12.00	−11.60	−2.40	−2.32	15.94
C	160	12.50	2,000	20.00	8.00	0.00	1,280	0	−36.00	−36.00	−7.20	−7.20	11.60
D	200	10.00	2,000	20.00	14.00	0.05	2,800	10	40.00	40.50	8.00	8.10	25.36
E	500	4.00	2,000	20.00	6.00	0.00	3,000	0	50.00	50.00	10.00	10.00	27.17
Total			**10,000**	**100.00**			**11,040**	**48**			**10.40**	**10.88**	**100.00**
Index Value			**1,000**				**1,104**	**4.80**	**10.40**	**10.88**			

Divisor = 10

BOP = Beginning of period

EOP = End of period

Type of Index	BOP Value	Return (%)	EOP Value
Price Return	1,000.00	10.40	1,104.00
Total Return	1,000.00	10.88	1,108.80

Second, after the index is constructed and the prices of constituent securities change, the index is no longer equally weighted. Therefore, maintaining equal weights requires frequent adjustments (rebalancing) to the index.

3.2.3 *Market-Capitalization Weighting*

In **market-capitalization weighting**, or value weighting, the weight on each constituent security is determined by dividing its market capitalization by the total market capitalization (the sum of the market capitalization) of all the securities in the index. Market capitalization or value is calculated by multiplying the number of shares outstanding by the market price per share.

The market-capitalization weight of security i is:

$$w_i^M = \frac{Q_i P_i}{\sum_{j=1}^{N} Q_j P_j} \tag{14}$$

where

w_i = fraction of the portfolio that is allocated to security i or weight of security i

Q_i = number of shares outstanding of security i

P_i = share price of security i

N = number of securities in the index

Exhibit 4 illustrates the values, weights, and single-period returns following inception of a market-capitalization-weighted index for the same five-security market. Security A, with 3,000 shares outstanding and a price of 50 per share, has a market capitalization of 150,000 or 26.29 percent (150,000/570,500) of the entire index portfolio. The resulting index weights in the exhibit reflect the relative value of each security as measured by its market capitalization.

As shown in Exhibits 1, 3, and 4, the weighting method affects the index's returns. The price and total returns of the market-capitalization index in Exhibit 4 (1.49 percent and 2.13 percent, respectively) differ significantly from those of the price-weighted (3.45 percent and 4.33 percent, respectively) and equal-weighted (10.40 percent and 10.88 percent respectively) indexes. To understand the source and magnitude of the difference, compare the weights and returns of each security under each of the weighting methods. The weight of Security A, for example, ranges from 49.26 percent in the price-weighted index to 20 percent in the equal-weighted index. With a price return of 10 percent, Security A contributes 4.93 percent to the price return of the price-weighted index, 2.00 percent to the price return of the equal-weighted index, and 2.63 percent to the price return of the market-capitalization-weighted index. With a total return of 11.50 percent, Security A contributes 5.66 percent to the total return of the price-weighted index, 2.30 percent to the total return of the equal-weighted index, and 3.02 percent to the total return of the market-capitalization-weighted index.

3.2.3.1 Float-Adjusted Market-Capitalization Weighting

In **float-adjusted market-capitalization weighting**, the weight on each constituent security is determined by adjusting its market capitalization for its **market float**. Typically, market float is the number of shares of the constituent security that are available to the investing public. For companies that are closely held, only a portion of the shares outstanding are available to the investing public (the rest are held by a small group of controlling investors). In addition to excluding shares held by controlling shareholders, most float-adjusted market-capitalization-weighted indexes also exclude shares held by other corporations and governments. Some providers of indexes that are designed to represent the investment opportunities of global investors further reduce the number of shares included

Exhibit 4 Example of a Market-Capitalization-Weighted Equity Index

Stock	Shares Out-standing	BOP Price	BOP Market Cap	BOP Weight (%)	EOP Price	Dividends Per Share	EOP Market Cap	Total Dividends	Price Return (%)	Total Return (%)	BOP Weight × Price Return (%)	BOP Weight × Total Return (%)	EOP Weight (%)
A	3,000	50.00	150,000	26.29	55.00	0.75	165,000	2,250	10.00	11.50	2.63	3.02	28.50
B	10,000	25.00	250,000	43.82	22.00	0.10	220,000	1,000	−12.00	−11.60	−5.26	−5.08	38.00
C	5,000	12.50	62,500	10.96	8.00	0.00	40,000	0	−36.00	−36.00	−3.95	−3.95	6.91
D	8,000	10.00	80,000	14.02	14.00	0.05	112,000	400	40.00	40.50	5.61	5.68	19.34
E	7,000	4.00	28,000	4.91	6.00	0.00	42,000	0	50.00	50.00	2.46	2.46	7.25
Total			**570,500**	**100.00**			**579,000**	**3,650**			**1.49**	**2.13**	**100.00**
Index Value			**1,000**				**1,014.90**	**6.40**	**1.49**	**2.13**			

Divisor = 570.50

BOP = Beginning of period

EOP = End of period

Type of Index	BOP Value	Return (%)	EOP Value
Price Return	1,000.00	1.49	1,014.90
Total Return	1,000.00	2.13	1,021.30

in the index by excluding shares that are not available to foreigner investors. The index providers may refer to these indexes as "free-float-adjusted market-capitalization-weighted indexes."

Float-adjusted market-capitalization-weighted indexes reflect the shares available for public trading by multiplying the market price per share by the number of shares available to the investing public (i.e., the float-adjusted market capitalization) rather than the total number of shares outstanding (total market capitalization). Currently, most market-capitalization-weighted indexes are float adjusted. Therefore, unless otherwise indicated, for the remainder of this reading, "market-capitalization" weighting refers to float-adjusted market-capitalization weighting.

The float-adjusted market-capitalization weight of security *i* is calculated as:

$$w_i^M = \frac{f_i Q_i P_i}{\sum_{j=1}^{N} f_j Q_j P_j} \tag{15}$$

where

f_i = fraction of shares outstanding in the market float

w_i = fraction of the portfolio that is allocated to security *i* or weight of security *i*

Q_i = number of shares outstanding of security *i*

P_i = share price of security *i*

N = number of securities in the index

Exhibit 5 illustrates the values, weights, and single-period returns following inception of a float-adjusted market-capitalization-weighted equity index using the same five securities as before. The low percentage of shares of Security D in the market float compared with the number of shares outstanding indicates that the security is closely held.

The primary advantage of market-capitalization weighting (including float adjusted) is that constituent securities are held in proportion to their value in the target market. The primary disadvantage is that constituent securities whose prices have risen the most (or fallen the most) have a greater (or lower) weight in the index (i.e., as a security's price rises relative to other securities in the index, its weight increases; and as its price decreases in value relative to other securities in the index, its weight decreases). This weighting method leads to overweighting stocks that have risen in price (and may be overvalued) and underweighting stocks that have declined in price (and may be undervalued). The effect of this weighting method is similar to a momentum investment strategy in that over time, the securities that have risen in price the most will have the largest weights in the index.

3.2.4 *Fundamental Weighting*

Fundamental weighting attempts to address the disadvantages of market-capitalization weighting by using measures of a company's size that are independent of its security price to determine the weight on each constituent security. These measures include book value, cash flow, revenues, earnings, dividends, and number of employees.

Some fundamental indexes use a single measure, such as total dividends, to weight the constituent securities, whereas others combine the weights from several measures to form a composite value that is used for weighting.

Exhibit 5 Example of Float-Adjusted Market-Capitalization-Weighted Equity Index

Stock	Shares Out-standing	% Shares in Market Float	Shares in Index	BOP Price	BOP Float-Adjusted Market Cap	BOP Weight (%)	EOP Price	Dividends Per Share	Ending Float-Adjusted Market Cap	Total Dividends	Price Return (%)	Total Return (%)	BOP Weight × Price Return (%)	BOP Weight × Total Return (%)	EOP Weight (%)

Total Return	1,000.00	−0.94	990.56

Letting F_i denote a given fundamental size measure of company i, the fundamental weight on security i is:

$$w_i^F = \frac{F_i}{\sum_{j=1}^{N} F_j} \tag{16}$$

Relative to a market-capitalization-weighted index, a fundamental index with weights based on such an item as earnings will result in greater weights on constituent securities with earnings yields (earnings divided by price) that are higher than the earnings yield of the overall market-weighted portfolio. Similarly, stocks with earnings yields less than the yield on the overall market-weighted portfolio will have lower weights. For example, suppose there are two stocks in an index. Stock A has a market capitalization of €200 million, Stock B has a market capitalization of €800 million, and their aggregate market capitalization is €1 billion (€1,000 million). Both companies have earnings of €20 million and aggregate earnings of €40 million. Thus, Stock A has an earnings yield of 10 percent (20/200) and Stock B has an earnings yield of 2.5 percent (20/800). The earnings weight of Stock A is 50 percent (20/40), which is higher than its market-capitalization weight of 20 percent (200/1,000). The earnings weight of Stock B is 50 percent (20/40), which is less than its market-capitalization weight of 80 percent (800/1,000). Relative to the market-cap-weighted index, the earnings-weighted index over-weights the high-yield Stock A and under-weights the low-yield Stock B.

The most important property of fundamental weighting is that it leads to indexes that have a “value” tilt. That is, a fundamentally weighted index has ratios of book value, earnings, dividends, etc. to market value that are higher than its market-capitalization-weighted counterpart. Also, in contrast to the momentum “effect” of market-capitalization-weighted indexes, fundamentally weighted indexes generally will have a contrarian “effect” in that the portfolio weights will shift away from securities that have increased in relative value and toward securities that have fallen in relative value whenever the portfolio is rebalanced.

INDEX MANAGEMENT: REBALANCING AND RECONSTITUTION

4

f describe rebalancing and reconstitution of an index;

So far, we have discussed index construction. Index management entails the two remaining questions:

- When should the index be rebalanced?
- When should the security selection and weighting decisions be re-examined?

4.1 Rebalancing

Rebalancing refers to adjusting the weights of the constituent securities in the index. To maintain the weight of each security consistent with the index’s weighting method, the index provider rebalances the index by adjusting the weights of the constituent securities on a regularly scheduled basis (rebalancing dates)—usually quarterly. Rebalancing is necessary because the weights of the constituent securities change as their market prices change. Note, for example, that the weights of the securities in the equal-weighted index (Exhibit 3) at the end of the period are no longer equal (i.e., 20 percent):

Security A	19.93%
Security B	15.94
Security C	11.60
Security D	25.36
Security E	27.17

In rebalancing the index, the weights of Securities D and E (which had the highest returns) would be decreased and the weights of Securities A, B, and C (which had the lowest returns) would be increased. Thus, rebalancing creates turnover within an index.

Price-weighted indexes are not rebalanced because the weight of each constituent security is determined by its price. For market-capitalization-weighted indexes, rebalancing is less of a concern because the indexes largely rebalance themselves. In our market-capitalization index, for example, the weight of Security C automatically declined from 10.96 percent to 6.91 percent, reflecting the 36 percent decline in its market price. Market-capitalization weights are only adjusted to reflect mergers, acquisitions, liquidations, and other corporate actions between rebalancing dates.

4.2 Reconstitution

Reconstitution is the process of changing the constituent securities in an index. It is similar to a portfolio manager deciding to change the securities in his or her portfolio. Reconstitution is part of the rebalancing cycle. The reconstitution date is the date on which index providers review the constituent securities, re-apply the initial criteria for inclusion in the index, and select which securities to retain, remove, or add. Constituent securities that no longer meet the criteria are replaced with securities that do meet the criteria. Once the revised list of constituent securities is determined, the weighting method is re-applied. Indexes are reconstituted to reflect changes in the target market (bankruptcies, de-listings, mergers, acquisitions, etc.) and/or to reflect the judgment of the selection committee.

Reconstitution creates turnover in a number of different ways, particularly for market-capitalization-weighted indexes. When one security is removed and another is added, the index provider has to change the weights of the other securities in order to maintain the market-capitalization weighting of the index.

The frequency of reconstitution is a major issue for widely used indexes and their constituent securities. The Russell 2000 Index, for example, reconstitutes annually. It is used as a benchmark by numerous investment funds, and each year, prior to the index's reconstitution, the managers of these funds buy stocks they think will be added to the index—driving those stocks' prices up—and sell stocks they think will be deleted from the index—driving those stocks' prices down. Exhibit 6 illustrates a historical example of the potential impact of these decisions. Beginning in late April 2009, some managers began acquiring and bidding up the price of Uranium Energy Corporation (UEC) because they believed that it would be included in the reconstituted Russell 2000 Index. On 12 June, Russell listed UEC as a preliminary addition to the Russell 2000 Index and the Russell 3000 Index.[2] By that time, the stock value had increased by more than 300 percent. Investors continued to bid up the stock price in the weeks following the announcement, and the stock closed on the reconstitution date of 30 June at USD2.90, up nearly 400 percent for the quarter.

---

[2] According to the press release, final membership in the index would be published after market close on Friday, 26 June.

USES OF MARKET INDEXES

5

g describe uses of security market indexes;

Indexes were initially created to give a sense of how a particular security market performed on a given day. With the development of modern financial theory, their uses in investment management have expanded significantly. Some of the major uses of indexes include:

- gauges of market sentiment;
- proxies for measuring and modeling returns, systematic risk, and risk-adjusted performance;
- proxies for asset classes in asset allocation models;
- benchmarks for actively managed portfolios; and
- model portfolios for such investment products as index funds and exchange-traded funds (ETFs).

Investors using security market indexes must be familiar with how various indexes are constructed in order to select the index or indexes most appropriate for their needs.

5.1 Gauges of Market Sentiment

The original purpose of stock market indexes was to provide a gauge of investor confidence or market sentiment. As indicators of the collective opinion of market participants, indexes reflect investor attitudes and behavior. The Dow Jones Industrial Average has a long history, is frequently quoted in the media, and remains a popular gauge of market sentiment. It may not accurately reflect the overall attitude of investors or the "market," however, because the index consists of only 30 of the thousands of US stocks traded each day.

5.2 Proxies for Measuring and Modeling Returns, Systematic Risk, and Risk-Adjusted Performance

The capital asset pricing model (CAPM) defines beta as the systematic risk of a security with respect to the entire market. The market portfolio in the CAPM consists of all risky securities. To represent the performance of the market portfolio, investors use a broad index. For example, the Tokyo Price Index (TOPIX) and the S&P 500 often serve as proxies for the market portfolio in Japan and the United States, respectively, and are used for measuring and modeling systematic risk and market returns.

Security market indexes also serve as market proxies when measuring risk-adjusted performance. The beta of an actively managed portfolio allows investors to form a passive alternative with the same level of systematic risk. For example, if the beta of an actively managed portfolio of global stocks is 0.95 with respect to the MSCI World Index, investors can create a passive portfolio with the same systematic risk by investing 95 percent of their portfolio in a MSCI World Index fund and holding the remaining 5 percent in cash. Alpha, the difference between the return of the actively managed portfolio and the return of the passive portfolio, is a measure of risk-adjusted return or investment performance. Alpha can be the result of manager skill (or lack thereof), transaction costs, and fees.

5.3 Proxies for Asset Classes in Asset Allocation Models

Because indexes exhibit the risk and return profiles of select groups of securities, they play a critical role as proxies for asset classes in asset allocation models. They provide the historical data used to model the risks and returns of different asset classes.

5.4 Benchmarks for Actively Managed Portfolios

Investors often use indexes as benchmarks to evaluate the performance of active portfolio managers. The index selected as the benchmark should reflect the investment strategy used by the manager. For example, an active manager investing in global small-capitalization stocks should be evaluated using a benchmark index, such as the FTSE Global Small Cap Index, which includes approximately 4,400 liquid small-capitalization stocks across 47 countries as of August 2018.

The choice of an index to use as a benchmark is important because an inappropriate index could lead to incorrect conclusions regarding an active manager's investment performance. Suppose that the small-cap manager underperformed the small-cap index but outperformed a broad equity market index. If investors use the broad market index as a benchmark, they might conclude that the small-cap manager is earning his or her fees and should be retained or given additional assets to invest. Using the small-cap index as a benchmark might lead to a very different conclusion.

5.5 Model Portfolios for Investment Products

Indexes also serve as the basis for the development of new investment products. Using indexes as benchmarks for actively managed portfolios has led some investors to conclude that they should invest in the benchmarks instead. Based on the CAPM's conclusion that investors should hold the market portfolio, broad market index funds have been developed to function as proxies for the market portfolio.

Investment management firms initially developed and managed index portfolios for institutional investors. Eventually, mutual fund companies introduced index funds for individual investors. Subsequently, investment management firms introduced exchange-traded funds, which are managed the same way as index mutual funds but trade like stocks.

The first ETFs were based on existing indexes. As the popularity of ETFs increased, index providers created new indexes for the specific purpose of forming ETFs, leading to the creation of numerous narrowly defined indexes with corresponding ETFs. The VanEck Vectors Vietnam ETF, for example, allows investors to invest in the equity market of Vietnam.

The choice of indexes to meet the needs of investors is extensive. Index providers are constantly looking for opportunities to develop indexes to meet the needs of investors.

EQUITY INDEXES

6

h describe types of equity indexes;

k compare types of security market indexes.

A wide variety of equity indexes exist, including broad market, multi-market, sector, and style indexes.

6.1 Broad Market Indexes

A broad equity market index, as its name suggests, represents an entire given equity market and typically includes securities representing more than 90 percent of the selected market. For example, the Shanghai Stock Exchange Composite Index (SSE) is a market-capitalization-weighted index of all shares that trade on the Shanghai Stock Exchange. In the United States, the Wilshire 5000 Total Market Index is a market-capitalization-weighted index that includes all US equities with readily available prices and is designed to represent the entire US equity market.[3] The Russell 3000, consisting of the largest 3,000 stocks by market capitalization, represents approximately 98 percent of the US equity market.

6.2 Multi-Market Indexes

Multi-market indexes usually comprise indexes from different countries and regions and are designed to represent multiple security markets. Multi-market indexes may represent multiple national markets, geographic regions, economic development groups, and, in some cases, the entire world. World indexes are of importance to investors who take a global approach to equity investing without any particular bias toward a particular country or region. A number of index providers publish families of multi-market equity indexes.

---

[3] Despite its name, the Wilshire 5000 has no constraint on the number of securities that can be included. It included approximately 5,000 securities at inception.

MSCI offers a number of multi-market indexes. As shown in Exhibit 7, MSCI classifies countries and regions along two dimensions: level of economic development and geographic region. Developmental groups, which MSCI refers to as market classifications, include developed markets, emerging markets, and frontier markets. The geographic regions are largely divided by longitudinal lines of the globe: the Americas, Europe with Africa, and Asia with the Pacific. MSCI provides country- and region-specific indexes for each of the developed and emerging markets within its multi-market indexes. MSCI periodically reviews the classifications of markets in its indexes for movement from frontier markets to emerging markets and from emerging markets to developed markets and reconstitutes the indexes accordingly.

Exhibit 7 MSCI Global Investable Market Indexes (as of October 2018)

Developed Markets

Americas	Europe and Middle East	Pacific
Canada, United States	Austria, Belgium, Denmark, Finland, France, Germany, Ireland, Israel, Italy, Netherlands, Norway, Portugal, Spain, Sweden, Switzerland, United Kingdom	Australia, Hong Kong SAR, Japan, New Zealand, Singapore

Emerging Markets

Americas	Europe, Middle East, Africa	Asia
Brazil, Chile, Colombia, Mexico, Peru	Czech Republic, Egypt, Greece, Hungary, Poland, Qatar, Russia, South Africa, Turkey, United Arab Emirates	Chinese mainland, India, Indonesia, South Korea, Malaysia, Pakistan, Philippines, Taiwan region, Thailand

Frontier Markets

Americas	Europe & CIS	Africa	Middle East	Asia
Argentina	Croatia, Estonia, Lithuania, Kazakhstan, Romania, Serbia, Slovenia	Kenya, Mauritius, Morocco, Nigeria, Tunisia, WAEMU[1]	Bahrain, Jordan, Kuwait, Lebanon, Oman	Bangladesh, Sri Lanka, Vietnam

MSCI Standalone Market Indexes[2]

Europe, Middle East, and Africa	Americas	Europe and CIS	Africa	Middle East
Saudi Arabia	Jamaica, Panama,[3] Trinidad & Tobago	Bosnia Herzegovina, Bulgaria, Ukraine	Botswana, Ghana, Zimbabwe	Palestine

[1] The West African Economic and Monetary Union (WAEMU) consists of the following countries: Benin, Burkina Faso, Ivory Coast, Guinea-Bissau, Mali, Niger, Senegal, and Togo. Currently the MSCI WAEMU Indexes include securities classified in Senegal, Ivory Coast, and Burkina Faso.

[2] The MSCI Standalone Market Indexes are not included in the MSCI Emerging Markets Index or MSCI Frontier Markets Index. However, these indexes use either the Emerging Markets or the Frontier Markets methodological criteria concerning size and liquidity.

[3] MSCI Panama Index has been launched as a Standalone Market Index.

Source: adapted from MSCI (https://www.msci.com/en/market-cap-weighted-indexes), October 2018.

6.2.1 *Fundamental Weighting in Multi-Market Indexes*

Some index providers weight the securities within each country/region by market capitalization and then weight each country/region in the overall index in proportion to its relative GDP, effectively creating fundamental weighting in multi-market indexes. GDP-weighted indexes were some of the first fundamentally weighted indexes created. Introduced in 1987 by MSCI to address the 60 percent weight of Japanese equities in the market-capitalization-weighted MSCI EAFE Index at the time, GDP-weighted indexes reduced the allocation to Japanese equities by half.[4]

6.3 Sector Indexes

Sector indexes represent and track different economic sectors—such as consumer goods, energy, finance, health care, and technology—on either a national, regional, or global basis. Because different sectors of the economy behave differently over the course of the business cycle, some investors may seek to overweight or underweight their exposure to particular sectors.

Sector indexes are organized as families; each index within the family represents an economic sector. Typically, the aggregation of a sector index family is equivalent to a broad market index. Economic sector classification can be applied on a global, regional, or country-specific basis, but no universally agreed upon sector classification method exists.

Sector indexes play an important role in performance analysis because they provide a means to determine whether a portfolio manager is more successful at stock selection or sector allocation. Sector indexes also serve as model portfolios for sector-specific ETFs and other investment products.

6.4 Style Indexes

Style indexes represent groups of securities classified according to market capitalization, value, growth, or a combination of these characteristics. They are intended to reflect the investing styles of certain investors, such as the growth investor, value investor, and small-cap investor.

6.4.1 *Market Capitalization*

Market-capitalization indexes represent securities categorized according to the major capitalization categories: large cap, midcap, and small cap. With no universal definition of these categories, the indexes differ on the distinctions between large cap and midcap and between midcap and small cap, as well as the minimum market-capitalization size required to be included in a small-cap index. Classification into categories can be based on absolute market capitalization (e.g., below €100 million) or relative market capitalization (e.g., the smallest 2,500 stocks).

6.4.2 *Value/Growth Classification*

Some indexes represent categories of stocks based on their classifications as either value or growth stocks. Different index providers use different factors and valuation ratios (low price-to-book ratios, low price-to-earnings ratios, high dividend yields, etc.) to distinguish between value and growth equities.

---

[4] Steven A. Schoenfeld, *Active Index Investing* (Hoboken, NJ: John Wiley & Sons, 2004):220.

6.4.3 *Market Capitalization and Value/Growth Classification*

Combining the three market-capitalization groups with value and growth classifications results in six basic style index categories:

- Large-Cap Value
- Mid-Cap Value
- Small-Cap Value
- Large-Cap Growth
- Mid-Cap Growth
- Small-Cap Growth

Because indexes use different size and valuation classifications, the constituents of indexes designed to represent a given style, such as small-cap value, may differ—sometimes substantially.

Because valuation ratios and market capitalizations change over time, stocks frequently migrate from one style index category to another on reconstitution dates. As a result, style indexes generally have much higher turnover than do broad market indexes.

7

FIXED-INCOME INDEXES

i. describe types of fixed-income indexes;

k. compare types of security market indexes.

A wide variety of fixed-income indexes exists, but the nature of the fixed-income markets and fixed-income securities leads to some very important challenges to fixed-income index construction and replication. These challenges are the number of securities in the fixed-income universe, the availability of pricing data, and the liquidity of the securities.

7.1 Construction

The fixed-income universe includes securities issued by governments, government agencies, and corporations. Each of these entities may issue a variety of fixed-income securities with different characteristics. As a result, the number of fixed-income securities is many times larger than the number of equity securities. To represent a specific fixed-income market or segment, indexes may include thousands of different securities. Over time, these fixed-income securities mature, and issuers offer new securities to meet their financing needs, leading to turnover in fixed-income indexes.

Another challenge in index construction is that fixed-income markets are predominantly dealer markets. This means that firms (dealers) are assigned to specific securities and are responsible for creating liquid markets for those securities by purchasing and selling them from their inventory. In addition, many securities do not trade frequently and, as a result, are relatively illiquid. As a result, index providers must contact dealers to obtain current prices on constituent securities to update the index or they must estimate the prices of constituent securities using the prices of traded fixed-income securities with similar characteristics.

These challenges can result in indexes with dissimilar numbers of bonds representing the same markets. The large number of fixed-income securities—combined with the lack of liquidity of some securities—has made it more costly and difficult, compared with equity indexes, for investors to replicate fixed-income indexes and duplicate their performance.

7.2 Types of Fixed-Income Indexes

The wide variety of fixed-income securities, ranging from zero-coupon bonds to bonds with embedded options (i.e., callable or putable bonds), results in a number of different types of fixed-income indexes. Similar to equities, fixed-income securities can be categorized according to the issuer's economic sector, the issuer's geographic region, or the economic development of the issuer's geographic region. Fixed-income securities can also be classified along the following dimensions:

- type of issuer (government, government agency, corporation);
- type of financing (general obligation, collateralized);
- currency of payments;
- maturity;
- credit quality (investment grade, high yield, credit agency ratings); and
- absence or presence of inflation protection.

Fixed-income indexes are based on these various dimensions and can be categorized as follows:

- aggregate or broad market indexes;
- market sector indexes;
- style indexes;
- economic sector indexes; and
- specialized indexes such as high-yield, inflation-linked, and emerging market indexes.

The first fixed-income index created, the Bloomberg Barclays US Aggregate Bond Index (formerly the Barclays Capital Aggregate Bond Index), is an example of a single-country aggregate index. Designed to represent the broad market of US fixed-income securities, it comprises approximately 8,000 securities, including US Treasury, government-related, corporate, mortgage-backed, asset-backed, and commercial mortgage-backed securities.

Aggregate indexes can be subdivided by market sector (government, government agency, collateralized, corporate); style (maturity, credit quality); economic sector, or some other characteristic to create more narrowly defined indexes. A common distinction reflected in indexes is between investment grade (e.g., those with a Standard & Poor's credit rating of BBB– or better) and high-yield securities. Investment-grade indexes are typically further subdivided by maturity (i.e., short, intermediate, or long) and by credit rating (e.g., AAA, BBB, etc.).[5] The wide variety of fixed-income indexes reflects the partitioning of fixed-income securities on the basis of a variety of dimensions.

Exhibit 8 illustrates how the major types of fixed-income indexes can be organized on the basis of various dimensions.

Exhibit 8 Dimensions of Fixed-Income Indexes

Market	Global
	Regional
	Country or currency zone

(continued)

---

[5] Credit ratings are discussed in depth in the Level I CFA Program reading "Fundamentals of Credit Analysis."

Exhibit 8 (Continued)

Type	Corporate	Collateralized *Securitized* *Mortgage-backed*	Government agency	Government
Maturity	For example, 1–3, 3–5, 5–7, 7–10, 10+ years; short-term, medium-term, or long-term			
Credit quality	For example, AAA, AA, A, BBB, etc.; Aaa, Aa, A, Baa, etc.; investment grade, high yield			

All aggregate indexes include a variety of market sectors and credit ratings. The breakdown of the Bloomberg Barclays Global Aggregate Bond Index by market sectors and by credit rating is shown in Exhibit 9 and Exhibit 10, respectively.

INDEXES FOR ALTERNATIVE INVESTMENTS

8

j describe indexes representing alternative investments;

k compare types of security market indexes.

Many investors seek to lower the risk or enhance the performance of their portfolios by investing in assets classes other than equities and fixed income. Interest in alternative assets and investment strategies has led to the creation of indexes designed to represent broad classes of alternative investments. Three of the most widely followed alternative investment classes are commodities, real estate, and hedge funds.

8.1 Commodity Indexes

Commodity indexes consist of futures contracts on one or more commodities, such as agricultural products (rice, wheat, sugar), livestock (cattle, hogs), precious and common metals (gold, silver, copper), and energy commodities (crude oil, natural gas).

Although some commodity indexes may include the same commodities, the returns of these indexes may differ because each index may use a different weighting method. Because commodity indexes do not have an obvious weighting mechanism, such as market capitalization, commodity index providers create their own weighting methods. Some indexes, such as the Thomson Reuters/Core Commodity CRB Index (TR/CC CRB Index), formerly known as the Commodity Research Bureau (CRB) Index, contain a fixed number of commodities that are weighted equally. The S&P GSCI uses a combination of liquidity measures and world production values in its weighting scheme and allocates more weight to commodities that have risen in price. Other indexes have fixed weights that are determined by a committee.

The different weighting methods can also lead to large differences in exposure to specific commodities. The S&P GSCI in 2018, for example, weights the energy-sector approximately 50% higher and the agriculture sector 40% lower than the CRB Index. These differences result in indexes with very different risk and return profiles. Unlike commodity indexes, broad equity and fixed-income indexes that target the same markets share similar risk and return profiles.

The performance of commodity indexes can also be quite different from their underlying commodities because the indexes consist of futures contracts on the commodities rather than the actual commodities. Index returns are affected by factors other than changes in the prices of the underlying commodities because futures contracts must be continually "rolled over" (i.e., replacing a contract nearing expiration with a new contract). Commodity index returns reflect the risk-free interest rate, the changes in future prices, and the roll yield. Therefore, a commodity index return can be quite different from the return based on changes in the prices of the underlying commodities.

8.2 Real Estate Investment Trust Indexes

Real estate indexes represent not only the market for real estate securities but also the market for real estate—a highly illiquid market and asset class with infrequent transactions and pricing information. Real estate indexes can be categorized as appraisal indexes, repeat sales indexes, and real estate investment trust (REIT) indexes.

REIT indexes consist of shares of publicly traded REITs. REITS are public or private corporations organized specifically to invest in real estate, either through ownership of properties or investment in mortgages. Shares of public REITs are traded on the world's various stock exchanges and are a popular choice for investing in commercial real estate properties. Because REIT indexes are based on publicly traded REITs with continuous market pricing, the value of REIT indexes is calculated continuously.

The FTSE EPRA/NAREIT global family of REIT indexes shown in Exhibit 11 seeks to represent trends in real estate stocks worldwide and includes representation from the European Public Real Estate Association (EPRA) and the National Association of Real Estate Investment Trusts (NAREIT).

8.3 Hedge Fund Indexes

Hedge fund indexes reflect the returns on hedge funds. **Hedge funds** are private investment vehicles that typically use leverage and long and short investment strategies.

A number of research organizations maintain databases of hedge fund returns and summarize these returns into indexes. These database indexes are designed to represent the performance of the hedge funds on a very broad global level (hedge funds in general) or the strategy level. Most of these indexes are equal weighted and represent the performance of the hedge funds within a particular database.

Most research organizations rely on the voluntary cooperation of hedge funds to compile performance data. As unregulated entities, however, hedge funds are not required to report their performance to any party other than their investors. Therefore, each hedge fund decides to which database(s) it will report its performance. As a result, rather than index providers determining the constituents, the constituents determine the index.

Frequently, a hedge fund reports its performance to only one database. The result is little overlap of funds covered by the different indexes. With little overlap between their constituents, different global hedge fund indexes may reflect very different performance for the hedge fund industry over the same period of time.

Another consequence of the voluntary performance reporting is the potential for survivorship bias and, therefore, inaccurate performance representation. This means that hedge funds with poor performance may be less likely to report their performance to the database or may stop reporting to the database, so their returns may be excluded when measuring the return of the index. As a result, the index may not accurately reflect actual hedge fund performance so much as the performance of hedge funds that are performing well.

REPRESENTATIVE INDEXES WORLDWIDE

As indicated in this reading, the choice of indexes to meet the needs of investors is extensive. Investors using security market indexes must be careful in their selection of the index or indexes most appropriate for their needs. The following table illustrates the variety of indexes reflecting different asset classes, markets, and weighting methods.

Index	**Representing**	**Number of Securities**	**Weighting Method**	**Comments**
Dow Jones Industrial Average	US blue chip companies	30	Price	The oldest and most widely known US equity index. *Wall Street Journal* editors choose 30 stocks from among large, mature blue-chip companies.
Nikkei Stock Average	Japanese blue chip companies	225	Modified price	Known as the Nikkei 225 and originally formulated by Dow Jones & Company. Because of extreme variation in price levels of component securities, some high-priced shares are weighted as a fraction of share price.
TOPIX	All companies listed on the Tokyo Stock Exchange First Section	Varies	Float-adjusted market cap	Represents about 93 percent of the market value of all Japanese equities. Contains a large number of very small, illiquid stocks, making exact replication difficult.
MSCI All Country World Index	Stocks of 23 developed and 24 emerging markets	Varies	Free-float-adjusted market cap	Composed of companies representative of the market structure of developed and emerging market countries in the Americas, Europe/Middle East, and Asia/Pacific regions. Price return and total return versions available in both USD and local currencies.
S&P Developed Ex-US BMI Energy Sector Index	Energy sector of developed global markets outside the United States	Varies	Float-adjusted market cap	Serves as a model portfolio for the SPDR® S&P Energy Sector Exchange-Traded Fund (ETF).
Bloomberg Barclays Global Aggregate Bond Index	Investment-grade bonds in the North American, European, and Asian markets	Varies	Market cap	Formerly known as Lehman Brothers Global Aggregate Bond Index.
Markit iBoxx Euro High-Yield Bond Indexes	Sub-investment-grade euro-denominated corporate bonds	Varies	Market cap and variations	Rebalanced monthly. Represents tradable part of market. Price and total return versions available with such analytical values as yield, duration, modified duration, and convexity. Provides platform for research and structured products.
FTSE EPRA/NAREIT Global Real Estate Index	Real estate securities in the North American, European, and Asian markets	Varies	Float-adjusted market cap	The stocks of REITs that constitute the index trade on public stock exchanges and may be constituents of equity market indexes.

Index	Representing	Number of Securities	Weighting Method	Comments
HFRX Global Hedge Fund Index	Overall composition of the HFR database	Varies	Asset weighted	Comprises all eligible hedge fund strategies. Examples include convertible arbitrage, distressed securities, market neutral, event driven, macro, and relative value arbitrage. Constituent strategies are asset weighted on the basis of asset distribution within the hedge fund industry.
HFRX Equal Weighted Strategies EUR Index	Overall composition of the HFR database	Varies	Equal weighted	Denominated in euros and is constructed from the same strategies as the HFRX Global Hedge Fund Index.
Morningstar Style Indexes	US stocks classified by market cap and value/growth orientation	Varies	Float-adjusted market cap	The nine indexes defined by combinations of market cap (large, mid, and small) and value/growth orientation (value, core, growth) have mutually exclusive constituents and are exhaustive with respect to the Morningstar US Market Index. Each is a model portfolio for one of the iShares Morningstar ETFs.

SUMMARY

This reading explains and illustrates the construction, management, and uses of security market indexes. It also discusses various types of indexes. Security market indexes are invaluable tools for investors, who can select from among thousands of indexes representing a variety of security markets, market segments, and asset classes. These indexes range from those representing the global market for major asset classes to those representing alternative investments in specific geographic markets. To benefit from the use of security market indexes, investors must understand their construction and determine whether the selected index is appropriate for their purposes. Frequently, an index that is well suited for one purpose may not be well suited for other purposes. Users of indexes must be familiar with how various indexes are constructed in order to select the index or indexes most appropriate for their needs.

Among the key points made in this reading are the following:

- Security market indexes are intended to measure the values of different target markets (security markets, market segments, or asset classes).
- The constituent securities selected for inclusion in the security market index are intended to represent the target market.
- A price return index reflects only the prices of the constituent securities.
- A total return index reflects not only the prices of the constituent securities but also the reinvestment of all income received since the inception of the index.
- Methods used to weight the constituents of an index range from the very simple, such as price and equal weightings, to the more complex, such as market-capitalization and fundamental weightings.

- Choices in index construction—in particular, the choice of weighting method—affect index valuation and returns.
- Index management includes 1) periodic rebalancing to ensure that the index maintains appropriate weightings and 2) reconstitution to ensure the index represents the desired target market.
- Rebalancing and reconstitution create turnover in an index. Reconstitution can dramatically affect prices of current and prospective constituents.
- Indexes serve a variety of purposes. They gauge market sentiment and serve as benchmarks for actively managed portfolios. They act as proxies for measuring systematic risk and risk-adjusted performance. They also serve as proxies for asset classes in asset allocation models and as model portfolios for investment products.
- Investors can choose from security market indexes representing various asset classes, including equity, fixed-income, commodity, real estate, and hedge fund indexes.
- Within most asset classes, index providers offer a wide variety of indexes, ranging from broad market indexes to highly specialized indexes based on the issuer's geographic region, economic development group, or economic sector or other factors.
- Proper use of security market indexes depends on understanding their construction and management.

PRACTICE PROBLEMS

1 A security market index represents the:

A risk of a security market.

B security market as a whole.

C security market, market segment, or asset class.

2 Security market indexes are:

A constructed and managed like a portfolio of securities.

B simple interchangeable tools for measuring the returns of different asset classes.

C valued on a regular basis using the actual market prices of the constituent securities.

3 When creating a security market index, an index provider must first determine the:

A target market.

B appropriate weighting method.

C number of constituent securities.

4 One month after inception, the price return version and total return version of a single index (consisting of identical securities and weights) will be equal if:

A market prices have not changed.

B capital gains are offset by capital losses.

C the securities do not pay dividends or interest.

5 The values of a price return index and a total return index consisting of identical equal-weighted dividend-paying equities will be equal:

A only at inception.

B at inception and on rebalancing dates.

C at inception and on reconstitution dates.

6 An analyst gathers the following information for an equal-weighted index comprised of assets Able, Baker, and Charlie:

Security	Beginning of Period Price (€)	End of Period Price (€)	Total Dividends (€)
Able	10.00	12.00	0.75
Baker	20.00	19.00	1.00
Charlie	30.00	30.00	2.00

The price return of the index is:

A 1.7%.

B 5.0%.

C 11.4%.

7 An analyst gathers the following information for an equal-weighted index comprised of assets Able, Baker, and Charlie:

© 2011 CFA Institute. All rights reserved.

Security	Beginning of Period Price (€)	End of Period Price (€)	Total Dividends (€)
Able	10.00	12.00	0.75
Baker	20.00	19.00	1.00
Charlie	30.00	30.00	2.00

The total return of the index is:

A 5.0%.

B 7.9%.

C 11.4%.

8 An analyst gathers the following information for a price-weighted index comprised of securities ABC, DEF, and GHI:

Security	Beginning of Period Price (£)	End of Period Price (£)	Total Dividends (£)
ABC	25.00	27.00	1.00
DEF	35.00	25.00	1.50
GHI	15.00	16.00	1.00

The price return of the index is:

A –4.6%.

B –9.3%.

C –13.9%.

9 An analyst gathers the following information for a market-capitalization-weighted index comprised of securities MNO, QRS, and XYZ:

Security	Beginning of Period Price (¥)	End of Period Price (¥)	Dividends per Share (¥)	Shares Outstanding
MNO	2,500	2,700	100	5,000
QRS	3,500	2,500	150	7,500
XYZ	1,500	1,600	100	10,000

The price return of the index is:

A –9.33%.

B –10.23%.

C –13.90%.

10 An analyst gathers the following information for a market-capitalization-weighted index comprised of securities MNO, QRS, and XYZ:

Security	Beginning of Period Price (¥)	End of Period Price (¥)	Dividends Per Share (¥)	Shares Outstanding
MNO	2,500	2,700	100	5,000
QRS	3,500	2,500	150	7,500
XYZ	1,500	1,600	100	10,000

The total return of the index is:

A 1.04%.

B –5.35%.

C –10.23%.

11 When creating a security market index, the target market:

A determines the investment universe.

B is usually a broadly defined asset class.

C determines the number of securities to be included in the index.

12 An analyst gathers the following data for a price-weighted index:

	Beginning of Period		End of Period	
Security	Price (€)	Shares Outstanding	Price (€)	Shares Outstanding
A	20.00	300	22.00	300
B	50.00	300	48.00	300
C	26.00	2,000	30.00	2,000

The price return of the index over the period is:

A 4.2%.

B 7.1%.

C 21.4%.

13 An analyst gathers the following data for a value-weighted index:

	Beginning of Period		End of Period	
Security	Price (£)	Shares Outstanding	Price (£)	Shares Outstanding
A	20.00	300	22.00	300
B	50.00	300	48.00	300
C	26.00	2,000	30.00	2,000

The return on the value-weighted index over the period is:

A 7.1%.

B 11.0%.

C 21.4%.

14 An analyst gathers the following data for an equally-weighted index:

	Beginning of Period		End of Period	
Security	Price (¥)	Shares Outstanding	Price (¥)	Shares Outstanding
A	20.00	300	22.00	300
B	50.00	300	48.00	300
C	26.00	2,000	30.00	2,000

The return on the index over the period is:

A 4.2%.

B 6.8%.

C 7.1%.

15 Which of the following index weighting methods requires an adjustment to the divisor after a stock split?

A Price weighting.

B Fundamental weighting.

C Market-capitalization weighting.

16 If the price return of an equal-weighted index exceeds that of a market-capitalization-weighted index comprised of the same securities, the *most likely* explanation is:

A stock splits.

B dividend distributions.

C outperformance of small-market-capitalization stocks.

17 A float-adjusted market-capitalization-weighted index weights each of its constituent securities by its price and:

A its trading volume.

B the number of its shares outstanding.

C the number of its shares available to the investing public.

18 Which of the following index weighting methods is most likely subject to a value tilt?

A Equal weighting.

B Fundamental weighting.

C Market-capitalization weighting.

19 Rebalancing an index is the process of periodically adjusting the constituent:

A securities' weights to optimize investment performance.

B securities to maintain consistency with the target market.

C securities' weights to maintain consistency with the index's weighting method.

20 Which of the following index weighting methods requires the most frequent rebalancing?

A Price weighting.

B Equal weighting.

C Market-capitalization weighting.

21 Reconstitution of a security market index reduces:

A portfolio turnover.

B the need for rebalancing.

C the likelihood that the index includes securities that are not representative of the target market.

22 Security market indexes are used as:

A measures of investment returns.

B proxies to measure unsystematic risk.

C proxies for specific asset classes in asset allocation models.

23 Uses of market indexes do not include serving as a:

A measure of systemic risk.

B basis for new investment products.

C benchmark for evaluating portfolio performance.

24 Which of the following statements regarding sector indexes is *most* accurate? Sector indexes:

A track different economic sectors and cannot be aggregated to represent the equivalent of a broad market index.

B provide a means to determine whether an active investment manager is more successful at stock selection or sector allocation.

C apply a universally agreed upon sector classification system to identify the constituent securities of specific economic sectors, such as consumer goods, energy, finance, health care.

25 Which of the following is an example of a style index? An index based on:

A geography.

B economic sector.

C market capitalization.

26 Which of the following statements regarding fixed-income indexes is *most* accurate?

A Liquidity issues make it difficult for investors to easily replicate fixed-income indexes.

B Rebalancing and reconstitution are the only sources of turnover in fixed-income indexes.

C Fixed-income indexes representing the same target market hold similar numbers of bonds.

27 An aggregate fixed-income index:

A comprises corporate and asset-backed securities.

B represents the market of government-issued securities.

C can be subdivided by market or economic sector to create more narrowly defined indexes.

28 Fixed-income indexes are *least likely* constructed on the basis of:

A maturity.

B type of issuer.

C coupon frequency.

29 Commodity index values are based on:

A futures contract prices.

B the market price of the specific commodity.

C the average market price of a basket of similar commodities.

30 Which of the following statements is *most* accurate?

A Commodity indexes all share similar weighting methods.

B Commodity indexes containing the same underlying commodities offer similar returns.

C The performance of commodity indexes can be quite different from that of the underlying commodities.

31 Which of the following is *not* a real estate index category?

A Appraisal index.

B Initial sales index.

C Repeat sales index.

32 A unique feature of hedge fund indexes is that they:

A are frequently equal weighted.

B are determined by the constituents of the index.

C reflect the value of private rather than public investments.

33 The returns of hedge fund indexes are *most likely*:

A biased upward.

B biased downward.

C similar across different index providers.

34 In comparison to equity indexes, the constituent securities of fixed-income indexes are:

A more liquid.

B easier to price.

C drawn from a larger investment universe.

SOLUTIONS

1. C is correct. A security market index represents the value of a given security market, market segment, or asset class.
2. A is correct. Security market indexes are constructed and managed like a portfolio of securities.
3. A is correct. The first decision is identifying the target market that the index is intended to represent because the target market determines the investment universe and the securities available for inclusion in the index.
4. C is correct. The difference between a price return index and a total return index consisting of identical securities and weights is the income generated over time by the underlying securities. If the securities in the index do not generate income, both indexes will be identical in value.
5. A is correct. At inception, the values of the price return and total return versions of an index are equal.
6. B is correct. The price return is the sum of the weighted returns of each security. The return of Able is 20 percent [(12 – 10)/10]; of Baker is –5 percent [(19 – 20)/20]; and of Charlie is 0 percent [(30 – 30)/30]. The price return index assigns a weight of 1/3 to each asset; therefore, the price return is 1/3 × [20% + (–5%) + 0%] = 5%.
7. C is correct. The total return of an index is calculated on the basis of the change in price of the underlying securities plus the sum of income received or the sum of the weighted total returns of each security. The total return of Able is 27.5 percent; of Baker is 0 percent; and of Charlie is 6.7 percent:

   Able: (12 – 10 + 0.75)/10 = 27.5%

   Baker: (19 – 20 + 1)/20 = 0%

   Charlie: (30 – 30 + 2)/30 = 6.7%

   An equal-weighted index applies the same weight (1/3) to each security's return; therefore, the total return = 1/3 × (27.5% + 0% + 6.7%) = 11.4%.
8. B is correct. The price return of the price-weighted index is the percentage change in price of the index: (68 – 75)/75 = –9.33%.

Security	**Beginning of Period Price (£)**	**End of Period Price (£)**
ABC	25.00	27.00
DEF	35.00	25.00
GHI	15.00	16.00
TOTAL	75.00	68.00

9. B is correct. The price return of the index is (48,250,000 – 53,750,000)/53,750,000 = –10.23%.

Security	**Beginning of Period Price (¥)**	**Shares Outstanding**	**Beginning of Period Value (¥)**	**End of Period Price (¥)**	**End of Period Value (¥)**
MNO	2,500	5,000	12,500,000	2,700	13,500,000
QRS	3,500	7,500	26,250,000	2,500	18,750,000

(continued)

Security	Beginning of Period Price (¥)	Shares Outstanding	Beginning of Period Value (¥)	End of Period Price (¥)	End of Period Value (¥)
XYZ	1,500	10,000	15,000,000	1,600	16,000,000
Total			53,750,000		48,250,000

10 B is correct. The total return of the market-capitalization-weighted index is calculated below:

Security	Beginning of Period Value (¥)	End of Period Value (¥)	Total Dividends (¥)	Total Return (%)
MNO	12,500,000	13,500,000	500,000	12.00
QRS	26,250,000	18,750,000	1,125,000	–24.29
XYZ	15,000,000	16,000,000	1,000,000	13.33
Total	53,750,000	48,250,000	2,625,000	–5.35

11 A is correct. The target market determines the investment universe and the securities available for inclusion in the index.

12 A is correct. The sum of prices at the beginning of the period is 96; the sum at the end of the period is 100. Regardless of the divisor, the price return is 100/96 – 1 = 0.042 or 4.2 percent.

13 B is correct. It is the percentage change in the market value over the period:

Market value at beginning of period: (20 × 300) + (50 × 300) + (26 × 2,000) = 73,000

Market value at end of period: (22 × 300) + (48 × 300) + (30 × 2,000) = 81,000

Percentage change is 81,000/73,000 – 1 = 0.1096 or 11.0 percent with rounding.

14 C is correct. With an equal-weighted index, the same amount is invested in each security. Assuming $1,000 is invested in each of the three stocks, the index value is $3,000 at the beginning of the period and the following number of shares is purchased for each stock:

Security A: 50 shares

Security B: 20 shares

Security C: 38.46 shares.

Using the prices at the beginning of the period for each security, the index value at the end of the period is $3,213.8: ($22 × 50) + ($48 × 20) + ($30 × 38.46). The price return is $3,213.8/$3,000 – 1 = 7.1%.

15 A is correct. In the price weighting method, the divisor must be adjusted so the index value immediately after the split is the same as the index value immediately prior to the split.

16 C is correct. The main source of return differences arises from outperformance of small-cap securities or underperformance of large-cap securities. In an equal-weighted index, securities that constitute the largest fraction of the market are underrepresented and securities that constitute only a small fraction of the market are overrepresented. Thus, higher equal-weighted index returns will occur if the smaller-cap equities outperform the larger-cap equities.

17 C is correct. “Float” is the number of shares available for public trading.

18 B is correct. Fundamental weighting leads to indexes that have a value tilt.

19 C is correct. Rebalancing refers to adjusting the weights of constituent securities in an index to maintain consistency with the index's weighting method.

20 B is correct. Changing market prices will cause weights that were initially equal to become unequal, thus requiring rebalancing.

21 C is correct. Reconstitution is the process by which index providers review the constituent securities, re-apply the initial criteria for inclusion in the index, and select which securities to retain, remove, or add. Constituent securities that no longer meet the criteria are replaced with securities that do. Thus, reconstitution reduces the likelihood that the index includes securities that are not representative of the target market.

22 C is correct. Security market indexes play a critical role as proxies for asset classes in asset allocation models.

23 A is correct. Security market indexes are used as proxies for measuring market or systematic risk, not as measures of systemic risk.

24 B is correct. Sector indexes provide a means to determine whether a portfolio manager is more successful at stock selection or sector allocation.

25 C is correct. Style indexes represent groups of securities classified according to market capitalization, value, growth, or a combination of these characteristics.

26 A is correct. The large number of fixed-income securities—combined with the lack of liquidity of some securities—makes it costly and difficult for investors to replicate fixed-income indexes.

27 C is correct. An aggregate fixed-income index can be subdivided by market sector (government, government agency, collateralized, corporate), style (maturity, credit quality), economic sector, or some other characteristic to create more narrowly defined indexes.

28 C is correct. Coupon frequency is not a dimension on which fixed-income indexes are based.

29 A is correct. Commodity indexes consist of futures contracts on one or more commodities.

30 C is correct. The performance of commodity indexes can be quite different from that of the underlying commodities because the indexes consist of futures contracts on the commodities rather than the actual commodities.

31 B is correct. It is not a real estate index category.

32 B is correct. Hedge funds are not required to report their performance to any party other than their investors. Therefore, each hedge fund decides to which database(s) it will report its performance. Thus, for a hedge fund index, constituents determine the index rather than index providers determining the constituents.

33 A is correct. Voluntary performance reporting may lead to survivorship bias, and poorer performing hedge funds will be less likely to report their performance.

34 C is correct. The fixed-income market has more issuers and securities than the equity market.

Market Efficiency

by Sean Cleary, PhD, CFA, Howard J. Atkinson, CIMA, ICD.D, CFA, and Pamela Peterson Drake, PhD, CFA

Sean Cleary, PhD, CFA, is at Queen's University (Canada). Howard J. Atkinson, CIMA, ICD.D, CFA, is at Horizons ETF Management (Canada) Inc. (Canada). Pamela Peterson Drake, PhD, CFA, is at James Madison University (USA).

LEARNING OUTCOMES

Mastery	*The candidate should be able to:*
☐	**a.** describe market efficiency and related concepts, including their importance to investment practitioners;
☐	**b.** contrast market value and intrinsic value;
☐	**c.** explain factors that affect a market's efficiency;
☐	**d.** contrast weak-form, semi-strong-form, and strong-form market efficiency;
☐	**e.** explain the implications of each form of market efficiency for fundamental analysis, technical analysis, and the choice between active and passive portfolio management;
☐	**f.** describe market anomalies;
☐	**g.** describe behavioral finance and its potential relevance to understanding market anomalies.

INTRODUCTION

1

Market efficiency concerns the extent to which market prices incorporate available information. If market prices do not fully incorporate information, then opportunities may exist to make a profit from the gathering and processing of information. The subject of market efficiency is, therefore, of great interest to investment managers, as illustrated in Example 1.

© 2019 CFA Institute. All rights reserved.

EXAMPLE 1

Market Efficiency and Active Manager Selection

The chief investment officer (CIO) of a major university endowment fund has listed eight steps in the active manager selection process that can be applied both to traditional investments (e.g., common equity and fixed-income securities) and to alternative investments (e.g., private equity, hedge funds, and real assets). The first step specified is the evaluation of market opportunity:

> What is the opportunity and why is it there? To answer this question, we start by studying capital markets and the types of managers operating within those markets. We identify market inefficiencies and try to understand their causes, such as regulatory structures or behavioral biases. We can rule out many broad groups of managers and strategies by simply determining that the degree of market inefficiency necessary to support a strategy is implausible. Importantly, we consider the past history of active returns meaningless unless we understand why markets will allow those active returns to continue into the future.[1]

The CIO's description underscores the importance of not assuming that past active returns that might be found in a historical dataset will repeat themselves in the future. **Active returns** refer to returns earned by strategies that do *not* assume that all information is fully reflected in market prices.

Governments and market regulators also care about the extent to which market prices incorporate information. Efficient markets imply informative prices—prices that accurately reflect available information about fundamental values. In market-based economies, market prices help determine which companies (and which projects) obtain capital. If these prices do not efficiently incorporate information about a company's prospects, then it is possible that funds will be misdirected. By contrast, prices that are informative help direct scarce resources and funds available for investment to their highest-valued uses.[2] Informative prices thus promote economic growth. The efficiency of a country's capital markets (in which businesses raise financing) is an important characteristic of a well-functioning financial system.

The remainder of this reading is organized as follows. Sections 2 and 3 provide specifics on how the efficiency of an asset market is described and discuss the factors affecting (i.e., contributing to and impeding) market efficiency. Sections 4 and 5 present an influential three-way classification of the efficiency of security markets and discuss its implications for fundamental analysis, technical analysis, and portfolio management. Sections 6 and 7 present several market anomalies (apparent market inefficiencies that have received enough attention to be individually identified and named) and describe how these anomalies relate to investment strategies. Section 8 introduces behavioral finance and how that field of study relates to market efficiency. A summary concludes the reading.

---

[1] The CIO is Christopher J. Brightman, CFA, of the University of Virginia Investment Management Company, as reported in Yau, Schneeweis, Robinson, and Weiss (2007, pp. 481–482).

[2] This concept is known as allocative efficiency.

THE CONCEPT OF MARKET EFFICIENCY

2

a describe market efficiency and related concepts, including their importance to investment practitioners;

b contrast market value and intrinsic value;

2.1 The Description of Efficient Markets

An **informationally efficient market** (an **efficient market**) is a market in which asset prices reflect new information quickly and rationally. An efficient market is thus a market in which asset prices reflect all past and present information.[3]

In this section we expand on this definition by clarifying the time frame required for an asset's price to incorporate information as well as describing the elements of information releases assumed under market efficiency. We discuss the difference between market value and intrinsic value and illustrate how inefficiencies or discrepancies between these values can provide profitable opportunities for active investment. As financial markets are generally not considered being either completely efficient or inefficient, but rather falling within a range between the two extremes, we describe a number of factors that contribute to and impede the degree of efficiency of a financial market. Finally, we conclude our overview of market efficiency by illustrating how the costs incurred by traders in identifying and exploiting possible market inefficiencies affect how we interpret market efficiency.

Investment managers and analysts, as noted, are interested in market efficiency because the extent to which a market is efficient affects how many profitable trading opportunities (market inefficiencies) exist. Consistent, superior, risk-adjusted returns (net of all expenses) are not achievable in an efficient market.[4] In an efficient market, a **passive investment** strategy (i.e., buying and holding a broad market portfolio) that does not seek superior risk-adjusted returns can be preferred to an **active investment** strategy because of lower costs (for example, transaction and information-seeking costs). By contrast, in a very inefficient market, opportunities may exist for an active investment strategy to achieve superior risk-adjusted returns (net of all expenses in executing the strategy) as compared with a passive investment strategy. In inefficient markets, an active investment strategy may outperform a passive investment strategy on a risk-adjusted basis. Understanding the characteristics of an efficient market and being able to evaluate the efficiency of a particular market are important topics for investment analysts and portfolio managers.

An efficient market is a market in which asset prices reflect information quickly. But what is the time frame of "quickly"? Trades are the mechanism by which information can be incorporated into asset transaction prices. The time needed to execute trades to exploit an inefficiency may provide a baseline for judging speed of adjustment.[5] The time frame for an asset's price to incorporate information must be at least as long as the shortest time a trader needs to execute a transaction in the asset. In certain markets, such as foreign exchange and developed equity markets, market efficiency relative to certain types of information has been studied using time frames as short as one minute or less. If the time frame of price adjustment allows many traders to earn profits with little risk, then the market is relatively inefficient. These considerations lead to the observation that market efficiency can be viewed as falling on a continuum.

---

[3] This definition is convenient for making several instructional points. The definition that most simply explains the sense of the word *efficient* in this context can be found in Fama (1976): "An efficient capital market is a market that is efficient in processing information" (p. 134).

[4] The technical term for *superior* in this context is *positive abnormal* in the sense of higher than expected given the asset's risk (as measured, according to capital market theory, by the asset's contribution to the risk of a well-diversified portfolio).

[5] Although the original theory of market efficiency does not quantify this speed, the basic idea is that it is sufficiently swift to make it impossible to consistently earn abnormal profits. Chordia, Roll, and Subrahmanyam (2005) suggest that the adjustment to information on the New York Stock Exchange (NYSE) is between 5 and 60 minutes.

Finally, an important point is that in an efficient market, prices should be expected to react only to the elements of information releases that are not anticipated fully by investors—that is, to the "unexpected" or "surprise" element of such releases. Investors process the unexpected information and revise expectations (for example, about an asset's future cash flows, risk, or required rate of return) accordingly. The revised expectations enter or get incorporated in the asset price through trades in the asset. Market participants who process the news and believe that at the current market price an asset does not offer sufficient compensation for its perceived risk will tend to sell it or even sell it short. Market participants with opposite views should be buyers. In this way the market establishes the price that balances the various opinions after expectations are revised.

EXAMPLE 2

Price Reaction to the Default on a Bond Issue

Suppose that a speculative-grade bond issuer announces, just before bond markets open, that it will default on an upcoming interest payment. In the announcement, the issuer confirms various reports made in the financial media in the period leading up to the announcement. Prior to the issuer's announcement, the financial news media reported the following: 1) suppliers of the company were making deliveries only for cash payment, reducing the company's liquidity; 2) the issuer's financial condition had probably deteriorated to the point that it lacked the cash to meet an upcoming interest payment; and 3) although public capital markets were closed to the company, it was negotiating with a bank for a private loan that would permit it to meet its interest payment and continue operations for at least nine months. If the issuer defaults on the bond, the consensus opinion of analysts is that bondholders will recover approximately $0.36 to $0.38 per dollar face value.

1 If the market for the bond is efficient, the bond's market price is *most likely* to fully reflect the bond's value after default:
   - **A** in the period leading up to the announcement.
   - **B** in the first trade prices after the market opens on the announcement day.
   - **C** when the issuer actually misses the payment on the interest payment date.

2 If the market for the bond is efficient, the piece of information that bond investors *most likely* focus on in the issuer's announcement is that the issuer had:
   - **A** failed in its negotiations for a bank loan.
   - **B** lacked the cash to meet the upcoming interest payment.
   - **C** been required to make cash payments for supplier deliveries.

Solution to 1:

B is correct. The announcement removed any uncertainty about default. In the period leading up to the announcement, the bond's market price incorporated a probability of default, but the price would not have fully reflected the bond's value after default. The possibility that a bank loan might permit the company to avoid default was not eliminated until the announcement.

Solution to 2:

A is correct. The failure of the loan negotiations first becomes known in this announcement. The failure implies default.

2.2 Market Value versus Intrinsic Value

Market value is the price at which an asset can currently be bought or sold. **Intrinsic value** (sometimes called **fundamental value**) is, broadly speaking, the value that would be placed on it by investors if they had a complete understanding of the asset's investment characteristics.[6] For a bond, for example, such information would include its interest (coupon) rate, principal value, the timing of its interest and principal payments, the other terms of the bond contract (indenture), a precise understanding of its default risk, the liquidity of its market, and other issue-specific items. In addition, market variables such as the term structure of interest rates and the size of various market premiums applying to the issue (for default risk, etc.) would enter into a discounted cash flow estimate of the bond's intrinsic value (discounted cash flow models are often used for such estimates). The word *estimate* is used because in practice, intrinsic value can be estimated but is not known for certain.

If investors believe a market is highly *efficient*, they will usually accept market prices as accurately reflecting intrinsic values. Discrepancies between market price and intrinsic value are the basis for profitable active investment. Active investors seek to own assets selling below perceived intrinsic value in the marketplace and to sell or sell short assets selling above perceived intrinsic value.

If investors believe an asset market is relatively *inefficient*, they may try to develop an independent estimate of intrinsic value. The challenge for investors and analysts is estimating an asset's intrinsic value. Numerous theories and models, including the dividend discount model, can be used to estimate an asset's intrinsic value, but they all require some form of judgment regarding the size, timing, and riskiness of the future cash flows associated with the asset. The more complex an asset's future cash flows, the more difficult it is to estimate its intrinsic value. These complexities and the estimates of an asset's market value are reflected in the market through the buying and selling of assets. The market value of an asset represents the intersection of supply and demand—the point that is low enough to induce at least one investor to buy while being high enough to induce at least one investor to sell. Because information relevant to valuation flows continually to investors, estimates of intrinsic value change, and hence, market values change.

EXAMPLE 3

Intrinsic Value

1 An analyst estimates that a security's intrinsic value is lower than its market value. The security appears to be:

---

[6] Intrinsic value is often defined as the present value of all expected future cash flows of the asset.

  - **A** undervalued.
  - **B** fairly valued.
  - **C** overvalued.

2 A market in which assets' market values are, on average, equal to or nearly equal to intrinsic values is *best described* as a market that is attractive for:

  - **A** active investment.
  - **B** passive investment.
  - **C** both active and passive investment.

3 Suppose that the future cash flows of an asset are accurately estimated. The asset trades in a market that you believe is efficient based on most evidence, but your estimate of the asset's intrinsic value exceeds the asset's market value by a moderate amount. The *most likely* conclusion is that you have:

  - **A** overestimated the asset's risk.
  - **B** underestimated the asset's risk.
  - **C** identified a market inefficiency.

Solution to 1:

C is correct. The market is valuing the asset at more than its true worth.

Solution to 2:

B is correct because an active investment is not expected to earn superior risk-adjusted returns if the market is efficient. The additional costs of active investment are not justified in such a market.

Solution to 3:

B is correct. If risk is underestimated, the discount rate being applied to find the present value of the expected cash flows (estimated intrinsic value) will be too low and the intrinsic value estimate will be too high.

3

FACTORS AFFECTING MARKET EFFICIENCY INCLUDING TRADING COSTS

a describe market efficiency and related concepts, including their importance to investment practitioners;

c explain factors that affect a market's efficiency;

For markets to be efficient, prices should adjust quickly and rationally to the release of new information. In other words, prices of assets in an efficient market should "fully reflect" all information. Financial markets, however, are generally not classified at the two extremes as either completely inefficient or completely efficient but, rather, as exhibiting various degrees of efficiency. In other words, market efficiency should be viewed as falling on a continuum between extremes of completely efficient, at one end, and completely inefficient, at the other. Asset prices in a highly efficient market, by definition, reflect information more quickly and more accurately than in a less-efficient market. These degrees of efficiency also vary through time, across geographical markets, and by type of market. A number of factors contribute to and impede the degree of efficiency in a financial market.

3.1 Market Participants

One of the most critical factors contributing to the degree of efficiency in a market is the number of market participants. Consider the following example that illustrates the relationship between the number of market participants and market efficiency.

EXAMPLE 4

Illustration of Market Efficiency

Assume that the shares of a small market capitalization (cap) company trade on a public stock exchange. Because of its size, it is not considered "blue-chip" and not many professional investors follow the activities of the company.[7] A small-cap fund analyst reports that the most recent annual operating performance of the company has been surprisingly good, considering the recent slump in its industry. The company's share price, however, has been slow to react to the positive financial results because the company is not being recommended by the majority of research analysts. This mispricing implies that the market for this company's shares is less than fully efficient. The small-cap fund analyst recognizes the opportunity and immediately recommends the purchase of the company's shares. The share price gradually increases as more investors purchase the shares once the news of the mispricing spreads through the market. As a result, it takes a few days for the share price to fully reflect the information.

Six months later, the company reports another solid set of interim financial results. But because the previous mispricing and subsequent profit opportunities have become known in the market, the number of analysts following the company's shares has increased substantially. As a result, as soon as unexpected information about the positive interim results are released to the public, a large number of buy orders quickly drive up the stock price, thereby making the market for these shares more efficient than before.

A large number of investors (individual and institutional) follow the major financial markets closely on a daily basis, and if mispricings exist in these markets, as illustrated by the example, investors will act so that these mispricings disappear quickly. Besides the number of investors, the number of financial analysts who follow or analyze a security or asset should be positively related to market efficiency. The number of market participants and resulting trading activity can vary significantly through time. A lack of trading activity can cause or accentuate other market imperfections that impede market efficiency. In fact, in many of these markets, trading in many of the listed stocks is restricted for foreigners. By nature, this limitation reduces the number of market participants, restricts the potential for trading activity, and hence reduces market efficiency.

---

[7] A "blue-chip" share is one from a well-recognized company that is considered to be high quality but low risk. This term generally refers to a company that has a long history of earnings and paying dividends.

EXAMPLE 5

Factors Affecting Market Efficiency

The expected effect on market efficiency of opening a securities market to trading by foreigners would *most likely* be to:

A decrease market efficiency.

B leave market efficiency unchanged.

C increase market efficiency.

Solution:

C is correct. The opening of markets as described should increase market efficiency by increasing the number of market participants.

3.2 Information Availability and Financial Disclosure

Information availability (e.g., an active financial news media) and financial disclosure should promote market efficiency. Information regarding trading activity and traded companies in such markets as the New York Stock Exchange, the London Stock Exchange, and the Tokyo Stock Exchange is readily available. Many investors and analysts participate in these markets, and analyst coverage of listed companies is typically substantial. As a result, these markets are quite efficient. In contrast, trading activity and material information availability may be lacking in smaller securities markets, such as those operating in some emerging markets.

Similarly, significant differences may exist in the efficiency of different types of markets. For example, many securities trade primarily or exclusively in dealer or over-the-counter (OTC) markets, including bonds, money market instruments, currencies, mortgage-backed securities, swaps, and forward contracts. The information provided by the dealers that serve as market makers for these markets can vary significantly in quality and quantity, both through time and across different product markets.

Treating all market participants fairly is critical for the integrity of the market and explains why regulators place such an emphasis on "fair, orderly, and efficient markets."[8] A key element of this fairness is that all investors have access to the information necessary to value securities that trade in the market. Rules and regulations that promote fairness and efficiency in a market include those pertaining to the disclosure of information and illegal insider trading.

For example, US Securities and Exchange Commission's (SEC's) Regulation FD (Fair Disclosure) requires that if security issuers provide nonpublic information to some market professionals or investors, they must also disclose this information to the public.[9] This requirement helps provide equal and fair opportunities, which is important in encouraging participation in the market. A related issue deals with illegal insider trading. The SEC's rules, along with court cases, define illegal insider trading as trading in securities by market participants who are considered insiders "while in possession of material, nonpublic information about the security."[10] Although these rules cannot guarantee that some participants will not have an advantage over others and that insiders will not trade on the basis of inside information, the civil and criminal penalties associated with breaking these rules are intended to discourage illegal insider trading and promote fairness. In the European Union, insider trading laws are generally enshrined in legislation and enforced by regulatory and judicial authorities.[11]

[9] Regulation FD, "Selective Disclosure and Insider Trading," 17 CFR Parts 240, 243, and 249, effective 23 October 2000.

3.3 Limits to Trading

Arbitrage is a set of transactions that produces riskless profits. Arbitrageurs are traders who engage in such trades to benefit from pricing discrepancies (inefficiencies) in markets. Such trading activity contributes to market efficiency. For example, if an asset is traded in two markets but at different prices, the actions of buying the asset in the market in which it is underpriced and selling the asset in the market in which it is overpriced will eventually bring these two prices together. The presence of these arbitrageurs helps pricing discrepancies disappear quickly. Obviously, market efficiency is impeded by any limitation on arbitrage resulting from operating inefficiencies, such as difficulties in executing trades in a timely manner, prohibitively high trading costs, and a lack of transparency in market prices.

Some market experts argue that restrictions on short selling limit arbitrage trading, which impedes market efficiency. **Short selling** is the transaction whereby an investor sells shares that he or she does not own by borrowing them from a broker and agreeing to replace them at a future date. Short selling allows investors to sell securities they believe to be overvalued, much in the same way they can buy those they believe to be undervalued. In theory, such activities promote more efficient pricing. Regulators and others, however, have argued that short selling may exaggerate downward market movements, leading to crashes in affected securities. In contrast, some researchers report evidence indicating that when investors are unable to borrow securities, that is to short the security, or when costs to borrow shares are high, market prices may deviate from intrinsic values.[12] Furthermore, research suggests that short selling is helpful in price discovery (that is, it facilitates supply and demand in determining prices).[13]

3.4 Transaction Costs and Information-Acquisition Costs

The costs incurred by traders in identifying and exploiting possible market inefficiencies affect the interpretation of market efficiency. The two types of costs to consider are transaction costs and information-acquisition costs.

- *Transaction costs*: Practically, transaction costs are incurred in trading to exploit any perceived market inefficiency. Thus, "efficient" should be viewed as efficient within the bounds of transaction costs. For example, consider a violation of the principle that two identical assets should sell for the same price in different markets. Such a violation can be considered to be a rather simple possible exception to market efficiency because prices appear to be inconsistently processing information. To exploit the violation, a trader could arbitrage by simultaneously shorting the asset in the higher-price market and buying the asset in the lower-price market. If the price discrepancy between the two markets is smaller than the transaction costs involved in the arbitrage for the lowest cost traders, the arbitrage will not occur, and both prices are in effect efficient within the bounds of arbitrage. These bounds of arbitrage are relatively narrow in highly liquid markets, such as the market for US Treasury bills, but could be wide in illiquid markets.

---

[10] Although not the focus of this particular reading, it is important to note that a party is considered an insider not only when the individual is a corporate insider, such as an officer or director, but also when the individual is aware that the information is nonpublic information [Securities and Exchange Commission, Rules 10b5-1 ("Trading on the Basis of Material Nonpublic Information in Insider Trading Cases") and Rule 10b5-2 "Duties of Trust or Confidence in Misappropriation Insider Trading Cases")].

[11] See the European Union's Market Abuse Regulation (Regulation (EU) no. 596/2014 of the European Parliament and of the Council of 16 April 2014 on market abuse) and Directive for Criminal Sanctions for Market Abuse (Directive 2014/57/EU of the European Parliament and of the Council of 16 April 2014 on criminal sanctions for market abuse).

[12] See Deng, Mortal, and Gupta (2017) and references therein."

[13] See Bris, Goetzmann, and Zhu (2009).

- *Information-acquisition costs:* Practically, expenses are always associated with gathering and analyzing information. New information is incorporated in transaction prices by traders placing trades based on their analysis of information. Active investors who place trades based on information they have gathered and analyzed play a key role in market prices adjusting to reflect new information. The classic view of market efficiency is that active investors incur information acquisition costs but that money is wasted because prices already reflect all relevant information. This view of efficiency is very strict in the sense of viewing a market as inefficient if active investing can recapture any part of the costs, such as research costs and active asset selection. Grossman and Stiglitz (1980) argue that prices must offer a return to information acquisition; in equilibrium, if markets are efficient, returns net of such expenses are just fair returns for the risk incurred. The modern perspective views a market as inefficient if, after deducting such costs, active investing can earn superior returns. Gross of expenses, a return should accrue to information acquisition in an efficient market.

In summary, a modern perspective calls for the investor to consider transaction costs and information-acquisition costs when evaluating the efficiency of a market. A price discrepancy must be sufficiently large to leave the investor with a profit (adjusted for risk) after taking account of the transaction costs and information-acquisition costs to reach the conclusion that the discrepancy may represent a market inefficiency. Prices may somewhat less than fully reflect available information without there being a true market opportunity for active investors.

4

FORMS OF MARKET EFFICIENCY

d contrast weak-form, semi-strong-form, and strong-form market efficiency;

Eugene Fama developed a framework for describing the degree to which markets are efficient.[14] In his efficient market hypothesis, markets are efficient when prices reflect *all* relevant information at any point in time. This means that the market prices observed for securities, for example, reflect the information available at the time.

In his framework, Fama defines three forms of efficiency: weak, semi-strong, and strong. Each form is defined with respect to the available information that is reflected in prices.

---

[14] Fama (1970).

Forms of Market Efficiency	**Market Prices Reflect:** **Past Market Data**	 **Public Information**	 **Private Information**
Weak form of market efficiency	✓		
Semi-strong form of market efficiency	✓	✓	
Strong form of market efficiency	✓	✓	✓

A finding that investors can consistently earn **abnormal returns** by trading on the basis of information is evidence contrary to market efficiency. In general, abnormal returns are returns in excess of those expected given a security's risk and the market's return. In other words, abnormal return equals actual return less expected return.

4.1 Weak Form

In the **weak-form efficient market hypothesis**, security prices fully reflect *all past market data*, which refers to all historical price and trading volume information. If markets are weak-form efficient, past trading data are already reflected in current prices and investors cannot predict future price changes by extrapolating prices or patterns of prices from the past.[15]

Tests of whether securities markets are weak-form efficient require looking at patterns of prices. One approach is to see whether there is any serial correlation in security returns, which would imply a predictable pattern.[16] Although there is some weak correlation in daily security returns, there is not enough correlation to make this a profitable trading rule after considering transaction costs.

An alternative approach to test weak-form efficiency is to examine specific trading rules that attempt to exploit historical trading data. If any such trading rule consistently generates abnormal risk-adjusted returns after trading costs, this evidence will contradict weak-form efficiency. This approach is commonly associated with **technical analysis**, which involves the analysis of historical trading information (primarily pricing and volume data) in an attempt to identify recurring patterns in the trading data that can be used to guide investment decisions. Many technical analysts, also referred to as "technicians," argue that many movements in stock prices are based, in large part, on psychology. Many technicians attempt to predict how market participants will behave, based on analyses of past behavior, and then trade on those predictions. Technicians often argue that simple statistical tests of trading rules are not conclusive because they are not applied to the more sophisticated trading strategies that can be used and that the research excludes the technician's subjective judgment. Thus, it is difficult to definitively refute this assertion because there are an unlimited number of possible technical trading rules.

Can technical analysts profit from trading on past trends? Overall, the evidence indicates that investors cannot consistently earn abnormal profits using past prices or other technical analysis strategies in developed markets.[17] Some evidence suggests, however, that there are opportunities to profit on technical analysis in countries with developing markets, including Hungary, Bangladesh, and Turkey, among others.[18]

---

[15] Market efficiency should not be confused with the random walk hypothesis, in which price changes over time are independent of one another. A random walk model is one of many alternative expected return generating models. Market efficiency does not require that returns follow a random walk.

[16] Serial correlation is a statistical measure of the degree to which the returns in one period are related to the returns in another period.

[17] Bessembinder and Chan (1998) and Fifield, Power, and Sinclair (2005).

[18] Fifield, Power, and Sinclair (2005), Chen and Li (2006), and Mobarek, Mollah, and Bhuyan (2008).

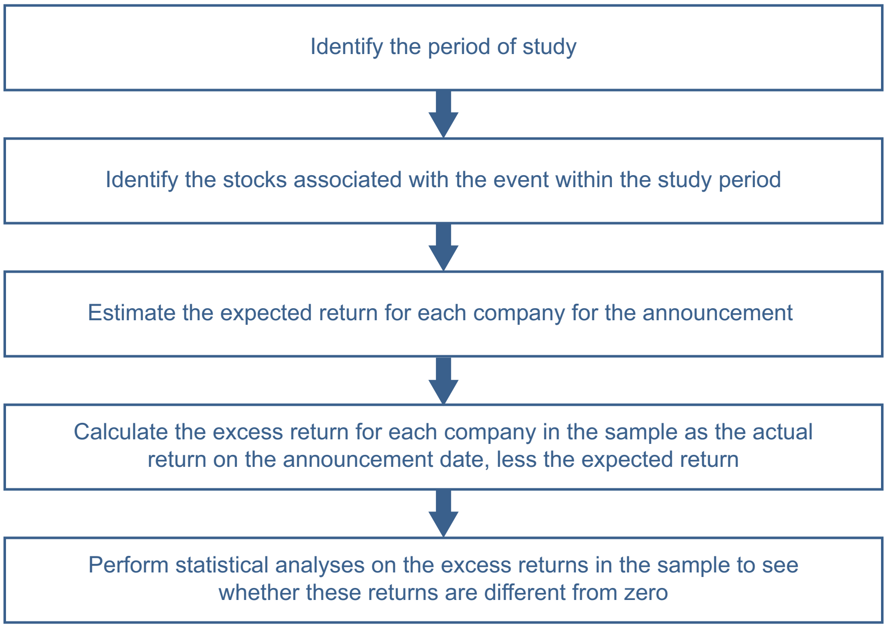
4.2 Semi-Strong Form

In a **semi-strong-form efficient market**, prices reflect all publicly known and available information. Publicly available information includes financial statement data (such as earnings, dividends, corporate investments, changes in management, etc.) and financial market data (such as closing prices, shares traded, etc.). Therefore, the semi-strong form of market efficiency encompasses the weak form. In other words, if a market is semi-strong efficient, then it must also be weak-form efficient. A market that quickly incorporates all publicly available information into its prices is semi-strong efficient.

In a semi-strong market, efforts to analyze publicly available information are futile. That is, analyzing earnings announcements of companies to identify underpriced or overpriced securities is pointless because the prices of these securities already reflect all publicly available information. If markets are semi-strong efficient, no single investor has access to information that is not already available to other market participants, and as a consequence, no single investor can gain an advantage in predicting future security prices. In a semi-strong efficient market, prices adjust quickly and accurately to new information. Suppose a company announces earnings that are higher than expected. In a semi-strong efficient market, investors would not be able to act on this announcement and earn abnormal returns.

A common empirical test of investors' reaction to information releases is the event study. Suppose a researcher wants to test whether investors react to the announcement that the company is paying a special dividend. The researcher identifies a sample period and then those companies that paid a special dividend in the period and the date of the announcement. Then, for each company's stock, the researcher calculates the expected return on the share for the event date. This expected return may be based on many different models, including the capital asset pricing model, a simple market model, or a market index return. The researcher calculates the excess return as the difference between the actual return and the expected return. Once the researcher has calculated the event's excess return for each share, statistical tests are conducted to see whether the abnormal returns are statistically different from zero. The process of an event study is outlined in Exhibit 1.

Exhibit 1 The Event Study Process



Identify the period of study
Identify the stocks associated with the event within the study period
Estimate the expected return for each company for the announcement
Calculate the excess return for each company in the sample as the actual return on the announcement date, less the expected return
Perform statistical analyses on the excess returns in the sample to see whether these returns are different from zero

How do event studies relate to efficient markets? In a semi-strong efficient market, share prices react quickly and accurately to public information. Therefore, if the information is good news, such as better-than-expected earnings, one would expect the company's shares to increase immediately at the time of the announcement; if it is bad news, one would expect a swift, negative reaction. If actual returns exceed what is expected in absence of the announcement and these returns are confined to the announcement period, then they are consistent with the idea that market prices react quickly to new information. In other words, the finding of excess returns at the time of the announcement does not necessarily indicate market inefficiency. In contrast, the finding of consistent excess returns following the announcement would suggest a trading opportunity. Trading on the basis of the announcement—that is, once the announcement is made—would not, on average, yield abnormal returns.

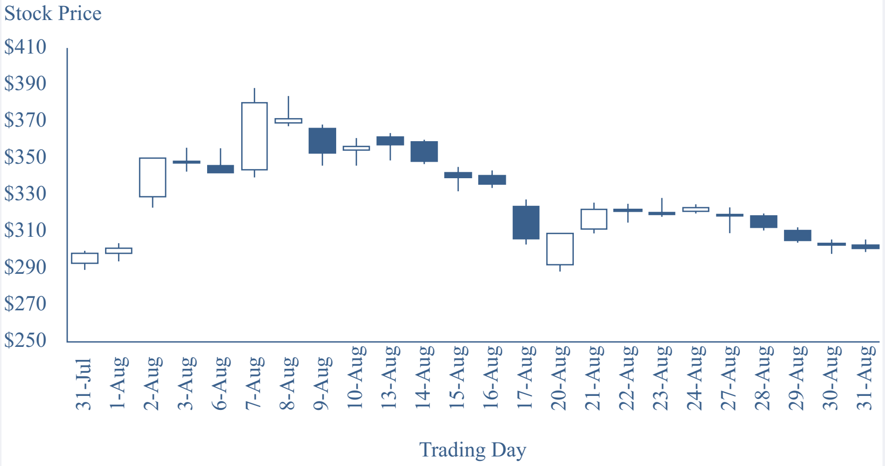
EXAMPLE 6

Information Arrival and Market Reaction

Consider an example of a news item and its effect on a share's price. The following events related to Tesla, Inc. in August of 2018:

1 August 2018	After the market closes, Tesla, Inc., publicly reports that there was a smaller-than expected cash burn for the most recent quarter.
2 August 2018	Elon Musk, Chairman and CEO of Tesla, Inc., notifies Tesla's board of directors that he wants to take the company private. This is not public information at this point.
7 August 2018	Before the market opens, the *Financial Times* reports that a Saudi fund has a $2 billion investment in Tesla. During market trading, Musk announces on Twitter "Am considering taking Tesla private at $420. Funding secured." [Twitter, Elon Musk @elonmusk, 9:48 a.m., 7 August 2018]
24 August 2018	After the market closed, Musk announces that he no longer intends on taking Tesla private.

Exhibit 2 Price of Tesla, Inc. Stock: 31 July 2018–31 August 2018



Note: Open-High-Low-Close graph of Tesla's stock price, with white rectangles indicating upward movement in the day and black rectangles indicating downward movement during the day.
Source of data: Yahoo! Finance.

Is the fact that the price of Tesla moves up immediately on the day after the Q2 earnings (the first day of trading with this information) indicative of efficiency regarding information? Most likely.

Does the fact that the price of Tesla moves up but does not reach $420 on the day the going-private Twitter announcement is made mean that investors underreacted? Not necessarily. There was confusion and uncertainty about the going-private transaction at the time, so the price did not close in on the proposed $420 per share for going private.

Does the fact that the market price of the stock declined well before the issue of going-private was laid to rest by Musk mean that the market is inefficient? Not necessarily. There were numerous analyses, discussions, and other news regarding the likelihood of the transaction, all of which was incorporated in the price of the stock before the going-private transaction was dismissed by Musk.

Researchers have examined many different company-specific information events, including stock splits, dividend changes, and merger announcements, as well as economy-wide events, such as regulation changes and tax rate changes. The results of most research are consistent with the view that developed securities markets might be semi-strong efficient. But some evidence suggests that the markets in developing countries may not be semi-strong efficient.[19]

4.3 Strong Form

In a **strong-form efficient market**, security prices fully reflect both public and private information. A market that is strong-form efficient is, by definition, also semi-strong- and weak-form efficient. In the case of a strong-form efficient market, insiders would not be able to earn abnormal returns from trading on the basis of private information. A strong-form efficient market also means that prices reflect all private information, which means that prices reflect everything that the management of a company knows about the financial condition of the company that has not been publicly released. However, this is not likely because of the strong prohibitions against insider trading that are found in most countries. If a market is strong-form efficient, those with insider information cannot earn abnormal returns.

---

[19] See Gan, Lee, Hwa, and Zhang (2005) and Raja, Sudhahar, and Selvam (2009).

Researchers test whether a market is strong-form efficient by testing whether investors can earn abnormal profits by trading on nonpublic information. The results of these tests are consistent with the view that securities markets are not strong-form efficient; many studies have found that abnormal profits can be earned when nonpublic information is used.[20]

IMPLICATIONS OF THE EFFICIENT MARKET HYPOTHESIS

5

e explain the implications of each form of market efficiency for fundamental analysis, technical analysis, and the choice between active and passive portfolio management;

The implications of efficient markets to investment managers and analysts are important because they affect the value of securities and how these securities are managed. Several implications can be drawn from the evidence on efficient markets for developed markets:

- Securities markets are weak-form efficient, and therefore, investors cannot earn abnormal returns by trading on the basis of past trends in price.
- Securities markets are semi-strong efficient, and therefore, analysts who collect and analyze information must consider whether that information is already reflected in security prices and how any new information affects a security's value.
- Securities markets are not strong-form efficient because securities laws are intended to prevent exploitation of private information.

5.1 Fundamental Analysis

Fundamental analysis is the examination of publicly available information and the formulation of forecasts to estimate the intrinsic value of assets. Fundamental analysis involves the estimation of an asset's value using company data, such as earnings and sales forecasts, and risk estimates as well as industry and economic data, such as economic growth, inflation, and interest rates. Buy and sell decisions depend on whether the current market price is less than or greater than the estimated intrinsic value.

The semi-strong form of market efficiency says that all available public information is reflected in current prices. So, what good is fundamental analysis? Fundamental analysis is necessary in a well-functioning market because this analysis helps the market participants understand the value implications of information. In other words, fundamental analysis facilitates a semi-strong efficient market by disseminating value-relevant information. And, although fundamental analysis requires costly information, this analysis can be profitable in terms of generating abnormal returns if the analyst creates a comparative advantage with respect to this information.[21]

---

[20] Evidence that finds that markets are not strong-form efficient include Jaffe (1974) and Rozeff and Zaman (1988).

5.2 Technical Analysis

Investors using **technical analysis** attempt to profit by looking at patterns of prices and trading volume. Although some price patterns persist, exploiting these patterns may be too costly and, hence, would not produce abnormal returns.

Consider a situation in which a pattern of prices exists. With so many investors examining prices, this pattern will be detected. If profitable, exploiting this pattern will eventually affect prices such that this pattern will no longer exist; it will be arbitraged away. In other words, by detecting and exploiting patterns in prices, technical analysts assist markets in maintaining weak-form efficiency. Does this mean that technical analysts cannot earn abnormal profits? Not necessarily, because there may be a possibility of earning abnormal profits from a pricing inefficiency. But would it be possible to earn abnormal returns on a consistent basis from exploiting such a pattern? No, because the actions of market participants will arbitrage this opportunity quickly, and the inefficiency will no longer exist.

5.3 Portfolio Management

If securities markets are weak-form and semi-strong-form efficient, the implication is that active trading, whether attempting to exploit price patterns or public information, is not likely to generate abnormal returns. In other words, portfolio managers cannot beat the market on a consistent basis, so therefore, passive portfolio management should outperform active portfolio management. Researchers have observed that mutual funds do not, on average, outperform the market on a risk-adjusted basis.[22] Mutual funds perform, on average, similar to the market before considering fees and expenses and perform worse than the market, on average, once fees and expenses are considered. Even if a mutual fund is not actively managed, there are costs to managing these funds, which reduces net returns.

So, what good are portfolio managers? The role of a portfolio manager is not necessarily to beat the market but, rather, to establish and manage a portfolio consistent with the portfolio's objectives, with appropriate diversification and asset allocation, while taking into consideration the risk preferences and tax situation of the investor.

6

MARKET PRICING ANOMALIES - TIME SERIES AND CROSS-SECTIONAL

f describe market anomalies;

Although considerable evidence shows that markets are efficient, researchers have identified a number of apparent market inefficiencies or anomalies. These market anomalies, if persistent, are exceptions to the notion of market efficiency. Researchers conclude that a **market anomaly** may be present if a change in the price of an asset or security cannot directly be linked to current relevant information known in the market or to the release of new information into the market.

---

[21] Brealey (1983).

[22] See Malkiel (1995). One of the challenges to evaluating mutual fund performance is that the researcher must control for survivorship bias.

The validity of any evidence supporting the potential existence of a market inefficiency or anomaly must be *consistent* over reasonably long periods. Otherwise, a detected market anomaly may largely be an artifact of the sample period chosen. In the widespread search for discovering profitable anomalies, many findings could simply be the product of a process called **data mining**, also known as **data snooping**. In generally accepted research practice, an initial hypothesis is developed which is based on economic rationale. Tests are then conducted on objectively selected data to either confirm or reject the original hypothesis. However, with data mining the process is typically reversed: data are examined with the intent to develop a hypothesis, instead of developing a hypothesis first. This is done by analyzing data in various manners, and even utilizing different empirical approaches until you find support for a desired result, in this case a profitable anomaly.

Can researchers look back on data and find a trading strategy that would have yielded abnormal returns? Absolutely. Enough data snooping often can detect a trading strategy that would have worked in the past by chance alone. But in an efficient market, such a strategy is unlikely to generate abnormal returns on a consistent basis in the future. Also, although identified anomalies may appear to produce excess returns, it is generally difficult to profitably exploit the anomalies after accounting for risk, trading costs, and so on.

Several well-known anomalies are listed in Exhibit 3. This list is by no means exhaustive, but it provides information on the breadth of the anomalies. A few of these anomalies are discussed in more detail in the following sections. The anomalies are placed into categories based on the research method that identified the anomaly. Time-series anomalies were identified using time series of data. Cross-sectional anomalies were identified based on analyzing a cross section of companies that differ on some key characteristics. Other anomalies were identified by a variety of means, including event studies.

Exhibit 3 Sampling of Observed Pricing Anomalies

Time Series	Cross-Sectional	Other
January effect	Size effect	Closed-end fund discount
Day-of-the-week effect	Value effect	Earnings surprise
Weekend effect	Book-to-market ratios	Initial public offerings
Turn-of-the-month effect	P/E ratio effect	Distressed securities effect
Holiday effect	Value Line enigma	Stock splits
Time-of-day effect		Super Bowl
Momentum		
Overreaction		

6.1 Time-Series Anomalies

Two of the major categories of time-series anomalies that have been documented are 1) calendar anomalies and 2) momentum and overreaction anomalies.

6.1.1 *Calendar Anomalies*

In the 1980s, a number of researchers reported that stock market returns in January were significantly higher compared to the rest of the months of the year, with most of the abnormal returns reported during the first five trading days in January. Since its first documentation in the 1980s, this pattern, known as the **January effect**, has been observed in most equity markets around the world. This anomaly is also known as the **turn-of-the-year effect**, or even often referred to as the "small firm in January effect" because it is most frequently observed for the returns of small market capitalization stocks.[23]

The January effect contradicts the efficient market hypothesis because excess returns in January are not attributed to any new and relevant information or news. A number of reasons have been suggested for this anomaly, including tax-loss selling. Researchers have speculated that, in order to reduce their tax liabilities, investors sell their "loser" securities in December for the purpose of creating capital losses, which can then be used to offset any capital gains. A related explanation is that these losers tend to be small-cap stocks with high volatility.[24] This increased supply of equities in December depresses their prices, and then these shares are bought in early January at relatively attractive prices. This demand then drives their prices up again. Overall, the evidence indicates that tax-loss selling may account for a portion of January abnormal returns, but it does not explain all of it.

Another possible explanation for the anomaly is so-called "window dressing", a practice in which portfolio managers sell their riskier securities prior to 31 December. The explanation is as follows: many portfolio managers prepare the annual reports of their portfolio holdings as of 31 December. Selling riskier securities is an attempt to make their portfolios appear less risky. After 31 December, a portfolio manager would then simply purchase riskier securities in an attempt to earn higher returns. However, similar to the tax-loss selling hypothesis, the research evidence in support of the window dressing hypothesis explains some, but not all, of the anomaly.

Recent evidence for both stock and bond returns suggests that the January effect is not persistent and, therefore, is not a pricing anomaly. Once an appropriate adjustment for risk is made, the January "effect" does not produce abnormal returns.[25]

Several other calendar effects, including the day-of-the-week and the weekend effects,[26] have been found. These anomalies are summarized in Exhibit 4.[27] But like the size effect, which will be described later, most of these anomalies have been eliminated over time. One view is that the anomalies have been exploited such that the effect has been arbitraged away. Another view, however, is that increasingly sophisticated statistical methodologies fail to detect pricing inefficiencies.

---

[23] There is also evidence of a January effect in bond returns that is more prevalent in high-yield corporate bonds, similar to the small-company effect for stocks.

[24] See Roll (1983).

[25] See, for example, Kim (2006).

[26] For a discussion of several of these anomalous patterns, see Jacobs and Levy (1988).

[27] The weekend effect consists of a pattern of returns around the weekend: abnormal positive returns on Fridays followed by abnormally negative returns on Mondays. This is a day-of-the-week effect that specifically links Friday and Monday returns. It is interesting to note that in 2009, the weekend effect in the United States was inverted, with 80 percent of the gains from March 2009 onward coming from the first trading day of the week.

Exhibit 4 Calendar-Based Anomalies

Anomaly	Observation
Turn-of-the-month effect	Returns tend to be higher on the last trading day of the month and the first three trading days of the next month.
Day-of-the-week effect	The average Monday return is negative and lower than the average returns for the other four days, which are all positive.
Weekend effect	Returns on weekends tend to be lower than returns on weekdays.
Holiday effect	Returns on stocks in the day prior to market holidays tend to be higher than other days.

6.1.2 *Momentum and Overreaction Anomalies*

Momentum anomalies relate to short-term share price patterns. One of the earliest studies to identify this type of anomaly was conducted by Werner DeBondt and Richard Thaler, who argued that investors overreact to the release of unexpected public information.[28] Therefore, stock prices will be inflated (depressed) for those companies releasing good (bad) information. This anomaly has become known as the overreaction effect. Using the overreaction effect, they proposed a strategy that involved buying "loser" portfolios and selling "winner" portfolios. They defined stocks as winners or losers based on their total returns over the previous three- to five-year period. They found that in a subsequent period, the loser portfolios outperformed the market, while the winner portfolios underperformed the market. Similar patterns have been documented in many, but not all, global stock markets as well as in bond markets. One criticism is that the observed anomaly may be the result of statistical problems in the analysis.

A contradiction to weak-form efficiency occurs when securities that have experienced high returns in the short term tend to continue to generate higher returns in subsequent periods.[29] Empirical support for the existence of momentum in stock returns in most stock markets around the world is well documented. If investors can trade on the basis of momentum and earn abnormal profits, then this anomaly contradicts the weak form of the efficient market hypothesis because it represents a pattern in prices that can be exploited by simply using historical price information.[30]

Researchers have argued that the existence of momentum is rational and not contrary to market efficiency because it is plausible that there are shocks to the expected growth rates of cash flows to shareholders and that these shocks induce a serial correlation that is rational and short lived.[31] In other words, having stocks with some degree of momentum in their security returns may not imply irrationality but, rather, may reflect prices adjusting to a shock in growth rates.

---

[28] DeBondt and Thaler (1985).

[29] Notice that this pattern lies in sharp contrast to DeBondt and Thaler's reversal pattern that is displayed over longer periods of time. In theory, the two patterns could be related. In other words, it is feasible that prices are bid up extremely high, perhaps too high, in the short term for companies that are doing well. In the longer term (three-to-five years), the prices of these short-term winners correct themselves and they do poorly.

[30] Jegadeesh and Titman (2001).

[31] Johnson (2002).

6.2 Cross-Sectional Anomalies

Two of the most researched cross-sectional anomalies in financial markets are the size effect and the value effect.

6.2.1 *Size Effect*

The size effect results from the observation that equities of small-cap companies tend to outperform equities of large-cap companies on a risk-adjusted basis. Many researchers documented a small-company effect soon after the initial research was published in 1981. This effect, however, was not apparent in subsequent studies.[32] Part of the reason that the size effect was not confirmed by subsequent studies may be because of the fact that if it were truly an anomaly, investors acting on this effect would reduce any potential returns. But some of the explanation may simply be that the effect as originally observed was a chance outcome and, therefore, not actually an inefficiency.

6.2.2 *Value Effect*

A number of global empirical studies have shown that value stocks, which are generally referred to as stocks that have below-average price-to-earnings (P/E) and market-to-book (M/B) ratios, and above-average dividend yields, have consistently outperformed growth stocks over long periods of time.[33] If the effect persists, the value stock anomaly contradicts semi-strong market efficiency because all the information used to categorize stocks in this manner is publicly available.

Fama and French developed a three-factor model to predict stock returns.[34] In addition to the use of market returns as specified by the capital asset pricing model (CAPM), the Fama and French model also includes the size of the company as measured by the market value of its equity and the company's book value of equity divided by its market value of equity, which is a value measure. The Fama and French model captures risk dimensions related to stock returns that the CAPM model does not consider. Fama and French find that when they apply the three-factor model instead of the CAPM, the value stock anomaly disappears.

7

OTHER ANOMALIES, IMPLICATIONS OF MARKET PRICING ANOMALIES

f describe market anomalies;

A number of additional anomalies has been documented in the financial markets, including the existence of closed-end investment fund discounts, price reactions to the release of earnings information, returns of initial public offerings, and the predictability of returns based on prior information.

---

[32] Although a large number of studies documents a small-company effect, these studies are concentrated in a period similar to that of the original research and, therefore, use a similar data set. The key to whether something is a true anomaly is persistence in out-of-sample tests. Fama and French (2008) document that the size effect is apparent only in microcap stocks but not in small- and large-cap stocks and these microcap stocks may have a significant influence in studies that document a size effect.

[33] For example, see Capaul, Rowley, and Sharpe (1993) and Fama and French (1998).

[34] Fama and French (1995).

7.1 Closed-End Investment Fund Discounts

A closed-end investment fund issues a fixed number of shares at inception and does not sell any additional shares after the initial offering. Therefore, the fund capitalization is fixed unless a secondary public offering is made. The shares of closed-end funds trade on stock markets like any other shares in the equity market (i.e., their prices are determined by supply and demand).

Theoretically, these shares should trade at a price approximately equal to their net asset value (NAV) per share, which is simply the total market value of the fund's security holdings less any liabilities divided by the number of shares outstanding. An abundance of research, however, has documented that, on average, closed-end funds trade at a discount from NAV. Most studies have documented average discounts in the 4–10 percent range, although individual funds have traded at discounts exceeding 50 percent and others have traded at large premiums.[35]

The closed-end fund discount presents a puzzle because conceptually, an investor could purchase all the shares in the fund, liquidate the fund, and end up making a profit. Some researchers have suggested that these discounts are attributed to management fees or expectations of the managers' performance, but these explanations are not supported by the evidence.[36] An alternative explanation for the discount is that tax liabilities are associated with unrealized capital gains and losses that exist prior to when the investor bought the shares, and hence, the investor does not have complete control over the timing of the realization of gains and losses.[37] Although the evidence supports this hypothesis to a certain extent, the tax effect is not large enough to explain the entire discount. Finally, it has often been argued that the discounts exist because of liquidity problems and errors in calculating NAV. The illiquidity explanation is plausible if shares are recorded at the same price as more liquid, publicly traded stocks; some evidence supports this assertion. But as with tax reasons, liquidity issues explain only a portion of the discount effect.

Can these discounts be exploited to earn abnormal returns if transaction costs are taken into account? No. First, the transaction costs involved in exploiting the discount—buying all the shares and liquidating the fund—would eliminate any profit.[38] Second, these discounts tend to revert to zero over time. Hence, a strategy to trade on the basis of these discounts would not likely be profitable.[39]

7.2 Earnings Surprise

Although most event studies have supported semi-strong market efficiency, some researchers have provided evidence that questions semi-strong market efficiency. One of these studies relates to the extensively examined adjustment of stock prices to earnings announcements.[40] The unexpected part of the earnings announcement, or **earnings surprise**, is the portion of earnings that is unanticipated by investors and, according to the efficient market hypothesis, merits a price adjustment. Positive (negative) surprises should cause appropriate and rapid price increases (decreases). Several studies have been conducted using data from numerous markets around the world. Most of the results indicate that earnings surprises are reflected quickly in stock prices, but the adjustment process is not always efficient. In particular, although a substantial adjustment occurs prior to and at the announcement date, an adjustment also occurs after the announcement.[41]

---

[35] See Dimson and Minio-Kozerski (1999) for a review of this literature.

[36] See Lee, Sheifer, and Thaler (1990).

[37] The return to owners of closed-end fund shares has three parts: 1) the price appreciation or depreciation of the shares themselves, 2) the dividends earned and distributed to owners by the fund, and 3) the capital gains and losses earned by the fund that are distributed by the fund. The explanation of the anomalous pricing has to do with the timing of the distribution of capital gains.

[38] See, for example, the study by Pontiff (1996), which shows how the cost of arbitraging these discounts eliminates the profit.

[39] See Pontiff (1995).

[40] See Jones, Rendleman, and Latané (1984).

As a result of these slow price adjustments, companies that display the largest positive earnings surprises subsequently display superior stock return performance, whereas poor subsequent performance is displayed by companies with low or negative earnings surprises.[42] This finding implies that investors could earn abnormal returns using publicly available information by buying stocks of companies that had positive earnings surprises and selling those with negative surprises.

Although there is support for abnormal returns associated with earnings surprises, and some support for such returns beyond the announcement period, there is also evidence indicating that these observed abnormal returns are an artifact of studies that do not sufficiently control for transaction costs and risk.[43]

7.3 Initial Public Offerings (IPOs)

When a company offers shares of its stock to the public for the first time, it does so through an initial public offering (or IPO). This offering involves working with an investment bank that helps price and market the newly issued shares. After the offering is complete, the new shares trade on a stock market for the first time. Given the risk that investment bankers face in trying to sell a new issue for which the true price is unknown, it is perhaps not surprising to find that, on average, the initial selling price is set too low and that the price increases dramatically on the first trading day. The percentage difference between the issue price and the closing price at the end of the first day of trading is often referred to as the degree of underpricing.

The evidence suggests that, on average, investors who are able to buy the shares of an IPO at their offering price may be able to earn abnormal profits. For example, during the internet bubble of 1995–2000, many IPOs ended their first day of trading up by more than 100 percent. Such performance, however, is not always the case. Sometimes the issues are priced too high, which means that share prices drop on their first day of trading. In addition, the evidence also suggests that investors buying after the initial offering are not able to earn abnormal profits because prices adjust quickly to the "true" values, which supports semi-strong market efficiency. In fact, the subsequent long-term performance of IPOs is generally found to be below average. Taken together, the IPO underpricing and the subsequent poor performance suggests that the markets are overly optimistic initially (i.e., investors overreact).

Some researchers have examined closely why IPOs may appear to have anomalous returns. Because of the small size of the IPO companies and the method of equally weighting the samples, what appears to be an anomaly may simply be an artifact of the methodology.[44]

---

[41] Not surprisingly, it is often argued that this slow reaction contributes to a momentum pattern.

[42] A similar pattern has been documented in the corporate bond market, where bond prices react too slowly to new company earnings announcements as well as to changes in company debt ratings.

[43] See Brown (1997) for a summary of evidence supporting the existence of this anomaly. See Zarowin (1989) for evidence regarding the role of size in explaining abnormal returns to surprises; Alexander, Goff, and Peterson (1989) for evidence regarding transaction costs and unexpected earnings strategies; and Kim and Kim (2003) for evidence indicating that the anomalous returns can be explained by risk factors.

[44] See Brav, Geczy, and Gompers (1995).

7.4 Predictability of Returns Based on Prior Information

A number of researchers have documented that equity returns are related to prior information on such factors as interest rates, inflation rates, stock volatility, and dividend yields.[45] But finding that equity returns are affected by changes in economic fundamentals is not evidence of market inefficiency and would not result in abnormal trading returns.[46]

Furthermore, the relationship between stock returns and the prior information is not consistent over time. For example, in one study, the relationship between stock prices and dividend yields changed from positive to negative in different periods.[47] Hence, a trading strategy based on dividend yields would not yield consistent abnormal returns.

7.5 Implications for Investment Strategies

Although it is interesting to consider the anomalies just described, attempting to benefit from them in practice is not easy. In fact, most researchers conclude that observed anomalies are not violations of market efficiency but, rather, are the result of statistical methodologies used to detect the anomalies. As a result, if the methodologies are corrected, most of these anomalies disappear.[48] Another point to consider is that in an efficient market, overreactions may occur, but then so do under-reactions.[49] Therefore, on average, the markets are efficient. In other words, investors face challenges when they attempt to translate statistical anomalies into economic profits. Consider the following quote regarding anomalies from the *Economist* ("Frontiers of Finance Survey," 9 October 1993):

> Many can be explained away. When transactions costs are taken into account, the fact that stock prices tend to over-react to news, falling back the day after good news and bouncing up the day after bad news, proves unexploitable: price reversals are always within the bid-ask spread. Others such as the small-firm effect, work for a few years and then fail for a few years. Others prove to be merely proxies for the reward for risk taking. Many have disappeared since (and because) attention has been drawn to them.

It is difficult to envision entrusting your retirement savings to a manager whose strategy is based on buying securities on Mondays, which tends to have negative returns on average, and selling them on Fridays. For one thing, the negative Monday returns are merely an average, so on any given week, they could be positive. In addition, such a strategy would generate large trading costs. Even more importantly, investors would likely be uncomfortable investing their funds in a strategy that has no compelling underlying economic rationale.

BEHAVIORAL FINANCE

8

g describe behavioral finance and its potential relevance to understanding market anomalies.

---

[45] See, for example, Fama and Schwert (1977) and Fama and French (1988).

[46] See Fama and French (2008).

[47] Schwert (2003, Chapter 15).

[48] Fama (1998).

[49] This point is made by Fama (1998).

Behavioral finance examines investor behavior to understand how people make decisions, individually and collectively. Behavioral finance does not assume that people consider all available information in decision-making and act rationally by maximizing utility within budget constraints and updating expectations consistent with Bayes' formula. The resulting behaviors may affect what is observed in the financial markets.

In a broader sense, behavioral finance attempts to explain why individuals make the decisions that they do, whether these decisions are rational or irrational. The focus of much of the work in this area is on the behavioral biases that affect investment decisions. The behavior of individuals, in particular their behavioral biases, has been offered as a possible explanation for a number of pricing anomalies.

Most asset-pricing models assume that markets are rational and that the intrinsic value of a security reflects this rationality. But market efficiency and asset-pricing models do not require that each individual is rational—rather, only that the market is rational. If individuals deviate from rationality, other individuals are assumed to observe this deviation and respond accordingly. These responses move the market toward efficiency. If this does not occur in practice, it may be possible to explain some market anomalies referencing observed behaviors and behavioral biases.

8.1 Loss Aversion

In most financial models, the assumption is that investors are risk averse. **Risk aversion** refers to the tendency of people to dislike risk and to require higher expected returns to compensate for exposure to additional risk. Behavioral finance allows for the possibility that the dissatisfaction resulting from a loss exceeds the satisfaction resulting from a gain of the same magnitude. **Loss aversion** refers to the tendency of people to dislike losses more than they like comparable gains. This results in a strong preference for avoiding losses as opposed to achieving gains.[50] Some argue that behavioral theories of loss aversion can explain observed overreaction in markets. If loss aversion is more important than risk aversion, researchers should observe that investors overreact.[51] Although loss aversion can explain the overreaction anomaly, evidence also suggests that under reaction is just as prevalent as overreaction, which counters these arguments.

8.2 Herding

Herding behavior has been advanced as a possible explanation of under reaction and overreaction in financial markets. **Herding** occurs when investors trade on the same side of the market in the same securities, or when investors ignore their own private information and/or analysis and act as other investors do. Herding is clustered trading that may or may not be based on information.[52] Herding may result in under- or over-reaction to information depending upon the direction of the herd.

8.3 Overconfidence

A behavioral bias offered to explain pricing anomalies is overconfidence. If investors are overconfident, they overestimate their ability to process and interpret information about a security. Overconfident investors may not process information appropriately, and if there is a sufficient number of these investors, stocks will be mispriced.[53] But most researchers argue that this mispricing is temporary, with prices correcting eventually. If it takes a sufficiently long time for prices to become correctly priced and the mispricing is predictable, it may be possible for investors to earn abnormal profits.

---

[50] See DeBondt and Thaler (1985) and Tversky and Kahneman (1981).

[51] See Fama (1998).

[52] The term used when there is herding without information is "spurious herding."

Evidence has suggested that overconfidence results in mispricing for US, UK, German, French, and Japanese markets.[54] This overconfidence, however, is predominantly in higher-growth companies, whose prices react slowly to new information.[55]

8.4 Information Cascades

An application of behavioral theories to markets and pricing focuses on the role of personal learning in markets. Personal learning is what investors learn by observing outcomes of trades and what they learn from "conversations"—ideas shared among investors about specific assets and the markets.[56] Social interaction and the resultant contagion is important in pricing and may explain such phenomena as price changes without accompanying news and mistakes in valuation.

Biases that investors possess can lead to herding behavior or information cascades. Herding and information cascades are related but not identical concepts. An **information cascade** is the transmission of information from those participants who act first and whose decisions influence the decisions of others. Those who are acting on the choices of others may be ignoring their own preferences in favor of imitating the choices of others. In particular, information cascades may occur with respect to the release of accounting information because accounting information may be difficult to interpret and may be noisy. For example, the release of earnings is difficult to interpret because it is necessary to understand how the number was arrived at and noisy because it is uncertain what the current earnings imply about future earnings.

Information cascades may result in serial correlation of stock returns, which is consistent with overreaction anomalies. Do information cascades result in correct pricing? Some argue that if a cascade is leading toward an incorrect value, this cascade is "fragile" and will be corrected because investors will ultimately give more weight to public information or the trading of a recognized informed trader.[57] Information cascades, although documented in markets, do not necessarily mean that investors can exploit knowledge of them as profitable trading opportunities.

Are information cascades rational? If the informed traders act first and uninformed traders imitate the informed traders, this behavior is consistent with rationality. The imitation trading by the uninformed traders may help the market incorporate relevant information and improve market efficiency.[58] However, the imitation trading may lead to an overreaction to information. The empirical evidence indicates that information cascades are greater for a stock when the information quality regarding the company is poor.[59] Information cascades may enhance the information available to investors.

---

[53] Another aspect to overconfidence is that investors who are overconfident in their ability to select investments and manage a portfolio tend to use less diversification, investing in what is most familiar. Therefore, investor behavior may affect investment results—returns and risk—without implications for the efficiency of markets.

[54] Scott, Stumpp, and Xu (2003) and Boujelbene Abbes, Boujelbene, and Bouri (2009).

[55] Scott, Stumpp, and Xu (2003).

[56] Hirshleifer and Teoh (2009).

[57] Avery and Zemsky (1999).

[58] Another alternative is that the uninformed traders are the majority of the market participants and the imitators are imitating not because they agree with the actions of the majority but because they are looking to act on the actions of the uninformed traders.

[59] Avery and Zemsky (1999) and Bikhchandani, Hirshleifer, and Welch (1992).

8.5 Other Behavioral Biases

Other behavioral biases that have been put forth to explain observed investor behavior include the following:

- **representativeness**—investors assess new information and probabilities of outcomes based on similarity to the current state or to a familiar classification;
- **mental accounting**—investors keep track of the gains and losses for different investments in separate mental accounts and treat those accounts differently;
- **conservatism**—investors tend to be slow to react to new information and continue to maintain their prior views or forecasts; and
- **narrow framing**—investors focus on issues in isolation and respond to the issues based on how the issues are posed.[60]

The basic idea behind behavioral finance is that investors are humans and, therefore, imperfect. These observed less than rational behaviors may help explain observed pricing anomalies. The beliefs investors have about a given asset's value may not be homogeneous. But an issue, which is controversial, is whether these insights can help someone identify and exploit any mispricing. In other words, can investors use knowledge of behavioral biases to predict how asset prices will be affected and act based on the predictions to earn abnormal profits?

8.6 Behavioral Finance and Investors

Behavior biases can affect all market participants, from the novice investor to the most experienced investment manager. An understanding of behavioral finance can help market participants recognize their own and others' behavioral biases. As a result of this recognition, they may be able to respond and make improved decisions, individually and collectively.

8.7 Behavioral Finance and Efficient Markets

The use of behavioral finance to explain observed pricing is an important part of the understanding of how markets function and how prices are determined. Whether there is a behavioral explanation for market anomalies remains a debate. Pricing anomalies are continually being uncovered, and then statistical and behavioral explanations are offered to explain these anomalies.

On the one hand, if investors must be rational for efficient markets to exist, then all the imperfections of human investors suggest that markets cannot be efficient. On the other hand, if all that is required for markets to be efficient is that investors cannot consistently beat the market on a risk-adjusted basis, then the evidence does support market efficiency.

SUMMARY

This reading has provided an overview of the theory and evidence regarding market efficiency and has discussed the different forms of market efficiency as well as the implications for fundamental analysis, technical analysis, and portfolio management.

---

[60] For a review of these behavioral issues, see Hirshleifer (2001).

The general conclusion drawn from the efficient market hypothesis is that it is not possible to beat the market on a consistent basis by generating returns in excess of those expected for the level of risk of the investment.

Additional key points include the following:

- The efficiency of a market is affected by the number of market participants and depth of analyst coverage, information availability, and limits to trading.
- There are three forms of efficient markets, each based on what is considered to be the information used in determining asset prices. In the weak form, asset prices fully reflect all market data, which refers to all past price and trading volume information. In the semi-strong form, asset prices reflect all publicly known and available information. In the strong form, asset prices fully reflect all information, which includes both public and private information.
- Intrinsic value refers to the true value of an asset, whereas market value refers to the price at which an asset can be bought or sold. When markets are efficient, the two should be the same or very close. But when markets are not efficient, the two can diverge significantly.
- Most empirical evidence supports the idea that securities markets in developed countries are semi-strong-form efficient; however, empirical evidence does not support the strong form of the efficient market hypothesis.
- A number of anomalies have been documented that contradict the notion of market efficiency, including the size anomaly, the January anomaly, and the winners–losers anomalies. In most cases, however, contradictory evidence both supports and refutes the anomaly.
- Behavioral finance uses human psychology, such as behavioral biases, in an attempt to explain investment decisions. Whereas behavioral finance is helpful in understanding observed decisions, a market can still be considered efficient even if market participants exhibit seemingly irrational behaviors, such as herding.

PRACTICE PROBLEMS

1 In an efficient market, the change in a company's share price is *most likely* the result of:

A insiders' private information.

B the previous day's change in stock price.

C new information coming into the market.

2 Regulation that restricts some investors from participating in a market will *most likely*:

A impede market efficiency.

B not affect market efficiency.

C contribute to market efficiency.

3 With respect to efficient market theory, when a market allows short selling, the efficiency of the market is *most likely* to:

A increase.

B decrease.

C remain the same.

4 Which of the following regulations will *most likely* contribute to market efficiency? Regulatory restrictions on:

A short selling.

B foreign traders.

C insiders trading with nonpublic information.

5 Which of the following market regulations will *most likely* impede market efficiency?

A Restricting traders' ability to short sell.

B Allowing unrestricted foreign investor trading.

C Penalizing investors who trade with nonpublic information.

6 If markets are efficient, the difference between the intrinsic value and market value of a company's security is:

A negative.

B zero.

C positive.

7 The intrinsic value of an undervalued asset is:

A less than the asset's market value.

B greater than the asset's market value.

C the value at which the asset can currently be bought or sold.

8 The market value of an undervalued asset is:

A greater than the asset's intrinsic value.

B the value at which the asset can currently be bought or sold.

C equal to the present value of all the asset's expected cash flows.

9 With respect to the efficient market hypothesis, if security prices reflect *only* past prices and trading volume information, then the market is:

A weak-form efficient.

© 2011 CFA Institute. All rights reserved.

B strong-form efficient.

C semi-strong-form efficient.

10 Which one of the following statements *best* describes the semi-strong form of market efficiency?

A Empirical tests examine the historical patterns in security prices.

B Security prices reflect all publicly known and available information.

C Semi-strong-form efficient markets are not necessarily weak-form efficient.

11 If markets are semi-strong efficient, standard fundamental analysis will yield abnormal trading profits that are:

A negative.

B equal to zero.

C positive.

12 If prices reflect all public and private information, the market is *best* described as:

A weak-form efficient.

B strong-form efficient.

C semi-strong-form efficient.

13 If markets are semi-strong-form efficient, then passive portfolio management strategies are *most likely* to:

A earn abnormal returns.

B outperform active trading strategies.

C underperform active trading strategies.

14 If a market is semi-strong-form efficient, the risk-adjusted returns of a passively managed portfolio relative to an actively managed portfolio are *most likely*:

A lower.

B higher.

C the same.

15 Technical analysts assume that markets are:

A weak-form efficient.

B weak-form inefficient.

C semi-strong-form efficient.

16 Fundamental analysts assume that markets are:

A weak-form inefficient.

B semi-strong-form efficient.

C semi-strong-form inefficient.

17 If a market is weak-form efficient but semi-strong-form inefficient, then which of the following types of portfolio management is *most likely* to produce abnormal returns?

A Passive portfolio management.

B Active portfolio management based on technical analysis.

C Active portfolio management based on fundamental analysis.

18 An increase in the time between when an order to trade a security is placed and when the order is executed *most likely* indicates that market efficiency has:

A decreased.

B remained the same.

C increased.

19 With respect to efficient markets, a company whose share price changes gradually after the public release of its annual report *most likely* indicates that the market where the company trades is:

A semi-strong-form efficient.

B subject to behavioral biases.

C receiving additional information about the company.

20 Which of the following is *least likely* to explain the January effect anomaly?

A Tax-loss selling.

B Release of new information in January.

C Window dressing of portfolio holdings.

21 If a researcher conducting empirical tests of a trading strategy using time series of returns finds statistically significant abnormal returns, then the researcher has *most likely* found:

A a market anomaly.

B evidence of market inefficiency.

C a strategy to produce future abnormal returns.

22 Which of the following market anomalies is inconsistent with weak-form market efficiency?

A Earnings surprise.

B Momentum pattern.

C Closed-end fund discount.

23 Researchers have found that value stocks have consistently outperformed growth stocks. An investor wishing to exploit the value effect should purchase the stock of companies with above-average:

A dividend yields.

B market-to-book ratios.

C price-to-earnings ratios.

24 With respect to rational and irrational investment decisions, the efficient market hypothesis requires:

A only that the market is rational.

B that all investors make rational decisions.

C that some investors make irrational decisions.

25 Observed overreactions in markets can be explained by an investor's degree of:

A risk aversion.

B loss aversion.

C confidence in the market.

26 Like traditional finance models, the behavioral theory of loss aversion assumes that investors dislike risk; however, the dislike of risk in behavioral theory is assumed to be:

A leptokurtic.

B symmetrical.

C asymmetrical.

SOLUTIONS

1 C is correct. Today's price change is independent of the one from yesterday, and in an efficient market, investors will react to new, independent information as it is made public.

2 A is correct. Reducing the number of market participants can accentuate market imperfections and impede market efficiency (e.g., restrictions on foreign investor trading).

3 A is correct. According to theory, reducing the restrictions on trading will allow for more arbitrage trading, thereby promoting more efficient pricing. Although regulators argue that short selling exaggerates downward price movements, empirical research indicates that short selling is helpful in price discovery.

4 C is correct. Regulation to restrict unfair use of nonpublic information encourages greater participation in the market, which increases market efficiency. Regulators (e.g., US SEC) discourage illegal insider trading by issuing penalties to violators of their insider trading rules.

5 A is correct. Restricting short selling will reduce arbitrage trading, which promotes market efficiency. Permitting foreign investor trading increases market participation, which makes markets more efficient. Penalizing insider trading encourages greater market participation, which increases market efficiency.

6 B is correct. A security's intrinsic value and market value should be equal when markets are efficient.

7 B is correct. The intrinsic value of an undervalued asset is greater than the market value of the asset, where the market value is the transaction price at which an asset can be currently bought or sold.

8 B is correct. The market value is the transaction price at which an asset can be currently bought or sold.

9 A is correct. The weak-form efficient market hypothesis is defined as a market where security prices fully reflect all market data, which refers to all past price and trading volume information.

10 B is correct. In semi-strong-form efficient markets, security prices reflect all publicly available information.

11 B is correct. If all public information should already be reflected in the market price, then the abnormal trading profit will be equal to zero when fundamental analysis is used.

12 B is correct. The strong-form efficient market hypothesis assumes all information, public or private, has already been reflected in the prices.

13 B is correct. Costs associated with active trading strategies would be difficult to recover; thus, such active trading strategies would have difficulty outperforming passive strategies on a consistent after-cost basis.

14 B is correct. In a semi-strong-form efficient market, passive portfolio strategies should outperform active portfolio strategies on a risk-adjusted basis.

15 B is correct. Technical analysts use past prices and volume to predict future prices, which is inconsistent with the weakest form of market efficiency (i.e., weak-form market efficiency). Weak-form market efficiency states that investors cannot earn abnormal returns by trading on the basis of past trends in price and volume.

16 C is correct. Fundamental analysts use publicly available information to estimate a security's intrinsic value to determine if the security is mispriced, which is inconsistent with the semi-strong form of market efficiency. Semi-strong-form market efficiency states that investors cannot earn abnormal returns by trading based on publicly available information.

17 C is correct. If markets are not semi-strong-form efficient, then fundamental analysts are able to use publicly available information to estimate a security's intrinsic value and identify misvalued securities. Technical analysis is not able to earn abnormal returns if markets are weak-form efficient. Passive portfolio managers outperform fundamental analysis if markets are semi-strong-form efficient.

18 A is correct. Operating inefficiencies reduce market efficiency.

19 C is correct. If markets are efficient, the information from the annual report is reflected in the stock prices; therefore, the gradual changes must be from the release of additional information.

20 B is correct. The excess returns in January are not attributed to any new information or news; however, research has found that part of the seasonal pattern can be explained by tax-loss selling and portfolio window dressing.

21 A is correct. Finding significant abnormal returns does not necessarily indicate that markets are inefficient or that abnormal returns can be realized by applying the strategy to future time periods. Abnormal returns are considered market anomalies because they may be the result of the model used to estimate the expected returns or may be the result of underestimating transaction costs or other expenses associated with implementing the strategy, rather than because of market inefficiency.

22 B is correct. Trading based on historical momentum indicates that price patterns exist and can be exploited by using historical price information. A momentum trading strategy that produces abnormal returns contradicts the weak form of the efficient market hypothesis, which states that investors cannot earn abnormal returns on the basis of past trends in prices.

23 A is correct. Higher than average dividend yield is a characteristic of a value stock, along with low price-to-earnings and low market-to-book ratios. Growth stocks are characterized by low dividend yields and high price-to-earnings and high market-to-book ratios.

24 A is correct. The efficient market hypothesis and asset-pricing models only require that the market is rational. Behavioral finance is used to explain *some* of the market anomalies as irrational decisions.

25 B is correct. Behavioral theories of loss aversion can explain observed overreaction in markets, such that investors dislike losses more than comparable gains (i.e., risk is not symmetrical).

26 C is correct. Behavioral theories of loss aversion allow for the possibility that the dislike for risk is not symmetrical, which allows for loss aversion to explain observed overreaction in markets such that investors dislike losses more than they like comparable gains.

EQUITY INVESTMENTS STUDY SESSION

12

Equity Investments (2)

This study session focuses on the characteristics, analysis, and valuation of equity securities. Various equity types including public and private equities are described. The various industry classification approaches for global equities and useful frameworks for conducting industry and individual company analysis are presented. Coverage of the three main equity valuation approaches (present value, multiplier, and asset based) conclude the session.

READING ASSIGNMENTS

Overview of Equity Securities

by Ryan C. Fuhrmann, CFA, and Asjeet S. Lamba, PhD, CFA

Ryan C. Fuhrmann, CFA, is at Fuhrmann Capital LLC (USA). Asjeet S. Lamba, PhD, CFA, is at the University of Melbourne (Australia).

LEARNING OUTCOMES

Mastery	*The candidate should be able to:*
☐	**a.** describe characteristics of types of equity securities;
☐	**b.** describe differences in voting rights and other ownership characteristics among different equity classes;
☐	**c.** compare and contrast public and private equity securities;
☐	**d.** describe methods for investing in non-domestic equity securities;
☐	**e.** compare the risk and return characteristics of different types of equity securities;
☐	**f.** explain the role of equity securities in the financing of a company's assets;
☐	**g.** contrast the market value and book value of equity securities;
☐	**h.** compare a company's cost of equity, its (accounting) return on equity, and investors' required rates of return.

IMPORTANCE OF EQUITY SECURITIES

1

Equity securities represent ownership claims on a company's net assets. As an asset class, equity plays a fundamental role in investment analysis and portfolio management because it represents a significant portion of many individual and institutional investment portfolios.

The study of equity securities is important for many reasons. First, the decision on how much of a client's portfolio to allocate to equities affects the risk and return characteristics of the entire portfolio. Second, different types of equity securities have different ownership claims on a company's net assets, which affect their risk and return characteristics in different ways. Finally, variations in the features of equity securities are reflected in their market prices, so it is important to understand the valuation implications of these features.

© 2019 CFA Institute. All rights reserved.

This reading provides an overview of equity securities and their different features and establishes the background required to analyze and value equity securities in a global context. It addresses the following questions:

- What distinguishes common shares from preference shares, and what purposes do these securities serve in financing a company's operations?
- What are convertible preference shares, and why are they often used to raise equity for unseasoned or highly risky companies?
- What are private equity securities, and how do they differ from public equity securities?
- What are depository receipts and their various types, and what is the rationale for investing in them?
- What are the risk factors involved in investing in equity securities?
- How do equity securities create company value?
- What is the relationship between a company's cost of equity, its return on equity, and investors' required rate of return?

The remainder of this reading is organized as follows. Section 1.1 provides an overview of global equity markets and their historical performance. Section 2 examines the different types and characteristics of equity securities, and Section 3 outlines the differences between public and private equity securities. Section 4 provides an overview of the various types of equity securities listed and traded in global markets. Section 5 discusses the risk and return characteristics of equity securities. Section 6 examines the role of equity securities in creating company value and the relationship between a company's cost of equity, its return on equity, and investors' required rate of return. The final section summarizes the reading.

1.1 Equity Securities in Global Financial Markets

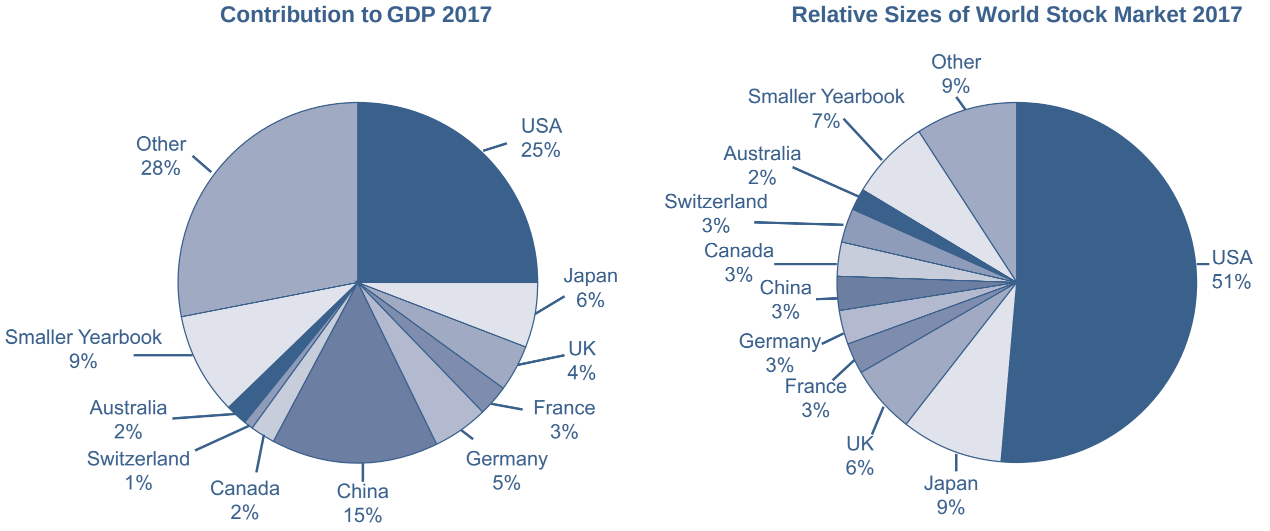
This section highlights the relative importance and performance of equity securities as an asset class. We examine the total market capitalization and trading volume of global equity markets and the prevalence of equity ownership across various geographic regions. We also examine historical returns on equities and compare them to the returns on government bonds and bills.

Exhibit 1 summarizes the contributions of selected countries and geographic regions to global gross domestic product (GDP) and global equity market capitalization. Analysts may examine the relationship between equity market capitalization and GDP as a rough indicator of whether the global equity market (or a specific country's or region's equity market) is under, over, or fairly valued, particularly compared to its long-run average.

Exhibit 1 illustrates the significant value that investors attach to publicly traded equities relative to the sum of goods and services produced globally every year. It shows the continued significance, and the potential over-representation, of US equity markets relative to their contribution to global GDP. That is, while US equity markets contribute around 51 percent to the total capitalization of global equity markets, their contribution to the global GDP is only around 25 percent. Following the stock market turmoil in 2008, however, the market capitalization to GDP ratio of the United States fell to 59 percent, which is significantly lower than its long-run average of 79 percent.

As equity markets outside the United States develop and become increasingly global, their total capitalization levels are expected to grow closer to their respective world GDP contributions. Therefore, it is important to understand and analyze equity securities from a global perspective.

Exhibit 1 Country and Regional Contributions to Global GDP and Equity Market Capitalization (2017)



Source: The WorldBank Databank *2017*, and Dimson, Marsh, and Staunton (2018).

Exhibit 2 lists the top 10 equity markets at the end of 2017 based on total market capitalization (in billions of US dollars), trading volume, and the number of listed companies.[1] Note that the rankings differ based on the criteria used. For example, the top three markets based on total market capitalization are the NYSE Euronext (US), NASDAQ OMX, and the Japan Exchange Group; however, the top three markets based on total US dollar trading volume are the Nasdaq OMX, NYSE Euronext (US), and the Shenzhen Stock Exchange, respectively.[2]

Exhibit 2 Equity Markets Ranked by Total Market Capitalization at the End of 2017 (Billions of US Dollars)

Rank	Name of Market	Total US Dollar Market Capitalization	Total US Dollar Trading Volume	Number of Listed Companies
1	NYSE Euronext (US)	\$22,081.4	\$16,140.1	2,286
2	NASDAQ OMX	\$10,039.4	\$33,407.1	2,949
3	Japan Exchange Group[a]	\$6,220.0	\$6,612.1	3,604
4	Shanghai Stock Exchange	\$5,084.4	\$7,589.3	1,396
5	Euronext[b]	\$4,393.0	\$1,981.6	1,255
6	Hong Kong Exchanges	\$4,350.5	\$1,958.8	2,118
7	Shenzhen Stock Exchanges	\$3,617.9	\$9,219.7	2,089

(continued)

---

[1] The market capitalization of an individual stock is computed as the share price multiplied by the number of shares outstanding. The total market capitalization of an equity market is the sum of the market capitalizations of each individual stock listed on that market. Similarly, the total trading volume of an equity market is computed by value weighting the total trading volume of each individual stock listed on that market. Total dollar trading volume is computed as the average share price multiplied by the number of shares traded.

[2] NASDAQ is the acronym for the National Association of Securities Dealers Automated Quotations.

Exhibit 2 (Continued)

Rank	Name of Market	Total US Dollar Market Capitalization	Total US Dollar Trading Volume	Number of Listed Companies
8	National Stock Exchange of India	\$2,351.5	\$1,013.3	1,897
9	BSE Limited[c]	\$2,331.6	\$183.0	5,616
10	Deutsche Börse	\$2,262.2	\$1,497.9	499

Notes:

[a] Japan Exchange Group is the merged entity containing the Tokyo Stock Exchange and Osaka Securities Exchange.

[b] From 2001, includes Netherlands, France, England, Belgium, and Portugal.

[c] Bombay Stock Exchange.

Source: Adapted from the *World Federation of Exchanges 2017 Report* (see http://www.world-exchanges.org). Note that market capitalization by company is calculated by multiplying its stock price by the number of shares outstanding. The market's overall capitalization is the aggregate of the market capitalizations of all companies traded on that market. The number of listed companies includes both domestic and foreign companies whose shares trade on these markets.

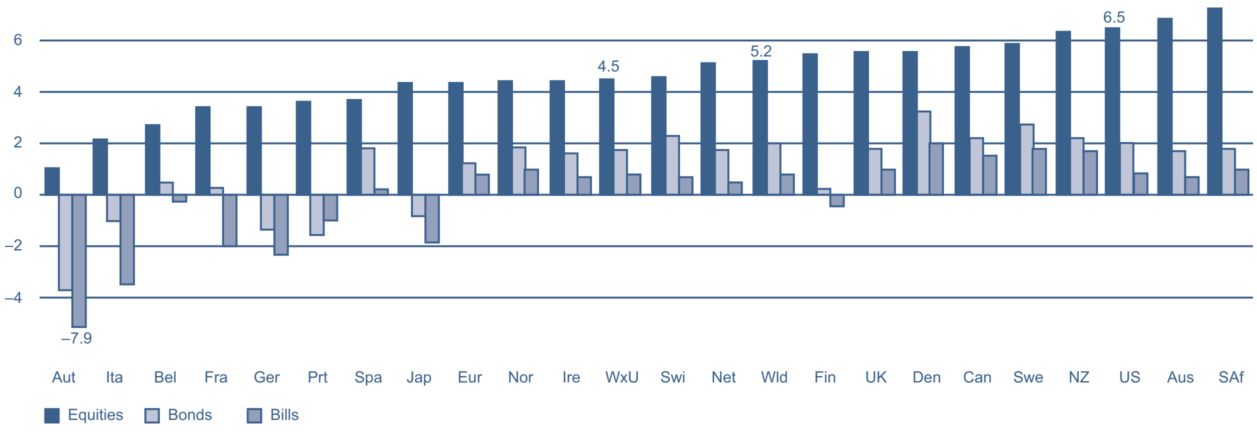
Exhibit 3 compares the *real* (or inflation-adjusted) compounded returns on government bonds, government bills, and equity securities in 21 countries plus the world index ("Wld"), the world ex-US ("WxU"), and Europe ("Eur") during the 118 years 1900–2017.[3] In real terms, government bonds and bills have essentially kept pace with the inflation rate, earning annualized real returns of less than 2 percent in most countries.[4] By comparison, real returns in equity markets have generally been around 3.5 percent per year in most markets—with a world average return of around 5.2 percent and a world average return excluding the United States just under 5 percent. During this period, South Africa and Australia were the best performing markets followed by the United States, New Zealand, and Sweden.

---

[3] The real return for a security is approximated by taking the nominal return and subtracting the observed inflation rate in that country.

[4] The exceptions are Austria, Belgium, Finland, France, Germany, Portugal, and Italy—where the average real returns on government bonds and/or bills have been negative. In general, that performance reflects the very high inflation rates in these countries during the World War years.

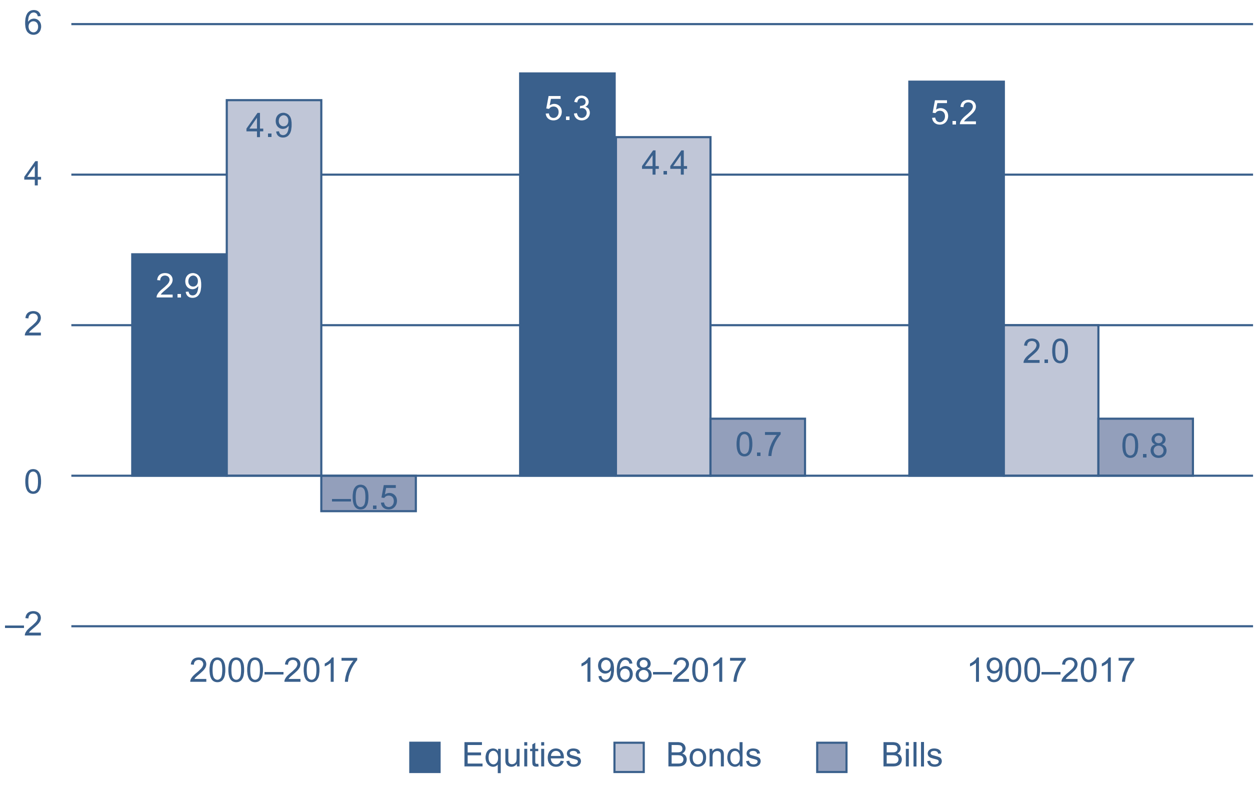
Exhibit 3 Real Returns on Global Equity Securities, Bonds, and Bills During 1900–2017



Source: Dimson, Marsh, and Staunton (2018).

Exhibit 4 shows the annualized real returns on major asset classes for the world index over 1900–2017.

Exhibit 4 Annualized Real Returns on Asset Classes for the World Index, 1900–2017

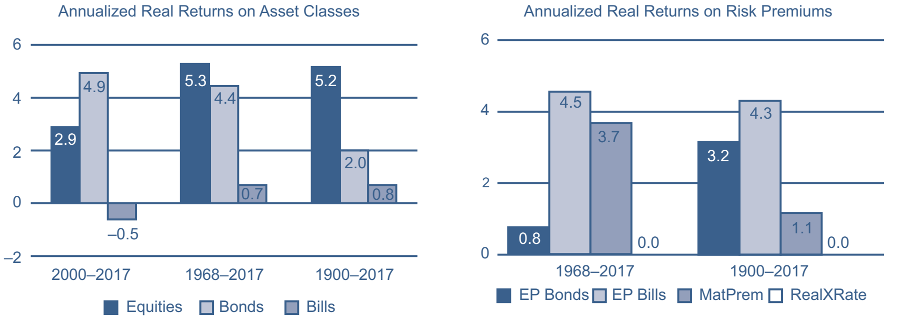


Source: Dimson, Marsh, and Staunton (2018).

The volatility in asset market returns is further highlighted in Exhibit 5, which shows the annualized risk premia for equity relative to bonds (EP Bonds), and equity relative to treasury bills (EP Bills). Maturity premium for government bond returns relative to treasury bill returns (Mat Prem) is also shown.

These observations and historical data are consistent with the concept that the return on securities is directly related to risk level. That is, equity securities have higher risk levels when compared with government bonds and bills, they earn higher rates of return to compensate investors for these higher risk levels, and they also tend to be more volatile over time.

Exhibit 5 **Annualized Real Returns on Asset Classes and Risk Premiums for the World Index since 1900–2017**



Notes: Equities are total returns, including reinvested dividend income. Bonds are total return, including reinvested coupons, on long-term government bonds. Bills denotes the total return, including any income, from Treasury bills. All returns are adjusted for inflation and are expressed as geometric mean returns. EP bonds denotes the equity risk premium relative to long-term government bonds. EP Bills denotes the equity premium relative to Treasury bills. MatPrem denotes the maturity premium for government bond returns relative to bill returns. RealXRate denotes the real (inflation-adjusted) change in the exchange rate against the US dollar.
Source: Dimson, Marsh, and Staunton (2018).

Given the high risk levels associated with equity securities, it is reasonable to expect that investors' tolerance for risk will tend to differ across equity markets. This is illustrated in Exhibit 6, which shows the results of a series of studies conducted by the Australian Securities Exchange on international differences in equity ownership. During the 2004–2014 period, equity ownership as a percentage of the population was lowest in South Korea (averaging 9.0 percent), followed by Germany (14.5 percent) and Sweden (17.7 percent). In contrast, Australia and New Zealand had the highest equity ownership as a percentage of the population (averaging more than 20 percent). In addition, there has been a relative decline in share ownership in several countries over recent years, which is not surprising given the recent overall uncertainty in global economies and the volatility in equity markets that this uncertainty has created.

Exhibit 6 International Comparisons of Stock Ownership: 2004–2014[5]

	2004	2006	2008	2010	2012	2014
Australia – Direct/ Indirect	55%	46%	41%	43%	38%	36%
South Korea – Shares	8	7	10	10	10	N/A
Germany – Shares/ Funds	16	16	14	13	15	13
Sweden – Shares	22	20	18	17	15	14
United Kingdom – Shares/Funds	22	20	18	N/A	17	N/A
New Zealand – Direct	23	26	N/A	22	23	26

Source: Adapted from the *2014 Australian Share Ownership Study* conducted by the Australian Securities Exchange (see http://www.asx.com.au). For Australia and the United States, the data pertain to direct and indirect ownership in equity markets; for other countries, the data pertain to direct ownership in shares and share funds. Data not available in specific years are shown as "N/A."

An important implication from the above discussion is that equity securities represent a key asset class for global investors because of their unique return and risk characteristics. We next examine the various types of equity securities traded on global markets and their salient characteristics.

CHARACTERISTICS OF EQUITY SECURITIES

2

a describe characteristics of types of equity securities;

b describe differences in voting rights and other ownership characteristics among different equity classes;

Companies finance their operations by issuing either debt or equity securities. A key difference between these securities is that debt is a liability of the issuing company, whereas equity is not. This means that when a company issues debt, it is contractually obligated to repay the amount it borrows (i.e., the principal or face value of the debt) at a specified future date. The cost of using these funds is called interest, which the company is contractually obligated to pay until the debt matures or is retired.

When the company issues equity securities, it is not contractually obligated to repay the amount it receives from shareholders, nor is it contractually obligated to make periodic payments to shareholders for the use of their funds. Instead, shareholders have a claim on the company's assets after all liabilities have been paid. Because of this residual claim, equity shareholders are considered to be owners of the company. Investors who purchase equity securities are seeking total return (i.e., capital or price appreciation and dividend income), whereas investors who purchase debt securities

---

[5] The percentages reported in the exhibit are based on samples of the adult population in each country who own equity securities either directly or indirectly through investment or retirement funds. For example, 36 percent of the adult population of Australia in 2014 (approximately 6.5 million people) owned equity securities either directly or indirectly. As noted in the study, it is not appropriate to make absolute comparisons across countries given the differences in methodology, sampling, timing, and definitions that have been used in different countries. However, trends across different countries can be identified.

(and hold until maturity) are seeking interest income. As a result, equity investors expect the company's management to act in their best interest by making operating decisions that will maximize the market price of their shares (i.e., shareholder wealth).

In addition to common shares (also known as ordinary shares or common stock), companies may also issue preference shares (also known as preferred stock), the other type of equity security. The following sections discuss the different types and characteristics of common and preference securities.

2.1 Common Shares

Common shares represent an ownership interest in a company and are the predominant type of equity security. As a result, investors share in the operating performance of the company, participate in the governance process through voting rights, and have a claim on the company's net assets in the case of liquidation. Companies may choose to pay out some, or all, of their net income in the form of cash dividends to common shareholders, but they are not contractually obligated to do so.[6]

Voting rights provide shareholders with the opportunity to participate in major corporate governance decisions, including the election of its board of directors, the decision to merge with or take over another company, and the selection of outside auditors. Shareholder voting generally takes place during a company's annual meeting. As a result of geographic limitations and the large number of shareholders, it is often not feasible for shareholders to attend the annual meeting in person. For this reason, shareholders may **vote by proxy**, which allows a designated party—such as another shareholder, a shareholder representative, or management—to vote on the shareholders' behalf.

Regular shareholder voting, where each share represents one vote, is referred to as **statutory voting**. Although it is the common method of voting, it is not always the most appropriate one to use to elect a board of directors. To better serve shareholders who own a small number of shares, **cumulative voting** is often used. Cumulative voting allows shareholders to direct their total voting rights to specific candidates, as opposed to having to allocate their voting rights evenly among all candidates. Total voting rights are based on the number of shares owned multiplied by the number of board directors being elected. For example, under cumulative voting, if four board directors are to be elected, a shareholder who owns 100 shares is entitled to 400 votes and can either cast all 400 votes in favor of a single candidate or spread them across the candidates in any proportion. In contrast, under statutory voting, a shareholder would be able to cast only a maximum of 100 votes for each candidate.

The key benefit to cumulative voting is that it allows shareholders with a small number of shares to apply all of their votes to one candidate, thus providing the opportunity for a higher level of representation on the board than would be allowed under statutory voting.
